The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 163 acres (8.2%). For the reasons cited above, the permanent loss of 163 acres habitat from the combined permanent impacts of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The Nuttall's woodpecker is a relatively mobile species and it is unlikely that construction activities associated with implementation of the RMDP would result in injury or

mortality of individual adult birds. However, foraging individuals may avoid or leave construction areas during construction activities. Also, implementation of the RMDP could result in mortality of young and/or eggs due to destruction of nests if construction/grading activities occurred during the nesting season of this species. Disruption of foraging activities could affect provisioning of young, thus potentially reducing survivorship and reproductive success. These impacts would be a substantial adverse impact on this species (significance criterion 1). Implementation of the SCP would not directly impact this species. Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The Nuttall's woodpecker is a relatively mobile species and it is unlikely that build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of individual adult birds. However, foraging individuals may avoid or leave construction areas during construction activities. Also, mortality of young and/or eggs due to destruction of nests could occur if construction/grading activities occurred during the nesting season of this species. Disruption of foraging activities could affect provisioning of young, thus potentially reducing survivorship and reproductive success. These impacts would be a substantial adverse impact on this species (significance criterion 1). Indirect, permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, fugitive dust, and nighttime illumination. Although construction would be of a short-term nature, if these activities occurred during the breeding season they could have a substantial direct adverse effect on this species due to potential disruption of nesting and foraging activities, potentially affecting reproductive success.

Potential long-term secondary impacts associated with urban development include noise (similar to the noise effects discussed above for least Bell’s vireo), nighttime illumination, invasive species such as giant reed, tamarisk, and Argentine ants, pesticide use resulting in loss of prey and/or secondary poisoning, increased human activity, harassment and predation by pet, stray, and feral cats and dogs, and increased mesopredators as a result of increased habitat fragmentation. These secondary impacts may result in abandonment of nests and lower reproductive success along the urban–open space edge over the long term.

RMDP facilities include a public trail and viewing platforms adjacent to and along the northern edge of the Santa Clara River corridor, as shown in **Figure 4.5-88**, Special-Status Riparian Bird Observations in Relation to Viewing Platforms. The trail and viewing platforms will be used by

the public during daytime hours. There is a potential for secondary impacts to Nuttall's woodpecker nesting in areas that are adjacent to the trail and viewing platforms. Secondary impacts primarily would include noise and general increases in human activity that could disrupt behavioral activities such as foraging, territory defense, and nesting, or increase physiological stress. In addition, there is the potential for increased trash along the trail that could enter the River Corridor SMA. Due to the very close proximity of viewing platforms and trails to riparian habitats, there is potential for unauthorized trespass by the public into sensitive habitat areas. Although there would be no lighting provided for evening use of the trail and viewing platforms, public access during the nighttime hours may still occur and could introduce fugitive light and noise. These impacts have the potential to affect the health of young, and potentially reduce survivorship and reproductive success.

Because the potential short-term and long-term secondary impacts could occur over a much broader area than the direct and indirect loss of habitat, secondary impacts would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for Nuttall's woodpecker (**Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 48 acres (2.4%) of permanent loss and 55 acres of temporary loss;
- Alternative 4 – 49 acres (2.5%) of permanent loss and 51 acres of temporary loss;
- Alternative 5 – 59 acres (3.0%) of permanent loss and 58 acres of temporary loss;
- Alternative 6 – 52 acres (2.6%) of permanent loss and 53 acres of temporary loss; and
- Alternative 7 – 14 acres (0.7%) of permanent loss and 47 acres of temporary loss.

Compared to Alternative 2, which would result in 64 acres (3.2%) of permanent habitat loss and 54 acres of temporary impacts, the permanent loss of habitat under Alternatives

3 through 6 would be somewhat reduced, and Alternative 7 would be substantially less. Compared to Alternative 2, the temporary loss of habitat would not be substantially different under Alternatives 3, 4, and 6, marginally greater under Alternative 5, and somewhat reduced under Alternative 7. The primary difference for permanent impacts under Alternative 7, compared to the other alternatives, is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Because the overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be somewhat to substantially reduced compared to Alternative 2, and temporary impacts would not be substantially different to somewhat reduced or marginally greater, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for Nuttall's woodpecker (**Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 78 acres (3.9%) of permanent loss;
- Alternative 4 – 73 acres (3.7%) of permanent loss;
- Alternative 5 – 71 acres (3.6%) of permanent loss;
- Alternative 6 – 43 acres (2.2%) of permanent loss; and
- Alternative 7 – 46 acres (2.3%) of permanent loss.

Compared to Alternative 2, which would result in 100 acres (5.0%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. There would be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 3 through 7.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for Nuttall's woodpecker:

- Alternative 3 – 126 acres (6.3%) of permanent loss;
- Alternative 4 – 122 acres (6.2%) of permanent loss;
- Alternative 5 – 130 acres (6.6%) of permanent loss;
- Alternative 6 – 95 acres (4.8%) of permanent loss; and
- Alternative 7 – 60 acres (3.0%) of permanent loss.

Compared to Alternative 2, which would result in 163 acres (8.2%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. There would generally be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 3, 4, 6, and 7. Alternative 5 would have the next largest impact compared to Alternative 2. Because the combined direct and indirect permanent loss of suitable habitat for Nuttall's woodpecker occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Impacts to Individuals

The potential for impacts to Nuttall's woodpecker individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Although adult birds would likely avoid injury or mortality, loss of young and/or eggs due to destruction of nests could occur, and provisioning of young could be disrupted, potentially reducing survivorship and reproductive success, if construction/grading activities occurred during the nesting season of this species. Indirect, permanent impacts (Impacts to Individuals) under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term secondary impacts include construction-related dust, noise, ground vibration, and nighttime illumination. These effects are more likely to occur during build-out of the Specific Plan, VCC, and Entrada planning areas than with implementation of the RMDP and the SCP

because of the much larger area of impact. If these impacts occur during the nesting season, reproductive success could be affected.

Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include noise; lighting; invasive species, such as giant reed, tamarisk, and Argentine ants; increased human activity; increased predation; and use of pesticides described above for Alternative 2.

There would be no viewing platforms constructed in the River Corridor SMA under Alternatives 3 through 7.

Because these potential short-term and long-term secondary effects could occur over a much broader area than direct or indirect loss of habitat, they would have a substantial adverse effect on the species and contribute to the reduction of its range and distribution. These long-term and short-term secondary impacts would be significant, absent mitigation for Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to Nuttall's woodpecker: (1) impacts to individuals; and (2) secondary impacts to individuals and suitable habitat outside the Project footprint.

Nesting by Nuttall's woodpecker has been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, impacts to individuals could occur if active nests are disturbed during vegetation clearing and construction/grading activities, including destruction of nests and loss of eggs and/or fledglings. Construction activities may also alter foraging behavior and thus potentially reduce the health of young and result in lower reproductive success. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

With regard to secondary effects, nesting and foraging activities by the Nuttall's woodpecker could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may alter foraging and provisioning of young. Construction-generated dust may affect habitat quality and both insect prey and vegetative food sources (*e.g.*, berries and sap) for the Nuttall's woodpecker. Lighting may induce physiological stress and increase the risk of predation by nocturnal predators such as raccoons. These short-term construction-related secondary impacts will be minimized by

conducting a survey to determine if active nests are present in the disturbance zone or within 300 feet and by retaining a qualified biologist during all vegetation clearing and grading activities. Several general measures will be implemented to protect wetland habitats that will reduce impacts to Nuttall's woodpecker. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities, biological monitoring during any stream diversions, restrictions on construction equipment operating in ponds or flowing water, and protection of water quality from mud, silt, and other pollutants. Long-term development-related impacts include invasive species such as giant reed and tamarisk and Argentine ants which may prey on nestlings; increased noise; introduction of secondary effects related to viewing platforms and trails along the River Corridor SMA (under Alternative 2 only); lighting; pesticides that may cause secondary poisoning and loss of prey; human disturbances of nest sites; and predation by pet, stray, and feral cats and dogs and other mesopredators. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of approximately 1,629 acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area will provide Nuttall's woodpeckers with relatively undisturbed habitat for nesting and foraging. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by nocturnal predators and reduce physiological stress. Limited recreational usage and access restrictions within the River Corridor SMA and High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect Nuttall's woodpeckers by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of secondary poisoning and loss of prey. Controls on Argentine ants will help reduce impacts on young in nests.

The specific mitigation measures for the Nuttall's woodpecker are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-126 IMPACTS TO INDIVIDUALS – NUTTALL'S WOODPECKER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of Nuttall's woodpecker individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during

development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to Nuttall's woodpecker individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to Nuttall's woodpecker individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-127 SECONDARY IMPACTS – NUTTALL'S WOODPECKER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to mitigate for long-term secondary effects on Nuttall's woodpecker associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as abandonment of nests caused by human activity, and greater vulnerability to nocturnal predators as a result of nighttime lighting. These mitigation measures provide for protection, restoration, enhancement, and management of habitat in open space for Nuttall's woodpecker that will offset secondary impacts. Mitigation measures to avoid and minimize impacts to riparian/wetland habitats and inadvertent impacts to habitat outside disturbance zones during construction will also be implemented.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The River Corridor SMA will preserve and enhance at least 341 acres of suitable habitat for Nuttall's woodpecker. The High Country SMA will preserve and enhance 885 acres of suitable habitat for Nuttall's woodpecker.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and oak tree replacement occur as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA, including the following: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These mitigation measures require that all grading perimeters

within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along the open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. These mitigation measures will address avoidance and minimization of downstream hydrology and water quality effects that could adversely affect Nuttall's woodpecker habitat and/or breeding populations.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to Nuttall's woodpecker, including short-term construction-related dust, noise, and ground vibration; and long-term impacts such as invasive species (including exotic plants and Argentine ants); increased human activity; greater vulnerability to predation by pet, stray, and feral cats and dogs; and impacts of pesticides such as secondary poisoning and loss of prey.

Secondary effects of noise and ground vibration during construction will be addressed by BIO-52 and BIO-56, as described above, which will mitigate these effects by identifying nest sites and providing for buffers between nests and construction activities.

Three mitigation measures, BIO-47, BIO-49, and BIO-70, will reduce impacts to the Nuttall's woodpecker during construction activities by protecting riparian/wetland habitats.

BIO-47 requires that slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area that will provide refuge for arroyo toad during construction.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species

adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. This will reduce impacts to Nuttall's woodpecker by protecting habitat quality and by minimizing impacts on its insect prey and vegetative food resources. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-1 through BIO-16 will improve long-term habitat quality for the Nuttall's woodpecker and include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-22 states that the Oak Resource Management Plan shall incorporate the findings of the Draft Newhall Ranch Mitigation Feasibility Report (Dudek 2007A) and areas identified as being suitable for oak woodland enhancement and creation shall be used for mitigation.

BIO-42 requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities. Fencing shall extend to the root protection zone.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity, and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail

systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impacts to Nuttall's woodpecker by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant from riparian areas is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the Nuttall's woodpecker would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

CALIFORNIA HORNED LARK (WL)

Life History

Horned larks (*Eremophila alpestris*) have a holarctic distribution, ranging from the Arctic south to central Asia and Mexico. There are numerous regional subspecies representing the superspecies across this holarctic range, including the California horned lark (*Eremophila alpestris* ssp. *actia*). The California horned lark is designated a Watch List species.

Horned larks are common and abundant residents in a variety of open habitats, usually where trees and shrubs are absent and can be found from sea level to elevations of 4,000 meters (13,123 feet) AMSL (Beason 1995). In general, the northernmost populations of horned lark are migratory, moving south during the winter into remaining areas of the breeding range. There are also southward movements into areas south of the breeding range, particularly in the southeastern United States (Beason 1995).

The California horned lark breeds and resides in the coastal region of California from Sonoma County southeast to the United States–Mexico border, including most of the San Joaquin Valley, and eastward to the foothills of the Sierra Nevada (Grinnell and Miller 1944; AOU 1998). It is found in grasslands along the coast and deserts near sea level and alpine dwarf-shrub habitat above the tree line. It is less common in mountain regions, on the north coast, and in coniferous or chaparral habitats (McCaskie *et al.* 1979). California horned larks breed from March through July, with a peak in activity in May and they frequently raise two broods in a season (Zeiner *et al.* 1990A).

Horned lark nests are associated with bare ground such as plowed or fall-planted fields and are often positioned on the north side of grass bunches, rocks, or bushes to provide shade from afternoon sun (Beason and Franks 1974; Hartman and Oring 2003). To a lesser extent, horned larks may nest on marshy soil (Mousley 1916; Verbeek 1967). During the spring and fall migration, horned larks use the same habitats occupied at other times of the year, with an increase in beaches and sand dunes and also mowed areas, such as airfields (Beason 1995). Winter habitat use is similar in structure to that used for breeding and migration with open, short vegetated habitats, beaches, sand dunes, and airfields (Grzybowski 1983; Beason 1995).

Horned larks feed nestlings mostly insects, snails, and spiders during the breeding season but typically consume forb and grass seeds and other plant matter during other seasons (Zeiner *et al.* 1990A). Individuals forage in either bare areas or in agricultural fields with low, short vegetation (Beason 1995). The California horned lark uses predominantly agriculture, grassland, and disturbed areas for foraging, as well as sparse shrub and scrub habitats (Garrett and Dunn 1981). In winter, flocks frequent roadsides, feedlots, and fields where manure from feedlots is spread.

In addition to direct loss of habitat and fragmentation, California horned larks are vulnerable to several effects related to agriculture and urbanization. Increased use of pesticides, specifically Carbofuran and Fenthion, have been shown to poison and kill horned larks (Beason 1995). The demonstrated deleterious effects of these pesticides illustrate that horned larks may be vulnerable to certain chemicals because of their ground-foraging habits and seasonally varying diet. Pesticides may also cause a decline in prey abundance. Mowing of grasslands occupied by nesting horned larks substantially increased nest failures (Kershner and Bollinger 1996). Horned lark nests can also be parasitized by brown-headed cowbirds, especially after the first brood when there are multiple broods in a single season (Beason 1995). Other development- and human-related impacts expected to affect this species include construction-related dust; noise and ground vibration; nighttime lighting, which may induce physiological stress and increase predation by nocturnal predators; and increased predation by pet, stray, and feral cats and dogs. Areas of increased moisture may attract Argentine ants that prey on nestlings.

Survey Results

The Project area provides suitable foraging and nesting habitat for California horned lark throughout the Specific Plan, VCC, and Entrada planning areas. Surveys for avian species have been conducted since 1988 along the Santa Clara River, Castaic Creek, and upland habitats of the Specific Plan, VCC, and Entrada planning areas. This species has been observed on site over multiple years during the annual bird surveys conducted from 1988 through 2008 along the Santa Clara River within riparian and upland habitat. Horned larks have been observed regularly foraging in plowed and graded fields near the Santa Clara River and Castaic Creek within the RMDP and VCC planning areas, and adjacent to the Entrada planning area in Castaic Junction. Most recently in December 2007 and January 2008, Bloom Biological, Inc. (2008) observed large flocks of foraging horned larks numbering from 250 to 500 individuals in the Wolcott agricultural fields and east alfalfa field, as well as smaller groups along the Santa Clara River. Nesting on site by the California horned lark has not been documented. Although focused surveys were not conducted for the California horned lark, the general bird surveys that have been conducted within the Santa Clara River and associated tributaries, including some of the agricultural areas near the River since 1988 would likely have observed and documented any nesting horned larks present on site. Although nesting has not been documented on site, California horned larks are thought to be a resident because of these numerous observations and because suitable foraging and nesting habitat is present throughout the Project site. Agriculture, California annual grassland, disturbed land, and purple needlegrass are suitable habitats for the California horned lark. A total of 5,118 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 212 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 4.1% of these habitats on site (**Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat). A total of 94 acres would be temporarily impacted.

The California horned lark is still a wide-ranging species and uses a variety of grassland, agricultural, and disturbed habitats. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 212 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,079 acres of suitable habitat would be permanently loss through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 60.2% of suitable habitats on site (**Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat).

A relatively large amount and percentage of suitable habitat for the California horned lark would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from approximately 60.2% of suitable habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,291 acres (64.3%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of the California horned lark in the Project area, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because the California horned lark is highly mobile, it is unlikely that RMDP-related construction activities would result in injury or mortality of adult birds of this species, but wintering flocks may avoid or leave construction areas. Implementation of the SCP would not directly impact this species. This species has not been observed nesting on site; however, it is considered a breeding resident based on common occurrence on site during general avian surveys. Vegetation clearing or grading activities occurring during the nesting season could result in destruction of nests, eggs, and young; interfere with foraging and provisioning of young; or cause adults to abandon nests. Because of the special status of this bird species and the potential for destruction of nests, eggs, or young, and interference with foraging and provisioning, during construction/grading activities associated with implementation of the RMDP, such impacts would have a substantial direct adverse effect on this species; impede the use of a native wildlife nursery site; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent and temporary impacts to individuals, but over a much larger area. Wintering flocks may be displaced from foraging areas, and clearing or grading activities during the nesting season could result in destruction of nests, eggs, or young; interfere with foraging and provisioning; or cause nest abandonment. Such impacts would have a substantial direct adverse effect on this species; impede the use of a native wildlife nursery site; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term construction-related activities associated with the RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect California horned larks in areas adjacent to construction zones. Short-term secondary impacts could include exposure to construction-related dust, noise, ground vibration, and nighttime lighting. Disturbance associated with human activity during construction could also result in a decrease in nesting success because this species uses open ground for nesting and foraging and is susceptible to harassment by humans. Over the long term, the close proximity of urban development to suitable California horned lark habitat resulting from build-out of the Specific Plan, VCC, and Entrada planning areas, could result in abandonment of nests; greater vulnerability to pesticides that may cause secondary poisoning and reduce its prey abundance; and greater vulnerability to predation by pet, stray, feral cats and dogs, and other mesopredators that could result in decreased nesting success. Nighttime lighting could induce physiological stress and increase predation by nocturnal predators. Argentine ants that are attracted to moist habitats may prey on nestlings. Cowbird nest parasitism also could reduce reproductive success. For these reasons, the potential short-term and long-term secondary impacts would have a substantial adverse effect on this species; would cause the species to drop below self-sustaining levels on site or rangewide; would interfere with the movement of the species between important habitat areas; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for California horned lark (**Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 197 acres (3.8%) of permanent loss and 132 acres of temporary loss;
- Alternative 4 – 179 acres (3.5%) of permanent loss and 142 acres of temporary loss;
- Alternative 5 – 234 acres (4.6%) of permanent loss and 118 acres of temporary loss;
- Alternative 6 – 238 acres (4.6%) of permanent loss and 132 acres of temporary loss; and
- Alternative 7 – 112 acres (2.2%) of permanent loss and 438 acres of temporary loss.

Compared to Alternative 2, which would result in 212 acres (4.1%) of permanent habitat loss and 94 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 and 4 would be somewhat less, would be somewhat more under Alternatives 5 and 6, and would be substantially less under Alternative 7. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be somewhat more and would be substantially more under Alternative 7. The difference between Alternative 7 (substantially less permanent impacts and substantially more temporary impacts) and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be less than or similar in magnitude compared to Alternative 2 and percentages of permanent loss would be 4.6% or less (Alternatives 5 and 6), these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for California

horned lark (**Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 2,955 acres (57.7%) of permanent loss;
- Alternative 4 – 2,821 acres (55.1%) of permanent loss;
- Alternative 5 – 2,767 acres (54.1%) of permanent loss;
- Alternative 6 – 2,548 acres (49.8%) of permanent loss; and
- Alternative 7 – 2,087 acres (40.8%) of permanent loss.

Compared to Alternative 2, which would result in 3,079 acres (60.2%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 6 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, but would still be substantial, these impacts would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for California horned lark:

- Alternative 3 – 3,152 acres (61.6%) of permanent loss;
- Alternative 4 – 3,000 acres (58.6%) of permanent loss;
- Alternative 5 – 3,001 acres (58.6%) of permanent loss;
- Alternative 6 – 2,785 acres (54.4%) of permanent loss; and
- Alternative 7 – 2,200 acres (43.0%) of permanent loss.

Compared to Alternative 2, which would result in 3,291 acres (64.3%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect

impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, there would also be generally successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7 (although Alternatives 4 and 5 would have nearly identical impacts), and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7. Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for California horned lark occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial and therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to California horned lark individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Wintering flocks may be displaced from foraging areas, and clearing or grading activities during the nesting season could result in destruction of nests, eggs, or young; interfere with foraging and provisioning; or cause nest abandonment. Impacts to individual California horned larks occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term impacts include construction-related dust, noise, ground vibration, and nighttime lighting. Increased human activity could cause nesting failures. These effects are more likely to occur during build-out of the Specific Plan, VCC, and Entrada planning areas than implementation of the RMDP and the SCP because of the much larger area of impact.

Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include increased human activity; increased predation by pet, stray, and feral cats and dogs and mesopredators; secondary poisoning and loss of prey from pesticides;

nighttime lighting; Argentine ants; and cowbird nest parasitism, as described above for Alternative 2.

These secondary impacts would permanently reduce California horned lark populations along the urban–open space edge and contribute to the reduction of the range and distribution of this species in the Project area. Short-term and long-term secondary impacts would be significant, absent mitigation under Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to California horned lark: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals outside the Project footprint.

Wintering flocks of California horned lark commonly occur in the agricultural fields and grasslands in the Project area. Nesting by this species has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. However, for the purpose of this analysis, it is assumed that California horned larks could nest on site. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, wintering flocks could be displaced from suitable foraging habitat by construction activities. Impacts to individuals also could occur if California horned larks were to nest on site and active nests were disturbed during vegetation clearing and construction/grading activities, resulting in the destruction of the nests and loss of eggs and/or young. Construction activities may also interfere with foraging and provisioning of young or cause abandonment of nests due to human activity, noise, and ground vibration. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable habitat for the California horned lark resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,220 acres (43.0%) under Alternative 7 to 3,291 acres (64.3%) under Alternative 2. This would be a substantial loss of suitable habitat for this species and will alter its use of the Project area for foraging, and potentially nesting. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a permanent open space system that will provide suitable habitat to support both foraging and breeding by the California horned lark in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 896 acres of suitable habitat for the California horned lark in the High Country SMA and the Salt Creek area (**Figure 4.5-3**), as well as 100 acres in the River Corridor SMA.

With regard to secondary effects, foraging and, potentially, nesting activities by the California horned lark could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may cause adults to vacate foraging areas and abandon nests, if breeding were to occur, due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to predators. These short-term construction-related secondary impacts will be minimized by conducting pre-construction surveys to determine if active nests, are present in the disturbance zone or within 300 feet, and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include lighting; pesticides, which may cause direct and secondary poisoning and loss of prey; human disturbances of nest sites; predation and harassment by pet, stray, and feral cats and dogs and other mesopredators; Argentine ants that may prey on nestlings; and cowbird nest parasitism, which could reduce reproductive success. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 896 acres of suitable habitat in the High Country SMA and Salt Creek area and 100 acres in the River Corridor SMA will provide California horned larks with relatively undisturbed habitat for foraging and potentially nesting. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by predators and reduce behavioral disturbances and physiological stress. Limited recreational usage and access restrictions within the High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect California horned larks by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of direct and secondary poisoning and loss of prey.

The specific mitigation measures for the California horned lark are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-128 IMPACTS TO INDIVIDUALS – CALIFORNIA HORNED LARK

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of California horned lark individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during

development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to California horned lark individuals

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to California horned lark individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-129 LOSS OF HABITAT – CALIFORNIA HORNED LARK

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for California horned lark through habitat protection, restoration and enhancement, and management.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The High Country SMA will protect and manage at least 571 acres of suitable habitat for the California horned lark.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measure to mitigate for the loss of habitat for the California horned lark through habitat protection, restoration and enhancement, and management.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. The Salt Creek area includes 324 acres of suitable habitat for the California horned lark.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the California horned lark would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-130 SECONDARY IMPACTS – CALIFORNIA HORNED LARK

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on the California horned lark associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such noise, increased human activity, and greater vulnerability to nocturnal predators as a result of nighttime lighting. These mitigation measures provide for protection, restoration, enhancement, and management of habitat in open space for California horned lark that will offset secondary impacts by providing high-quality habitat away from development areas. Mitigation measures to minimize inadvertent impacts to habitat outside construction zones will also be implemented.

SP-4.6-53 and SP-4.6-59, as described above, will be implemented to mitigate impacts from increased short-term human activity associated with construction.

SP-4.6-36 through SP-4.6-42, as described above and which generally refer to habitat protection in the High Country SMA, will be implemented to mitigate for long-term habitat fragmentation effects and increased human activity.

SP-4.6-29 through SP-4.6-32 will be implemented to mitigate for impacts related to increased human activity in the High Country SMA through limiting access to daytime use of the designated trail system; prohibiting pets (with the exception of horses on established trails); prohibiting hunting, fishing, and motor or off-trail bike riding; and providing trail design guidelines to minimize impacts to native habitats.

SP-4.6-33 will be implemented to mitigate potential adverse edge effects by permitting construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-34 and SP-4.6-35 require that all grading perimeters within High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to California horned lark, including short-term construction-related dust, noise, ground vibration, and increased human activity; and long-term effects such as increased human activity, predation by pet, stray, and feral cats and dogs, indirect poisoning and loss of prey from pesticide use, Argentine ants that may prey on nestlings, and cowbird nest parasitism which could reduce reproductive success.

BIO-52 and BIO-56, as described above, will mitigate the effects of noise and ground vibration by identifying nest sites and providing for buffers between nests and construction activities.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-19, as described above, will mitigate for increased human activity in the Project area through habitat protection and management in the Salt Creek area.

BIO-63 and BIO-69 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-64 will be implemented to prevent poisoning and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-78 requires implementation of a cowbird trapping program once vegetation clearing begins. The program shall be implemented each day beginning April 1 and concluding on or about November 1, through the construction, maintenance, and monitoring period of the riparian restoration sites. In the event that trapping is terminated after the first few years of development, subsequent phases of the RMDP development shall trigger initiation of trapping surveys.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impacts to California horned lark by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the California horned lark would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

ALLEN'S HUMMINGBIRD (NESTING) (CALIFORNIA SPECIAL ANIMAL)

Life History

Two subspecies of Allen's hummingbird (*Selasphorus sasin*) are recognized (AOU 1957), but they are indistinguishable in the field. *S. s. sasin* is a smaller, migratory species that breeds in a narrow strip along the Pacific Coast from southwest Oregon south to southern California. This subspecies has never been documented breeding inland more than about 32 kilometers from the coast (Grinnell and Miller 1944), but it is possible that local inland breeding occurs since birds have been observed in northwest California during the breeding season (Small 1994). *S. s. sasin* winters in central Mexico and occasionally in the Gulf Coast region of the southeast United States (Phillips 1975; Mitchell 2000; Newfield 1983). On its way to its wintering range, Allen's hummingbird usually stays near the coast, but is also commonly observed in the mountains of southern California (Garrett and Dunn 1981) and occasionally is observed in the Sierra Nevada (Gaines 1988). *S. s. sedentarius* is larger than the nominate subspecies and is a non-migratory resident of the Channel Islands and of coastal Los Angeles (Palos Verdes Peninsula), Orange County, and extreme northern San Diego County. Breeding inland from the coast has recently been documented for this species (Mitchell 2000). It is rare to see Allen's hummingbirds during the winter except in the range of *S. s. sedentarius* (Zeiner *et al.* 1990A).

The vegetation communities most commonly used by breeding Allen's hummingbirds are coastal scrub, valley foothill hardwood, and valley foothill riparian habitats. Coastal scrub used by this species usually contains at least a scattering of trees. Allen's hummingbirds also use vegetation dominated by Douglas fir (*Pseudotsuga menziesii*), redwood (*Sequoia sempervirens*), Bishop pine (*Pinus muricata*), and non-native eucalyptus and cypress trees (*Cupressus* spp.). Live oak woodlands and urban habitats are also occasionally used (Zeiner *et al.* 1990A; Mitchell 2000). *S. s. sedentarius* populations on the Channel Islands usually use riparian woodlands and tall, dense chaparral on north-facing slopes (Yeaton and Laughrin 1976). Habitats used by *S. s. sasin* during migration include the previously described habitats as well as humid pine–oak woodland and montane chaparral, open coniferous forest, and mixed woodland habitats at higher inland elevations (Grinnell and Miller 1944; Mitchell 2000).

The breeding range of *S. s. sasin* overlaps almost exactly with the range of bush monkeyflower, one of the hummingbird's favored plants. Other plant species used by Allen's hummingbird include Indian paintbrush (*Castilleja* spp.), columbine (*Aquilegia formosa*), currants and gooseberries (*Ribes* spp.), Indian pink (*Silene laciniata, S. californica*), Indian warrior (*Pedicularis densiflora*), twinflower (*Lonicera involucrata*), penstemon (*Penstemon* and *Keckiella* spp.), ceanothus (*Ceanothus* spp.), pitcher sage (*Salvia spathacea*), madrone (*Arbutus menziesii*), and manzanita (*Arctostaphylos* spp.) (Mitchell 2000). Hedge nettle (*Stachys* spp.), California fuchsia (*Epilobium canum*), and red larkspur (*Delphinium cardinale*) provide nectar

for migrating individuals in higher elevations. Ornamentals and non-native plants such as tree tobacco are also used by the species during migration.

Nests are typically located 0.5 to 10 meters off the ground in trees or shrubs in densely vegetated areas. Willows and other dense thickets in riparian areas are common nesting sites. Bush monkeyflower as well as eucalyptus and other trees are also used. Unlike the Anna's hummingbird, which occurs sympatrically, Allen's hummingbird rarely nests near human habitation or in man-made structures.

Threats for this species are poorly defined and few concerns have been identified. Eucalyptus groves, tree tobacco, ornamental plants, and artificial feeders—all human-related food sources—provide ample quantities of nectar for this species during the fall and winter, when many native plants are not in bloom. Concerns regarding the population status primarily are based on the small geographic area of breeding and wintering range of the species. Although no specific threats have been identified for Allen's hummingbird, several potential development- and human-related impacts may affect this species' nesting and foraging activities, including construction-related dust; noise and ground vibration; and nighttime lighting. Over the long term, pet, stray, and feral cats may prey on this species. Argentine ants may also prey on nestlings, particularly in riparian areas. Invasive species in riparian areas, such as giant reed and tamarisk, also would be expected to adversely affect nesting and foraging habitat for this species.

Survey Results

The Project area provides suitable foraging, nesting, and migration habitat for Allen's hummingbird throughout the Specific Plan, VCC, and Entrada planning areas. Surveys for upland bird species have been conducted throughout the Project area and in nearby areas between 1995 and 2007.

Allen's hummingbird was documented numerous times in the Project area in 2004 (Guthrie 2004B, 2004C, 2004G). *Selasphorus* hummingbirds observed in other years along the Santa Clara River within and adjacent to the Specific Plan area could be either rufous hummingbird (*S. rufus*) or Allen's hummingbirds (Guthrie 2002A, 2002C; Bloom Biological 2007A, 2008). According to Bloom Biological, a few of both species (rufous or Allen's hummingbirds) undoubtedly use the Project area during migration (Bloom Biological 2007A). Most observations of *Selasphorus* hummingbirds were made in March or April. However, a few observations, including those of individuals in the VCC planning area, have been made in June or July (Guthrie 2002A, 2004C, 2004G), suggesting that some *Selasphorus* hummingbirds are residents and not just migrants in the Project area. Since rufous hummingbirds are migratory, observations made in summer are probably of the non-migratory subspecies of Allen's hummingbird.

The habitats being used by observed Allen's hummingbirds were not documented. However, because many of these observations were made during focused surveys for the coastal California gnatcatcher, a species that uses coastal scrub, it is likely that Allen's hummingbirds were observed in coastal scrub habitat. The species may have also been observed in riparian habitats, since some of the surveys during which it was observed were focused surveys for least Bell's vireo, southwestern willow flycatcher, and yellow-billed cuckoo. Woodland habitats, also used by Allen's hummingbirds, were also surveyed during upland surveys, although perhaps not as thoroughly as the scrub and riparian habitats. The surveys were adequate to conclude that small numbers of Allen's hummingbirds use the Project area during southward-bound migration or as year-round residents. Overall, however, this species is considered fairly uncommon in the Project area.

Suitable habitat for Allen's hummingbird in the Project area includes coastal scrub alliances and associations, southern cottonwood–willow riparian, southern willow scrub, riparian scrub (alluvial scrub, arrow weed scrub, big sagebrush scrub, big sagebrush–California buckwheat, giant reed, Mexican elderberry, mulefat scrub, southern willow scrub, and shrub tamarisk), and oak woodlands (coast live oak woodland, mixed oak woodland and forest, and valley oak woodland). A total of 6,331 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 102 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.6% of these habitats on site (**Figure 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat). A total of 53 acres would be temporarily impacted.

Allen’s hummingbird is still a wide-ranging species and uses a variety of scrub, riparian, and woodland habitats. The construction of RMDP facilities would be phased over a long

period of time and thousands of acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 102 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 1,627 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 25.7% of these habitats on site (**Figure 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat).

A relatively large amount and percentage of suitable habitat on site for Allen's hummingbird would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from 25.7% of suitable habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 1,729 acres (27.3%). Because of the large amount and percentage of habitat loss, the combined direct and indirect impacts to suitable habitat would have a substantial adverse effect on the distribution of Allen's hummingbird in the Project area, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Based on the results from past surveys, Allen's hummingbird is considered fairly common in the Project area. Because these birds are highly mobile, it is unlikely that RMDP-related construction activities would result in injury or mortality of adult birds of this species, but foraging individuals may be displaced from construction areas. Implementation of the SCP would not directly impact this species. Though this species has not been observed nesting on site, the Project area is within the species' nesting range. Also, *Selasphorus* hummingbirds have been documented in the Project area during the summer, when migratory *Selasphorus* hummingbirds would have already passed through the area (Guthrie 2002A, 2004B, 2004C, 2004G). Because the rufous hummingbird is exclusively migratory in the Project region, *Selasphorus* hummingbirds documented in the Project area during the summer are likely the non-migratory subspecies of Allen's hummingbird. As year-round residents, therefore, these individuals probably use the Project area for breeding. Clearing or grading activities occurring during the nesting season could result in destruction of nests, eggs, or young, interfere with foraging and provisioning of young, or cause nest abandonment. These impacts would be a substantial adverse impact on this species (significance criterion 1). Implementation of the SCP would not directly impact this species. Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct impacts to individuals, but over a much larger area. Foraging individuals may be displaced from construction areas, and clearing or grading activities occurring during the nesting season could result in the destruction of nests, eggs, or young, interference with foraging and provisioning of young, or abandonment of nests (significance criterion 1). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

In the short term, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas occurring during the breeding season would have the potential to affect Allen's hummingbirds in areas adjacent to construction zones. These impacts could include exposure to construction-related dust, noise, ground vibration, and nighttime illumination. Dust may degrade foraging habitat quality, noise and ground vibration could disrupt foraging and nesting activities, and nighttime illumination could induce physiological stress and increase predation by nocturnal predators. Potential long-

term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include increased human activity, which may affect nesting behavior; and greater vulnerability to nocturnal predators as a result of nighttime lighting, as well as greater vulnerability to predation by pet, stray, and feral cats and other mesopredators within about 200 feet of the urban–open space edge. Attraction of Argentine ants to moist habitats, especially riparian areas, could result in predation on nestlings. These secondary impacts would permanently reduce Allen's hummingbird populations along the urban–open space edge and contribute to the reduction of the range and distribution of this species in the Project area (significance criteria 1 and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for Allen's hummingbird (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 85 acres (1.3%) of permanent loss and 55 acres of temporary loss;
- Alternative 4 – 85 acres (1.3%) of permanent loss and 50 acres of temporary loss;
- Alternative 5 – 99 acres (1.6%) of permanent loss and 61 acres of temporary loss;
- Alternative 6 – 79 acres (1.3%) of permanent loss and 58 acres of temporary loss; and
- Alternative 7 – 35 acres (0.5%) of permanent loss and 71 acres of temporary loss.

Compared to Alternative 2, which would result in 102 acres (1.6%) of permanent habitat loss and 53 acres of temporary impacts, the permanent loss of habitat under Alternative 5 would be not substantially different; Alternatives 3, 4, and 6 would be somewhat less; and Alternative 7 would be substantially less. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3, 4, 5, and 6 would be not substantially different to marginally greater, while Alternative 7 would be somewhat more. The difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in substantially fewer permanent impacts and greater temporary impacts under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be less than or similar in magnitude to overall habitat loss under Alternative 2, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to suitable habitat for Allen's hummingbird (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 1,515 acres (23.9%) of permanent loss;
- Alternative 4 – 1,469 acres (23.2%) of permanent loss;
- Alternative 5 – 1,419 acres (22.4%) of permanent loss;
- Alternative 6 – 1,146 acres (18.1%) of permanent loss; and
- Alternative 7 – 1,061 acres (16.8%) of permanent loss.

Compared to Alternative 2, which would result in 1,627 acres (25.7%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that would reduce impacts to Allen's hummingbird suitable habitat under Alternative 7 compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than overall habitat loss under Alternative 2, but still substantial, these impacts would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for Allen's hummingbird:

- Alternative 3 – 1,600 acres (25.3%) of permanent loss;
- Alternative 4 – 1,553 acres (24.5%) of permanent loss;
- Alternative 5 – 1,518 acres (24.0%) of permanent loss;
- Alternative 6 – 1,226 acres (19.4%) of permanent loss; and
- Alternative 7 – 1,096 acres (17.3%) of permanent loss.

Compared to Alternative 2, which would result in 1,729 acres (27.3%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, there would also be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for Allen's hummingbird occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial and therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to Allen's hummingbird individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Foraging individuals may be displaced from construction areas, and clearing or grading activities occurring during the nesting season could result in the destruction of nests, eggs, or young, interference with foraging and provisioning of young, or abandonment of nests (significance criterion 1). Impacts to individual Allen's hummingbirds occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban

development. Short-term impacts include construction-related dust, noise, ground vibration, and nighttime illumination. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include increased human activity, and increased predation from nocturnal predators; pet, stray, and feral cats; and Argentine ants; as described above for Alternative 2. These secondary impacts would permanently reduce Allen's hummingbird populations along the urban–open space edge and contribute to the reduction of the range and distribution of this species in the Project area. Short-term and long-term secondary impacts would be significant, absent mitigation for Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to Allen's hummingbird: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Allen's hummingbird has been commonly observed on site. Nesting by this species has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas, but suitable nesting habitat is present and the species has been observed during the nesting season. For the purpose of this analysis, it is assumed that Allen's hummingbirds could nest on site. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, individuals could be displaced from suitable foraging habitat by construction activities. Impacts to individuals also could occur if Allen's hummingbirds were to nest on site and active nests were disturbed during vegetation clearing and construction/grading activities, resulting in the destruction of the nests and loss of eggs and/or young. Construction activities may also interfere with foraging and provisioning of young, and cause abandonment of nests due to human activity, noise, and ground vibration. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable habitat for the Allen's hummingbird resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 1,096 acres (17.3%) under Alternative 7 to 1,729 acres (27.3%) under Alternative 2. This would be a substantial loss of suitable habitat for this species and will alter its use of the Project area for foraging and, potentially, nesting. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a permanent open space system that will provide suitable habitat to support both foraging and breeding by the Allen's hummingbird in the Project vicinity. Implementation of these mitigation

measures will result in protection and management of 3,579 acres of the suitable habitat for this species in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With regard to secondary effects, foraging and, potentially, nesting activities by the Allen's hummingbird could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may cause adults to vacate foraging areas and abandon nests, if breeding were to occur, due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to predators. These short-term construction-related secondary impacts will be minimized by conducting pre-construction surveys to determine if active nests are present in the disturbance zone or within 300 feet, and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include increased human activity; lighting; and predation by pet, stray, and feral cats and Argentine ants. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 3,579 acres of suitable habitat in the River Corridor, High Country SMA, and Salt Creek area will provide Allen's hummingbirds with relatively undisturbed habitat for foraging and potentially nesting. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by predators and reduce behavioral disturbances and physiological stress. Limited recreational usage and access restrictions within the High Country SMA; control of pet, stray, and feral cats in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect Allen's hummingbirds by allowing them to nest and forage without disturbance. Argentine ant monitoring and controls will be implemented.

The specific mitigation measures for the Allen's hummingbird are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-131 IMPACTS TO INDIVIDUALS – ALLEN'S HUMMINGBIRD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of Allen's hummingbird individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during

development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to Allen's hummingbird individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to Allen's hummingbirds would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-132 LOSS OF HABITAT – ALLEN'S HUMMINGBIRD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for Allen's hummingbird through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor

SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The River Corridor SMA will preserve and enhance at least 380 acres of suitable habitat for Allen's hummingbird**.** The High Country SMA will preserve and enhance at least 2,187 acres of suitable habitat for Allen's hummingbird.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and that oak tree replacement occur as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA, including the following: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for Allen's hummingbird through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years

or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Implementation of BIO-19, BIO-20, and BIO-21 will minimize and mitigate impacts to Allen's hummingbird by preserving and restoring a large amount of suitable habitat in three interconnected preserved open space areas: the High Country SMA, Salt Creek area, and River Corridor SMA. Implementation of BIO-1 through BIO-16 will ensure that through restoration activities, riparian areas remain high-quality suitable habitat for Allen's hummingbird.

BIO-55 requires that maps of suitable riparian habitat be updated for special-status avian species, and the creation or enhancement of habitat shall be similar to the habitat removed.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for Allen's hummingbird would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-133 SECONDARY IMPACTS – ALLEN'S HUMMINGBIRD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on Allen's hummingbird associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as abandonment of nests due to human activity, and greater vulnerability to nocturnal predators as a result of nighttime lighting. Mitigation measures to minimize inadvertent impacts to habitat outside construction zones will also be implemented.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and that generally refer to habitat protection, restoration and enhancement, and management, will be implemented to mitigate for long-term habitat fragmentation effects and increased human activity.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along the open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only on developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to Allen's hummingbird, including short-term, construction-related dust, noise, ground vibration,

and increased human activity; and long-term effects such as, increased human activity, greater vulnerability to predation by pet, stray, and feral cats and Argentine ants.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, will mitigate for increased human activity in the Project area through habitat protection, restoration and enhancement, and management.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent

feasible. This measure will also reduce impacts to Allen's hummingbird by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant from riparian areas is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to Allen's hummingbird would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

BELL'S SAGE SPARROW (NESTING) (BCC, WL)

Life History

The sage sparrow (*Amphispiza belli*) occurs in western North America from interior west-central Washington east through western Wyoming and south through northern Baja California and Mexico. This distribution includes the states of Idaho, California, Nevada, Colorado, New Mexico, Arizona, and Texas. In California, the sage sparrow occurs east of the Cascade Range, in the Sierra Nevada, on the western edges of the Owens Valley and the Mojave Desert, in the foothills surrounding the Central Valley, and in the Transverse, Peninsular, and Coast Ranges (Zeiner *et al.* 1990A).

Five subspecies of sage sparrow are recognized, two of which are migratory (County of Riverside 2008). The subspecies Bell's sage sparrow (formerly known as Bell's sparrow), *A. b. belli*, occurs as a nonmigratory resident on the western slope of the central Sierra Nevada Range and in the coastal ranges of California southward from Marin County and Trinity County, extending into north-central Baja California (County of Riverside 2008).

The sage sparrow occupies semi-open habitats with evenly spaced shrubs that are one to two meters (3.3 to 6.6 feet) high (County of Riverside 2008). For site selection, specific shrub species may be less important than overall vertical structure, habitat patchiness, and vegetation density (Wiens and Rotenberry 1981). Bell's sage sparrow is uncommon to fairly common in dry chaparral and coastal sage scrub along the coastal lowlands, inland valleys, and lower foothills of the mountains within its range. The Bell's sage sparrow often occupies chamise chaparral in the northern part of its range (Gaines 1988; Unitt 1984) and in coastal San Diego County (Bolger *et al.* 1997). High, overgrown chaparral stands generally have fewer sage sparrows than shorter shrubs recovering from recent fires. At higher elevations in southern California, Bell's sage sparrow often occurs in big sagebrush (County of Riverside 2008). Because the species is often missing from what appears to be suitable habitat, researchers postulate that other unknown habitat characteristics may be important (County of Riverside 2008). Sage sparrows seek cover in fairly dense stands in chaparral and scrub habitats during the breeding season.

Sage sparrows primarily forage on the ground, usually near or under the edges of shrubs (Zeiner *et al.* 1990A; County of Riverside 2008). During the breeding season, the species consumes adult and larval insects, spiders, seeds, small fruits, and succulent vegetation (County of Riverside 2008).

Bell's sage sparrow usually nests in sagebrush or chaparral, and may have two broods per nesting season (Ehrlich *et al.* 1988). It prefers to nest in shrubs of intermediate size, usually between 50 and 70 centimeters (1.6 and 2.3 feet) tall. Shrubs of this size usually provide favorable foraging sites, avenues of movement, and sufficient cover. Nest site selection is probably more

influenced by structure and density of shrubs than by shrub species (County of Riverside 2008). Host shrubs tend to have at least 75% live material. In areas that are more open, nest sites are selected within clumps of shrubs (County of Riverside 2008). In Riverside County, nests of Bell's sage sparrow have been found in brittlebush, black sage, California buckwheat, California sagebrush, and bush mallow. In other locations, chamise, white sage, cholla, ceanothus, and willows have been used by the species (County of Riverside 2008). Sage sparrows also nest occasionally in bunchgrass or on the ground under shrubs (County of Riverside 2008).

Breeding territory sizes for the sage sparrow vary widely, ranging from 24 to over 40 pairs per 40 hectares (100 acres). Territory boundaries may change slightly from day to day, but typically do not overlap (County of Riverside 2008). Territories for Bell's sage sparrow in San Diego and Riverside counties varied from 0.75 to 5.7 hectares (1.9 to 14.1 acres) (County of Riverside 2008). In an earlier study in Riverside County (Carlson 1983), breeding densities for this subspecies were 94 to 111 territories per square kilometer (241 to 284 territories per square mile) in unburned coastal sagebrush scrub.

The largest threat to the sage sparrow is the loss and fragmentation of appropriate shrub habitat. Like other species, it has lost suitable habitat to urbanization and agricultural conversion, especially in southern California (County of Riverside 2008). Fragmentation of shrubland habitats, whether by wildfire, shrub die-off, or human-caused disturbance, significantly affects sage sparrows. This species is more likely to remain in an area that has high shrub cover, low disturbance, large patch sizes, and high within-site spatial similarity. Bell's sage sparrow occurs less often in small patches and near developed edges (Carlson 2002; Bolger *et al.* 1997). In one study in San Diego County (Bolger *et al.* 1997), it was one of four species (of many studied) whose abundance was most reduced by habitat fragmentation. This species is also vulnerable to brown-headed cowbird nest parasitism (County of Riverside 2008), which is increased near habitat edges. Grazing may result in habitat degradation and reduction of populations, such as on San Clemente Island where removal of grazing animals resulted in the recovery of native vegetation and sage sparrow populations (County of Riverside 2008). Proximity to humans also increases the possibility of predation by domestic cats.

Sage sparrows are also affected by fire frequencies (Chase and Carlson 2002). Bell's sage sparrow in particular prefers areas where shrub cover is relatively low and dispersed (Lovio 1999). Long-term fire suppression promotes tall, dense shrublands that are not suitable sage sparrows (County of Riverside 2008). However, if fires occur too frequently, sage sparrows abandon habitats where non-native annual grasses replace shrubs.

Other development- and human-related impacts that could affect this species include construction-related dust; noise and ground vibration; nighttime lighting, which may induce physiological stress and increase predation by nocturnal predators; and pesticides, which may reduce vegetative food sources (seeds) and prey or cause secondary poisoning. Areas of

increased moisture along the open space–urban interface may attract Argentine ants that prey on nestlings.

Survey Results

Suitable chaparral and coastal scrub habitat for Bell's sage sparrow is located throughout the Project area. Surveys for upland bird species have been conducted throughout the Project area and in nearby areas between 1995 and 2008.

Bell's sage sparrow has never been detected within the Project area, but two individuals were observed in April 2004 during a focused bird survey in the Legacy Village project site (Guthrie 2004C). This site is adjacent to the Specific Plan area, just south of Mission Village and east of Potrero Village. Like the Specific Plan site, the Legacy Village project site contains California sagebrush scrub and other upland habitats suitable for Bell's sage sparrow. Individuals in the Legacy Village project site were observed in dry sage scrub habitat on cliffs near the eastern edge of the study site and probably nest in small numbers in the area (Guthrie 2004C).

Most of the upland surveys for birds were focused surveys for coastal California gnatcatcher. Because the gnatcatcher uses similar (although denser) coastal scrub habitat, the gnatcatcher surveys would have resulted in detection of Bell's sage sparrow wherever this species was present in coastal scrub habitat. However, Bell's sage sparrows also use chaparral habitats, which might not have been surveyed as thoroughly as scrub habitats because they are not used by California gnatcatchers and are often too dense to penetrate. Bloom Biological, Inc. (2007A, 2008), considers the Bell's sage sparrow to be a resident in chamise-dominated chaparral and in sage scrub along ridgelines throughout much of the Santa Clara Valley; however, it was not detected in the 2007 survey, which extended marginally into typical sage sparrow habitat on the higher slopes and ridgelines. Based on surveys and an evaluation by Bloom Biological, Inc. (2007A, 2008), the Bell's sage sparrow is considered a likely resident in the chaparral habitat but it probably does not occur in high numbers because the species has not been detected for over a dozen years during surveys of suitable sage scrub habitat. It could, however, be present within the chaparral habitat on site. Suitable habitat for Bell's sage sparrow, based on the species life history information provided above, generally includes scrub and chaparral. However, based on the results of Guthrie and Bloom studies summarized above that included surveys of scrub habitats as part of focused surveys for the California gnatcatcher, the Bell's sage sparrow does not appear to use the coastal scrub habitats on site. This species is known to also occur in chaparral, perhaps predominantly within this region (Garrett and Dunn 1981), and may be using chaparral habitat exclusively, thus explaining the lack of observation over the many years of surveys of sage scrub habitats. Thus, for the purposes of this EIS/EIR analysis, the suitable habitat for Bell's sage sparrow is considered to be chaparral vegetation communities, including undifferentiated chaparral scrubs, chamise chaparral, and scrub oak chaparral. A total of 2,146 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 26 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.2% of these habitats on site (**Figure 4.5-102**, Alternative 2 Impacts to Scrub and Chaparral Wildlife Habitat). A total of 1.5 acres would be temporarily impacted.

The Bell's sage sparrow is still a wide-ranging species, but probably occurs in low numbers on site given the few observations of the species in the Project vicinity (*i.e.*, two observations in Legacy Village). The construction of RMDP facilities would be phased over a long period of time and approximately 1,494 acres of suitable habitat would be available for this species in the High Country SMA and Salt Creek area at any given time. Therefore, the permanent loss of 26 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 431 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 20.1% of suitable

habitat on site (**Figure 4.5-102**, Alternative 2 Impacts to Scrub and Chaparral Wildlife Habitat).

A relatively large amount and percentage of suitable habitat for Bell's sage sparrow would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from approximately 22.1% of suitable habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 457 acres (21.3%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of Bell's sage sparrow in the Project area, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because the Bell's sage sparrow is highly mobile, it is unlikely that RMDP-related construction activities would result in mortality of adult birds of this species. However, birds would be physically displaced from occupied habitat. Implementation of the SCP would not directly impact this species. This species has not been observed nesting on site; however, it is considered likely to be present based on its presence on the Legacy Village project site. Bell's sage sparrow is a non-migratory subspecies, thus, if present, it would nest on site, and vegetation clearing or grading during the nesting season could result in destruction of nests, eggs, or young, or cause nest abandonment. Because of the special status of this bird species and the potential for injury or mortality of individual birds and, specifically, for destruction of nest, eggs, or young; interference with foraging and provisioning of young, resulting in reduced survivorship; or nest abandonment; such impacts would have a substantial direct adverse effect on this species (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct impacts to individuals, but over a much larger area. Construction and/or grading activities may occur during the nesting season and could result in the destruction of nest, eggs, or young, interfere with forging and provisioning of young, or cause nest abandonment. These impacts would have a substantial adverse impact on this species (significance criterion 1). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

In the short term, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas occurring during the breeding season would have the potential to affect Bell's sage sparrow in areas adjacent to construction zones. These impacts could include exposure to construction-related dust, noise, ground vibration, and nighttime lighting. Dust could degrade habitat quality, noise and ground vibration could affect nesting and foraging behavior, and nighttime lighting could induce physiological stress and increase predation by nocturnal predators. Potential long-term development-related secondary impacts include habitat fragmentation, habitat degradation from frequent wildfires, increased human activity, nighttime illumination, potential harassment by humans and pet, stray, and feral cats and dogs and other mesopredators, loss of food sources and secondary poisoning from pesticides, and cowbird nest parasitism and predation of nestlings by Argentine ants along the open space–development interface.

These short-term and long-term secondary impacts would permanently reduce the number of Bell's sage sparrows that may occur along the urban–open space edge, interfere with the movement of the species between habitat areas due to fragmentation, and contribute to the reduction of the range and distribution of the Bell's sage sparrow in the Project area (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for Bell's sage sparrow (**Figures 4.5-103** through **4.5-107**, Alternatives 3 through 7 Impacts to Scrub and Chaparral Wildlife Habitat):

- Alternative 3 – 25 acres (1.2%) of permanent loss and 1.8 acres of temporary loss;
- Alternative 4 – 27 acres (1.3%) of permanent loss and 1.5 acres of temporary loss;
- Alternative 5 – 27 acres (1.3%) of permanent loss and 1.8 acres of temporary loss;
- Alternative 6 – 24 acres (1.1%) of permanent loss and 1.8 acres of temporary loss; and
- Alternative 7 – 21 acres (1.0%) of permanent loss and 9.1 acres of temporary loss.

Compared to Alternative 2, which would result in 26 acres (1.2%) of permanent habitat loss and 1.5 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 through 7 would not be substantially different. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would not be substantially different and Alternative 7 would be substantially more. The difference between Alternative 7 impacts and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts to Bell's sage sparrow suitable habitat compared to the other alternatives.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude to the overall loss of habitat under Alternative 2, impacts under Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for Bell's sage sparrow (**Figures 4.5-103** through **4.5-107**, Alternatives 3 through 7 Impacts to Scrub and Chaparral Wildlife Habitat):

- Alternative 3 – 417 acres (19.4%) of permanent loss;
- Alternative 4 – 408 acres (19.0%) of permanent loss;
- Alternative 5 – 409 acres (19.1%) of permanent loss;
- Alternative 6 – 407 acres (18.9%) of permanent loss; and
- Alternative 7 – 327 acres (15.2%) of permanent loss.

Compared to Alternative 2, which would result in 431 acres (20.1%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would generally be successive reductions in

the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would reduce impacts to Bell's sage sparrow suitable habitat compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be somewhat or substantially less than overall habitat loss under Alternative 2, but still substantial, these impacts would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for Bell's sage sparrow:

- Alternative 3 – 443 acres (20.6%) of permanent loss;
- Alternative 4 – 435 acres (20.3%) of permanent loss;
- Alternative 5 – 436 acres (20.3%) of permanent loss;
- Alternative 6 – 431 acres (20.1%) of permanent loss; and
- Alternative 7 – 348 acres (16.2%) of permanent loss.

Compared to Alternative 2, which would result in 457 acres (21.3%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7; there would also be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7. There would be additional pullbacks from the Santa Clara River and its tributaries and other reductions to the Project footprint under Alternative 7 that would reduce impacts to Bell's sage sparrow suitable habitat compared to the other alternatives. Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for Bell's sage sparrow occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial and therefore would be significant, absent mitigation.

Impacts to Individuals

The potential impacts to Bell's sage sparrow individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than for Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Individuals could be displaced from occupied habitat by construction activities, and construction occurring during the nesting season could result in the destruction of nest, eggs, or young; interfere with foraging and provisioning of young, resulting in reduced survivorship; or cause nest abandonment. These impacts to individual Bell's sage sparrows occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development. Short-term impacts include construction-related dust, noise, ground vibration, and nighttime illumination, that could cause habitat degradation, disrupt nesting and foraging activities, and cause abandonment of nests. Potential long-term secondary impacts include habitat fragmentation, habitat degradation due to wildfire, increased human activity, nighttime illumination, increased predation, secondary poisoning, and cowbird parasitism, as described above for Alternative 2. These secondary impacts would permanently reduce Bell's sage sparrow populations along the urban–open space edge and contribute to the reduction of the range and distribution of this species in the Project area. Short-term and long-term secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to Bell's sage sparrow: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and habitat outside the Project footprint.

Bell's sage sparrow has not been observed in the Project area, but the species has been observed on the adjacent Legacy Village site. It is assumed to occur and nest in habitat on site that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. While adults are mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, individuals could be displaced from occupied habitat by construction activities.

Impacts to individuals also could occur if active nests were disturbed during vegetation clearing and construction/grading activities, resulting in the destruction of the nests and loss of eggs and/or young, or interfering with foraging or provisioning of young. Construction activities may also cause abandonment of nests due to human activity, noise, and ground vibration. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable habitat for the Bell's sage sparrow resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 348 acres (16.2%) under Alternative 7 to 457 acres (21.3%) under Alternative 2. This would be a substantial loss of suitable habitat for this species and will alter its use of the Project area. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a permanent open space system that will provide suitable habitat to support both foraging and breeding by the Bell's sage sparrow in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 1,488 acres of suitable habitat for the Bell's sage sparrow in the High Country SMA and the Salt Creek area (**Figure 4.5-3**).

With regard to secondary effects, foraging and nesting activities by the Bell's sage sparrow could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may cause adults to vacate territories and abandon nests due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to nocturnal predators. These short-term construction-related secondary impacts will be minimized by conducting pre-construction surveys to determine if active nests are present in the disturbance zone or within 300 feet, and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include habitat fragmentation; wildfire; increased human activity; lighting; pesticides, which may cause secondary poisoning and loss of food sources; harassment by pet, stray, and feral cats and dogs and other mesopredators; Argentine ants that may prey on nestlings; and cowbird nest parasitism, which could reduce reproductive success. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of approximately 1,488 acres of suitable habitat in the High Country SMA and Salt Creek area will provide Bell's sage sparrows with relatively undisturbed habitat. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by predators and reduce behavioral disturbances and physiological stress. Limited recreational usage and access restrictions within the High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect Bell's sage sparrows by allowing them to nest

and forage without disturbance. Cowbird trapping will be conducted, as necessary. Controls on pesticides will reduce the chance of secondary poisoning and loss of food sources.

The specific mitigation measures for the Bell's sage sparrow are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-134 IMPACTS TO INDIVIDUALS – BELL'S SAGE SPARROW

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of Bell's sage sparrow individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to Bell's sage sparrow individuals

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to Bell's sage sparrow individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-135 LOSS OF HABITAT – BELL'S SAGE SPARROW

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for Bell's sage sparrow through habitat protection, restoration and enhancement, and management.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The High Country SMA will protect and manage approximately 1,362 acres of suitable habitat for Bell's sage sparrow.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measure to mitigate for the loss of habitat for Bell's sage sparrow through habitat protection, restoration and enhancement, and management.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. The Salt Creek area includes 125 acres of suitable habitat for the Bell's sage sparrow.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the Bell's sage sparrow would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-136 SECONDARY IMPACTS – BELL'S SAGE SPARROW

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as habitat fragmentation, increased human activity, inadvertent impacts to habitat during construction, and nighttime lighting.

SP-4.6-36 through SP-4.6-42, as described above, refer to habitat protection and management in the High Country SMA that will be implemented to mitigate for long-term habitat fragmentation effects and increased human activity.

Several mitigation measures will control human activities in the High Country SMA. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 addresses edge effects along open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only on developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-34 and SP-4.6-35 require that all grading perimeters within the High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to biological resources outside the grading area in the High Country SMA.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to Bell's sage sparrow, including short-term construction-related dust, noise, ground vibration and increased human activity as well as long-term habitat fragmentation; increased human activity; greater vulnerability to predation by pet, stray, and feral cats and dogs and other mesopredators, as well as Argentine ants; loss of food sources and secondary poisoning from pesticide use; and cowbird nest parasitism.

BIO-52 and BIO-56, as described above, will mitigate the effects of noise and ground vibration by identifying nest sites and providing for buffers between nests and construction activities.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-19, as described above, will mitigate for habitat fragmentation effects and increased human activity in the Project area through habitat protection and management in the Salt Creek area.

BIO-63 and BIO-69 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-64 will be implemented to prevent poisoning and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impacts to Bell's sage sparrow by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

BIO-78 requires implementation of a cowbird trapping program once vegetation clearing begins. The program shall be implemented each day beginning April 1 and concluding on or about November 1, through the construction, maintenance, and monitoring period of the riparian restoration sites. In the event that trapping is terminated after the first few years of development, subsequent phases of the RMDP development shall trigger initiation of trapping surveys.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the Bell's sage sparrow would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

BLACK-CHINNED SPARROW (NESTING) (BCC, CALIFORNIA SPECIAL ANIMAL)

Life History

The black-chinned sparrow (*Spizella atrogularis*) occurs from central Mexico north to California, Arizona, New Mexico, Baja California, western Texas, and the southernmost regions of Nevada and Utah. In most of the United States and all of California, this species is not a year-round resident, but migrates south for the winter. In California, the black-chinned sparrow breeds in the inner North Coast Ranges, South Coast Ranges, and on the western slopes of the Sierra Nevada from Kern County north to Mariposa County. It occurs rarely in Shasta and Trinity Counties, on the eastern slope of the Sierra Nevada, and in the White Mountains (Tenney 1997; Winter 2002; Zeiner *et al.* 1990A). In Los Angeles County, this species breeds in the San Gabriel Mountains and occasionally in the Santa Monica Mountains (Winter 2002). Four subspecies of black-chinned sparrow are recognized (Tenney 1997; Winter 2002), two of which occur in California.

Climate and weather seem to affect the distribution of the black-chinned sparrow. In 1984 and 1985, black-chinned sparrows were observed in northern California far north of their normal range limits. This unusual event may have been driven by drought conditions, however similar conditions several years later did not lead to another irruption (Tenney 1997). In contrast, after a wet winter in 1992 and 1993, unusually high numbers of black-chinned sparrows were observed in Santa Barbara County (Tenney 1997).

The black-chinned sparrow occupies arid brushlands and chaparral although it less commonly occurs in coastal sage scrub (Unitt 2004; Garrett and Dunn 1981). The species may use open chaparral (Garrett and Dunn 1981), but usually favors moderately dense but not overgrown chaparral of mixed species and shows lowest numbers in thick old chaparral on north-facing slopes (Tenney 1997; Unitt 2004). In prime habitat, it can occur in large concentrations (Unitt 2004). The vegetation in which they occur is usually too dense to easily walk through (NatureServe 2007). Their suitable shrub habitat is typically 1 to 2 meters (3.3 to 6.6 feet) tall and often broken by rocky outcrops and scattered with larger shrubs or trees. In California, the black-chinned sparrow occurs in mixed chaparral, chamise–redshank chaparral, sagebrush, and in the understory of sparse pinyon–juniper, juniper, and other conifer habitats. In San Diego and Los Angeles counties, the black-chinned sparrow prefers chamise mixed with manzanita, our Lord's candle, scrub oak, and ceanothus. The black-chinned sparrow readily recolonizes recovering burned chaparral (Unitt 2004). The slopes on which the black-chinned sparrow occurs are usually south-facing and vary from gentle to steep (NatureServe 2007; Tenney 1997). The species is found from sea level to nearly 2,700 meters (8,860 feet) AMSL in elevation (NatureServe 2007).

The diet of the black-chinned sparrow consists of adult and larval insects in the breeding season and small seeds during the winter (Weathers 1983; NatureServe 2007).

Nests are usually built by females above the ground in dense shrubs. Pairs are usually observed near their nests and the size of any pair's territory may vary with habitat. Singing males are more closely spaced in moderately dense chaparral dominated by chamise than in overgrown scrub oak and sagebrush with scattered pines. One researcher (Tenney 1997) documented territories of 1.6 to 4.0 hectares (4.0 to 10 acres) per pair. Density estimates also vary based on habitat and may be misleading because the species may be locally common on one hillside, then absent for long stretches of similar habitat. Four pairs per square mile (260 hectares) were observed in sagebrush in the Providence Mountains Relative densities are particularly high in the arid chaparral slopes of Los Angeles compared to other regions sampled in the Breeding Bird Survey between 1966 and 1991 (Tenney 1997).

Populations of black-chinned sparrows are declining in California, especially in the privately owned foothills of California that are being developed rapidly (NatureServe 2007; Tenney 1997; Winter 2002). Between 1980 and 2000, a 2.2% decrease per year in numbers in California was recorded, compared to a 0.2% decrease elsewhere in the bird's range, although the data were highly variable, and had small sample sizes and low detection rates (Sauer *et al.* 2001). Bolger *et al.* (1997) concluded that the black-chinned sparrow is highly sensitive to habitat fragmentation; however, this conclusion assumed that the individuals were uniformly distributed over their study area prior to urbanization. Black-chinned sparrow distributions may vary, from occurring in very dense populations to not being present at all for large expanses within the same patch of habitat (Unitt 2004); therefore, the assumption of uniform distribution may not be accurate and these results should be viewed with caution. Overgrazing may also degrade the chaparral habitat, and overgrazing of grasslands during the winter may affect grass seed abundance, which is this species' primary food source during winter (Tenney 1997). Off-road vehicles have caused degradation of breeding habitat on San Benito Mountain in San Benito County, California (Tenney 1997). Other development- and human-related impacts that could affect this species include construction-related dust; noise and ground vibration; nighttime lighting, which may induce physiological stress and increase predation by nocturnal predators; and pesticides, which may reduce prey or cause secondary poisoning. Areas of increased moisture along the open space–urban interface may attract Argentine ants that prey on nestlings.

Survey Results

Suitable chaparral and coastal scrub habitat for the black-chinned sparrow is located throughout the Project area. Surveys for upland bird species have been conducted throughout the Project area and in nearby areas between 1995 and 2008.

The black-chinned sparrow was not detected within the Project area or region during any of these surveys. Most of the upland surveys for birds were focused surveys for coastal California gnatcatcher. Because the gnatcatcher uses similar (although denser) coastal scrub habitat, the gnatcatcher surveys would have resulted in detection of the black-chinned sparrow if this species

was commonly present in coastal scrub habitat. However, black-chinned sparrows also use chaparral habitats, which might not have been surveyed as thoroughly as scrub habitats because they are not used by California gnatcatchers and are often too dense to penetrate. Bloom Biological, Inc. (2008) evaluated the potential for this species to occur and concluded that although it has not been observed, it is likely to occur as a migrant on coastal scrub- and chaparral-covered hillsides and a few may remain to breed on rugged slopes. However, because the species has not been detected on site for over a dozen years, it is not believed to commonly occur within the Project area and it is not expected to breed on site. Because suitable habitat is present in the Project area and it could occur as a migrant, potential impacts to this species are analyzed in this EIS/EIR. For the purposes of this EIS/EIR analysis, the suitable habitat for black-chinned sparrow is considered to be chaparral (undifferentiated chaparral scrubs, chamise chaparral, and scrub oak chaparral) and coastal scrub alliances and associations. A total of 6,574 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 80 acres of suitable habitat would be directly permanently lost through implementation of the RMDP and the SCP, representing 1.2% of these habitats on site (**Figure 4.5-102**, Alternative 2 Impacts to Scrub and Chaparral Wildlife Habitat). A total of 9.0 acres would be directly temporarily impacted.

The black-chinned sparrow is still a wide-ranging species and not expected to commonly occur on site (if it did occur, it would be in very small numbers). The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable chaparral habitat in the High Country SMA and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 80 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during

construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 1,971 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 30.0% of these habitats on site (**Figure 4.5-102**, Alternative 2 Impacts to Scrub and Chaparral Wildlife Habitat).

While a relatively large amount and percentage of suitable winter foraging habitat and potential breeding habitat for low numbers of the black-chinned sparrow would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas, based on the absence of observations of this species on site and expected rare occurrence as a migrant, this habitat is expected to be rarely used for foraging or nesting by black-chinned sparrows. Furthermore, during migration black-chinned sparrows use coastal scrub and chaparral habitats throughout the state and are not restricted to any one migration route or winter habitat area. For these reasons, the loss of 30% of the habitat on site would not have a substantial adverse effect on this species; interfere with the movement of the species between important habitat areas; cause the species population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,051 acres (31.2%). Although a large amount and percentage of habitat would be lost, for the reasons cited above, a loss of 31.2% of suitable habitat on site would not have a substantial adverse effect on the black-chinned sparrow. The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because this species is highly mobile and uses the site rarely, if at all, for either nesting or foraging, direct impacts from implementation of the RMDP and the SCP would be highly unlikely to result in injury or mortality of adults or destruction of nests, young, or eggs as a result of vegetation clearing or grading activities. Furthermore, pre-construction surveys for nesting birds are required by EIS/EIR Mitigation Measure BIO-56, so, in the unlikely event that the species nested on site, no nests, eggs, nestlings, and/or fledglings would be lost as a direct result of construction activities. Any migrants on site during construction activities may be displaced from removed habitat, but there would be substantial available habitat for this species elsewhere in the Project vicinity. Because no substantial impacts from implementation the RMDP and the SCP are expected to occur, the Project would not have a substantial direct adverse effect on this species; cause the species population to drop below self-sustaining levels on site or rangewide; interfere with the movement of the species between important habitat areas; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct impacts to individuals. The black-chinned sparrow is highly mobile and not expected to nest on site. Individuals may be displaced from suitable habitat, but no injury or mortality of adults or destruction of nests, eggs, or young is expected to occur. Indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

In the short term, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would have the potential to affect this species in suitable habitat adjacent to construction zones. These impacts could include exposure to construction-related dust, noise, ground vibration, and nighttime illumination that could inhibit the species from using suitable habitat for foraging or nesting. However, the species is only expected to use the site rarely as a migrant or for breeding, and would likely occur in very low numbers based on an evaluation of the habitat on site (Bloom Biological 2007A). The potential for short-term secondary impacts to the black-chinned sparrow is very low.

Potential long-term secondary effects, such as habitat fragmentation impacts; increased human activity; increased pet, stray, and feral cats and dogs; and pesticide use are unlikely to

substantially affect this species because it can use a variety of coastal scrub and chaparral habitats within the region and is highly mobile. The species would not be vulnerable to the nest predation issues associated with development edges because it is not known to nest in the Project region.

For these reasons, potential short-term and long-term secondary impacts would not have a substantial adverse effect on this species; interfere with the movement of the species between important habitat areas; cause the species population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the black-chinned sparrow (**Figures 4.5-103** through **4.5-107**, Alternatives 3 through 7 Impacts to Scrub and Chaparral Wildlife Habitat):

- Alternative 3 – 76 acres (1.2%) of permanent loss and 12 acres of temporary loss;
- Alternative 4 – 77 acres (1.2%) of permanent loss and 8.7 acres of temporary loss;
- Alternative 5 – 82 acres (1.2%) of permanent loss and 14 acres of temporary loss;
- Alternative 6 – 68 acres (1.0%) of permanent loss and 16 acres of temporary loss; and
- Alternative 7 – 42 acres (0.6%) of permanent loss and 43 acres of temporary loss.

Compared to Alternative 2, which would result in 80 acres (1.2%) of permanent habitat loss and 9.0 acres of temporary impacts, the permanent loss of habitat would not be substantially different under Alternatives 3 through 5, and would be somewhat less under Alternatives 6 and 7. Compared to Alternative 2, the temporary loss of habitat would not be substantially different under Alternatives 3 through 6 and would be somewhat greater under Alternative 7. Alternative 7 would have reduced permanent impacts and greater temporary impacts to black-chinned sparrow habitat compared to the other alternatives, primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

The overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be less than or similar in magnitude to the overall loss of habitat under Alternative 2, and would be somewhat greater under Alternative 7; therefore, for the reasons cited above for Alternative 2, the impacts under Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the black-chinned sparrow (**Figures 4.5-103** through **4.5-107**, Alternatives 3 through 7 Impacts to Scrub and Chaparral Wildlife Habitat):

- Alternative 3 – 1,866 acres (28.4%) of permanent loss;
- Alternative 4 – 1,814 acres (27.6%) of permanent loss;
- Alternative 5 – 1,766 acres (26.9%) of permanent loss;
- Alternative 6 – 1,517 acres (23.1%) of permanent loss; and
- Alternative 7 – 1,349 acres (20.5%) of permanent loss.

Compared to Alternative 2, which would result in 1,971 acres (30.0%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would reduce the loss of suitable habitat for black-chinned sparrow compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be substantially less than the overall loss of habitat under Alternative 2, these impacts would be adverse but not significant under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the black-chinned sparrow:

- Alternative 3 – 1,942 acres (29.5%) of permanent loss;
- Alternative 4 – 1,892 acres (28.8%) of permanent loss;
- Alternative 5 – 1,848 acres (28.1%) of permanent loss;
- Alternative 6 – 1,586 acres (24.1%) of permanent loss; and
- Alternative 7 – 1,391 acres (21.2%) of permanent loss.

Compared to Alternative 2, which would result in 2,051 acres (31.2%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7; there would also be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7. There would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 that would reduce impacts to suitable habitat for black-chinned sparrow compared to the other alternatives.

Because the overall combined loss of habitat from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be substantially less than the overall loss of habitat under Alternative 2, these impacts would be adverse but not significant under Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to black-chinned sparrow individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than for Alternative 2. Migrant individuals may occasionally be displaced from suitable habitat, but injury or mortality of adults or destruction of nests, eggs, or young is not expected to occur. Therefore, this impact (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development. Because of the low probability of the black-chinned sparrow occurring on site

either as a migrant or for breeding, short-term and long-term secondary impacts would be adverse but not significant under Alternatives 3 through 7.

Mitigation Strategy and Summary

No mitigation is required for impacts to the black-chinned sparrow because all impacts were determined to be adverse but not significant. As noted above, BIO-56 requires pre-construction surveys for all native nesting birds to determine if active nests are present in the disturbance zone or within 300 feet (500 feet for raptors). If active nests are found, clearing and construction in the vicinity will be postponed at the discretion of the biologist, until the nest is vacated. This measure will protect black-chinned sparrow nests in the unlikely event it nests on site in the future within or adjacent to development areas, and no black-chinned sparrow nests, eggs, nestlings, and/or fledglings would be lost as a direct result of construction activities. Several other mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of approximately 3,487 acres of suitable habitat in the High Country SMA, Salt Creek area, and River Corridor SMA. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction because individuals will have access to foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction and controls on lighting. Long-term effects such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; and pesticides will also be mitigated through a variety of measures.

COSTA'S HUMMINGBIRD (NESTING) (CALIFORNIA SPECIAL ANIMAL)

Life History

Costa's hummingbird (*Calypte costae*) is found in southern California, Arizona, Baja California, and western Mexico, but also extends into Nevada, extreme southeastern Utah, and southeastern New Mexico. This species is most abundant in the deserts of southern California and Arizona from March to April at the height of the breeding season. Costa's hummingbird breeds along the western edge of the San Joaquin Valley and the eastern edge of the Sierra Nevada (McCaskie *et al.* 1979). In winter, it is largely restricted to the southern coast, but it also winters in southern deserts (Garrett and Dunn 1981). Most desert breeders depart by late May, but numbers remain high on the coast until late September (Zeiner *et al.* 1990A). There is upslope movement after breeding and during fall migration (Garrett and Dunn 1981).

Costa's hummingbird occurs primarily in more arid habitats than where other hummingbirds occur in California. Primary habitats are desert wash, edges of desert riparian and valley foothill riparian, coastal scrub, desert scrub, desert succulent scrub, lower-elevation chaparral, and palm oasis (Zeiner *et al.* 1990A). Along the California coast and in coastal mountain ranges, the species uses xeric habitats, especially California coastal scrub or sage scrub and dry open stretches of chaparral (Garrett and Dunn 1981; Unitt 1984; Baltosser and Scott 1996). Costa's hummingbirds in the Santa Monica Mountains have a strong preference for the drier and more open expanses in and around the mountains, including southern and western exposures, sage-covered slopes, and oak savannas (Baltosser and Scott 1996). In the San Gabriel Mountains, they occur in foothills, in chaparral and coastal scrub communities where the shrub canopy is sparse, and where black sage is abundant (Baltosser and Scott 1996). Costa's hummingbird is a persistent breeder in suburbs and coastal scrub remnants on the Palos Verdes peninsula and elsewhere, but the species is not as successful as Anna's hummingbird (Wells *et al.* 1978).

Costa's hummingbirds are nectar feeders, but also forage for spiders and small insects. Black sage and white sage are common nectar sources in late April to June; heart-leaved penstemon and tree tobacco are common from July to August; and woolly bluecurls and bush-monkeyflower are also visited (Baltosser and Scott 1996). On burned areas, the species is attracted to sticky nama, vinegarweed, and purple penstemon as well as to black sage (Baltosser and Scott 1996). In winter, exotic shrubs such as bottlebrush are an important food source (Garrett and Dunn 1981).

Nests are placed in a wide variety of trees, cacti, shrubs, woody forbs, and sometimes vines (Baltosser and Scott 1996). Territory size of the male is often quite large and is typically 1.0 to 1.5 hectares (2.5 to 3.7 acres), containing scattered tall perches and many food sources (Zeiner *et al.* 1990A). After fledging, juveniles often remain near the nest, but dispersal information thereafter is not known for this species (Baltosser and Scott 1996).

The main threat to Costa's hummingbird is loss of habitat. The species relies on several habitats threatened by development, such as coastal scrub habitat. In southern California, Costa's hummingbird has shown some adaptability to agricultural and urban development; it has been documented to breed in orchards in Los Angeles County, and it presently breeds and winters in coastal suburbs (Baltosser and Scott 1996). While hummingbirds generally can adapt to bird feeders and ornamental plants, Anna's hummingbird probably outcompetes Costa's hummingbird in such places (Baltosser and Scott 1996). Other development- and human-related impacts that could affect this species include construction-related dust; noise and ground vibration; nighttime lighting, which may induce physiological stress and increase predation by nocturnal predators; disturbance by humans and pet, stray, and feral cats; and the increased risk of fire, which affects native flowers by promoting non-native grasses and forbs, and destroys nesting trees that are not fire resistant. Areas of increased moisture along the open space–urban interface may attract Argentine ants, which prey on nestlings.

Survey Results

Suitable upland and riparian habitat for the Costa's hummingbird is present throughout the Specific Plan, VCC, and Entrada planning areas. No focused surveys for the Costa's hummingbird have been conducted, but suitable upland and riparian habitat for this species has been surveyed during surveys for other bird species. Surveys for upland bird species have been conducted throughout the Project area and in nearby areas between 1995 and 2007.

On site, this species has not been observed to nest; however, it occurs as a migrant and has the potential to breed in coastal scrub and chaparral on the hillsides within the Project area (Bloom Biological 2007A, 2008). The Costa's hummingbird has been observed over multiple years during the bird surveys conducted from 1988 through 2006 along the Santa Clara River within riparian scrub and woodland habitat (Guthrie 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1998A, 1998B, 1999A, 1999B, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2005A, 2005B, 2006A, 2006C; Labinger *et al.* 1995, 1996, 1997B; Labinger and Greaves 1999A). Other observations have been made in the VCC planning area (Guthrie 1994A, 1995A, 1996A, 1999A, 2000E, 2001A, 2002A, 2003A, 2004B, 2005A, 2006C) and off site within the Castaic Junction area (Guthrie 1988, 1989, 1993A, 1994A, 1997A, 2000F, 2001A, 2002A, 2003A, 2004I, 2006C; Dudek and Associates 2006E). The primary survey limitation is that focused surveys have not been conducted for Costa's hummingbird and no specific observations were mapped.

Because the Costa's hummingbird has regularly been observed during surveys in both upland shrublands and riparian areas, it is expected to occur throughout suitable habitat in the Project area, including alluvial scrub, coastal scrub alliances and associations, chaparral (undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral), and riparian communities (alluvial scrub, big sagebrush scrub, Mexican elderberry, mulefat scrub, southern

coast live oak riparian forest, southern cottonwood–willow riparian, and southern willow scrub). A total of 7,106 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 136 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.9% of these habitats on site (**Figure 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat). A total of 62 acres would be directly temporarily impacted.

Costa's hummingbird is still a wide-ranging species and uses a variety of scrub, chaparral, and riparian habitats. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 136 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 1,992 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 28.0% of these habitats on site (**Figure 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat).

A relatively large amount and percentage of suitable habitat on site for Costa's hummingbird would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from 28.0% of suitable habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,128 acres (29.9%). Because of the large amount and percentage of habitat loss, the combined direct and indirect impacts to suitable habitat would have a substantial adverse effect on the distribution of Costa's hummingbird in the Project area, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Based on the results from past surveys, Costa's hummingbird is considered to be fairly common as a migrant in the Project area, but it also has the potential to breed on site in the coastal scrub and chaparral. Because these birds are highly mobile, it is unlikely that RMDP-related construction activities would result in injury or mortality of adult birds, but foraging or nesting individuals may be displaced from suitable habitat. Implementation of the SCP would not directly impact this species. Costa's hummingbird also has the potential to breed on site, and vegetation clearing or grading activities associated with implementation of the RMDP occurring during the nesting season could result in the destruction of nests, eggs, or young; interfere with foraging and provisioning of young; or cause nest abandonment. These impacts would have a substantial adverse impact on this species (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent and temporary impacts to individuals, but over a much larger area. Construction and/or grading activities may occur during the nesting season and could result in the destruction of nests, eggs, or young; interfere with foraging and provisioning of young; or cause nest abandonment. These impacts would have a substantial adverse impact on this species (significance criterion 1). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

In the short term, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas occurring during the breeding season would have the potential to affect Costa's hummingbirds in areas adjacent to construction zones. These impacts could include exposure to construction-related dust, noise, ground vibration, and nighttime illumination. Dust may degrade foraging habitat quality, noise and ground vibration could disrupt foraging and nesting activities, and nighttime illumination could induce physiological stress and increase predation by nocturnal predators. ,Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include increased human activity, which may affect nesting behavior; and greater vulnerability to nocturnal predators as a result of nighttime lighting, as well as greater vulnerability to predation by pet, stray, and feral cats and other mesopredators within about 200 feet of the urban–open space edge. Attraction of Argentine ants to moist habitats, especially riparian areas, could result in predation on nestlings. These secondary impacts would permanently reduce Costa's hummingbird populations along the urban–open space edge and contribute to the reduction of the range and distribution of this species in the Project area (significance criteria 1 and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for Costa's hummingbird (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 116 acres (1.6%) of permanent loss and 66 acres of temporary loss;
- Alternative 4 – 119 acres (1.7%) of permanent loss and 58 acres of temporary loss;
- Alternative 5 – 129 acres (1.8%) of permanent loss and 71 acres of temporary loss;
- Alternative 6 – 102 acres (1.4%) of permanent loss and 67 acres of temporary loss; and
- Alternative 7 – 51 acres (0.7%) of permanent loss and 77 acres of temporary loss.

Compared to Alternative 2, which would result in 136 acres (1.9%) of permanent habitat loss and 62 acres of temporary impacts, the permanent loss of habitat under Alternative 5 would not be substantially different, Alternative 4 would be marginally less, Alternatives 3 and 6 would be somewhat less, and Alternative 7 would be substantially less. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3, 4, 5, and 6 would not be substantially different and Alternative 7 would be marginally greater. The difference between permanent loss of habitat for Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries and other changes to the Project footprint under Alternative 7 that would result in substantially reduced permanent impacts to suitable habitat for Costa's hummingbird and relatively greater temporary impacts compared to the other alternatives.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be less than or similar in magnitude to the overall loss of habitat under Alternative 2, impacts under Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for Costa's hummingbird (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 1,883 acres (26.5%) of permanent loss;
- Alternative 4 – 1,829 acres (25.7%) of permanent loss;
- Alternative 5 – 1,778 acres (25.0%) of permanent loss;

- Alternative 6 – 1,525 acres (21.5%) of permanent loss; and
- Alternative 7 – 1,354 acres (19.1%) of permanent loss.

Compared to Alternative 2, which would result in 1,992 acres (28.0%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would reduce impacts to suitable habitat for Costa's hummingbird compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar in magnitude to or somewhat less than the overall loss of habitat under Alternative 2, but still substantial, these impacts would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for Costa's hummingbird:

- Alternative 3 – 1,999 acres (28.1%) of permanent loss;
- Alternative 4 – 1,948 acres (27.4%) of permanent loss;
- Alternative 5 – 1,907 acres (26.8%) of permanent loss;
- Alternative 6 – 1,627 acres (22.9%) of permanent loss; and
- Alternative 7 – 1,405 acres (19.8%) of permanent loss.

Compared to Alternative 2, which would result in 2,128 acres (29.9%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, there would also be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 that would reduce impacts to suitable habitat for Costa's hummingbird compared to the other

alternatives. Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for Costa's hummingbird occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial and therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to Costa's hummingbird individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Foraging individuals may be displaced from construction areas, and clearing or grading activities occurring during the nesting season could result in the destruction of nests, eggs, or young; interference with foraging and provisioning of young; or abandonment of nests (significance criterion 1). Impacts to individual Costa's hummingbirds occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development. Short-term impacts include construction-related dust, noise, ground vibration, and nighttime illumination. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include increased human activity and increased predation by nocturnal predators; pet, stray, and feral cats; and Argentine ants; as described above for Alternative 2. These secondary impacts would permanently reduce Costa's hummingbird populations along the urban–open space edge and contribute to the reduction of the range and distribution of this species in the Project area. Short-term and long-term secondary impacts would be significant, absent mitigation, for Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to Costa's hummingbird: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Costa's hummingbird has been commonly observed on site. Nesting by this species has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas, but suitable nesting habitat is present and the species has been observed during the nesting season. For the purpose of this analysis, it is assumed that Costa's hummingbirds could nest on site. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, individuals could be displaced from suitable foraging habitat by construction activities. Impacts to individuals also could occur if Costa's hummingbirds were to nest on site and active nests were disturbed during vegetation clearing and construction/grading activities, resulting in the destruction of the nests and loss of eggs and/or young. Construction activities may also interfere with foraging and provisioning of young, and cause abandonment of nests due to human activity, noise, and ground vibration. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable habitat for the Costa's hummingbird resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 1,405 acres (19.8%) under Alternative 7 to 2,128 acres (29.9%) under Alternative 2. This would be a substantial loss of suitable habitat for this species and will alter its use of the Project area for foraging, and potentially nesting. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a permanent open space system that will provide suitable habitat to support both foraging and breeding by the Costa's hummingbird in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 3,861 acres of the suitable habitat for this species in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With regard to secondary effects, foraging, and potentially nesting, activities by the Costa's hummingbird could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may cause adults to vacate foraging areas and abandon nests, if breeding were to occur, due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to predators. These short-term construction-related secondary impacts will be minimized by conducting pre-construction surveys to determine if active nests are present in the disturbance zone or within 300 feet and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include increased human activity; lighting; and predation by pet, stray, and feral cats and Argentine ants. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management

of 3,861 acres of suitable habitat in the River Corridor, High Country SMA, and Salt Creek area will provide Costa's hummingbirds with relatively undisturbed habitat for foraging and potentially nesting. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by predators and reduce behavioral disturbances and physiological stress. Limited recreational usage and access restrictions within the High Country SMA; control of pet, stray, and feral cats in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect Costa's hummingbirds by allowing them to nest and forage without disturbance. Argentine ant monitoring and controls will be implemented.

The specific mitigation measures for the Costa's hummingbird are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-137 IMPACTS TO INDIVIDUALS – COSTA'S HUMMINGBIRD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of Costa's hummingbird individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to Costa's hummingbird individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to Costa's hummingbirds would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-138 LOSS OF HABITAT – COSTA'S HUMMINGBIRD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for Costa's hummingbird through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The River Corridor SMA will preserve and

enhance approximately 381 acres of suitable habitat for Costa's hummingbird. The High Country SMA will preserve and enhance approximately 2,701 acres of suitable habitat for Costa's hummingbird.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and that oak tree replacement occur as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA, including the following: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate the loss of habitat for Costa's hummingbird through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. The Salt Creek area includes 778 acres of suitable habitat for the Costa’s hummingbird.

BIO-20 states that approximately 1,900 acres of coastal scrub that provides habitat for Costa’s hummingbird shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any

burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Implementation of BIO-19, BIO-20, and BIO-21 will minimize and mitigate impacts to Costa's hummingbird by preserving and restoring a large amount of suitable habitat in three interconnected preserved open space areas: the High Country SMA, Salt Creek area, and River Corridor SMA. Implementation of BIO-1 through BIO-16 will ensure that through restoration activities, riparian areas remain high-quality suitable habitat for Costa's hummingbird.

BIO-55 requires that maps of suitable riparian habitat be updated for special-status avian species, and the creation or enhancement of habitat be similar to the habitat removed.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the Costa's hummingbird would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-139 SECONDARY IMPACTS – COSTA'S HUMMINGBIRD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on Costa's hummingbird associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as abandonment of nests due to human activity and greater vulnerability to nocturnal predators as a result of nighttime lighting. Mitigation measures to minimize inadvertent impacts to habitat outside construction zones will also be implemented.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and that generally refer to habitat protection, restoration and enhancement, and management, will be implemented to mitigate long-term habitat fragmentation effects and increased human activity.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed

to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along the open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only on developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to Costa's hummingbird, including short-term, construction-related dust, noise, ground vibration, and increased human activity; and long-term effects, such as increased human activity and greater vulnerability to predation by pet, stray, and feral cats and Argentine ants.

BIO-52 and BIO-56, as described above, will mitigate the effects of noise by identifying nest sites and providing for buffers between nests and construction activities.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, will mitigate for increased human activity in the Project area through habitat protection, restoration and enhancement, and management.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impacts to Costa's hummingbird by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant from riparian areas is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to Costa's hummingbird would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

RUFOUS HUMMINGBIRD (NESTING) (BCC, CALIFORNIA SPECIAL ANIMAL)

Life History

The rufous hummingbird (*Selasphorus rufus*) historically has occurred in western North America and Mexico. Its breeding range extends from coastal southeast Alaska inland to the eastern foothills of the Rocky Mountains in Alberta and British Columbia, Canada, and south to extreme northern California and parts of Idaho and Montana. Its wintering range extends south from southern California through most of Mexico and the coastal regions of the Gulf Coast states. Rufous hummingbirds occurring between the breeding and wintering range are migrants.

The status and distribution of the rufous hummingbird in California is uncertain because of potential confusion with Allen's hummingbird (*Selasphorus sasin*) (Small 1994). However, the extreme northwestern coastal region of the state (Trinity and Humboldt counties) is the southern limit of its breeding range and southern California is the northern extent of its wintering range (McCaskie *et al.* 1979, 1988; Healy and Calder 2006; Zeiner *et al.* 1990A). In northern California, this species may also breed east into the foothills and slopes of the northern and east-central Sierra Nevada. The rufous hummingbird travels through the lowlands and foothills in California between February and early May on its way north to its breeding grounds. Some individuals may remain in southern California as uncommon summer residents (Grinnell and Miller 1944; Zeiner *et al.* 1990A). In the fall, southbound individuals may return through California *via* the Trinity Alps, Cascades, Sierras, and southern deserts, although many return south through the Rocky Mountains on the other side of the Great Basin Desert (Healy and Calder 2006; Zeiner *et al.* 1990A). During migration through the mountains, rufous hummingbirds have been documented between 1,700 and 2,400 meters (5,577 to 7,874 feet) AMSL in elevation. The rufous hummingbird is also a rare migrant on the Channel Islands and the Farallon Islands (Zeiner *et al.* 1990A).

Recently, increasing observations of this species have been made in late fall or winter in the southeast United States (North Carolina, Arkansas, Louisiana, and Florida) and even in several northeastern states. It is likely that artificial hummingbird feeders in these areas attract wintering individuals and contribute significantly to their survival, detectability, regularity of occurrence, and annual returns. Before feeders were so common and widespread, most rufous hummingbirds wandering east probably died in the fall (Healy and Calder 2006).

The rufous hummingbird uses a variety of habitats that provide nectar-producing flowers. In its breeding range, the species uses open expanses as well as coniferous forests, deciduous woods, riparian thickets, swamps, meadows, agricultural areas, parks, and residential areas (Healy and Calder 2006). In areas of Mexico where the rufous hummingbird winters, it has been documented in oak forests with interspersed pine and junipers, shrubby habitats, and in openings in woodlands and forests (Healy and Calder 2006). In California, rufous hummingbirds have been documented in high montane meadows and valley foothill hardwood, valley foothill

hardwood–conifer, riparian, and chaparral habitats (Zeiner *et al.* 1990A). During spring and fall migration, rufous hummingbirds have also been documented in a variety of habitats, including montane meadows and disturbed areas that contain suitable nectar sources for foraging (Healy and Calder 2006). The species also uses forested and brushy secondary succession communities created after fires and logging (Bloom Biological 2007A).

The rufous hummingbird breeds from May to early July, typically nesting in the lower branches of conifers, including spruces, pines, firs, hemlocks, and cedars. The species has also been documented nesting in hardwoods or shrubs (Healy and Calder 2006).

Significant population declines of the rufous hummingbird have been documented, varying from 0.8% to 2.3% each year between 1980 and 2004 in British Columbia, Oregon, and Washington (USGS 2007). If these declines are real, however, there is no obvious cause for them, because secondary succession after disturbances such as logging, fires, and road construction should lead to an increase in nectar sources from flowering forbs and shrubs (Healy and Calder 2006). The current global population of rufous hummingbirds is approximately 6.5 million (Healy and Calder 2006), a figure that does not approach thresholds for serious population decline.

The greatest threat to this species is likely unseasonable cold that affects nectar sources and kills insects (Zeiner *et al.* 1990A). The species is being documented more and more often outside its former wintering range (Hill *et al.* 1998), and it is possible that feeders may elevate populations above natural levels, at least locally. Other development- and human-related impacts that could affect this species include construction-related dust; noise and ground vibration; nighttime lighting, which may induce physiological stress and increase predation by nocturnal predators; and disturbance by humans and pet, stray, and feral cats.

Survey Results

The Project area provides suitable foraging habitat for migrant rufous hummingbirds. The rufous hummingbird does not nest within the Project region. Migrant rufous hummingbirds have been occasionally observed within and near the Project area in several different years from 1995 to 2007. Three rufous hummingbirds were observed in April 1998 west of the Project area along the Santa Clara River between the Ventura County line and the western limit of the Las Brisas Ranch (Guthrie 1998A). Three rufous hummingbirds were observed in early April of 1999 north of Route 126 in what is now the Homestead West area (Guthrie 1999B). One individual was observed in late March 2004 within a study area including Potrero Valley, Oak Valley, Long Canyon, and the Onion Fields (the exact location was not recorded) (Guthrie 2004D). Another individual was observed in early April of 2004 in the southern half of the Legacy Village area (Guthrie 2004C), which is adjacent to the Project area just south of Mission Village and east of Potrero Village. *Selasphorus* hummingbirds that were either rufous or Allen's hummingbirds were observed in other years along the Santa Clara River within and adjacent to the Specific Plan area (Guthrie 2002A, 2002C; Bloom Biological 2007A, 2008). According to Bloom Biological,

Inc., individuals of both species undoubtedly use the Project area during migration (Bloom Biological 2007A). Most observations of unidentified (to species level) *Selasphorus* hummingbirds were made in March or April and were probably migrants of one or both species. Individuals observed in June or July (Guthrie 2002A) could have been resident Allen's hummingbirds or migrant rufous hummingbirds. Overall, the rufous hummingbird is considered a fairly uncommon transitory migrant in the Project area and does not nest on site.

Suitable foraging habitat for migrant rufous hummingbirds in the Project area includes shrublands (coastal scrub alliances and associations, undifferentiated chaparral scrubs, chamise chaparral, and scrub oak chaparral), oak woodlands (coast live oak woodland, valley oak woodland, mixed oak woodland and forest), valley oak/grass, river wash, and riparian scrubs, woodlands, and forests (big sagebrush scrub, big sagebrush–California buckwheat, Mexican elderberry, mulefat scrub, southern coast live oak riparian forest, southern cottonwood–willow riparian, and southern willow scrub). A total of 8,769 acres of suitable foraging habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 165 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.9% of suitable habitat on site (**Figure 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat). A total of 101 acres would be temporarily impacted.

The rufous hummingbird is still a wide-ranging species and uses a variety of scrub, chaparral, riparian, and woodland habitats. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 165 acres of habitat and

temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 2,023 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 23.1% of these habitats on site (**Figure 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat).

The rufous hummingbird is still a wide-ranging species and is a fairly uncommon transitory migrant in the Project area. The infrequent observations of migrating individuals on site suggest that it is not dependent on the Project area for migration. Furthermore, this species uses a variety of scrub, chaparral, riparian and woodland habitats and at least 5,350 acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would remain as protected open space after build-out of the area. Therefore, this permanent loss of habitat as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,188 acres (25.0%).

Because the rufous hummingbird is still a wide-ranging species and is a fairly uncommon transitory migrant in the Project area, this combined loss of habitat would not have a substantial adverse effect on this species; have the potential to substantially reduce the

habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Rufous hummingbirds are highly mobile; therefore, it is unlikely that RMDP-related construction activities would result in injury or mortality of adult birds migrating through the Project area. Migrants, however, may be displaced from foraging areas during construction, but there would be substantial alternative habitat available on site. Vegetation clearing and grading would not result in destruction of young or eggs of this species because it is not expected to nest on site. Implementation of the SCP also would not directly impact this species. Construction and grading activities related to implementation of the RMDP would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

The potential for indirect permanent impacts to rufous hummingbird individuals is similar to that described above for direct permanent and temporary impacts. Injury or mortality of migrating individuals is unlikely to occur, and this species is not expected to nest on site. Migrants, however, may be displaced from foraging areas during construction, but there would be substantial alternative habitat available on site. Therefore, build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

Construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would be short term, and potential short-term secondary impacts, such as fugitive dust, ground vibration, noise, nighttime illumination, and increased human activity, would affect a small proportion of rufous hummingbirds migrating through the Project area.

Similarly, potential long-term development-related secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas, such as nighttime illumination, noise, increased human activity, and predation by pet, stray, and feral cats and dogs and other mesopredators, would affect very few individuals migrating through the Project area. Further, there would be adequate habitat for migrants well away from development edges.

These potential short-term and long-term secondary impacts would not have a substantial adverse effect on this species; cause the species population to drop below self-sustaining levels on site or rangewide; interfere with the movement of the species between important habitat areas; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the rufous hummingbird (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 143 acres (1.6%) of permanent loss and 109 acres of temporary loss;
- Alternative 4 – 146 acres (1.7%) of permanent loss and 96 acres of temporary loss;
- Alternative 5 – 158 acres (1.8%) of permanent loss and 117 acres of temporary loss;

- Alternative 6 – 132 acres (1.5%) of permanent loss and 109 acres of temporary loss; and
- Alternative 7 – 60 acres (0.7%) of permanent loss and 121 acres of temporary loss.

Compared to Alternative 2, which would result in 165 acres (1.9%) of permanent habitat loss and 101 acres of temporary impacts, the permanent loss of habitat would not be substantially different under Alternative 5 and would be marginally reduced under Alternative 4, somewhat reduced under Alternatives 3 and 6, and substantially reduced under Alternative 7. Compared to Alternative 2, the temporary loss of habitat would not be substantially different under Alternatives 3 through 6, and would be marginally greater under Alternative 7. The difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries and other changes to the Project footprint under Alternative 7, which would result in substantially fewer permanent impacts and marginally greater temporary impacts to suitable habitat for the rufous hummingbird under Alternative 7 compared to the other alternatives.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, the impacts under Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the rufous hummingbird (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 1,890 acres (21.6%) of permanent loss;
- Alternative 4 – 1,821 acres (20.8%) of permanent loss;
- Alternative 5 – 1,768 acres (20.2%) of permanent loss;
- Alternative 6 – 1,489 acres (17.0%) of permanent loss; and
- Alternative 7 – 1,352 acres (15.4%) of permanent loss.

Compared to Alternative 2, which would result in 2,023 acres (23.1%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 6 and 7 would impact substantially fewer acres of suitable habitat for rufous hummingbird compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than the overall loss of habitat under Alternative 2, the impacts under Alternatives 3 through 7 would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the rufous hummingbird:

- Alternative 3 – 2,032 acres (23.2%) of permanent loss;
- Alternative 4 – 1,966 acres (22.4%) of permanent loss;
- Alternative 5 – 1,926 acres (22.0%) of permanent loss;
- Alternative 6 – 1,622 acres (18.5%) of permanent loss; and
- Alternative 7 – 1,412 acres (16.1%) of permanent loss.

Compared to Alternative 2, which would result in 2,188 acres (25.0%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts, with Alternatives 6 and 7 having the fewest impacts compared to the other alternatives. Because the combined direct and indirect permanent loss of suitable habitat for the rufous hummingbird occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than the habitat loss under Alternative 2, the impacts under Alternatives 3 through 7 would be adverse but not significant.

Impacts to Individuals

The potential for impacts to rufous hummingbird individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Injury or mortality of migrating individuals is unlikely to occur, and this species is not expected to nest on site. Foraging individuals, however, may be displaced during construction, but substantial alternative foraging habitat would be available. Therefore, construction and/or grading activities would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or

rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Direct and indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development. Short-term impacts include construction-related dust, noise, vibration, and nighttime illumination. These effects are more likely to occur during build-out of the Specific Plan, VCC, and Entrada planning areas than during implementation of the RMDP and the SCP because of the much larger area of impact associated with build-out of the Specific Plan, VCC, and Entrada planning areas. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include increased human activity and increased predation, as described above for Alternative 2. Because the rufous hummingbird is a migrant and there would be adequate suitable habitat well away from development edges, these potential short-term and long-term secondary impacts would not have a substantial adverse effect on the species or contribute to the reduction of its range and distribution. The secondary impacts under Alternatives 3 through 7 would be adverse but not significant.

Mitigation Strategy and Summary

No mitigation is required for impacts to the rufous hummingbird because all impacts were determined to be adverse but not significant. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of approximately 5,350 acres of suitable habitat in the High Country SMA, Salt Creek area, and River Corridor SMA. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction because migrating individuals will have access to habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction and controls on lighting. Long-term effects such as increased human activity; pet, stray, and feral cats and dogs; and lighting will also be mitigated through a variety of measures.

SOUTHERN CALIFORNIA RUFOUS-CROWNED SPARROW (WL)

Life History

The rufous-crowned sparrow (*Aimophila ruficeps*) is a resident of the southwest region of the United States, with a range that extends east from California to Arkansas and south through Mexico and discontinuously to southern Baja California. East of the Rocky Mountains, the rufous-crowned sparrow winters from central and southern Oklahoma to northern Texas and south into Mexico (Terres 1980; NatureServe Explorer 2007).

The southern California rufous-crowned sparrow (*A. r. canescens*), also called the ashy rufous-crowned sparrow (Collins 1999B), is one of three Pacific coast subspecies. The current distribution of the southern California rufous-crowned sparrow is restricted to a narrow belt of semiarid coastal scrub and sparse chaparral from Santa Barbara south to the northwestern corner of Baja California (Todd 1922; Grinnell 1926; Grinnell and Miller 1944; Bent 1968; Zeiner *et al.* 1990A; Unitt 1984; Collins 1999A). The southern California rufous-crowned sparrow is considered a resident throughout its range. No true migratory movements have been recorded, though limited movements to lower elevations in some areas have been reported during especially severe winters (Collins 1999B).

The southern California rufous-crowned sparrow occupies moderate to steep hillsides that are rocky, grassy, or covered by coastal scrub or chaparral. It is a secretive species, seeking cover in shrubs, rocks, grass, and forb patches. Highly suitable habitat consists of sparse, low brush or grass that is interspersed with boulders and outcrops (Willet 1912, 1933; Grinnell 1915, 1926; Grinnell and Miller 1944; Bent 1968; Pulliam and Mills 1977; Phillips *et al.* 1983; Unitt 1984; Ehrlich *et al.* 1988; Root 1988; Terres 1980; Verner and Boss 1980). The southern California rufous-crowned sparrow often occurs near the edges of denser scrub and chaparral associations, but usually does not occur within these associations. Some observers have noted a preference for south- or west-facing slopes and a preference for coastal sagebrush over other vegetation types (Collins 1999B; Barlow 1902; Grinnell 1915; Grinnell and Miller 1944; Bent 1968; Root 1988). The southern California rufous-crowned sparrow often thrives in open expanses that have recently been burned (Collins 1999B). Its elevation range in California (Collins 1999B) is between 60 and 1,400 meters (197 and 4,593 feet) AMSL.

Physical and vegetative characteristics of habitat used by the southern California rufous-crowned sparrow were quantified by Collins (1999A). Occupied sites generally are west-, south-, and east-facing slopes vegetated with low, fairly open cover of shrubs and grass. Most of the occupied sites (89%) were on slopes of 15° to 60° and almost 50% of the sites were on fairly steep slopes between 30° and 45°. Rock outcrops were present on 61% of the occupied sites. Shrub cover averaged 50% and grass cover averaged 29% on occupied sites. Shrub height was generally low in this study, averaging 0.8 meter (2.6 feet). The dominant shrubs associated with

the habitats used by this species included coastal sagebrush, purple sage, black sage, California encelia, coyote brush, mock heather, deer weed, giant rye, and buckwheat.

Although details of the diet of the southern California rufous-crowned sparrow are poorly known, like most sparrows, the diet of this species appears to be a mixture of small invertebrates and seeds of grasses and forbs. The species forages primarily on the ground, but also low in bushes and in the litter beneath them.

Southern California rufous-crowned sparrows are not gregarious and only flock as family groups of no greater than five or six (Bent 1968; Wolf 1977). Territorial males are closely spaced in coastal scrub and more widely spaced in chaparral that is regenerating after a fire. Average territory size is estimated to be about 1.5 hectares (3.7 acres) in chaparral (Cody 1974) and 0.8 hectare (2.0 acres) in southern California coastal scrub (Bent 1968).

Females build nests directly on the ground, concealing them at the base of a bunchgrass clump or shrub (Terres 1980; Verner and Boss 1980; Ellison 1998). Less often, nests are located in shrubs or under rock overhangs (Collins 1999A).

Habitat loss, degradation, and fragmentation are the main threats to the southern California rufous-crowned sparrow (Collins 1999B; Thorngate and Parsons 2005). The conversion of coastal scrub and other suitable open scrub habitats to agriculture and urban development has reduced the available habitat for this resident species (Bent 1968; Unitt 1984; Collins 1999B). Fragmentation of remaining habitat is also a concern. In one study in San Diego County, southern California rufous-crowned sparrows were more abundant in larger patches of suitable habitat than in smaller, more fragmented patches (Bolger, Scott, *et al.* 1997). Fire suppression has probably also contributed to the decline of this species by promoting dense, uniform stands of scrub and chaparral that are not suitable for this species (Collins 1999B; Thorngate and Parsons 2005). Rufous-crowned sparrows may benefit from moderate grazing and trampling by cattle, which opens up denser shrub vegetation (Jones 1998), but intense grazing may cause available shrub cover to become too sparse. Domestic cats may be a significant predator along urban edges. Female rufous-crowned sparrows have been known to abandon nests temporarily if disturbed repeatedly during nest-building, egg-laying, or incubation (Collins 1999B). Several other human- or development-related factors may affect rufous-crowned sparrows. Construction-related impacts include dust; noise and ground vibration; increased human activity in close proximity to nesting and foraging areas; and lighting, which may alter behavior, induce physiological stress, and increase predation risk. Additional potential long-term effects related to development include increased human activity, which may disturb nesting; pesticides, which may contaminate vegetative food sources (seeds), cause loss of prey, or cause secondary poisoning; lighting; and Argentine ants, which may occur in moist edge areas and prey on nestlings.

Survey Results

Numerous surveys for upland bird species have been conducted throughout the Project area and in nearby areas between 1995 and 2008. Although focused surveys for the southern California rufous-crowned sparrow were not conducted, it has been observed over multiple years during these surveys as a fairly common resident in the coastal scrub within the Project area during annual bird surveys. It has been observed foraging in uplands and near the Santa Clara River (Bloom Biological 2008; Guthrie 2000A, 2000B, 2001A, 2002C, 2004A, 2004D) and was observed nesting in 2007 (Bloom Biological 2007A). Suitable nesting and foraging habitat for this species is present throughout the Project area. Based on the numerous and regular observations of this species in past bird surveys, the southern California rufous-crowned sparrow is considered to nest and forage throughout the Project area in California sagebrush scrubs (California sagebrush scrub and associations, California sagebrush–black sage, California sagebrush–California buckwheat scrub, California sagebrush scrub–undifferentiated chaparral) and big sagebrush–California buckwheat. A total of 4,327 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 30 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 0.7% of these habitats on site (**Figure 4.5-102**, Alternative 2 Impacts to Scrub and Chaparral Wildlife Habitat). A total of 2.3 acres would be temporarily impacted.

The southern California rufous-crowned sparrow is still a wide-ranging species and fairly common in coastal scrub, including in scrub habitats in the Project area. The construction of RMDP facilities would be phased over a long period of time and approximately 1,980 acres of suitable habitat in the High Country SMA, Salt Creek area, and River Corridor SMA would be available for this species at any given time.

Therefore, the permanent loss of 30 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 1,487 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 34.4% of these habitats on site (**Figure 4.5-102**, Alternative 2 Impacts to Scrub and Chaparral Wildlife Habitat).

Although the southern California rufous-crowned sparrow is still a wide-ranging species and common on site, the build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on the distribution of this species on site by eliminating it from approximately 34.4% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). This indirect permanent impact (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 1,517 acres (35.1%). Although the southern California rufous-crowned sparrow is still a wide-ranging species and common on site, implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on the distribution of this species on site by eliminating it from approximately 35.1% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The southern California rufous-crowned sparrow is a relatively mobile species and it is unlikely that construction activities associated with implementation of the RMDP would result in injury or mortality individual adult birds. However, birds would be physically displaced from occupied habitat. Implementation of the SCP would not directly impact this species. Vegetation clearing or grading during the nesting season could result in destruction of nests, eggs, or young, cause nest abandonment, or alter foraging behavior and provisioning of young, which could result in reduced survivorship and reduced reproductive success. Because of the special status of this bird species and the potential for injury or mortality of individual birds, and specifically destruction of nest, eggs, or young, interference with foraging and provisioning of young, or nest abandonment, such impacts would have a substantial direct adverse effect on this species; (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct impacts to individuals, but over a much larger area. Construction and/or grading activities may occur during the nesting season and could result in the destruction of nest, eggs, or young, interfere with foraging and provisioning of young, or cause nest abandonment. These impacts would have a substantial adverse impact on this species (significance criterion 1). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

In the short term, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas occurring during the breeding season would have the potential to affect southern California rufous-crowned sparrow in areas adjacent to construction zones. These impacts could include exposure to construction-related dust, noise, ground vibration, and nighttime lighting. Dust could degrade habitat quality, noise and ground vibration could affect nesting and foraging behavior, and nighttime lighting could induce physiological stress and increase predation by nocturnal predators. Potential long-term development-related secondary impacts include habitat fragmentation, habitat degradation from frequent wildfires, increased human activity, nighttime illumination, potential harassment by humans and pet, stray, and feral cats and dogs and other mesopredators, loss of food sources and secondary poisoning from pesticides, and predation of nestlings by Argentine ants along the open space-development interface.

These short-term and long-term secondary impacts would permanently reduce the number of southern California rufous-crowned sparrows that may occur along the urban–open space edge, interfere with the movement of the species between habitat areas due to fragmentation, and contribute to the reduction of the range and distribution of the southern California rufous-crowned sparrow in the Project area (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for southern California rufous-crowned sparrow (**Figures 4.5-103** through **4.5-107**, Alternatives 3 through 7 Impacts to Scrub and Chaparral Wildlife Habitat):

- Alternative 3 – 28 acres (0.6%) of permanent loss and 4.5 acres of temporary loss;
- Alternative 4 – 28 acres (0.6%) of permanent loss and 2.0 acres of temporary loss;
- Alternative 5 – 32 acres (0.7%) of permanent loss and 6.0 acres of temporary loss;
- Alternative 6 – 28 acres (0.6%) of permanent loss and 7.6 acres of temporary loss; and
- Alternative 7 – 19 acres (0.4%) of permanent loss and 13 acres of temporary loss.

Compared to Alternative 2, which would result in 30 acres (0.7%) of permanent habitat loss and 2.3 acres of temporary impacts, the permanent loss of habitat would not be substantially different under Alternatives 3 through 6, and would be somewhat reduced under Alternative 7. Compared to Alternative 2, the temporary loss of habitat would not be substantially different under Alternatives 3 through 6, and would be marginally higher under Alternative 7. The difference for Alternative 7 compared to the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries as well as other reductions to the Project footprint under Alternative 7 that would result in fewer permanent impacts and more temporary impacts to suitable habitat for the southern California rufous-crowned sparrow compared to the other alternatives.

Because the overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude to somewhat reduced compared to the loss of habitat under Alternative 2, and temporary impacts would be similar in magnitude under Alternatives 3 through 6 and would be marginally higher

under Alternative 7, the impacts would be adverse but not significant for Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to suitable habitat for southern California rufous-crowned sparrow (**Figures 4.5-103** through **4.5-107**, Alternatives 3 through 7 Impacts to Scrub and Chaparral Wildlife Habitat):

- Alternative 3 – 1,408 acres (32.5%) of permanent loss;
- Alternative 4 – 1,368 acres (31.6%) of permanent loss;
- Alternative 5 – 1,316 acres (30.4%) of permanent loss;
- Alternative 6 – 1,088 acres (25.1%) of permanent loss; and
- Alternative 7 – 1,007 acres (23.3%) of permanent loss.

Compared to Alternative 2, which would result in 1,487 acres (34.4%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would reduce impacts to suitable habitat for southern California rufous-crowned sparrow compared to the other alternatives.

Although habitat loss under Alternatives 3 through 7 would be less than Alternative 2, a relatively large amount and percentage of suitable habitat for the southern California rufous-crowned sparrow would still be permanently lost as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under these alternatives, ranging from 23.3% under Alternative 7 to 32.5% under Alternative 3. This permanent loss of habitat would have a substantial adverse effect on a special-status species and substantially reduce its numbers and restrict its range on site. The indirect permanent impacts (Loss of Habitat) under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and

Entrada planning areas would result in the following impacts to suitable habitat for southern California rufous-crowned sparrow:

- Alternative 3 – 1,436 acres (33.2%) of permanent loss;
- Alternative 4 – 1,396 acres (32.3%) of permanent loss;
- Alternative 5 – 1,349 acres (31.2%) of permanent loss;
- Alternative 6 – 1,116 acres (25.8%) of permanent loss; and
- Alternative 7 – 1,026 acres (23.7%) of permanent loss.

Compared to Alternative 2, which would result in 1,517 acres (35.1%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons cited above for indirect permanent impacts. This permanent loss of habitat would have a substantial adverse effect on a special-status species and substantially reduce its numbers and restrict its range on site. The combined direct and indirect permanent impacts (Loss of Habitat) under Alternatives 3 through 7 would be significant, absent mitigation.

Impacts to Individuals

The potential impacts to southern California rufous-crowned sparrow individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than for Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Individuals could be displaced from occupied habitat by construction activities, and construction occurring during the nesting season could result in the destruction of nest, eggs, or young, interfere with foraging and provisioning of young, or cause nest abandonment. These impacts to individual southern California rufous-crowned sparrows occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development. Short-term impacts include construction-related dust, noise, ground vibration, and nighttime illumination, that could cause habitat degradation, disrupt nesting and foraging activities, and abandonment of nests. Potential long-term secondary impacts include habitat

fragmentation, habitat degradation due to wildfire, increased human activity, nighttime illumination, increased predation, and secondary poisoning, as described above for Alternative 2. These secondary impacts would permanently reduce southern California rufous-crowned sparrow populations along the urban–open space edge and contribute to the reduction of the range and distribution of this species in the Project area. Short-term and long-term secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to southern California rufous-crowned sparrow: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and habitat outside the Project footprint.

The southern California rufous-crowned sparrow is a relatively common breeding resident on site in habitat that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. While adults are mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, individuals could be displaced from occupied habitat by construction activities. Impacts to individuals also could occur if active nests were disturbed during vegetation clearing and construction/grading activities, resulting in the destruction of the nests and loss of eggs and/or young, or interfere with foraging or provisioning of young. Construction activities may also cause abandonment of nests due to human activity, noise, and ground vibration. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable habitat for the southern California rufous-crowned sparrow resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 1,026 acres (23.7%) under Alternative 7 to 1,517 acres (35.1%) under Alternative 2. This would be a substantial loss of suitable habitat for this species and will alter its use of the Project area. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a permanent open space system that will provide suitable habitat to support both foraging and breeding by the southern California rufous-crowned sparrow in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 1,936 acres of suitable habitat for the southern California rufous-crowned sparrow in the High Country SMA and the Salt Creek area, with an additional 51 acres in the River Corridor SMA (**Figure 4.5-3**).

With regard to secondary effects, foraging and nesting activities by the southern California rufous-crowned sparrow could be adversely affected in the short term by increased human

activity, noise, ground vibration, dust, and lighting. These secondary effects may cause adults to vacate territories and abandon nests due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to nocturnal predators. These short-term construction-related secondary impacts will be minimized by conducting pre-construction surveys to determine if active nests, are present in the disturbance zone or within 300 feet and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include habitat fragmentation; wildfire; increased human activity; lighting; pesticides, which may cause secondary poisoning and loss of food resources; harassment by pet, stray, and feral cats and dogs and other mesopredators; and Argentine ants that may prey on nestlings. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 1,936 acres of suitable habitat in the High Country SMA and Salt Creek area will provide southern California rufous-crowned sparrows with relatively undisturbed habitat. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by predators and reduce behavioral disturbances and physiological stress. Limited recreational usage and access restrictions within the High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect southern California rufous-crowned sparrows by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of direct and secondary poisoning and loss of food sources.

The specific mitigation measures for the southern California rufous-crowned sparrow are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-140 IMPACTS TO INDIVIDUALS – SOUTHERN CALIFORNIA RUFOUS-CROWNED SPARROW

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate impacts to southern California rufous-crowned sparrow individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to southern California rufous-crowned sparrow individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to California rufous-crowned sparrow individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-141 LOSS OF HABITAT – SOUTHERN CALIFORNIA RUFOUS-CROWNED SPARROW

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for southern California rufous-crowned sparrow through habitat protection, restoration and enhancement, and management.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The High Country SMA will protect and manage at least 1,307 acres of suitable habitat for southern California rufous-crowned sparrow.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measure to mitigate for the loss of habitat for southern California rufous-crowned sparrow through habitat protection, restoration and enhancement, and management.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. The Salt Creek area includes 629 acres of suitable habitat for the southern California rufous-crowned sparrow.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the southern California rufous-crowned sparrow would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-142 SECONDARY IMPACTS – SOUTHERN CALIFORNIA RUFOUS-CROWNED SPARROW

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as habitat fragmentation, increased human activity, inadvertent impacts to habitat during construction, and nighttime lighting.

SP-4.6-36 through SP-4.6-42, as described above, refer to habitat protection and management in the High Country SMA that will be implemented to mitigate for long-term habitat fragmentation effects and increased human activity.

Several mitigation measures will control human activities in the High Country SMA. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 addresses edge effects along open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only on developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-34 and SP-4.6-35 require that all grading perimeters within the High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to biological resources outside the grading area in the High Country SMA.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to southern California rufous-crowned sparrow, including short-term construction-related dust, noise, ground vibration and increased human activity as well as long-term habitat fragmentation, increased human activity, greater vulnerability to predation by pet, stray, and feral cats and dogs and other mesopredators, as well as Argentine ants, and loss of food sources and secondary poisoning from pesticide use.

BIO-52 and BIO-56, as described above, will mitigate the effects of noise and ground vibration by identifying nest sites and providing for buffers between nests and construction activities.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-19 through BIO-21, as described above, will mitigate for increased human activity in the Project area through habitat protection, restoration and enhancement, and management.

BIO-63 and BIO-69 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-64 will be implemented to prevent poisoning and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impacts to southern California rufous-crowned sparrow by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the southern California rufous-crowned sparrow would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

CHIPPING SPARROW (NESTING) (CALIFORNIA SPECIAL ANIMAL)

Life History

The chipping sparrow (*Spizella passerina*) is a very common and widespread species that breeds from eastern Alaska through Canada, southward to the southern United States, and into Mexico and Central America. Its winter range extends into Mexico, Central America, and the southern tier of the United States (Middleton 1998). The chipping sparrow is a common migrant and summer visitor throughout most of California, excluding the Central Valley, southern deserts, and alpine areas. Some individuals move downslope to winter from the Central Valley to southern Mexico but it is unknown what portion of the breeding population remains in the state and what portion migrates farther south (Zeiner *et al.* 1990A). In southwestern California, the population tends to consist of year-round residents but the breeding populations may be replaced or augmented by a different wintering population (Zeiner *et al.* 1990A).

Chipping sparrows prefer open wooded habitats with a sparse or low herbaceous layer and few shrubs, if any (Zeiner *et al.* 1990A). Breeding habitats vary with geographic location, but chipping sparrows prefer open, grassy, coniferous forests, woodland glades or edge, prairie aspen groves, and river and lake shorelines (Johnson 1968; Stull 1968; Rising 1996). In coastal California and at lower elevations along foothills, the chipping sparrow is found in a variety of woodland types with grassy understory, including orchards, edges of oak woodlands, mixed evergreen (Douglas fir (*Pseudotsuga menziesii*) and redwood (*Sequoia sempervirens*)) forests, and less frequently in cypress (*Cupressus* spp.) and eucalyptus tree (*Eucalyptus* spp.) groves where these habitats border on gently sloping grasslands or open meadows (Middleton 1998). The species requires trees for nesting and singing and often forages in nearby herbaceous and open shrub habitats, including dry margins of wet meadows (Zeiner *et al.* 1990A). Fall and spring migration habitat includes open grassy areas, old weedy fields, and areas along hedgerows, but the chipping sparrow is also found in desert scrub, sagebrush scrub, and chaparral; around oases; on mountain ridges; and in suburban backyards (Jewett *et al*. 1953; Stull 1968; Alcorn 1988; Veit and Petersen 1993; Small 1994).

The chipping sparrow is adaptable to human developments and appears to have benefited from human occupation of North America (Middleton 1998). The chipping sparrow now appears to be more common and abundant in suburban areas and around rural residences, orchards, and farms than in undisturbed habitats (Middleton 1998; Reynolds and Knapton 1984).

The chipping sparrow feeds mostly on insects and other invertebrates during the breeding season and feeds mostly on grass and forb seeds for the remainder of the year (Martin *et al.* 1961). They forage primarily on the ground or in low vegetation (Forbush 1913; Stull 1968; Oberholser 1974; Allaire and Fisher 1975).

Chipping sparrow territory sizes vary individually and seasonally, but range from approximately 0.2 to 0.4 hectare (0.5 to 1.0 acre) (Bradley 1940; Walkinshaw 1944; Sutton 1960; Stull 1968; Keller 1979; Albrecht and Oring 1995).

The breeding season usually begins in April or May, but can begin as early as late March (Zeiner *et al.* 1990A; Middleton 1998). In California, the species usually nests in conifers, but deciduous trees or shrubs are also used (Grinnell and Miller 1944). Nests are rarely more than 12 meters (40 feet) above the ground, or, rarely, are on the ground (Bent 1968), and are usually concealed in dense foliage near branch ends. Chipping sparrows have a clutch size of three to five eggs, and young fledge about nine to 10 days after hatching (Middleton 1998). The species typically rear one brood annually, although a second brood may occur, depending on the early success of the first nest (Middleton 1998). After young reach independence, they collect into flocks varying from about five to 15 birds. These small flocks are common during late summer and early autumn as they forage in open weedy spaces.

California populations of the chipping sparrow may be declining, although other studies and anecdotal evidence do not necessarily support observation, and regional declines in the western United States appear to be offset by increases in the east and Midwest (Middleton 1998). This possible decline may be due to a reversion of land back to forest or due to more intensive farming practices (Middleton 1998). Also, forest-clearing and habitat fragmentation may have increased this species' exposure to cowbird parasitism (DeSante and George 1994; Rising 1996). Outside California, the chipping sparrow is one of the most common hosts of brown-headed cowbirds. Within California, the Sierra Nevada population appears to be an infrequent host, and no information is available for other California populations (Zeiner *et al.* 1990A). Predation is also major cause of nest failure; however, the impact varies with season and geographic location, and nothing is known about the nest failures due to predation for the California population (Middleton 1998). Additionally, the competition with urban-related house sparrows and house finches may have a negative affect on the chipping sparrow population, and domestic cats are likely predators in nestlings and adults (Walkinshaw 1952; Stull 1968; Veit and Petersen 1993). Other development- and human-related impacts that could affect this species include construction-related dust; noise and ground vibration; and nighttime lighting, which may induce physiological stress and increase predation by nocturnal predators. Pesticides may reduce prey and cause secondary poisoning and Argentine ants may prey on nestlings.

Survey Results

Riparian bird surveys have been conducted for multiple years between 1988 and 2008 along the Santa Clara River in the Project area in suitable habitat for the chipping sparrow, generally from the I-5 Bridge to Las Brisas Bridge west of the Ventura County line (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B,

2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C; Labinger and Greaves 1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A); within Castaic Creek, Salt Creek, High Country SMA, and portions of the Santa Clara River adjacent to the Project site by Dudek and Associates (2006B, 2006D, 2006E); and within Castaic Creek and the Santa Clara River from the I-5 Bridge to Las Brisas Bridge west of the Ventura County line by Bloom Biological, Inc. in 2007 and 2008 (Bloom Biological 2007A, 2008).

Upland bird surveys also have been conducted throughout the Project area and in nearby areas between 1995 and 2008 by a variety of consulting firms, covering Landmark Village, Mission Village, and Homestead East and West areas as well as Potrero, Long, and Chiquito canyons and the upland habitats along the Santa Clara River (Bloom Biological 2007A, 2008; Dudek and Associates 2006C; Guthrie 2000A, 2000B, 2004A, 2004D, 2004E; Impact Sciences 2000; RECON and Impact Sciences 1996; SAIC 2003). The High Country SMA and Salt Creek area (in the Specific Plan area) were surveyed by Dudek and Associates in 2005 (2006B). Upland surveys have also been conducted in the VCC (Dudek and Associates 2006D; Guthrie 2004B) and Entrada planning areas (Dudek and Associates 2006E; Guthrie 2004G). Areas near the Project area that have been surveyed for upland bird species include the Legacy Village area adjacent to the Project area on the south and east (Guthrie 2004C), the Castaic Junction area just north of the Entrada planning area (Guthrie 2004F, 2004I), the Riverpark site (now referred to as River Village) upstream of the Specific Plan area (Compliance Biology 2003), and upland areas upstream of the VCC planning area, including the Castaic Mesa area (PCR 1998; Compliance Biology 2006A, 2006D).

The chipping sparrow has been observed as a common migrant in the Project area; for example, one to 12 individuals were observed near edges of agricultural fields most days in early March 2007 (Bloom Biological 2007A). It has been observed over multiple years between 1988 and 2007 in riparian scrub and woodland habitat in the Santa Clara River, as well as from the Ventura County line to the western limit of the Las Brisas Ranch (Guthrie 1994B, 1997B), near Grapevine Mesa (Guthrie 2000B) and Homestead Canyon (Guthrie 2004A), and in the VCC planning area (Guthrie 1991A, 1991B, 1992C, 1993A, 1999A). The Project area is within this species' year-round range, so even though the observations occurred in early spring and no observations occurred later in the breeding season, the chipping sparrow could occur on site as a breeding bird and is analyzed as such.

Suitable habitats for the chipping sparrow on site include coast live oak woodland, mixed oak woodland, valley oak woodland, valley oak/grass, riparian scrub, and southern willow scrub. A total of 1,490 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 12 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 0.8% of these habitats on site (**Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat). A total of 6.3 acres would be temporarily impacted.

The chipping sparrow is still a wide-ranging species and uses a variety of riparian scrub and woodland habitats. It is a commonly observed migrant on site and may nest in the Project area. The construction of RMDP facilities would be phased over a long period of time and more than 1,000 acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 12 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 86 acres (5.8%) of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas (**Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat**)**.

The chipping sparrow is still a common and wide-ranging species and uses a variety of riparian scrub and woodland habitats during migration and potentially for nesting. Following build-out, approximately 1,280 acres of woodland and riparian scrub habitats would be protected and managed in the River Corridor SMA, High Country SMA, and Salt Creek area. The loss 86 acres of habitat that would occur as a result of construction and/or grading activities would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 98 acres (6.6%). Because the chipping sparrow is a common and wide-ranging species and because approximately 1,280 acres of habitat for this species would remain after build-out, the combined direct and indirect impacts to 98 acres of suitable habitat would not have a substantial adverse effect on the distribution of the chipping sparrow in the Project area, and thus would not substantially reduce its numbers and restrict its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The chipping sparrow is a relatively mobile species, and it is unlikely that Project-related construction activities would result in injury or mortality of individual adult birds. However, foraging individuals may avoid or leave construction areas during construction activities. Also, implementation of the RMDP could result in mortality of young and/or eggs due to destruction of nests if construction/grading activities occurred during the nesting season of this species. Disruption of foraging activities could affect provisioning of young, thus affecting reproductive success. These impacts would be a substantial adverse impact on this species (significance criterion 1). Implementation of the SCP would not directly impact this species. Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The chipping sparrow is a relatively mobile species and it is unlikely that build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of individual adult birds. However, foraging individuals may avoid or leave construction areas during construction activities. Also, mortality of young and/or eggs due to destruction of nests could occur if construction/grading activities occurred during the nesting season of this species. Disruption of foraging activities could affect provisioning of young, thus affecting reproductive success. These impacts would be a substantial adverse impact on this species (significance criterion 1). Indirect, permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, fugitive dust, and nighttime illumination. Although construction would be of a short-term nature, if these activities occurred during the breeding season they could have a substantial direct adverse effect on this species due to potential disruption of nesting and foraging activities, potentially affecting reproductive success.

Potential long-term development-related secondary impacts related to RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas include increased human activity; nighttime illumination; pesticides which may reduce prey and cause secondary poisoning; greater vulnerability to predation by pet, stray, and feral cats and dogs, and other mesopredators; Argentine ants which may prey on nestlings; and habitat fragmentation-related edge effects that may increase the exposure of chipping sparrows to cowbird parasitism. Urban-related noise is not considered to be a potential significant effect on this species because of its apparent adaptability to urban settings. The aforementioned secondary impacts would permanently reduce chipping sparrow populations and contribute to the reduction of the range and distribution of the chipping sparrow in the Project area (significance criteria 1 and 7).

Short-term and long-term secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the chipping sparrow (**Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 11 acres (0.8%) of permanent loss and 6.4 acres of temporary loss;
- Alternative 4 – 11 acres (0.7%) of permanent loss and 6.2 acres of temporary loss;
- Alternative 5 – 15 acres (1.0%) of permanent loss and 6.6 acres of temporary loss;
- Alternative 6 – 20 acres (1.4%) of permanent loss and 6.5 acres of temporary loss; and
- Alternative 7 – 5.6 acres (0.4%) of permanent loss and 15 acres of temporary loss.

Compared to Alternative 2, which would result in 12 acres (0.8%) of permanent habitat loss and 6.3 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 and 4 would not be substantially different, would be marginally to somewhat more under Alternatives 5 and 6, and would be somewhat less under Alternative 7. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be the same or not substantially different, and Alternative 7 would be substantially more. The difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in fewer permanent impacts and greater temporary impacts.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be small and generally similar to or less than Alternative 2, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the chipping sparrow (**Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 67 acres (4.5%) of permanent loss;
- Alternative 4 – 66 acres (4.5%) of permanent loss;

- Alternative 5 – 66 acres (4.5%) of permanent loss;
- Alternative 6 – 41 acres (2.8%) of permanent loss; and
- Alternative 7 – 44 acres (3.0%) of permanent loss.

Compared to Alternative 2, which would result in 86 acres (5.8%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts, with Alternatives 3, 4, and 5 having moderate reductions and Alternatives 6 and 7 having more substantial reductions. Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be relatively small and less than Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the chipping sparrow:

- Alternative 3 – 78 acres (5.3%) of permanent loss;
- Alternative 4 – 77 acres (5.1%) of permanent loss;
- Alternative 5 – 82 acres (5.5%) of permanent loss;
- Alternative 6 – 61 acres (4.1%) of permanent loss; and
- Alternative 7 – 50 acres (3.4%) of permanent loss.

Compared to Alternative 2, which would result in 98 acres (6.6%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts, with Alternatives 3, 4, and 5 having moderate reductions and Alternatives 6 and 7 having more substantial reductions. Because the combined direct and indirect permanent loss of habitat from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be relatively small and less than Alternative 2, these impacts would be adverse but not significant.

Impacts to Individuals

The potential impacts to chipping sparrow individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project

footprint under the different alternatives. Although adult birds would likely avoid injury or mortality, loss of young and/or eggs due to destruction of nests could occur, and provisioning of young could be disrupted, if construction/grading activities occurred during the nesting season of this species. Impacts to individual chipping sparrows occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term secondary impacts include construction-related dust, noise, ground vibration, and nighttime illumination. These effects are more likely to occur during build-out of the Specific Plan, VCC, and Entrada planning areas than with implementation of the RMDP and the SCP because of the much larger area of impact. If these impacts occur during the nesting season, reproductive success could be affected

Potential long-term secondary impacts associated with implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas include habitat fragmentation-related edge effects, increased human activity, nighttime illumination, and increased predation, pesticides, Argentine ants, and cowbird parasitism, as described above for Alternative 2. These long-term secondary impacts would permanently reduce the chipping sparrow population along the urban–open space edge and contribute to the reduction of the range and distribution of this species in the Project area. Short-term and long-term secondary impacts would be significant, absent mitigation under Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to chipping sparrow: (1) impacts to individuals; and (2) secondary impacts to individuals and suitable habitat outside the Project footprint.

Nesting by chipping sparrow has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. However, suitable nesting habitat is present on site and the Project area is within this species' breeding range. Therefore it is assumed that chipping sparrow could nest on site. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, impacts

to individuals could occur if active nests are disturbed during vegetation clearing and construction/grading activities, including destruction of nests and loss of eggs and/or fledglings. Construction activities may also alter foraging behavior and thus potentially reduce the health of young and result in lower reproductive success. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

With regard to secondary effects, nesting and foraging activities by the chipping sparrow could be adversely affected in the short-term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may alter foraging and provisioning of young. Construction-generated dust may affect habitat quality and both insect prey and vegetative food sources (*e.g.*, berries and sap) for the chipping sparrow. Lighting may induce physiological stress and increase the risk of predation by nocturnal predators. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 300 feet, and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include habitat fragmentation, which may increase cowbird nest parasitism; lighting; pesticides that may cause secondary poisoning and loss of prey; human disturbances of nest sites; predation by pet, stray, and feral cats and dogs and other mesopredators; and Argentine ants which may prey on nestlings. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of approximately 1,261 acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area will provide chipping sparrows with relatively undisturbed habitat for nesting and foraging. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by nocturnal predators and reduce physiological stress. Limited recreational usage and access restrictions within the River Corridor SMA and High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect chipping sparrows by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of secondary poisoning and loss of prey. Controls on Argentine ants will help reduce impacts on young in nests. Cowbird trapping will be conducted as necessary.

The specific mitigation measures for the chipping sparrow are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-143 IMPACTS TO INDIVIDUALS – CHIPPING SPARROW

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of chipping sparrow individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to chipping sparrow individuals

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to chipping sparrow individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-144 SECONDARY IMPACTS – CHIPPING SPARROW

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to mitigate for long-term secondary effects on chipping sparrow associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as habitat fragmentation, increased human activity, and greater vulnerability to nocturnal predators as a result of nighttime lighting. These mitigation measures provide for protection, restoration, enhancement, and management of habitat in open space for chipping sparrow that will offset secondary impacts. Mitigation measures to avoid and minimize impacts to riparian/wetland habitats and inadvertent impacts to habitat outside disturbance zones during construction will also be implemented.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The River Corridor SMA will preserve and enhance approximately 14 acres of suitable riparian scrub habitat for chipping sparrow. The High Country SMA will preserve and enhance approximately867 acres of suitable habitat for chipping sparrow.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and oak tree replacement occur as

described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA, including the following: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These mitigation measures require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along the open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to chipping sparrow, including short-term construction-related dust, noise, and ground vibration; and long-term impacts such as habitat fragmentation and associated cowbird nest parasitism; Argentine ants; increased human activity; greater vulnerability to predation by pet, stray, and feral cats and dogs; and pesticide use resulting in secondary poisoning and loss of prey.

Secondary effects of noise and ground vibration during construction will be addressed by BIO-52 and BIO-56, as described above, which will mitigate these effects by identifying nest sites and providing for buffers between nests and construction activities.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. This will reduce impacts to chipping sparrow by protecting habitat quality and by minimizing impacts on its insect prey and vegetative food resources. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-1 through BIO-16 will improve long-term habitat quality for the chipping sparrow and include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-22 states that the Oak Resource Management Plan shall incorporate the findings of the Draft Newhall Ranch Mitigation Feasibility Report (Dudek 2007A) and areas identified as being suitable for oak woodland enhancement and creation shall be used for mitigation.

BIO-42 requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities. Fencing shall extend to the root protection zone.

BIO-63 and BIO-69 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-78 requires implementation of a cowbird trapping program once vegetation clearing begins. The program shall be implemented each day beginning April 1 and concluding on or about November 1, through the construction, maintenance, and monitoring period of the riparian restoration sites. In the event that trapping is terminated after the first few years of development, subsequent phases of the RMDP development shall trigger initiation of trapping surveys.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impacts to chipping sparrow by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant from riparian areas is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the chipping sparrow would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

HERMIT WARBLER (NESTING) (CDFG TRUST RESOURCE)

Life History

The hermit warbler (*Dendroica occidentalis*) is locally common in coniferous forests. Based on available records, the hermit warbler breeds in southwestern Washington, south through the Sierra Nevada mountains, and into southern California and west-central Nevada. Non-breeding (migratory) populations can be found in Washington, Oregon, California, Colorado, Nevada, Arizona, New Mexico, and Texas (NatureServe 2007).

Hermit warblers occur in conifer and mixed forests, shrubland, chaparral, and conifer and mixed woodlands (NatureServe 2007). This species is habitat specific and nests on the upper, open branches of old growth Douglas-fir (*Pseudotsuga menziesii*) and pine (*Pinus* spp.) trees. In California, the hermit warbler has been observed nesting in mature ponderosa pine (*Pinus ponderosa*), montane hardwood conifer, mixed conifer, Douglas-fir, coast redwood (*Sequoia sempervirens*), and Jeffery pine (*P. jeffreyi*) (Zeiner *et al.* 1990A). Hermit warblers are most often found in the interior of large mature coniferous forests that are over 30 years old, and they are almost completely absent from stands under 20 years old (Seattle Audubon Society 2006).

Hermit warblers forage on small invertebrates such as small spiders, caterpillars, beetles, flies, wasps, stone flies, and true bugs (Pearson 1997) that they glean from foliage and twigs at height of five to 25 meters (16 to 82 feet) while hopping along or hovering. They can also fly out and catch aerial insects.

The breeding season of the hermit warbler in California occurs from April through July. The migrant breeding wave passes into breeding areas from April to May and out from August to September. Nesting occurs through late April and into early July. The female-built nests usually are in the cover of mature forests, though ground nesting does occur (Munson 1984). Clutch size is three to five per nest (Zeiner *et al.* 1990A), and nestlings are active outside the nest within 10 days of hatching (Seattle Audubon Society 2006).

In addition to direct loss of habitat, hermit warblers are vulnerable to several effects related to development. These birds require dense, old growth forests for foraging and breeding grounds. They abandon managed areas that eliminate forest canopy or fragment habitat. The hermit warbler is also vulnerable to brown-headed cowbird nest parasitism in areas where habitat fragmentation has increased edge habitats (NatureServe 2007). Several other human- or development-related factors may affect hermit warblers. Construction-related impacts include dust; noise and ground vibration; increased human activity in close proximity to nesting and foraging areas; and lighting, which may alter behavior, induce physiological stress, and increase predation risk. Additional potential long-term effects related to development include increased human activity, which may disturb nesting; domestic cats which may prey on adults; pesticides,

which may cause loss of prey or secondary poisoning; and lighting. Where this species nests in fragmented habitats, it is also vulnerable to brown-headed cowbird nest parasitism.

Survey Results

Bird surveys were conducted from 1988 through 2006 within the portion of the Santa Clara River and Castaic Creek in and adjacent to the Project boundary in areas of suitable habitat for the hermit warbler (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000A, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004A, 2004B, 2004C, 2004D, 2004E, 2004F, 2004G, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C; Labinger *et al.* 1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A). The surveys primarily were conducted in the riparian areas in the Santa Clara River corridor and on both sides of the River. Surveys were also conducted in the Project vicinity by Bloom Biological, Inc. from February through June, 2007, including about 25 miles of the Santa Clara River and its major tributaries in and around the Project site. The survey covered all habitats within the floodplain and one-half mile on each side of the River (Bloom Biological 2007A). Additional surveys for special-status species in habitat suitable for hermit warbler were conducted within Castaic Creek, Salt Creek, the High Country SMA, and portions of the Santa Clara River adjacent to the Project site by Dudek (Dudek and Associates 2006B, 2006D, 2006E), within other portions of the Specific Plan area not already mentioned (Dudek and Associates 2006C; Impact Sciences 2000; SAIC 2003), and within areas upstream of the VCC planning area, including the Castaic Mesa area, by PCR in 1998 and Compliance Biology in 2006 (PCR 1998; Compliance Biology 2006A, 2006D).

This species has been observed within the woodland habitat on site in several years during the bird surveys conducted from 1988 through 2006 along the Santa Clara River (Guthrie 1994B, 1996B, 2002C). The Project area is within the winter range of this species; this species typically nests in mature forests at higher elevations in the Sierra Nevada and higher elevations of the Coast and Transverse Mountain ranges (Zeiner *et al.* 1990A). All observed individuals were thought to be migrants; no nesting by this species has been confirmed on site. For the purpose of the impact analysis, it is assumed that nesting does not occur on site, and all impacts would be to migrating individuals that forage on site.

Suitable foraging habitat for migrant hermit warblers on site includes California walnut woodland, coast live oak woodland, mixed oak woodland and forest, southern coast live oak riparian forest, valley oak woodland, and valley oak/grass. A total of 1,495 acres of suitable habitat for migrant hermit warblers is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 9.4 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 0.6% of suitable habitat on site (**Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat). A total of 1.4 acres would be temporarily impacted.

The hermit warbler is still a wide-ranging species and uses a variety of woodland forest and oak riparian habitats during migration. The construction of RMDP facilities would be phased over a long period of time and more than 1,000 acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 9.4 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 85 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 5.7% of these habitats on site (**Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat).

The hermit warbler is still a wide-ranging species and only uses the Project area during migration. Following build-out, approximately 1,290 acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would remain as protected open space. Therefore, the loss of 85 acres of habitat as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 95 acres (6.3%).

The hermit warbler is still a wide-ranging species and only uses the Project area during migration. Following build-out, approximately 1,290 acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would remain as protected open space. Therefore, the combined loss of 95 acres of habitat would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Hermit warblers are highly mobile; therefore, it is unlikely that RMDP-related construction activities would result in injury or mortality of adult birds migrating through the Project area. Because this species does not nest on site, implementation of the RMDP and the SCP would not result in destruction of nests, young, or eggs as a result of vegetation clearing or grading activities. Any migrants on site during construction activities may be displaced from removed habitat, but there would be substantial available habitat for this species elsewhere in the Project vicinity. Because no substantial impacts from implementation the RMDP and the SCP are expected to occur, the Project would not have a substantial direct adverse effect on this species; cause the species population to

drop below self-sustaining levels on site or rangewide; interfere with the movement of the species between important habitat areas; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct impacts to individuals. The hermit warbler is highly mobile and not expected to nest on site. Individuals may be displaced from suitable habitat, but no injury or mortality of adults or destruction of nests, eggs, or young is expected to occur. Indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

In the short term, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would have the potential to affect this species in suitable habitat adjacent to construction zones. These impacts could include exposure to construction-related dust, noise, ground vibration, and nighttime illumination that could inhibit the species from using suitable habitat for foraging. Potential long-term secondary effects, such as habitat fragmentation impacts, increased human activity, and increased pet, stray, and feral cats and dogs, and pesticide use are unlikely to substantially affect species because it can use a variety of woodland habitats within the region and is highly mobile. The species would not be vulnerable to the nest predation or cowbird nest parasitism issues associated with development edges because it is not known to nest in the Project region.

For these reasons, potential short-term and long-term secondary impacts would not have a substantial adverse effect on this species; interfere with the movement of the species between important habitat areas; cause the species population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to suitable habitat for the hermit warbler (**Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 9.6 acres (0.6%) of permanent loss and 1.4 acres of temporary loss;
- Alternative 4 – 9.0 acres (0.6%) of permanent loss and 1.4 acres of temporary loss;
- Alternative 5 – 13 acres (0.9%) of permanent loss and 1.4 acres of temporary loss;
- Alternative 6 – 18 acres (1.2%) of permanent loss and 1.4 acres of temporary loss; and
- Alternative 7 – 5.7 acres (0.4%) of permanent loss and 13 acres of temporary loss.

Compared to Alternative 2, which would result in 9.4 acres (0.6%) of permanent habitat loss and 1.4 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 and 4 would be the same, under Alternatives 5 and 6 would be somewhat more, and under Alternative 7 would be marginally less. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be the same, and under Alternative 7 would be substantially more. The difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in substantially fewer permanent impacts and greater temporary impacts under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, these impacts from Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to suitable habitat for the hermit warbler (**Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 66 acres (4.4%) of permanent loss;
- Alternative 4 – 65 acres (4.3%) of permanent loss;
- Alternative 5 – 66 acres (4.4%) of permanent loss;
- Alternative 6 – 41 acres (2.7%) of permanent loss; and
- Alternative 7 – 44 acres (3.0%) of permanent loss.

Compared to Alternative 2, which would result in 85 acres (5.7%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 6 and 7

would impact substantially fewer acres than the other alternatives; these reductions are primarily due to reductions of the project footprint for the various alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the hermit warbler:

- Alternative 3 – 76 acres (5.1%) of permanent loss;
- Alternative 4 – 74 acres (4.9%) of permanent loss;
- Alternative 5 – 79 acres (5.3%) of permanent loss;
- Alternative 6 – 59 acres (3.9%) of permanent loss; and
- Alternative 7 – 50 acres (3.4%) of permanent loss.

Compared to Alternative 2, which would result in 95 acres (6.3%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts, with Alternatives 6 and 7 having the fewest impacts compared to the other alternatives. These reductions are primarily due to reductions of the project footprint for the various alternatives. Because the combined direct and indirect permanent loss of suitable habitat for the hermit warbler occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Impacts to Individuals

The potential for impacts to hermit warbler individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than for Alternative 2. Migrant individuals may occasionally be displaced from suitable habitat, but injury or mortality of adults or destruction of nests, eggs, or young is not expected to occur. Therefore, this impact (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development. Because migrating individuals could use a variety of alternative woodland habitats in the Project region, short-term and long-term secondary impacts would be adverse but not significant under Alternatives 3 through 7.

Mitigation Strategy and Summary

No mitigation is required for impacts to the hermit warbler because all impacts were determined to be adverse but not significant. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of approximately 1,290 acres of suitable habitat in the High Country SMA, Salt Creek area, and River Corridor SMA. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction because migrating individuals will have access to habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction and controls on lighting. Long-term effects such as increased human activity; pet, stray, and feral cats and dogs; pesticides; and lighting will also be mitigated through a variety of measures.

LAWRENCE'S GOLDFINCH (NESTING) (BCC, CALIFORNIA SPECIAL ANIMAL)

Life History

Lawrence's goldfinch (*Carduelis lawrencei*) is locally common along the western edge of the southern deserts, from Santa Clara and Monterey counties south through coastal slopes, and occasionally surrounding the foothills of the Central Valley (Zeiner *et al.* 1990A). This species is unusual in that it generally migrates in an east to west direction between breeding areas in California and wintering areas in northern Mexico, southern Arizona, and New Mexico. Lawrence's goldfinch primarily breeds in California, but also south into northern Baja California, Mexico. Breeding tends to be concentrated in the foothills of the southern Sierra Nevada through the southern coastal ranges, and southward into the transverse ranges (Gough *et al.* 1998). During the non-breeding season, Lawrence's goldfinch can be found in north-central California, central and southern Arizona, southwestern New Mexico, west Texas, and northern Baja California and northern Sonora, Mexico (NatureServe 2007), although this species appears to have an erratic and complex distribution from year to year (Davis 1999).

The Lawrence's goldfinch uses cropland and hedgerows, shrubland and chaparral, conifer, hardwood, and mixed woodlands (NatureServe 2007). It prefers valley foothill woodlands and hardwood conifer forests, southern California desert riparian, palm oasis, pinyon–juniper, and lower montane areas. In California, the Lawrence's goldfinch has been observed nesting in oaks, cypress, sycamore, cedars, and riparian thickets (Zeiner *et al.* 1990A).

The Lawrence's goldfinch is primarily a seed eater with a preference for fiddleneck (*Amsinckia* sp.), but it occasionally eats insects and fruits (Davis 1999). Individuals forage in tall annual weed patches, meadows, open hillsides, riparian areas, agricultural margins, and chaparral areas (Davis 1999). It gleans seeds while perched, forages for fallen seeds from the ground, and pecks at fleshy fruits.

The breeding season of the Lawrence's goldfinch in California is March through August, with nesting occurring through mid-April to early July.

In addition to direct loss of habitat, Lawrence's goldfinch is vulnerable to overgrazing, soil disturbance/grading, and fire, which generally cause habitat degradation. Altered fire regime may cause vegetation type conversion from woodland, chaparral, and shrubland to non-native grasslands, increasing annual seed plant cover and causing the direct loss of available mature trees, chaparral, and shrubs that provide vertical structure necessary for many bird species, including Lawrence's goldfinch. This species may also be vulnerable to brown-headed cowbird nest parasitism along habitat edges in fragmented habitat (NatureServe 2007). Native birds such as Lawrence's goldfinch are vulnerable to urban-adapted native and non-native mesopredators such as raccoons, skunks, opossums, and domestic cats; in small, isolated habitat patches where coyotes, which prey on these species, are absent (Crooks *et al.* 2001; Crooks and Soulé (1999).

Several other human- or development-related factors may affect Lawrence's goldfinch. Construction-related impacts include dust; noise and ground vibration; increased human activity in close proximity to nesting and foraging areas; and lighting, which may alter behavior, induce physiological stress, and increase predation risk. Additional potential long-term effects related to development include increased human activity, which may disturb nesting or result in habitat degradation from trampling; pesticides, which may contaminate food sources and cause secondary poisoning; lighting; and Argentine ants, which may prey on nestlings.

Survey Results

Suitable nesting and foraging habitat for Lawrence's goldfinch is present within the Specific Plan area, the Salt Creek area, and the VCC and Entrada planning areas. This species has been observed in coastal scrub in the northern and northeastern portions of the Project area and within the riparian habitats in the Santa Clara River over multiple years within the Specific Plan and Entrada planning areas during annual bird surveys.

Bird surveys were conducted by Daniel Guthrie from 1988 through 2006 within the portion of the Santa Clara River and Castaic Creek in and adjacent to the Project boundary in areas of suitable habitat for Lawrence's goldfinch (1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000A, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004A, 2004B, 2004C, 2004D, 2004E, 2004F, 2004G, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C). The surveys were conducted in the riparian areas in the Santa Clara River corridor and on both sides of the River, including some of the agriculture areas near the River. Extensive field surveys were also conducted on portions of Newhall Land and Farming Company property by Bloom Biological, Inc. from February through June 2007. The Bloom Biological, Inc. survey area consisted of approximately 25 miles of the Santa Clara River and its major tributaries in and around the Project site. The survey covered all habitats within the riverbed and one-half mile on each side of the River (Bloom Biological 2007A). Bloom Biological, Inc. found Lawrence's goldfinch to be a common migrant throughout the survey area and a fairly common resident in oak woodlands. Two to 70 individuals were recorded daily throughout the month of March, mostly in migrant flocks. This relatively high frequency of observations just prior to the nesting season suggests that Lawrence's goldfinch likely uses habitat within the Project area for breeding and nesting.

Additional surveys in suitable habitat for Lawrence's goldfinch were conducted within portions of the Santa Clara River in 1994, 1996, 1997, and 1998 (Labinger *et al.* 1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A); within Castaic Creek, Salt Creek, High Country SMA, and portions of the Santa Clara River adjacent to the Project site by Dudek and Associates (2006B, 2006D, 2006E); within other areas of the Specific Plan area not already mentioned (Dudek and Associates 2006C; Impact Sciences 2000; SAIC 2003); within areas upstream of the

VCC planning area, including the Castaic Mesa area by PCR in 1998 and by Compliance Biology in 2006 (PCR 1998; Compliance Biology 2006A, 2006D); and along the Santa Clara River and in uplands throughout the Project area by Bloom Biological, Inc. (2008).

The Project area provides both foraging and nesting habitat for the species. Coast live oak woodland, valley oak woodland, mixed oak woodland, southern coast live oak riparian forest, southern cottonwood–willow riparian forest, southern willow scrub, and riparian scrub provide nesting and foraging habitat for Lawrence's goldfinch on site and total 1,451 acres in the Project area. Additional suitable foraging only habitat in the Project area includes big sagebrush scrub, California sagebrush scrub and associations, California sagebrush–black sage, California sagebrush–California buckwheat scrub, California sagebrush scrub–undifferentiated chaparral, undifferentiated chaparral scrubs, and chamise chaparral that total 6,563 acres. The combined suitable nesting and/or foraging habitat in the Project area totals 8,014 acres.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 128 acres of suitable nesting and/or foraging habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.6% of these habitats on site (**Figure 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat). Of these impacts, 48 acres are nesting and foraging habitat (*i.e.*, coast live oak woodland, valley oak woodland, mixed oak woodland, southern coast live oak riparian forest, southern cottonwood–willow riparian forest, southern willow scrub, and riparian scrub), representing 3.3% of this habitat on site. The remaining 80 acres of impact are to foraging habitat only, representing 1.2% of this habitat on site. A total of 55 acres of suitable nesting and/or foraging habitat would be temporarily impacted, of which 46 acres are nesting and foraging habitat and 9.3 acres are foraging habitat only.

The Lawrence's goldfinch is still a wide-ranging species and uses a variety of scrub, chaparral, riparian, and woodland habitats. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 128 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 2,037 acres of suitable nesting and/or foraging habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 25.4% of these habitats on site (**Figure 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat). Of these impacts, 73 acres are nesting and foraging habitat, representing 5.0% of this habitat on site. The remaining 1,964 acres of impact are to foraging habitat only, representing 29.9% of this habitat on site.

The Lawrence's goldfinch is still relatively widespread and common throughout its range. However, the overall loss of 25.4% of nesting and/or foraging habitat, including 5.0% of foraging and nesting habitat and 29.9% of foraging habitat only, would be a substantial habitat loss on site. This impact would be considered a substantial adverse effect on the habitat of a special-status species; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable nesting and/or foraging habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,164 acres (27.0%). Of

these impacts, 121 acres are nesting and foraging habitat, representing 8.3% of this habitat on site. The remaining 2,043 acres of impact are to foraging habitat only, representing 31.1% of this habitat on site.

The combined loss of 27.0% of nesting and/or foraging habitat, including 8.3% of foraging and nesting habitat and 31.1% of foraging habitat only, would be a substantial habitat loss on site. This impact would be considered a substantial adverse effect on the habitat of a special-status species; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The Lawrence's goldfinch is a highly mobile species and it is unlikely that construction activities associated with implementation of the RMDP would result in injury or mortality of individual adult birds. However, foraging individuals may avoid or leave construction areas during construction activities. In addition, implementation of the RMDP could result in mortality of young and/or eggs due to destruction of nests if construction/grading activities occurred during the nesting season of this species. Disruption of foraging activities could affect provisioning of young, thus affecting reproductive success. These impacts would be a substantial adverse impact on this species (significance criterion 1). Implementation of the SCP would not directly impact this species. Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The Lawrence's goldfinch is a mobile species and it is unlikely that build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of individual adult birds. However, foraging individuals may avoid or leave construction areas during construction activities. In addition, mortality of young and/or eggs due to destruction of nests could occur if construction/grading activities occurred during the nesting season of this species. Disruption of foraging activities could affect provisioning of young, thus affecting reproductive success. These impacts would be a substantial adverse impact on this species (significance criterion 1). Indirect, permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, fugitive dust, and nighttime illumination. Although construction would be of a short-term nature, if these activities occurred during the breeding season they could have a substantial direct adverse effect on this species due to potential disruption of nesting and foraging activities, potentially affecting reproductive success.

Potential long-term secondary impacts associated with urban development include noise; nighttime illumination; Argentine ants, which may prey on nestlings; pesticide use resulting in loss of prey and/or secondary poisoning; increased human activity; harassment and predation by pet, stray, and feral cats and dogs; and increased mesopredators as a result of increased habitat fragmentation. These secondary impacts may result in abandonment of nests and lower reproductive success along the urban–open space edge over the long term.

Because the potential short-term and long-term secondary impacts could occur over a much broader area than the direct and indirect loss of habitat, secondary impacts would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable nesting and/or foraging habitat for Lawrence's goldfinch (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 110 acres (1.4%) permanent loss and 57 acres of temporary loss of nesting and/or foraging habitat, including
    - 34 acres (2.3%) of permanent loss and 45 acres of temporary loss of nesting and foraging habitat

  - 76 acres (1.2) of permanent loss and 12 acres of temporary loss of foraging habitat only;
- Alternative 4 – 111 acres (1.4%) permanent loss and 51 acres of temporary loss of nesting and/or foraging habitat, including
  - 35 acres (2.5%) of permanent loss and 43 acres of temporary loss of nesting and foraging habitat
  - 77 acres (1.2%) of permanent loss and 8.7 acres of temporary loss of foraging habitat only;
- Alternative 5 – 125 acres (1.6%) permanent loss and 63 acres of temporary loss of nesting and/or foraging habitat, including
  - 44 acres (3.0%) of permanent loss and 48 acres of temporary loss of nesting and foraging habitat
  - 82 acres (1.2%) of permanent loss and 14 acres of temporary loss of foraging habitat only;
- Alternative 6 – 101 acres (1.3%) permanent loss and 60 acres of temporary loss of nesting and/or foraging habitat, including
  - 34 acres (2.3%) of permanent loss and 44 acres of temporary loss of nesting and foraging habitat
  - 68 acres (1.0%) of permanent loss and 16 acres of temporary loss of foraging habitat only; and
- Alternative 7 – 55 acres (0.7%) permanent loss and 56 acres of temporary loss of nesting and/or foraging habitat, including
  - 13 acres (0.9%) of permanent loss and 37 acres of temporary loss of nesting and foraging habitat
  - 42 acres (0.6%) of permanent loss and 43 acres of temporary loss of foraging habitat only.

Compared to Alternative 2 for nesting/and or foraging habitat, which would result in 128 acres (1.6%) of permanent loss and 55 acres of temporary impacts, Alternatives 3 through 6 would have not substantially different permanent and temporary impacts. Alternative 7 would have substantially reduced permanent impacts and substantially greater temporary impacts compared to the other alternatives. This general pattern is similar for permanent impacts to nesting and foraging habitat, with somewhat reduced impacts for Alternatives 3, 4, and 6, marginally reduced impacts for Alternative 5, and substantially reduced impacts for Alternative 7. For temporary impacts to nesting and foraging habitat, Alternatives 3 through 6 would have marginally different impacts and Alternative 7

would have somewhat reduced impacts. Compared to Alternative 2 for permanent loss of foraging habitat only, which would result in 80 acres (1.2%) of permanent loss, Alternatives 3 through 6 would have similar or marginally reduced impacts and Alternative 7 would have somewhat reduced impacts. Compared to Alternative 2 for temporary impacts to foraging habitat only, which would result in 9.0 acres of temporary loss, Alternatives 3 through 6 would not be substantially different, and Alternative 7 would be somewhat higher.

The relatively greater difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in fewer permanent impacts and relatively more temporary impacts.

The overall permanent loss of nesting and/or foraging habitat resulting from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be less than or similar in magnitude compared to Alternative 2. This impact would not be considered a substantial adverse effect on the habitat of a special-status species; would not have the potential to substantially reduce the habitat of the species on site or rangewide; would not cause the species to drop below self-sustaining levels on site or rangewide; would not threaten to eliminate the species on site or rangewide; and would not substantially reduce the number or restrict the range of the species. The direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant under Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for Lawrence's goldfinch (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 1,921 acres (24.0%) permanent loss of nesting and/or foraging habitat, including
  - 70 acres (4.8%) of permanent loss of nesting and foraging habitat
  - 1,851 acres (28.2%) of permanent loss of foraging habitat only;
- Alternative 4 – 1,865 acres (23,3%) permanent loss of nesting and/or foraging habitat, including
  - 57 acres (3.9%) of permanent loss of nesting and foraging habitat
  - 1,808 acres (27.5%) of permanent loss of foraging habitat only;

- Alternative 5 – 1,817 acres (22.7%) permanent loss of nesting and/or foraging habitat, including
  - 57 acres (3.9%) of permanent loss of nesting and foraging habitat
  - 1,760 acres (26.8%) of permanent loss of foraging habitat only;
- Alternative 6 – 1,543 acres (19.3%) permanent loss of nesting and/or foraging habitat, including
  - 32 acres (2.2%) of permanent loss of nesting and foraging habitat
  - 1,511 acres (23.0%) of permanent loss of foraging habitat only; and
- Alternative 7 – 1,377 acres (17.2%) permanent loss of nesting and/or foraging habitat, including
  - 13 acres (0.9%) of permanent loss of nesting and foraging habitat
  - 1,364 acres (20.8%) of permanent loss of foraging habitat only.

Compared to Alternative 2 for nesting/and or foraging habitat, which would result in 2,037 acres (25.4%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. This general pattern is similar for permanent impacts to nesting and foraging habitat. Compared to Alternative 2, which would result in 73 acres (5.0%) of permanent loss of nesting and foraging habitat, Alternatives 3 through 7 would have reduced impacts. Compared to Alternative 2 for permanent loss of foraging habitat only, which would result in 1,964 acres (29.9%) of permanent loss, Alternatives 3 through 6 would have reduced impacts. Overall for nesting and/or foraging habitat, Alternatives 4 through 7 would have fewer impacts than Alternative 3 because the VCC would not be constructed under Alternatives 4 through 7, and each would have successively fewer impacts due to other differences in the Project footprints. Alternative 7 would have the least amount of impact due to pullbacks from the Santa Clara River and its tributaries.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, all would result in impacts to nesting and foraging habitat and substantial impacts to foraging habitat only. These impacts would have a substantial adverse effect on the habitat of a special-status species; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species. Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for Lawrence's goldfinch:

- Alternative 3 – 2,031 acres (25.3%) permanent loss of nesting and/or foraging habitat, including
  - 96 acres (6.6%) of permanent loss of nesting and foraging habitat
  - 1,935 acres (29.5%) of permanent loss of foraging habitat only;
- Alternative 4 – 1,976 acres (24.7%) permanent loss of nesting and/or foraging habitat, including
  - 92 acres (6.3%) of permanent loss of nesting and foraging habitat
  - 1,885 acres (28.7%) of permanent loss of foraging habitat only;
- Alternative 5 – 1,942 acres (24.2%) permanent loss of nesting and/or foraging habitat, including
  - 101 acres (7.0%) of permanent loss of nesting and foraging habitat
  - 1,841 acres (28.1%) of permanent loss of foraging habitat only;
- Alternative 6 – 1,644 acres (20.5%) permanent loss of nesting and/or foraging habitat, including
  - 65 acres (4.5%) of permanent loss of nesting and foraging habitat
  - 1,579 acres (24.1%) of permanent loss of foraging habitat only; and
- Alternative 7 – 1,432 acres (17.9%) permanent loss of nesting and/or foraging habitat, including
  - 47 acres (3.2%) of permanent loss of nesting and foraging habitat
  - 1,385 acres (21.1%) of permanent loss of foraging habitat only.

Compared to Alternative 2 for nesting/and or foraging habitat, which would result in 2,164 acres (27.0%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. This general pattern is similar for permanent impacts to nesting and foraging habitat. Compared to Alternative 2, which would result in the loss of 120 acres (8.3%), Alternatives 3 through 7 would have reduced impacts. Compared to Alternative 2 for the combined direct and indirect permanent loss of foraging habitat only, which would result in 2,044 acres (31.1%) of permanent loss, Alternatives 3 through 6 would have reduced impacts. Overall for nesting and/or

foraging habitat, Alternatives 4 through 7 would have fewer combined direct and indirect permanent impacts than Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, and each would have successively fewer impacts due to other differences in the Project footprints. Alternative 7 would have the least amount of impact due to pullbacks from the Santa Clara River and its tributaries and other differences in the Project footprint.

Although Alternatives 3 through 7 would have reduced combined direct and indirect permanent impacts compared to Alternative 2, all would result in impacts to nesting and foraging habitat and substantial impacts to foraging habitat only. These combined direct and indirect permanent impacts would have a substantial adverse effect on the habitat of a special-status species; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species. Combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to Lawrence's goldfinch individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Although adult birds would likely avoid injury or mortality, loss of young and/or eggs due to destruction of nests could occur, and provisioning of young could be disrupted, if construction/grading activities occurred during the nesting season of this species. Indirect, permanent impacts (Impacts to Individuals) under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term secondary impacts include construction-related dust, noise, ground vibration, and nighttime illumination. These effects are more likely to occur during build-out of the Specific Plan, VCC, and Entrada planning areas than with implementation of the RMDP and the SCP

because of the much larger area of impact. If these impacts occur during the nesting season, reproductive success could be affected

Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include noise, lighting, Argentine ants, increased human activity, increased predation, and use of pesticides described above for Alternative 2.

Because these potential short-term and long-term secondary effects could occur over a much broader area than direct or indirect loss of habitat, they would have a substantial adverse effect on the species and contribute to the reduction of its range and distribution. These long-term and short-term secondary impacts would be significant, absent mitigation for Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to Lawrence's goldfinch: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and habitat outside the Project footprint.

The Lawrence's goldfinch is probably a relatively common breeding resident on site in habitat that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. While adults are mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, individuals could be displaced from occupied habitat by construction activities. Impacts to individuals also could occur if active nests were disturbed during vegetation clearing and construction/grading activities, resulting in the destruction of the nests and loss of eggs and/or young, or interfering with foraging or provisioning of young. Construction activities may also cause abandonment of nests due to human activity, noise, and ground vibration. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable nesting and/or foraging habitat for the Lawrence's goldfinch resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 1,432 acres (17.9%) under Alternative 7 to 2,164 acres (27.0%) under Alternative 2. This would be a substantial loss of suitable habitat for this species and will alter its use of the Project area. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a permanent open space system that will provide suitable habitat to support both foraging and breeding by the Lawrence's goldfinch in the Project vicinity. Implementation of these mitigation measures will

result in protection and management of approximately 4,332 acres of suitable habitat for the Lawrence's goldfinch in the River Corridor SMA, High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With regard to secondary effects, foraging and nesting activities by the Lawrence's goldfinch could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may cause adults to vacate territories and abandon nests due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to nocturnal predators. These short-term construction-related secondary impacts will be minimized by conducting pre-construction surveys to determine if active nests, are present in the disturbance zone or within 300 feet, and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include habitat fragmentation, which may increase cowbird nest parasitism; wildfire; increased human activity; lighting; pesticides, which may cause secondary poisoning and loss of food resources; harassment by pet, stray, and feral cats and dogs and other mesopredators; and Argentine ants that may prey on nestlings. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 4,264 acres of suitable habitat in the High Country SMA and Salt Creek area will provide Lawrence's goldfinch with relatively undisturbed habitat. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by predators and reduce behavioral disturbances and physiological stress. Limited recreational usage and access restrictions within the High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect Lawrence's goldfinch by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of direct and secondary poisoning and loss of food sources. Cowbird trapping will be conducted as necessary.

The specific mitigation measures for Lawrence's goldfinch are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-145 IMPACTS TO INDIVIDUALS – LAWRENCE'S GOLDFINCH

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of Lawrence's goldfinch individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or

endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to Lawrence's goldfinch individuals

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to Lawrence's goldfinch individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-146 LOSS OF HABITAT – LAWRENCE'S GOLDFINCH

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for Lawrence's goldfinch through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and

values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system (**Figure 4.5-3**). The River Corridor SMA will preserve and enhance at least 68.5 acres of suitable nesting and/or foraging habitat for Lawrence's goldfinch**.** The High Country SMA will preserve and enhance approximately 3,243 acres of suitable nesting and/or foraging habitat for Lawrence's goldfinch.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and that oak tree replacement occur as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA, including the following: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for Lawrence's goldfinch through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural

undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-42 requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities (County of Los Angeles 1988). Fencing shall extend to the root protection zone.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for Lawrence's goldfinch would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-147 SECONDARY IMPACTS – LAWRENCE'S GOLDFINCH

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects associated with build-out of the Specific Plan, VCC, and Entrada planning areas such as habitat fragmentation, increased human activity, inadvertent impacts to habitat during construction, and nighttime lighting.

SP-4.6-1 through SP-4.6-16, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, refer to habitat protection and management in the River Corridor SMA and High Country SMA that will be implemented to mitigate for long-term habitat fragmentation effects and increased human activity.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area.

Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These mitigation measures require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to Lawrence's goldfinch, including short-term construction-related dust, noise, ground vibration and increased human activity as well as long-term habitat fragmentation; increased human activity; greater vulnerability to predation by pet, stray, and feral cats and dogs and other mesopredators; Argentine ants; reduction of prey and secondary poisoning from pesticide use; and cowbird nest parasitism.

BIO-52 and BIO-56, as described above, will mitigate the effects of noise and ground vibration by identifying nest sites and providing for buffers between nests and construction activities.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e*., a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, will mitigate for increased human activity in the Project area through habitat protection, restoration and enhancement, and management.

BIO-42 requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities (County of Los Angeles 1988). Fencing shall extend to the root protection zone.

BIO-63 and BIO-69 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-64 will be implemented to prevent poisoning and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-78 requires implementation of a cowbird trapping program once vegetation clearing begins. The program shall be implemented each day beginning April 1 and concluding on or about November 1, through the construction, maintenance, and monitoring period of the riparian restoration sites. In the event that trapping is terminated after the first few years of development, subsequent phases of the RMDP development shall trigger initiation of trapping surveys.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impacts to Lawrence's goldfinch by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the Lawrence's goldfinch would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

OAK TITMOUSE (NESTING) (CALIFORNIA SPECIAL ANIMAL)

Life History

The oak titmouse (*Baeolophus inornatus*) generally occurs in the western portion of North America at low- to mid-elevations, up to 2,000 meters (6,650 feet) AMSL (Block 1990). This species breeds from southwestern Oregon south through California to northwestern Baja California, Mexico (Wilbur 1987; Cicero 2000). Its range includes most of western California, encircling, but not including, the San Joaquin Valley. Its range extends east from the coast through Kern County and onto the western slope of the Sierra Nevada, and north from San Diego County to Shasta County. Scattered local populations also occur north of Humboldt County, near the coast, and in Siskiyou County. The oak titmouse occurs with limited secondary contact with the juniper titmouse (*B. ridgwayi*) on the Modoc Plateau (Cicero 2000).

The oak titmouse inhabits a variety of habitat types but primarily occurs in oaks, especially those in warm, dry regions (Cicero 2000). This species occurs in montane hardwood–conifer; montane hardwood; blue, valley, and coastal oak woodlands (*Quercus douglasii*, *Q. lobata*, *Quercus* spp.); and montane and valley foothill riparian habitats (Zeiner *et al.* 1990A). The oak titmouse also occurs in western juniper (*Juniperus occidentalis*) woodland, open pine (*Pinus* spp.) forests, and communities of single-leaf pinyon (*Pinus monophylla*) or California juniper (*Juniperus californica*) mixed with Joshua trees (*Yucca brevifolia*) (Johnson and Cicero 1985; Cicero 2000), and it sometimes occurs in residential areas (Zeiner *et al.* 1990A). The oak titmouse generally breeds near water.

The oak titmouse feeds on insects, spiders, berries, acorns, and seeds (Zeiner *et al.* 1990A), with plant material constituting the majority of its diet in fall and winter (Cicero 2000). It also stores seeds (Davis *et al.* 1973). The oak titmouse generally forages in the woody portions of vegetation, including the subcanopy and bark surface, as well as within the foliage, but it also occasionally forages on the ground. It typically carries food to an elevated perch with good visibility in order to feed (Dixon 1949). The oak titmouse occasionally drinks water (Williams and Koenig 1980).

The oak titmouse breeds from March into July, with peak breeding occurring in April and May. Solitary pairs nest in natural tree holes or woodpecker-excavated cavities (Zeiner *et al.* 1990A), although it may excavate its own cavity or use artificial nest boxes (Cicero 2000). The oak titmouse is diurnally active and non-migratory (Zeiner *et al.* 1990A). Both members of a pair defend a territory year round (Dixon 1956). Juveniles appear to disperse long distances from parental territories, forced by aggressive interactions with the parents (Price 1936; Dixon 1949). In the San Francisco Bay region, oak titmouse territories were estimated to range from 1.7 and 2.6 hectares (4.2 to 6.4 acres) (Dixon 1949, 1956; Cicero 2000). Territory size likely differs geographically, with larger territories in habitats with lower productivity (Cicero 2000). The same territories are maintained through the breeding season as long as a suitable nest cavity is

present. Territories are generally reused by the same pairs year after year with boundaries remaining remarkably stable (Dixon 1949). The oak titmouse is considered to be one of the most sedentary species in the family Paridae (chickadees and titmice) (Cicero 2000).

This species is primarily threatened by loss of oak woodland habitat. In California, oak woodlands are being cleared for agriculture, rangeland, and urbanization (Cicero 2000). Southern California, the Central Valley, and the western foothills of Sierra Nevada have experienced the greatest losses in oak woodlands, especially since the 1970s (Adams *et al.* 1991; Mensing 1991; Cicero 2000). Although the oak titmouse is still common throughout its distribution, the sustainability of populations will depend on the conservation and management of oak woodlands. Trees with natural cavities are critical for oak titmouse nesting, which are also used by the introduced European starling, which occurs in large population in agricultural and urban areas and may be significant competitor with the oak titmouse for breeding sites. Several other human- or development-related factors may affect the oak titmouse. Construction-related impacts include dust; noise and ground vibration; increased human activity in close proximity to nesting and foraging areas; and lighting, which may alter behavior, induce physiological stress, and increase predation risk. Additional potential long-term effects related to development include increased human activity, which may disturb nesting; pesticides, which may contaminate food sources, cause reduction of insect prey, and cause secondary poisoning; lighting; and Argentine ants, which may prey on nestlings.

Survey Results

Suitable upland oak woodland and riparian habitat for the oak titmouse is present throughout the Project area. Although surveys specifically for the oak titmouse have not been conducted because of its relatively low sensitivity status (California Special Animal), suitable upland and riparian habitat for this species has been extensively surveyed during focused surveys for other bird species, during which all birds detected were recorded.

Surveys for upland bird species were conducted throughout the Project area and in nearby areas between 1995 and 2008. Surveys in the Specific Plan area covered the Landmark Village, Mission Village, and Homestead East and West areas as well as Potrero, Long, and Chiquito canyons and the upland habitats along the Santa Clara River (Bloom Biological 2007A, 2008; Dudek and Associates 2006C; Guthrie 2000A, 2000B, 2004A, 2004D, 2004E; Impact Sciences 2000; RECON and Impact Sciences 1996; SAIC 2003). The High Country SMA and Salt Creek area (in the Specific Plan area) were surveyed by Dudek and Associates in 2005 (2006B). Upland surveys have also been conducted in the VCC (Dudek and Associates 2006D; Guthrie 2004B) and Entrada planning areas (Dudek and Associates 2006E; Guthrie 2004G). Areas near the Project area that have been surveyed for upland bird species include the Legacy Village area adjacent to the Project area on the south and east (Guthrie 2004C), the Castaic Junction area just north of the Entrada planning area (Guthrie 2004F, 2004I), the Riverpark

site (now referred to as RiverVillage) upstream of the Specific Plan area (Compliance Biology 2003A), and upland areas upstream of the VCC planning area, including the Castaic Mesa area (PCR 1998; Compliance Biology 2006A, 2006D).

Surveys for riparian species have been conducted for multiple years (1988 through 2008) along the Santa Clara River. These surveys were conducted by Guthrie from 1988 through 2006 within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C); within portions of the Santa Clara River by Labinger *et al.* and Labinger and Greaves in 1994, 1996, 1997, and 1998 (Labinger *et al.* 1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A); within Castaic Creek, Salt Creek, High Country SMA, and portions of the Santa Clara River adjacent to the Project site by Dudek and Associates (2006B, 2006D, 2006E); and within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line by Bloom Biological, Inc. in 2007 (2007A).

These surveys have established that the oak titmouse is common and abundant in the Project area, and nests on site in southern cottonwood–willow riparian and coast live oak communities. It has been observed over multiple years along the Santa Clara River and in the Specific Plan, VCC, and Entrada planning areas. The oak titmouse was observed most recently by Guthrie in 2006 (2006C) and by Bloom Biological, Inc. in 2007 and (2007A, 2008). Most observations of this species were not mapped because of its common occurrence and low sensitivity status.

Suitable nesting habitat for oak titmouse in the Project area includes coast live oak woodland, mixed oak woodland, valley oak woodland, valley oak/grass, southern coast live oak riparian forest, and southern cottonwood–willow riparian. A total of 1,890 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 45 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 2.4% of these habitats on site (**Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat). A total of 41 acres would be temporarily impacted.

The oak titmouse is still a wide-ranging species and uses a variety of upland and riparian woodland habitats. The construction of RMDP facilities would be phased over a long period of time and at least 1,560 of acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 45 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 92 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 4.9% of these habitats on site (**Figures 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat).

The oak titmouse is still a wide-ranging species and is commonly observed in the Project area in a variety of riparian and woodland habitats. Approximately 1,560 acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would remain as protected open space after build-out of the area. Therefore, the permanent loss of 92 acres of habitat as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the

species population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 138 acres (7.3%). The oak titmouse is still a wide-ranging species, is commonly observed in the Project area in a variety of riparian and woodland habitats, and approximately 1,560 acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would remain as protected open space after build-out of the area. Therefore, the permanent loss of 138 acres of habitat would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The oak titmouse is a relatively mobile species and it is unlikely that construction activities associated with implementation of the RMDP would result in injury or mortality of individual adult birds. However, individuals may be displaced from territories within or near construction areas during construction activities. Also, implementation of the RMDP could result in mortality of young and/or eggs due to destruction of nests if construction/grading activities occurred during the nesting season of this species. Disruption of foraging activities could affect provisioning of young, thus affecting reproductive success. These impacts would be a substantial adverse impact on this species (significance criterion 1). Implementation of the SCP would not directly impact this species. Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The oak titmouse is a relatively mobile species and it is unlikely that build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of individual

adult birds. However, individuals may be displaced from territories within or near construction areas during construction activities. Also, mortality of young and/or eggs due to destruction of nests could occur if construction/grading activities occurred during the nesting season of this species. Disruption of foraging activities could affect provisioning of young, thus affecting reproductive success. These impacts would be a substantial adverse impact on this species (significance criterion 1). Indirect, permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, fugitive dust, and nighttime illumination. Although construction would be of a short-term nature, if these activities occurred during the breeding season they could have a substantial direct adverse effect on this species due to potential disruption of nesting and foraging activities, potentially affecting reproductive success.

Potential long-term secondary impacts associated with urban development include noise, nighttime illumination, Argentine ants which may prey on nestlings, pesticide use resulting in loss of food sources and/or secondary poisoning, increased human activity, harassment and predation by pet, stray, and feral cats and dogs, increased mesopredators as a result of increased habitat fragmentation, and increased competition with non-natives species such as European starling for nest sites. These secondary impacts may result in abandonment of nests and lower reproductive success along the urban–open space edge over the long term.

Because the potential short-term and long-term secondary impacts could occur over a much broader area than the direct and indirect loss of habitat, secondary impacts would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for oak titmouse (**Figures 4.5-109**

through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 33 acres (1.7%) of permanent loss and 40 acres of temporary loss;
- Alternative 4 – 33 acres (1.7%) of permanent loss and 38 acres of temporary loss;
- Alternative 5 – 42 acres (2.2%) of permanent loss and 43 acres of temporary loss;
- Alternative 6 – 34 acres (1.8%) of permanent loss and 39 acres of temporary loss; and
- Alternative 7 – 13 acres (0.7%) of permanent loss and 36 acres of temporary loss.

Compared to Alternative 2, which would result in 45 acres (2.4%) of permanent habitat loss and 41 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 through 6 would be marginally to somewhat reduced and Alternative 7 would be substantially less. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 7 would be not substantially different to somewhat reduced. The permanent impacts under Alternative 7 would be substantially less compared to the other alternatives due primarily to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Because the overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be marginally to substantially reduced compared to Alternative 2 and temporary impacts would be not substantially different to somewhat reduced, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for oak titmouse (**Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 72 acres (3.8%) of permanent loss;
- Alternative 4 – 68 acres (3.6%) of permanent loss;
- Alternative 5 – 68 acres (3.6%) of permanent loss;
- Alternative 6 – 41 acres (2.2%) of permanent loss; and
- Alternative 7 – 45 acres (2.4%) of permanent loss.

Compared to Alternative 2, which would result in 92 acres (4.9%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 and 5 would

have marginally reduced impacts compared to Alternative 3 and Alternatives 6 and 7 would have additional reductions compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than under Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for oak titmouse:

- Alternative 3 – 105 acres (5.6%) of permanent loss;
- Alternative 4 – 100 acres (5.3%) of permanent loss;
- Alternative 5 – 110 acres (5.8%) of permanent loss;
- Alternative 6 – 75 acres (4.0%) of permanent loss; and
- Alternative 7 – 59 acres (3.1%) of permanent loss.

Compared to Alternative 2, which would result in 138 acres (7.3%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. There would generally be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 3, 4, 6, and 7. Alternative 5 would have the next largest impact compared to Alternative 2. Because the combined direct and indirect permanent loss of suitable habitat for oak titmouse occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than under Alternative 2, these impacts would be adverse but not significant.

Impacts to Individuals

The potential for impacts to oak titmouse individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Although adult birds would likely avoid injury or mortality, loss of young and/or eggs due to destruction of nests could occur, and provisioning of young could be disrupted, if construction/grading activities occurred during the nesting season of this species. Indirect, permanent impacts (Impacts to Individuals) under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term secondary impacts include construction-related dust, noise, ground vibration, and nighttime illumination. These effects are more likely to occur during build-out of the Specific Plan, VCC, and Entrada planning areas than with implementation of the RMDP and the SCP because of the much larger area of impact. If these impacts occur during the nesting season, reproductive success could be affected

Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include noise, lighting, Argentine ants, increased human activity, increased predation, use of pesticides, and non-native competitors, described above for Alternative 2.

Because these potential short-term and long-term secondary effects could occur over a much broader area than direct or indirect loss of habitat, they would have a substantial adverse effect on the species and contribute to the reduction of its range and distribution. These long-term and short-term secondary impacts would be significant, absent mitigation for Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to oak titmouse: (1) impacts to individuals; and (2) secondary impacts to individuals and suitable habitat outside the Project footprint.

Nesting by oak titmouse occurs in areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, impacts to individuals could occur if active nests are disturbed during vegetation clearing and construction/grading activities, including destruction of nests and loss of eggs and/or fledglings. Construction activities may also alter foraging behavior and thus potentially reduce the health of young and result in lower reproductive success. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

With regard to secondary effects, nesting and foraging activities by the oak titmouse could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may alter foraging and provisioning of young. Construction-generated dust may affect habitat quality and both insect prey and vegetative food sources for the oak titmouse. Lighting may induce physiological stress and increase the risk of predation by nocturnal predators. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 300 feet, and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include invasive species such as Argentine ants which may prey on nestlings; increased noise; lighting; pesticides that may cause secondary poisoning and loss of prey; human disturbances of nest sites; predation by pet, stray, and feral cats and dogs and other mesopredators; and competition for nest sites with non-native species such as European starling. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of approximately 1,563 acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area will provide the oak titmouse with relatively undisturbed habitat for nesting and foraging. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by nocturnal predators and reduce physiological stress. Limited recreational usage and access restrictions within the River Corridor SMA and High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect the oak titmouse by allowing it to nest and forage without disturbance. Controls on pesticides will reduce the chance of secondary poisoning and loss of food sources. Controls on Argentine ants will help reduce impacts on young in nests.

The specific mitigation measures for the oak titmouse are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-148 IMPACTS TO INDIVIDUALS – OAK TITMOUSE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures avoid, minimize, and mitigate the loss of oak titmouse individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during

development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures that would reduce impacts to oak titmouse individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to oak titmouse individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-149 SECONDARY IMPACTS – OAK TITMOUSE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that would mitigate for long-term secondary effects on oak titmouse associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as abandonment of nests from human activity and greater vulnerability to nocturnal predators as a result of nighttime lighting. These mitigation measures provide for protection, restoration, enhancement, and management of habitat in open space for oak titmouse that will offset secondary impacts. Mitigation measures to minimize inadvertent impacts to habitat outside construction zones will also be implemented.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The River Corridor SMA will preserve and enhance at least 316 acres of suitable habitat for oak titmouse. The High Country SMA will preserve and enhance approximately 868 acres of suitable habitat for oak titmouse.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and oak tree replacement occur as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA, including the following: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These mitigation measures require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to the oak titmouse, including short-term construction-related dust, noise, and ground vibration; and long-term impacts such as Argentine ants; increased human activity; greater vulnerability to predation by pet, stray, and feral cats and dogs; and impacts of pesticides such as secondary poisoning and loss of food resources.

Secondary effects of noise and ground vibration during construction will be addressed by BIO-52 and BIO-56, as described above, which will mitigate these effects by identifying nest sites and providing for buffers between nests and construction activities.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. This will reduce impacts to the oak titmouse by protecting habitat quality and by minimizing impacts on its insect prey and vegetative food resources. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years

or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. The Salt Creek area supports approximately 380 acres of suitable habitat for the oak titmouse.

BIO-22 states that the Oak Resource Management Plan shall incorporate the findings of the Draft Newhall Ranch Mitigation Feasibility Report (Dudek 2007A) and areas identified as being suitable for oak woodland enhancement and creation shall be used for mitigation.

BIO-42 requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities (County of Los Angeles 1988). Fencing shall extend to the root protection zone.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or

cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impacts to oak titmouse by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant from riparian areas is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the oak titmouse would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

FRINGED MYOTIS (CALIFORNIA SPECIAL ANIMAL)

Life History

The fringed myotis (*Myotis thysanodes*) is widespread throughout the western United States, southern British Columbia, Canada, Mexico, and Central America (O'Farrell and Studier 1980). There are three subspecies of the fringed myotis: *M. t. thysanodes*, which has by far the largest range in the western United States; *M. t. aztecus*, which occurs only in southern Mexico; and *M. t. pahasapensis*, which occurs in a disjunct area comprising parts of eastern Wyoming, northeastern Colorado, southwestern South Dakota, and western Nebraska (Hall 1981). In California, the CNDDB (CDFG 2007A) contains 73 records for this species. Most records are in central and northern California, but 11 of the records are from counties in southern California: San Bernardino (five records); San Diego (three records); and one record each in Los Angeles, Riverside, and Ventura counties.

The fringed myotis typically occurs in a wide variety of desert, grass, and woodland habitats at middle elevations of 1,200 to 2,850 meters (3,937 to 9,350 feet) but is known from lower elevations along the west coast and may occur in pine–fir associations at higher elevations (O'Farrell and Studier 1980). Individuals observed in desert/steppe habitats were within a one-hour flight of forest and riparian habitats (O'Farrell and Studier 1980).

During their most active season (April through September), fringed myotis leave their roosts at sundown and forage for small beetles, which comprise about 73% of their diet, in the vegetation canopy (O'Farrell and Studier 1980). They return to the roost by daylight.

Females establish maternity colonies in late April in caves, tunnels, mines, and buildings where young are born and raised. Males establish solitary roost areas during the breeding season. Females leave by late September and probably migrate or disperse to winter hibernacula (Wilson and Ruff 1999). Young are born in late June to early July (O'Farrell and Studier 1980). Young develop rapidly, with flight occurring by 16 days of age, and are fully developed by 20 to 21 days.

The fringed myotis is sensitive to disturbance of roost sites by humans, potentially resulting in abandonment (O'Farrell and Studier 1980; Wilson and Ruff 1999). Such disturbances could also disrupt the interaction of females and young, such as females failing to retrieve young that have fallen from the neonate cluster, which can result in mortality of the young. Other plausible threats to fringed myotis resulting from construction activities include disturbances of day roosts from human activity, noise, and dust, as well as effects of dust on insect prey. Potential long-term impacts from urban development also include pet, stray, and feral animals' disturbances of roost sites; roost site and foraging habitat degradation, such as trampling and invasive species; and pesticides that may cause secondary poisoning and affect prey abundance.

Survey Results

Two focused bat surveys have been conducted in the Project area. Impact Sciences (2005) conducted acoustic surveys using the Anabat II Bat Detector in 2004 and conducted surveys using both the Anabat detector and mist netting in 2006 (Johnson 2006).

Figure 4.5-131 shows the 25 survey locations from 2004 and the six survey locations from 2006 (Impact Sciences 2005; Johnson 2006). The 2004 surveys were scattered through the Project area as well as in two locations on the Legacy Village site. The 2006 surveys were more concentrated, with three locations in Potrero Canyon, two locations along the Santa Clara River, and one location in upper Long Canyon.

There was one acoustic detection of the fringed myotis in the 2004 surveys, and there were no acoustic detections or captures of the species in the 2006 surveys. The 2004 detection of the fringed myotis (Impact Sciences 2005) was in coast live oak habitat, which is consistent with the known habitat association for this species. However, because there was only one detection in total and, as noted above, the distance range for detecting this species is relatively small, it is not possible to refine the habitats potentially used by this species in the Project area. For this reason, and because the fringed myotis is known to use a variety of habitats throughout its range, it is assumed to potentially use most of the natural vegetation communities on site, including alluvial scrub, arrow weed scrub, bulrush–cattail wetland, cismontane alkali marsh, southern cottonwood–willow riparian, Mexican elderberry, giant reed, coastal and valley freshwater marsh, herbaceous wetland, mulefat scrub, southern coast live oak riparian forest, southern willow scrub, shrub tamarisk, river wash, big sagebrush scrub, California sagebrush scrub, coyote brush scrub, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, California annual grassland, *Eriodictyon* scrub, purple needlegrass, coast live oak woodland, valley oak woodland, valley oak/grass, and California walnut woodland. A total of 11,466 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 207 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.8% of these communities on site. **Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats shows impacts to all vegetation communities because the fringed myotis is a foraging habitat generalist and thus potentially forages throughout the Project area. A total of 118 acres would be temporarily impacted.

The fringed myotis forages in a broad variety of habitats that comprise more than 11,000 acres in the Project area. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 207 acres of foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,161 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 27.6% of suitable habitat on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats).

A relatively large amount and percentage of on-site roosting and foraging habitats for the fringed myotis would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from 27.6% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,367 acres (29.4%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of the fringed myotis on site, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Fringed myotis are highly mobile, and it is unlikely that the proposed Project would result in direct mortality of adults occupying this habitat during construction and/or grading activities. However, if adults are flushed from a day roost site during construction activities, these individuals could become disoriented and unable to safely relocate to another roost site, resulting in an increased risk of injury or mortality. In addition, if construction activities directly impacted a colonial maternity site, young could be harassed, injured, or killed. Furthermore, even if young escaped direct harm, the loss of a maternity site resulting from implementation of the RMDP before young are independent of the mother likely would result in injury or mortality of the young due to their likely inability to safely relocate to another roost site. Implementation of the SCP would not directly impact this species. If a day roost site were established prior to construction activities in the Project footprint, direct impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. If a day roost site were established prior to construction activities in the Project footprint, impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect fringed myotis in areas adjacent to construction zones. There is no evidence of existing fringed myotis day roost sites, including maternity sites, in the Project area, based on focused bat surveys in 2004 and 2006 (Impact Sciences 2005; Johnson 2006). However, if a day roost site were established prior to construction activities in proximity to the construction zones, both short-term secondary impacts associated with construction activities and long-term secondary impacts to a roost site could occur. As noted above, increased human activity, noise, and dust associated with construction activities could cause fringed myotis to abandon day roosts, exposing both adults and young to injury and mortality due to their likely inability to safely relocate to another day roost. Although bats are highly mobile and could alter their foraging behavior to avoid construction areas, construction-generated dust may adversely affect foraging habitat by reducing their insect prey. Lighting in construction areas may also alter foraging behavior due to changing the distribution of insect prey attracted to lights and potentially causing increased competition among bats.

Long-term impacts of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would also increase potential secondary impacts through increased human activity, noise, and lighting for the same reason described above for construction impacts, but over the long term. Use of pesticides for agriculture or in landscaped areas may result in secondary poisoning and reduction of prey. Pet, stray, and feral cats and dogs may disturb roost sites.

Both short-term and long-term secondary impacts to a roost site and impacts to foraging bats would result in a substantial adverse effect on a special-status species (significance criterion 1) and would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to suitable habitat for the fringed myotis (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 185 acres (1.6%) of permanent loss and 132 acres of temporary loss;
- Alternative 4 – 180 acres (1.6%) of permanent loss and 115 acres of temporary loss;

- Alternative 5 – 212 acres (1.8%) of permanent loss and 141 acres of temporary loss;
- Alternative 6 – 211 acres (1.8%) of permanent loss and 136 acres of temporary loss; and
- Alternative 7 – 82 acres (0.7%) of permanent loss and 190 acres of temporary loss.

Compared to Alternative 2, which would result in 207 acres (1.8%) of permanent loss and 118 acres of temporary impacts, the combined permanent and temporary loss of foraging habitat under Alternative 3 would not be substantially different than Alternative 2, Alternative 4 would be marginally less and Alternative 6 marginally greater, Alternative 5 would be somewhat greater, and Alternative 7 would be somewhat less. The difference between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternative 3 through 7 would be similar in magnitude compared to Alternative 2, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to suitable habitat for the fringed myotis (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 2,949 acres (25.7%) of permanent loss;
- Alternative 4 – 2,825 acres (24.6%) of permanent loss;
- Alternative 5 – 2,742 acres (23.9%) of permanent loss;
- Alternative 6 – 2,423 acres (21.1%) of permanent loss; and
- Alternative 7 – 2,128 acres (18.6%) of permanent loss.

Compared to Alternative 2, which would result in 3,161 acres (27.6%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara

River and other changes in the Project footprint under Alternative 7 that reduce impacts to fringed myotis suitable habitat compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the fringed myotis occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the fringed myotis:

- Alternative 3 – 3,134 acres (27.3%) of permanent loss;
- Alternative 4 – 3,005 acres (26.2%) of permanent loss;
- Alternative 5 – 2,953 acres (25.8%) of permanent loss;
- Alternative 6 – 2,633 acres (23.0%) of permanent loss; and
- Alternative 7 – 2,210 acres (19.3%) of permanent loss.

Compared to Alternative 2, which would result in 3,367 acres (29.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the fringed myotis occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual fringed myotis as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the

relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual fringed myotis occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as increased human activity; dust; noise (from construction and traffic on roads and bridges); pet, stray, and feral cats and dogs; pesticides; and lighting. The loss or degradation of suitable habitat and impacts to individual fringed myotis due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to fringed myotis: (1) impacts to individuals; (2) loss of roosting and foraging habitat; and (3) secondary impacts to individuals and roosting sites and foraging habitat outside the Project footprint.

Impacts to individuals could occur if day roosting sites are disturbed during construction as a result of increased human activity, noise, dust, and lighting. As noted above, the fringed myotis is very sensitive to disturbances and may permanently abandon roost sites. In addition, disturbances may cause females to fail to retrieve young that have fallen from the neonate cluster, which can result in mortality of the young. If individuals, including adults and young, are flushed from a day roost during construction they would likely become disoriented and unable to safely relocate to another roost, resulting in increased risk of injury or mortality. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active bat roost sites and postpone work within 300 feet of any active maternity roost until young have fledged, and will create alternative roost sites to mitigate for any roost sites disturbed during construction, including creation of roosts under bridges and in culverts, where practicable, in consultation with CDFG.

The combined permanent loss of foraging habitat result from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,210 acres (19.3%) under Alternative 7 to 3,367 acres (29.4%) under Alternative 2. This would be a substantial loss of suitable foraging habitat and will alter the

foraging behavior of the fringed myotis in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable foraging habitat to support the fringed myotis in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 6,250 acres of suitable foraging habitat, as well as potential roosting sites, for the fringed myotis. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, bats are very sensitive to disturbances and thus roost sites outside of the construction zone could be adversely affected during construction due to increased human activity, dust, noise, and lighting. Dust may also affect their insect prey base. Impacts to active maternity sites in or within 300 feet of construction zones will be avoided until young have fledged, as noted above. Construction-generated dust will be controlled using standard measures such as chemical suppression and screening fencing where determined to be necessary. Potential long-term effects of development include lighting; increased human activity; pet, stray, and feral cats and dogs, which may cause roost abandonment; and use of pesticides, which may cause secondary poisoning or affect the prey base. The large open space system will provide adequate areas for roosting and foraging that will in part offset these impacts. Several specific mitigation measures will also be implemented to control human activities in open space areas where bats may roost, including homeowner education and restrictions on recreational activities. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in, or adjacent to, open space areas. All lighting along the edge of natural habitat areas will be downcast. Pesticides will be controlled through an integrated pest management (IPM) plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

The specific mitigation measures for the fringed myotis are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-150 IMPACTS TO INDIVIDUALS – FRINGED MYOTIS

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid, minimize, or mitigate impacts to fringed myotis individuals.

Measures Recommended by EIS/EIR

This EIS/EIR recommends three mitigation measures to reduce impacts to fringed myotis individuals. These mitigation measures primarily are designed to avoid impacts to active day roosts.

BIO-61 requires a pre-construction survey to determine if active roosts of special-status bats are present within 300 feet of the Project disturbance boundaries. If an active maternity roost is found, all work within 300 feet shall be postponed until the roost is vacated and juveniles have fledged. If a maternity roost is impacted, substitute roosting habitat shall be provided. Non-breeding bat hibernacula shall be vacated the evening between initial disturbance and clearing and grading activities.

BIO-68 requires creation of artificial roost sites to mitigate day roost sites found during pre-construction surveys conducted per BIO-61.

BIO-84 states that the culvert and bridge designs, where practicable, shall provide roosting habitat for bats. A qualified biologist shall work with the Project engineer in identifying and incorporating structures into the design that provide suitable roosting habitat for bat species occurring in the Project area.

BIO-52 will also be implemented as a general measure to avoid and minimize impacts to general wildlife during construction, including bats. BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to fringed myotis individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-151 LOSS OF HABITAT – FRINGED MYOTIS

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures that will mitigate for the permanent loss of habitat for the fringed myotis. These mitigation measures primarily relate to the establishment and management of a large open space system that will provide adequate suitable roosting and foraging habitat to support the fringed myotis and allow for its persistence in the Project area.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 relate to habitat restoration and management of the River Corridor SMA, which is an important foraging habitat resource for the fringed myotis. These measures provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects and will provide potential roosting and adequate foraging habitat in the Project area for the fringed myotis.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA. This measure will help enhance foraging habitat quality for the fringed myotis because insect diversity and abundance would be enhanced.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA are the same as required for the River Corridor SMA and oak tree replacement occurs as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines. This measure will help enhance foraging habitat quality for the fringed myotis and also will provide potential roost sites.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures to mitigate for the loss of habitat for the fringed myotis that relate to the establishment and management of a large open space system.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for fringed myotis would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-152 SECONDARY IMPACTS – FRINGED MYOTIS

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Secondary impacts during construction include increased human activity, dust, noise, and lighting. Dust may also affect the insect prey base of fringed myotis. Potential long-term effects of development include lighting; increased human activity; pet, stray, and feral cats and dogs that may disturb roost sites; and use of pesticides.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-56 to control lighting in natural areas that could affect fringed myotis roosting and foraging behavior. This measure requires that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several mitigation measures to reduce short-term and long-term secondary impacts to roost sites to a level that is adverse but not significant. BIO-61 and BIO-68, described above, will mitigate for short-term construction-related disturbance and human activity. BIO-61, BIO-68, and BIO-84, as described above, will also mitigate for the impacts from long-term disturbance associated with roads, bridges, lighting, and human activity.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an IPM plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to fringed myotis individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

LONG-LEGGED MYOTIS (CALIFORNIA SPECIAL ANIMAL)

Life History

The long-legged myotis (*Myotis volans*) is widespread throughout western North America, from extreme southeastern Alaska and western Canada (British Columbia and Alberta) south into Baja California and central Mexico (Hall 1981). In the United States, it occurs in all states in the zone west of North Dakota to the north and Texas on the south, and its range includes the far western portions of North and South Dakota, Nebraska, and Texas. In California, it occurs throughout the state except for the Central Valley, eastern Lassen and Modoc counties, and the non-mountainous regions of the Mojave and Colorado deserts (Zeiner *et al*. 1990B). For California, the CNDDB (CDFG 2007A) contains 110 records for this species that are scattered throughout suitable habitat areas in the state. Most records are in central and northern California, with nine records from counties in southern California: San Bernardino (six records), Los Angeles (two records), and San Diego (one record).

The long-legged myotis is a yearlong resident of California and primarily occurs in coniferous forests, but it also uses riparian and oak woodland habitats for roosting and foraging (Warner and Czaplewski 1984; Wilson and Ruff 1999; Zeiner *et al*. 1990B). Day roosts during warmer months typically are in hollow trees and under the bark of exfoliating trees (Zeiner *et al*. 1990B) but also include abandoned buildings, cracks in the ground, and crevices in canyons and cliff faces (Warner and Czaplewski 1984). Johnson *et al.* (2007) found that the long-legged myotis in a forested region of north-central Idaho used snags for roosts located mid-slope. This species uses caves and tunnels as winter hibernation areas, indicating local seasonal migrations. In addition to using forests and woodlands, the long-legged myotis also forages in coastal scrub, chaparral, and desert habitat (Zeiner *et al.* 1990B). Johnson *et al.* (2007) suggest that habitat selection is a function of preferred prey availability. Long-legged myotis occur at elevations ranging from 60 to 3,770 meters (197 to 12,370 feet) but are most commonly found at 2,000 to 3,000 meters (6,560 to 9,840 feet).

Long-legged myotis appear to be opportunistic feeders, foraging both within and above the forest canopy and congregating with other bat species at areas of high insect concentrations (Zeiner *et al.* 1990B). They may be moth specialists, but they also feed on a variety of insects, including true flies, gnats, midges, mosquitoes, termites, true bugs, leafhoppers, ants, bees, wasps, lacewings, and beetles. They are active throughout the night, with a peak of foraging activity three to four hours after dark (Warner and Czaplewski 1984).

Large maternity colonies of several hundred individuals are formed in day roosts (Zeiner *et al.* 1990B). Timing of births is variable and occurs from May to August, possibly in relation to climate (Czaplewski 1984). Young have been observed flying by mid-July (Zeiner *et al.* 1990B).

No documented threats to long-legged myotis colonies have been reported in the scientific literature, but, like most bats, this species is likely very sensitive to human disturbance and because it may also roost in abandoned buildings, it is vulnerable to vandalism, extermination, or inadvertent disturbance of roost sites. Other plausible threats to long-legged myotis resulting from construction activities include disturbances of day roosts from human activity, noise, and dust, as well as effects of dust on insect prey. Potential long-term impacts from urban development also include disturbance of roost sites by humans and pet, stray, and feral animals; roost site and foraging habitat degradation, such as by trampling and invasive species; and pesticides, which may cause secondary poisoning and affect prey abundance.

Survey Results

Two focused bat surveys have been conducted in the Project area. Impact Sciences (2005) conducted acoustic surveys using the Anabat II Bat Detector in 2004 and conducted surveys using both the Anabat detector and mist netting in 2006 (Johnson 2006) **Figure 4.5-131** shows the 25 survey locations from 2004 and the six survey locations from 2006 (Impact Sciences 2005; Johnson 2006). The 2004 surveys were scattered throughout the Project area as well as in two locations on the Legacy Village site. The 2006 surveys were more concentrated, with three locations in Potrero Canyon, two locations along the Santa Clara River, and one location in upper Long Canyon.

The presence of the long-legged myotis was not confirmed in the Project area during the acoustic and mist netting surveys conducted in 2004 and 2006 (Impact Sciences 2005; Johnson 2006). However, bats with acoustic signatures in the 40 kHz range, which is the range for the long-legged myotis, were detected on site in 2004 and 2006. Impact Sciences (2005) identified the 40 kHz frequency-range species in 2004 as the western small-footed myotis, but without additional information (*e.g.*, longer time-series recording or capture), this identification could not be confirmed. Based on the frequency data alone, the 40 kHz species could be western small-footed myotis, long-legged myotis, or little brown bat; therefore, all three species should be considered to be potentially present on site. In 2006, 40 kHz bat species were recorded in all three survey locations along Potrero Creek, along the Santa Clara River at Walcott Road, and at the plant nursery site in upper Long Canyon.

Although the Project area does not have prime habitat for the long-legged myotis (coniferous forests at high elevations), the species could roost on site in riparian and woodland habitats and buildings and could forage in all habitats throughout the Project area. For this reason, this species is assumed to potentially use most of the natural vegetation communities on site, including alluvial scrub, arrow weed scrub, bulrush–cattail wetland, cismontane alkali marsh, southern cottonwood–willow riparian, Mexican elderberry, giant reed, coastal and valley freshwater marsh, herbaceous wetland, mulefat scrub, southern coast live oak riparian forest, southern willow scrub, shrub tamarisk, river wash, big sagebrush scrub, California sagebrush

scrub, coyote brush scrub, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, California annual grassland, *Eriodictyon* scrub, purple needlegrass, coast live oak woodland, valley oak woodland, valley oak/grass, and California walnut woodland. A total of 11,466 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 207 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.8% of these communities on site. **Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats, shows impacts to all vegetation communities because the long-legged myotis is a foraging habitat generalist and thus potentially forages throughout the Project area. A total of 118 acres would be temporarily impacted.

The long-legged myotis forages in a broad variety of habitats that comprise more than 11,000 acres in the Project area. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 207 acres of foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the

species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,161 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 27.6% of suitable habitat on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats).

A relatively large amount and percentage of on-site roosting and foraging habitats for the long-legged myotis would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from 27.6% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,367 acres (29.4%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of the long-legged myotis on site, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Long-legged myotis are highly mobile, and it is unlikely that the proposed Project would result in direct mortality of adults occupying this habitat during construction and/or grading activities. However, if adults are flushed from a day roost site during construction activities, these individuals could become disoriented and unable to safely relocate to another roost site, resulting in an increased risk of injury or mortality. In addition, if construction activities directly impacted a colonial maternity site, young could be harassed, injured, or killed. Furthermore, even if young escaped direct harm, the loss of a maternity site resulting from implementation of the RMDP before young are independent of the mother likely would result in injury or mortality of the young due to their likely inability to safely relocate to another roost site. Implementation of the SCP

would not directly impact this species. If a day roost site were established prior to construction activities in the Project footprint, direct impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. If a day roost site were established prior to construction activities in the Project footprint, impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect long-legged myotis in areas adjacent to construction zones. There is no evidence of existing long-legged myotis day roost sites, including maternity sites, in the Project area, based on focused bat surveys in 2004 and 2006 (Impact Sciences 2005; Johnson 2006). However, if a day roost site were established prior to construction activities in proximity to the construction zones, both short-term secondary impacts associated with construction activities and long-term secondary impacts to a roost site could occur. As noted above, increased human activity, noise, and dust associated with construction activities could cause long-legged myotis to abandon day roosts, exposing both adults and young to injury and mortality due to their likely inability to safely relocate to another day roost. Although bats are highly mobile and could alter their foraging behavior to avoid construction areas, construction-generated dust may adversely affect foraging habitat by reducing their insect prey. Lighting in construction areas may also alter foraging behavior due to changing the distribution of insect prey attracted to lights and potentially causing increased competition among bats.

Long-term impacts of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would also increase potential secondary impacts through increased human activity, noise, and lighting for the same reasons described above for construction impacts, but over the long term. Use of pesticides for agriculture or in landscaped areas may result in secondary poisoning and reduction of prey. Pet, stray, and feral cats and dogs may disturb roost sites.

Both short-term and long-term secondary impacts to a roost site and impacts to foraging bats would result in a substantial adverse effect on a special-status species (significance criterion 1) and would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to suitable habitat for the long-legged myotis (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 185 acres (1.6%) of permanent loss and 132 acres of temporary loss;
- Alternative 4 – 180 acres (1.6%) of permanent loss and 115 acres of temporary loss;
- Alternative 5 – 212 acres (1.8%) of permanent loss and 141 acres of temporary loss;
- Alternative 6 – 211 acres (1.8%) of permanent loss and 136 acres of temporary loss; and
- Alternative 7 – 82 acres (0.7%) of permanent loss and 190 acres of temporary loss.

Compared to Alternative 2, which would result in 207 acres (1.8%) of permanent loss and 118 acres of temporary impacts, the combined permanent and temporary loss of foraging habitat under Alternative 3 would not be substantially different than Alternative 2, Alternative 4 would be marginally less and Alternative 6 marginally greater, Alternative 5 would be somewhat greater, and Alternative 7 would be somewhat less. The difference between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, these impacts for Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to suitable habitat for the long-legged myotis (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 2,949 acres (25.7%) of permanent loss;
- Alternative 4 – 2,825 acres (24.6%) of permanent loss;
- Alternative 5 – 2,742 acres (23.9%) of permanent loss;
- Alternative 6 – 2,423 acres (21.1%) of permanent loss; and
- Alternative 7 – 2,128 acres (218.6%) of permanent loss.

Compared to Alternative 2, which would result in 3,161 acres (27.6%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and other changes in the Project footprint under Alternative 7 that reduce impacts to long-legged myotis suitable habitat compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the long-legged myotis occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the long-legged myotis:

- Alternative 3 – 3,134 acres (27.3%) of permanent loss;
- Alternative 4 – 3,005 acres (26.2%) of permanent loss;
- Alternative 5 – 2,953 acres (25.8%) of permanent loss;

- Alternative 6 – 2,633 acres (23.0%) of permanent loss; and
- Alternative 7 – 2,210 acres (19.3%) of permanent loss.

Compared to Alternative 2, which would result in 3,367 acres (29.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the long-legged myotis occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual long-legged myotis as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. The impacts to individual long-legged myotis occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2, because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as increased human activity; dust; noise (from construction and traffic on roads and bridges); pet, stray, and feral cats and dogs; pesticides; and lighting. The loss or degradation of suitable habitat and impacts to individual long-legged myotis due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to long-legged myotis: (1) impacts to individuals; (2) loss of roosting and foraging habitat; and (3) secondary impacts to individuals, roosting sites, and foraging habitat outside the Project footprint.

Impacts to individuals could occur if day roosting sites are disturbed during construction as a result of increased human activity, noise, dust, and lighting. As noted above, bats are very sensitive to disturbances and may permanently abandon disturbed roost sites. If individuals, including adults and young, are flushed from a day roost during construction, they would likely become disoriented and unable to safely relocate to another roost, resulting in increased risk of injury or mortality. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active bat roost sites and postpone work within 300 feet of any active maternity roost until young have fledged, and will create alternative roost sites to mitigate for any roost sites disturbed during construction, including creation of roosts under bridges and in culverts, where practicable, in consultation with CDFG.

The combined permanent loss of foraging habitat resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,210 acres (19.3%) under Alternative 7 to 3,367 acres (29.4%) under Alternative 2. This would be a substantial loss of suitable foraging habitat and will alter the foraging behavior of the long-legged myotis in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable foraging habitat to support the long-legged myotis in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 6,250 acres of suitable foraging habitat, as well as potential roosting sites, for the long-legged myotis. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, bats are very sensitive to disturbances and thus roost sites outside the construction zone could be adversely affected during construction due to increased human activity, dust, noise, and lighting. Dust may also affect their insect prey base. Impacts to active maternity sites in or within 300 feet of construction zones will be avoided until young have fledged, as noted above. Construction-generated dust will be controlled using standard measures such as chemical suppression and screening fencing where determined necessary. Potential long-term effects of development include lighting, increased human activity, and pet, stray, and feral cats and dogs, which may cause roost abandonment; and use of pesticides, which may cause secondary poisoning or affect the prey base of the long-legged myotis. The large open space system will provide adequate areas for roosting and foraging that will in part offset these impacts. Several specific mitigation measures will also be implemented to control human

activities in open space areas where bats may roost, including homeowner education and restrictions on recreational activities. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting along the edge of natural habitat areas will be downcast. Pesticides will be controlled through an IPM plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

The specific mitigation measures for the long-legged myotis are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-153 IMPACTS TO INDIVIDUALS – LONG-LEGGED MYOTIS

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid, minimize, or mitigate impacts to long-legged myotis individuals.

Measures Recommended by EIS/EIR

This EIS/EIR recommends three mitigation measures to reduce impacts to long-legged myotis individuals. These mitigation measures primarily are designed to avoid impacts to active day roosts.

BIO-61 requires a pre-construction survey to determine if active roosts of special-status bats are present within 300 feet of the Project disturbance boundaries. If an active maternity roost is found, all work within 300 feet shall be postponed until the roost is vacated and juveniles have fledged. If a maternity roost is impacted, substitute roosting habitat shall be provided. Non-breeding bat hibernacula shall be vacated the evening between initial disturbance and clearing and grading activities.

BIO-68 requires creation of artificial roost sites to mitigate day roost sites found during pre-construction surveys conducted per BIO-61.

BIO-84 states that the culvert and bridge designs, where practicable, shall provide roosting habitat for bats. A qualified biologist shall work with the Project engineer in identifying and incorporating structures into the design that provide suitable roosting habitat for bat species occurring in the Project area.

BIO-52 will also be implemented as a general measure to avoid and minimize impacts to general wildlife during construction, including bats. BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings

with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to long-legged myotis individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-154 LOSS OF HABITAT – LONG-LEGGED MYOTIS

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures that will mitigate for the permanent loss of habitat for the long-legged myotis. These mitigation measures primarily relate to the establishment and management of a large open space system that will provide adequate suitable roosting and foraging habitat to support the long-legged myotis and allow for its persistence in the Project area.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 relate to habitat restoration and management of the River Corridor SMA, which is an important foraging habitat resource for the long-legged myotis. These measures provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects and will provide potential roosting and adequate foraging habitat in the Project area for the long-legged myotis.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA. This measure will help enhance foraging habitat quality for the long-legged myotis because insect diversity and abundance would be enhanced.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and that oak tree replacement occur as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines. This measure will help enhance foraging habitat quality for the long-legged myotis and also will provide potential roost sites.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures to mitigate for the loss of habitat for the long-legged myotis that relate to the establishment and management of a large open space system.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for long-legged myotis would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-155 SECONDARY IMPACTS – LONG-LEGGED MYOTIS

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Secondary impacts during construction include increased human activity, dust, noise, and lighting. Dust may also affect the insect prey base of the long-legged myotis. Potential long-term effects of development include lighting; increased human activity; pet, stray, and feral cats and dogs that may disturb roost sites; and use of pesticides.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-56 to control lighting in natural areas that could affect long-legged myotis roosting and foraging behavior. This measure requires that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several mitigation measures to reduce short-term and long-term secondary impacts to roost sites to a level that is adverse but not significant. BIO-61 and BIO-68, described above, will mitigate for short-term construction-related disturbance and human activity. BIO-61, BIO-68, and BIO-84, described above, will also mitigate for the impacts from long-term disturbance associated with roads, bridges, lighting, and human activity.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an IPM plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e*., a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to long-legged myotis individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7

WESTERN SMALL-FOOTED MYOTIS (CALIFORNIA SPECIAL ANIMAL)

Life History

The western small-footed myotis (*Myotis ciliolabrum*) is widespread throughout western North America, from western Canada south through the western United States to northern Baja California and central Mexico (Hall 1981). In the United States, the species occurs in all states west of, and including, North Dakota to the north and Texas to the south. The species is absent from the coastal regions of Washington, Oregon, and California south to about Ventura County (Zeiner *et al.* 1990B). In California, it occurs in coastal southern California, the foothills of the Sierra Nevada, and the Great Basin Desert, and it is absent from the higher elevations in the mountains and from the lower elevations in the Mojave and Colorado deserts (Zeiner *et al.* 1990B). In California, the CNDDB (CDFG 2007A) contains 39 records for this species that are scattered throughout the state. Eight of the records are from counties in southern California: San Bernardino (three records); Los Angeles (two records); and one record each in Imperial, San Diego, and Ventura counties.

The western small-footed myotis occurs in a wide variety of arid upland habitats at elevations ranging from sea level to 2,700 meters (8,860 feet) (Zeiner *et al.* 1990B). Habitats used by this species include riparian areas, woodlands, and brushy uplands (Holloway and Barclay 2001; Zeiner *et al.* 1990B). Western small-footed myotis day roosts include rock crevices, caves, tunnels and mines, and, sometimes, buildings and abandoned swallow nests (Holloway and Barclay 2001). They also use day roosts as nocturnal roosts (*i.e.*, they may return to the day roost during the night) or may use buildings and concrete underpasses strictly as nocturnal roosts (Holloway and Barclay 2001).

Western small-footed myotis forage for moths, true flies, gnats, midges, mosquitoes, true bugs, and beetles, often along the margins of trees and over water (Zeiner *et al.* 1990B).

Females establish maternity roosts, which may be solitary or colonial (with up to 20 individuals), where young are born and raised (Zeiner *et al.* 1990B). Males appear to establish solitary roosts during the breeding season (Zeiner *et al.* 1990B). Births generally occur in May and June, with a peak in late May (Zeiner *et al.* 1990B), and first flight by young occurs by about one month (Wilson and Ruff 1999).

No documented threats to western small-footed myotis colonies have been reported in the scientific literature, but, like most bats, this species is likely very sensitive to human disturbance and because it may roost in abandoned buildings and under bridges (nocturnal roosts), it is vulnerable to vandalism, extermination, or inadvertent disturbance of roost sites. Other plausible threats to western small-footed myotis resulting from construction activities include disturbances of day roosts from human activity, noise, and dust, as well as effects of dust on insect prey. Potential long-term impacts from urban development also include human and pet, stray, and feral

animals' disturbances of roost sites; roost site and foraging habitat degradation, such as by trampling and invasive species; and pesticides, which may cause secondary poisoning and affect prey abundance.

Survey Results

Two focused bat surveys have been conducted in the Project area. Impact Sciences (2005) conducted acoustic surveys using the Anabat II Bat Detector in 2004 and conducted surveys using both the Anabat detector and mist netting in 2006 (Johnson 2006).

Figure 4.5-131 shows the 25 survey locations from 2004 and the six survey locations from 2006 (Impact Sciences 2005; Johnson 2006). The 2004 surveys were scattered throughout the Project area as well as in two locations on the Legacy Village site. The 2006 surveys were more concentrated, with three locations in Potrero Canyon, two locations along the Santa Clara River, and one location in upper Long Canyon.

The presence of the western small-footed myotis was not confirmed in the Project area during the acoustic and mist netting surveys conducted in 2004 and 2006 (Impact Sciences 2005; Johnson 2006). However, bats with acoustic signatures in the 40 kHz range, which is the range for the western small-footed myotis, were detected on site in 2004 and 2006. Impact Sciences (2005) identified the 40 kHz frequency range species in 2004 as the western small-footed myotis, but without additional information (*e.g.*, longer time-series recording or capture), this identification could not be confirmed because this frequency is characteristic of western small-footed myotis, long-legged myotis, and little brown bat. In 2006, 40 kHz bat species were recorded in all three survey locations along Potrero Creek, along the Santa Clara River at Walcott Road, and at the plant nursery site in upper Long Canyon. Without definitive presence/absence information, for the purpose of this analysis, it is assumed that the western small-footed myotis occurs in the Project area.

Because the western small-footed myotis is a habitat generalist, it could forage in all habitats throughout the Project area. For this reason, and because the western small-footed myotis is known to use a variety of habitats throughout its range, it is assumed to potentially use most of the natural vegetation communities on site, including alluvial scrub, arrow weed scrub, bulrush–cattail wetland, cismontane alkali marsh, southern cottonwood–willow riparian, Mexican elderberry, giant reed, coastal and valley freshwater marsh, herbaceous wetland, mulefat scrub, southern coast live oak riparian forest, southern willow scrub, shrub tamarisk, river wash, big sagebrush scrub, California sagebrush scrub, coyote brush scrub, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, California annual grassland, *Eriodictyon* scrub, purple needlegrass, coast live oak woodland, valley oak woodland, valley oak/grass, and California walnut woodland. A total of 11,466 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 207 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.8% of these communities on site. **Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats, shows impacts to all vegetation communities because the western small-footed myotis is a foraging habitat generalist and thus potentially forages throughout the Project area. A total of 118 acres would be temporarily impacted.

The western small-footed myotis forages in a broad variety of habitats that comprise more than 11,000 acres in the Project area. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 207 acres of foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,161 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 27.6% of suitable habitat on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats).

A relatively large amount and percentage of on-site roosting and foraging habitat for the western small-footed myotis would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from 27.6% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,367 acres (29.4%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of the western small-footed myotis on site, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Western small-footed myotis are highly mobile, and it is unlikely that the proposed Project would result in direct mortality of adults occupying this habitat during construction and/or grading activities. However, if adults are flushed from a day roost site during construction activities, these individuals could become disoriented and unable to safely relocate to another roost site, resulting in an increased risk of injury or mortality. In addition, if construction activities directly impacted a colonial maternity site, young could be harassed, injured, or killed. Furthermore, even if young escaped direct harm, the loss of a maternity site resulting from implementation of the RMDP before young are independent of the mother likely would result in injury or mortality of the young due to their likely inability to safely relocate to another roost site. Implementation of the SCP would not directly impact this species. If a day roost site were established prior to construction activities in the Project footprint, direct impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this

occurred, direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. If a day roost site were established prior to construction activities in the Project footprint, impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect western small-footed myotis in areas adjacent to construction zones. There is no evidence of existing western small-footed myotis day roost sites, including maternity sites, in the Project area, based on focused bat surveys in 2004 and 2006 (Impact Sciences 2005; Johnson 2006). However, if a day roost site were established prior to construction activities in proximity to the construction zones, both short-term secondary impacts associated with construction activities and long-term secondary impacts to a roost site could occur. As noted above, increased human activity, noise, and dust associated with construction activities could cause western small-footed myotis to abandon day roosts, exposing both adults and young to injury and mortality due to their likely inability to safely relocate to another day roost. Although bats are highly mobile and could alter their foraging behavior to avoid construction areas, construction-generated dust may adversely affect foraging habitat by reducing their insect prey. Lighting in construction areas may also alter foraging behavior due to changing the distribution of insect prey attracted to lights and potentially causing increased competition among bats.

Long-term impacts of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would also increase potential secondary impacts through increased human activity, noise, and lighting for the same reasons described above for construction impacts, but over the long term. Use of pesticides for agriculture or in landscaped areas may result in secondary poisoning and reduction of prey. Pet, stray, and feral cats and dogs may disturb roost sites.

Both short-term and long-term secondary impacts to a roost site and impacts to foraging bats would result in a substantial adverse effect on a special-status species (significance criterion 1) and would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to suitable habitat for the western small-footed myotis (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 185 acres (1.6%) of permanent loss and 132 acres of temporary loss;
- Alternative 4 – 180 acres (1.6%) of permanent loss and 115 acres of temporary loss;
- Alternative 5 – 212 acres (1.8%) of permanent loss and 141 acres of temporary loss;
- Alternative 6 – 211 acres (1.8%) of permanent loss and 136 acres of temporary loss; and
- Alternative 7 – 82 acres (0.7%) of permanent loss and 190 acres of temporary loss.

Compared to Alternative 2, which would result in 207 acres (1.8%) of permanent loss and 118 acres of temporary impacts, the combined direct permanent and temporary loss of foraging habitat under Alternative 3 would not be substantially different than Alternative 2, Alternative 4 would be marginally less and Alternative 6 marginally greater, Alternative 5 would be somewhat greater, and Alternative 7 would be somewhat less. The difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, impacts for Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the western small-footed myotis (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 2,949 acres (25.7%) of permanent loss;
- Alternative 4 – 2,825 acres (24.6%) of permanent loss;
- Alternative 5 – 2,742 acres (23.9%) of permanent loss;
- Alternative 6 – 2,423 acres (21.1%) of permanent loss; and
- Alternative 7 – 2,128 acres (18.6%) of permanent loss.

Compared to Alternative 2, which would result in 3,161 acres (27.6%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and other changes in the Project footprint under Alternative 7 that reduce impacts to western small-footed myotis suitable habitat compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the western small-footed myotis occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the western small-footed myotis:

- Alternative 3 – 3,134 acres (27.3%) of permanent loss;
- Alternative 4 – 3,005 acres (26.2%) of permanent loss;
- Alternative 5 – 2,953 acres (25.8%) of permanent loss;
- Alternative 6 – 2,633 acres (23.0%) of permanent loss; and
- Alternative 7 – 2,210 acres (19.3%) of permanent loss.

Compared to Alternative 2, which would result in 3,367 acres (29.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed

under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the western small-footed myotis occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual western small-footed myotis as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual western small-footed myotis occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as increased human activity; dust; noise (from construction and traffic on roads and bridges); pet, stray, and feral cats and dogs; pesticides; and lighting. The loss or degradation of suitable habitat and impacts to individual western small-footed myotis due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to western small-footed myotis: (1) impacts to individuals; (2) loss of roosting and foraging habitat; and (3) secondary impacts to individuals, roosting sites, and foraging habitat outside the Project footprint.

Impacts to individuals could occur if day roosting sites are disturbed during construction as a result of increased human activity, noise, dust, and lighting. As noted above, bats are very sensitive to disturbances and may permanently abandon disturbed roost sites. If individuals,

including adults and young, are flushed from a day roost during construction, they would likely become disoriented and unable to safely relocate to another roost, resulting in increased risk of injury or mortality. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active bat roost sites and postpone work within 300 feet of any active maternity roost until young have fledged, and will create alternative roost sites to mitigate for any roost sites disturbed during construction, including creation of roosts under bridges and in culverts, where practicable, in consultation with CDFG.

The combined permanent loss of foraging habitat resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,210 acres (19.3%) under Alternative 7 to 3,367 acres (29.4%) under Alternative 2. This would be a substantial loss of suitable foraging habitat and will alter the foraging behavior of the western small-footed myotis in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable foraging habitat to support the western small-footed myotis in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 6,250 acres of suitable foraging habitat, as well as potential roosting sites, for the western small-footed myotis. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, bats are very sensitive to disturbances and thus roost sites outside the construction zone could be adversely affected during construction due to increased human activity, dust, noise, and lighting. Dust may also affect their insect prey base. Impacts to active maternity sites in or within 300 feet of construction zones will be avoided until young have fledged, as noted above. Construction-generated dust will be controlled using standard measures such as chemical suppression and screening fencing where determined necessary. Potential long-term effects of development include lighting, increased human activity, and pet, stray, and feral cats and dogs, which may cause roost abandonment; and use of pesticides, which may cause secondary poisoning or affect the prey base of the western small-footed myotis. The large open space system will provide adequate areas for roosting and foraging that will in part offset these impacts. Several specific mitigation measures will also be implemented to control human activities in open space areas where bats may roost, including homeowner education and restrictions on recreational activities. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting along the edge of natural habitat areas will be downcast. Pesticides will be controlled through an IPM plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

The specific mitigation measures for the western small-footed myotis are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-156 IMPACTS TO INDIVIDUALS – WESTERN SMALL-FOOTED MYOTIS

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid, minimize, or mitigate impacts to western small-footed myotis individuals.

Measures Recommended by EIS/EIR

This EIS/EIR recommends three mitigation measures to reduce impacts to western small-footed myotis individuals. These mitigation measures primarily are designed to avoid impacts to active day roosts.

BIO-61 requires a pre-construction survey to determine if active roosts of special-status bats are present within 300 feet of the Project disturbance boundaries. If an active maternity roost is found, all work within 300 feet shall be postponed until the roost is vacated and juveniles have fledged. If a maternity roost is impacted, substitute roosting habitat shall be provided. Non-breeding bat hibernacula shall be vacated the evening between initial disturbance and clearing and grading activities.

BIO-68 requires creation of artificial roost sites to mitigate day roost sites found during pre-construction surveys conducted per BIO-61.

BIO-84 states that the culvert and bridge designs, where practicable, shall provide roosting habitat for bats. A qualified biologist shall work with the Project engineer in identifying and incorporating structures into the design that provide suitable roosting habitat for bat species occurring in the Project area.

BIO-52 will also be implemented as a general measure to avoid and minimize impacts to general wildlife during construction, including bats. BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to western small-footed myotis individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-157 LOSS OF HABITAT – WESTERN SMALL-FOOTED MYOTIS

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures that will mitigate for the permanent loss of habitat for the western small-footed myotis. These mitigation measures primarily relate to the establishment and management of a large open space system that will provide adequate suitable roosting and foraging habitat to support the western small-footed myotis and allow for its persistence in the Project area.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 relate to habitat restoration and management of the River Corridor SMA, which is an important foraging habitat resource for the western small-footed myotis. These measures provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects and will provide potential roosting and adequate foraging habitat in the Project area for the western small-footed myotis.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA. This measure will help enhance foraging habitat quality for the western small-footed myotis because insect diversity and abundance would be enhanced.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and that oak tree replacement occur as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak

resources within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines. This measure will help enhance foraging habitat quality for the western small-footed myotis and also will provide potential roost sites.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures to mitigate for the loss of habitat for the western small-footed myotis that relate to the establishment and management of a large open space system.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for western small-footed myotis would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-158 SECONDARY IMPACTS – WESTERN SMALL-FOOTED MYOTIS

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Secondary impacts during construction include increased human activity, dust, noise, and lighting. Dust may also affect the insect prey base of the western small-footed myotis. Potential long-term effects of development include lighting; increased human activity; pet, stray, and feral cats and dogs that may disturb roost sites; and use of pesticides.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-56 to control lighting in natural areas that could affect western small-footed myotis roosting and foraging behavior. This measure requires that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several mitigation measures to reduce short-term and long-term secondary impacts to roost sites to a level that is adverse but not significant. BIO-61 and BIO-68, described above, will mitigate for short-term construction-related disturbance and human activity. BIO-61, BIO-68, and BIO-84, described above, will also mitigate for the impacts from long-term disturbance associated with roads, bridges, lighting, and human activity.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an IPM plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to western small-footed myotis individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

YUMA MYOTIS (CALIFORNIA SPECIAL ANIMAL)

Life History

The Yuma myotis (*Myotis yumanensis*) is widespread throughout western North America from British Columbia, Canada, south through the western United States to Baja California and central Mexico (Hall 1981). In the United States, the species occurs in all of Washington and Oregon, most of California, western Idaho and Montana, the extreme western portion of Nevada, the southeastern half of Utah, all of Arizona and New Mexico, and western Texas. It occurs throughout California except for the most arid areas of the Mojave and Colorado deserts (Zeiner *et al.* 1990B). The Yuma myotis is a yearlong resident and probably makes local migrations from day roosts used in the warmer months to winter hibernation roosts. The species is absent from areas without water sources because it is not well adapted to desert environments and dehydrates quickly if barred from access to water (Wilson and Ruff 1999). In California, the CNDDB (CDFG 2007A) contains 200 records for this species that are from throughout the state. Thirty-six of the records are from counties in southern California: San Diego (15 records), San Bernardino (eight records), Los Angeles (five records), Riverside (four records), and two records each from Imperial and Orange counties.

Although the Yuma myotis occurs in a wide variety of life zones at elevations ranging from sea level to 3,300 meters (10,820 feet), its actual distribution is closely associated with access to water (Zeiner *et al.* 1990B). Forests and woodlands are primary habitats, and foraging usually occurs within open, uncluttered habitats and occurs low, over water sources such as ponds, streams, and stock ponds (Brigham *et al*. 1992; Zeiner *et al.* 1990B). Yuma myotis day roosts include rock crevices; caves; mines; buildings; abandoned swallow nests; and large, live trees (Evelyn *et al*. 2004; Zeiner *et al.* 1990B).

The Yuma myotis typically forages over water sources for moths, true flies, gnats, midges, mosquitoes, termites, true bugs, caddisflies, ants, bees, and wasps (Brigham *et al*. 1992).

Females establish colonial maternity roosts with up to several thousand individuals where young are born and raised (Zeiner *et al.* 1990B). Males appear to establish solitary roosts during the breeding season or roost with other bat species (Wilson and Ruff 1999; Zeiner *et al.* 1990B). Births are variable, but generally occur in late May to mid-June, with a peak in early June in California (NatureServe 2007; Zeiner *et al.* 1990B). Time of first flight is unknown.

No documented threats to Yuma myotis colonies have been reported in the scientific literature, but, like most bats, this species is likely very sensitive to human disturbance and, because it may roost in large trees, abandoned buildings, and under bridges (nocturnal roosts), it is vulnerable to vandalism, extermination, or inadvertent disturbance of roost sites. Other plausible threats to Yuma myotis resulting from construction activities include disturbances of day roosts from human activity, noise, and dust, as well as effects of dust on insect prey. Potential long-term

impacts from urban development also include human and pet, stray, and feral animals' disturbances of roost sites; roost site and foraging habitat degradation, such as trampling and invasive species; and pesticides that may cause secondary poisoning and affect prey abundance.

Survey Results

Two focused bat surveys have been conducted in the Project area. Impact Sciences (2005) conducted acoustic surveys using the Anabat II Bat Detector in 2004 and conducted surveys using both the Anabat detector and mist netting in 2006 (Johnson 2006).

Figure 4.5-131 shows the 25 survey locations from 2004 and the six survey locations from 2006 (Impact Sciences 2005; Johnson 2006). The 2004 surveys were scattered through the Project area as well as in two locations on the Legacy Village site. The 2006 surveys were more concentrated, with three locations in Potrero Canyon, two locations along the Santa Clara River, and one location in upper Long Canyon.

The presence of the Yuma myotis was confirmed in the Project area through capture at The Old Road and I-5 survey site in 2006 (Johnson 2006). Its potential presence was also acoustically recorded in middle Potrero Creek and at the plant nursery site in upper Long Canyon in 2006. Bats with acoustic signatures in the 50 kHz range, which is the range for the Yuma myotis, were detected on site in 2004 and 2006. Impact Sciences (2005) identified the 50 kHz frequency-range species in 2004 as the California myotis, but without additional information (*e.g.*, longer time-series recording or capture), this identification could not be confirmed. Based on the frequency data alone, the 50 kHz species could be Yuma myotis or California myotis; therefore, both species are considered to be potentially present on site.

The Yuma myotis is assumed to potentially use the riparian and wetland vegetation communities on site most closely associated with perennial water sources, including bulrush–cattail wetland, cismontane alkali marsh, southern cottonwood–willow riparian, Mexican elderberry, giant reed, coastal and valley freshwater marsh, herbaceous wetland, mulefat scrub, southern coast live oak riparian forest, southern willow scrub, shrub tamarisk, big sagebrush scrub, big sagebrush–California buckwheat, and arrow weed scrub. A total of 732 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use

practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 67 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 9.2% of these communities on site (**Figure 4.5-54,** Impacts to Riparian/Wetland Wildlife Habitat). A total of 57 acres would be temporarily impacted.

The Yuma myotis forages in a variety of riparian and wetland habitats. The construction of RMDP facilities would be phased over a long period of time and hundreds of acres of suitable riparian and wetland habitat in the River Corridor SMA and associated tributaries would be available for this species at any given time. The permanent loss of 67 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. These permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 17 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 2.3% of these communities on site (**Figure 4.5-54,** Impacts to Riparian/Wetland Wildlife Habitat).

The Yuma myotis forages in a variety of riparian associated habitats and at least 560 acres of habitat for this species would be protected as open space following build-out, primarily in the River Corridor SMA (516 acres). In addition, restoration, revegetation, and enhancement of riparian habitat in the River Corridor would ensure no net loss of acreage and function. The permanent loss of 17 acres of habitat that would occur as a result of build-out of the Specific Plan, VCC, and Entrada planning areas therefore would

not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 84 acres (11.5%). Because the Yuma myotis forages in a variety of riparian-associated habitat, and because the construction activities would be phased over a long period of time, hundreds of acres of suitable riparian habitat in the River Corridor SMA and associated tributaries would be available for this species at any given time. Restoration, revegetation, and enhancement of riparian habitat in the River Corridor would ensure no net loss of acreage and function. Therefore, the permanent loss of 84 acres of habitat that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction. These impacts would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Yuma myotis are highly mobile, and it is unlikely that the proposed Project would result in direct mortality of adults occupying this habitat during construction and/or grading activities. However, if adults are flushed from a day roost site during construction activities, these individuals could become disoriented and unable to safely relocate to another roost site, resulting in an increased risk of injury or mortality. In addition, if construction activities directly impacted a colonial maternity site, young could be harassed, injured, or killed. Furthermore, even if young escaped direct harm, the loss of a maternity site resulting from the implementation of the RMDP before young are independent of the mother likely would result in injury or mortality of the young due to their likely inability to safely relocate to another roost site. Implementation of the SCP would not directly impact this species. If a day roost site were established prior to

construction activities in the Project footprint, direct impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. If a day roost site were established prior to construction activities in the Project footprint, impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect Yuma myotis in areas adjacent to construction zones. There is no evidence of existing Yuma myotis day roost sites, including maternity sites, in the Project area, based on focused bat surveys in 2004 and 2006 (Impact Sciences 2005; Johnson 2006). However, if a day roost site were established prior to construction activities in proximity to the construction zones, both short-term secondary impacts associated with construction activities and long-term secondary impacts to a roost site could occur. As noted above, increased human activity, noise, and dust associated with construction activities could cause Yuma myotis to abandon day roosts, exposing both adults and young to injury and mortality due to their likely inability to safely relocate to another day roost. Although bats are highly mobile and could alter their foraging behavior to avoid construction areas, construction-generated dust may adversely affect foraging habitat by reducing their insect prey. Lighting in construction areas may also alter foraging behavior due to changing the distribution of insect prey attracted to lights and potentially causing increased competition among bats.

Long-term impacts of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would also increase potential secondary impacts through increased human activity, noise, and lighting for the same reason described above for construction impacts, but over the long term. Use of pesticides for agriculture or in landscaped areas may result in secondary poisoning and reduction of prey. Pet, stray, and feral cats and dogs may disturb roost sites.

Both short-term and long-term secondary impacts to a roost site and impacts to foraging bats would result in a substantial adverse effect on a special-status species (significance criterion 1) and would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the Yuma myotis (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 47 acres (6.4%) of permanent loss and 58 acres of temporary loss;
- Alternative 4 – 48 acres (6.5%) of permanent loss and 54 acres of temporary loss;
- Alternative 5 – 54 acres (7.4%) of permanent loss and 62 acres of temporary loss;
- Alternative 6 – 42 acres (5.7%) of permanent loss and 56 acres of temporary loss; and
- Alternative 7 – 9.4 acres (1.3%) of permanent loss and 39 acres of temporary loss.

Compared to Alternative 2, which would result in 67 acres (9.2%) of permanent loss and 57 acres of temporary impacts, the combined direct permanent and temporary loss of habitat under Alternatives 3 through 7 would range from somewhat reduced (Alternative 5) to substantially reduced (Alternative 7). The substantial reduction in direct permanent and temporary impacts under Alternative 7 compared to Alternative 2 is primarily due the exclusion of the Commerce Center Drive Bridge and Potrero Canyon Bridge from the plan; reduced impacts would also occur under Alternative 7 because major tributary drainages would not be re-graded or realigned and bank stabilization would be constructed outside the 100-year floodplains of these drainages. Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be reduced but similar in magnitude compared to Alternative 2 and substantially reduced under Alternative 7, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the Yuma myotis (**Figures 4.5-55** through **59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 12 acres (1.7%) of permanent loss;
- Alternative 4 – 9.3 acres (1.3%) of permanent loss;

- Alternative 5 – 5.6 acres (0.8%) of permanent loss;
- Alternative 6 – 2.6 acres (0.4%) of permanent loss; and
- Alternative 7 – 1.3 acres (0.2%) of permanent loss.

Compared to Alternative 2, which would result in 17 acres (2.3%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed, and each alternative would have successively smaller development footprints within the Specific Plan and/or Entrada planning areas. Alternative 7 would have the least impact because there would be additional pullbacks from the Santa Clara River and other changes in the Project footprint that reduce impacts to Yuma myotis suitable habitat compared to the other alternatives. Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 6 is reduced but not substantially different than Alternative 2, and substantially reduced under Alternative 7, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the Yuma myotis:

- Alternative 3 – 59 acres (8.1%) of permanent loss;
- Alternative 4 – 57 acres (7.8%) of permanent loss;
- Alternative 5 – 60 acres (8.2%) of permanent loss;
- Alternative 6 – 44 acres (6.1%) of permanent loss; and
- Alternative 7 – 10.6 acres (1.5%) of permanent loss.

Compared to Alternative 2, which would result in 84 acres (11.5%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the development footprints in the Specific Plan and/or Entrada planning areas, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The relatively small combined direct and indirect permanent loss of habitat as a result of

construction/grading activities would not have a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of a native nursery site; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species on site or rangewide. Combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant for Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to individual Yuma myotis as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual Yuma myotis occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as increased human activity; dust; noise (from construction and traffic on roads and bridges); pet, stray, and feral cats and dogs; pesticides; and lighting. The loss or degradation of suitable habitat and impacts to individual Yuma myotis due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to Yuma myotis: (1) impacts to individuals; and (2) secondary impacts to individuals, roosting sites, and foraging habitat outside the Project footprint.

Impacts to individuals could occur if day roosting sites are disturbed during construction as a result of increased human activity, noise, dust, and lighting. As noted above, bats are very sensitive to disturbances and may permanently abandon disturbed roost sites. If individuals,

including adults and young, are flushed from a day roost during construction, they would likely become disoriented and unable to safely relocate to another roost, resulting in increased risk of injury or mortality. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active bat roost sites and postpone work within 300 feet of any active maternity roost until young have fledged, and will create alternative roost sites to mitigate for any roost sites disturbed during construction, including creation of roosts under bridges and in culverts, where practicable, in consultation with CDFG.

With respect to secondary effects, bats are very sensitive to disturbances and thus roost sites outside of the construction zone could be adversely affected during construction due to increased human activity, dust, noise, and lighting. Dust may also affect their insect prey base. Impacts to active maternity sites in or within 300 feet of construction zones will be avoided until young have fledged, as noted above. Construction-generated dust will be controlled using standard measures such as chemical suppression and screening fencing where determined to be necessary. Potential long-term effects of development include lighting; increased human activity; pet, stray, and feral cats and dogs, which may cause roost abandonment; and use of pesticides, which may cause secondary poisoning or affect the prey base. The primary mitigation for these long-term effects is the preservation of a large open space system that will provide suitable foraging habitat to support the Yuma myotis in the Project vicinity. Implementation of Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in protection and management of approximately 562 acres of suitable foraging habitat, as well as potential roosting sites, for the Yuma myotis. This habitat will be conserved within three main interconnected open space areas totaling approximately 6,300 acres: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**). Several specific mitigation measures will also be implemented to control human activities in open space areas where bats may roost, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting along the edge of natural habitat areas will be downcast. Pesticides will be controlled through an integrated pest management (IPM) plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

The specific mitigation measures for the Yuma myotis are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-159 IMPACTS TO INDIVIDUALS – YUMA MYOTIS

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid, minimize, or mitigate impacts to Yuma myotis individuals.

Measures Recommended by EIS/EIR

This EIS/EIR recommends three mitigation measures to reduce impacts to Yuma myotis individuals. These mitigation measures primarily are designed to avoid impacts to active day roosts.

BIO-61 requires a pre-construction survey to determine if active roosts of special-status bats are present within 300 feet of the Project disturbance boundaries. If an active maternity roost is found, all work within 300 feet shall be postponed until the roost is vacated and juveniles have fledged. If a maternity roost is impacted, substitute roosting habitat shall be provided. Non-breeding bat hibernacula shall be vacated the evening between initial disturbance and clearing and grading activities.

BIO-68 requires creation of artificial roost sites to mitigate day roost sites found during pre-construction surveys conducted per BIO-61.

BIO-84 states that the culvert and bridge designs, where practicable, shall provide roosting habitat for bats. A qualified biologist shall work with the Project engineer in identifying and incorporating structures into the design that provide suitable roosting habitat for bat species occurring in the Project area.

BIO-52 will also be implemented as a general measure to avoid and minimize impacts to general wildlife during construction, including bats. BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to Yuma myotis individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-160 SECONDARY IMPACTS – YUMA MYOTIS

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Secondary impacts during construction include increased human activity, dust, noise, and lighting. Dust may also affect the insect prey base of Yuma myotis. Potential long-term effects of development include lighting; increased human activity; pet, stray, and feral cats and dogs that may disturb roost sites; and use of pesticides.

Previously Incorporated Measures

The following mitigation measures describe preservation, restoration and enhancement, and management that will result in a large open space system that will provide suitable foraging habitat and potential roosting habitat for the Yuma myotis.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 relate to habitat restoration and management of the River Corridor SMA, which is an important foraging habitat resource for the Yuma myotis. These measures provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects and will provide potential roosting and adequate foraging habitat in the Project area for the Yuma myotis.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA. This measure will help enhance foraging habitat quality for the Yuma myotis because insect diversity and abundance would be enhanced.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA are the same as required for the River Corridor SMA and oak tree replacement occurs as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and

specifications shall follow County oak tree guidelines. This measure will help enhance foraging habitat quality for the Yuma myotis and also will provide potential roost sites.

The Newhall Ranch Specific Plan Program EIR also identified Mitigation Measure SP-4.6-56 to control lighting in natural areas that could affect Yuma myotis roosting and foraging behavior. This measure requires that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that relate to the establishment and management of a large open space system that will provide foraging habitat and potential roosting habitat for the Yuma myotis.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

This EIS/EIR also recommends several specific mitigation measures to reduce short-term and long-term secondary impacts to roost sites to a level that is adverse but not significant. BIO-61 and BIO-68, described above, will mitigate for short-term construction-related disturbance and human activity. BIO-61, BIO-68, and BIO-84, described above, will also mitigate for the impacts from long-term disturbance associated with roads, bridges, lighting, and human activity.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an IPM plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to Yuma myotis individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

AMERICAN BLACK BEAR (CDFG TRUST RESOURCE)

Life History

The American black bear (*Ursus americanus*) (black bear) is widespread throughout much of Canada and the mountainous regions of the western contiguous United States as well as much of Alaska; virtually all of the central, southern, and eastern forested regions of the United States; and south into Mexico (Hall 1981). It is absent from the grassland and agricultural regions of the Midwest and mideastern United States (NatureServe 2007). As of 1996, the black bear's global status was considered secure, including within California (NatureServe 2007). The black bear's abundance and distribution have increased in the northeastern United States, expanding back into its former range in western Oklahoma, northwestern Texas, and southwestern Kansas in the 1980s and 1990s (NatureServe 2007). Within California, it occurs in the Sierra Nevada and Cascade ranges, in the forested regions of northern California, and in the Transverse and Peninsular ranges of southern California south to the San Jacinto range in western Riverside County (Zeiner *et al.* 1990B). Recent sightings in San Diego County suggest that the species is expanding its range to the south (SDNHM 2007).

The black bear is found in dense, mature stands of a variety of forest habitats. It can utilize valley foothill riparian forests, wet meadows, and brushy stands of forests. Bears require large trees and hollow logs, hollow bases of trees, snags, or stumps for cover and hibernation. They may also den in caves or crevices, under roots, or in holes dug in the ground (Reid 1990). Black bears are opportunistic omnivores, and their diet is based on seasonal availability. In the spring, they normally eat grasses, forbs, and bird eggs; in the summer, they feed on insects and fruits; and in the fall, they feed on acorns and other nuts and fruits (Reid 1990; Zeiner *et al.* 1990B). They also graze on trees and shrubs, feed on fish and carrion, and more recently, commonly forage on human refuse as urban development encroaches into their habitat. They require available drinking water when not in hibernation but may also feed on succulent plants as a source of water. Where food resources are scattered and/or scarce, black bears are solitary and tend to spread out across the landscape (Wilson and Ruff 1999).

Litters of one to six cubs are born while the female is in hibernation, usually in January and February. However, in southern California bears may be active year-round, depending on weather conditions and available food resources. Cubs are weaned in the summer at about six months of age but stay with the mother until one to 1.5 years of age (Reid 1990; Zeiner *et al.* 1990B). Female offspring remain in their mothers' territories until adulthood, and male offspring disperse at one to four years of age and may travel as far as 136 miles, with an average dispersal of 38 miles (NatureServe 2007; Wilson and Ruff 1999). Black bears are capable of moving across a variety of terrains during dispersal; only large bodies of water, major urban areas, and very rugged alpine ridges are considered to be major obstacles to movement (NatureServe 2007). Black bears use undercrossings of various dimensions. For example, in Banff National Park,

Alberta, Canada, black bears used 10 of 11 monitored underpasses that ranged in size from 4.2 to 13.4 meters (13.8 to 43.9 feet) in width, 2.5 to 4.0 meters (8.2 to 13.1 feet) in height, and 25.6 to 97.1 meters (83.9 to 318.6 feet) in length, as well as at noise levels ranging from 63.8 to 70.5 dBA (Clevenger and Waltho 2000).

The black bear is protected in national parks, wilderness areas, and wildlife refuges but is at risk of local extirpation in many locales (NatureServe 2007). The primary threat to the black bear in unprotected areas is loss of habitat and increasing encounters with humans along wildland–urban edges. Black bears are highly adaptable to human development, where they are often attracted by food, which brings them into greater contact with humans (Wilson and Ruff 1999). More than 90% of deaths of black bears older than 1.5 years are from anthropogenic causes, including gunshots, trapping, vehicle collisions, and other human sources (Wilson and Ruff 1999).

Survey Results

A mammal assessment and survey for the Specific Plan area was conducted between March 1 and September 30, 2004 (Impact Sciences 2005), but no black bears were documented in this study. Black bear sign (scat and paw prints) was anecdotally observed within High Country SMA in 2005 (Dudek and Associates 2006B). The specific location was not recorded, but it is assumed that black bears use portions of the High Country SMA due to its connection to the Santa Susana Mountains to the south.

Black bears require dense, mature stands of a variety of forest habitats (valley foothill riparian forests, wet meadows, and brushy stands of forests). They also require large trees and hollow logs, hollow bases of trees, snags, or stumps for cover and hibernation. There may be some suitable denning habitat for the black bear in the High Country SMA or Salt Creek area; however, these areas would not be affected by implementation of the RMDP and the SCP or by build-out of the Specific Plan, VCC, or Entrada planning areas. Within the lower elevation areas proposed to be developed, bears may occur occasionally during foraging, movement, and dispersal. Because the areas proposed for development are not regularly used, impacts to suitable habitat for the black bear were not quantified. This species may occasionally use a portion of the Santa Clara River within the Specific Plan area for movement between the Santa Susana Mountains and Santa Monica Mountains to the south and the Los Padres National Forest and Angeles National Forest in the Sierra Madre Mountains to the north.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use

practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Black bears are known to occur in the High Country SMA and to move and disperse through the Project area. Habitat in the RMDP area is not suitable for denning due to a general lack of dense vegetation and cover. Impacts associated with the construction of RMDP facilities therefore would not impact suitable denning habitat for the black bear, but these areas could be used occasionally for foraging and movement. Implementation of the SCP would not directly affect this species. Because this species is still common and widespread in California and much of the United States, has not been directly observed in the development area, and because substantial habitat would remain in the High Country SMA and Salt Creek area following construction of RMDP facilities, direct permanent and temporary impacts (Loss of Habitat) associated with implementation of the RMDP and the SCP would be adverse but not significant.

Indirect Permanent Impacts

Low elevation areas proposed for development in the Project area also do not support suitable denning habitat for the black bear. Its activities in these areas would be limited to occasional foraging, movement, and dispersal, and it is likely that most of its use on the site occur in the more remote areas of the High Country SMA and Salt Creek area that would remain following build-out of the Specific Plan, VCC, and Entrada planning areas. Therefore, indirect permanent impacts associated with the build-out of the Specific Plan, VCC, and Entrada planning areas would not substantially affect suitable habitat for the black bear or substantially affect its use of the Project area such that it could not meet its life history needs. Indirect permanent impacts (Loss of Habitat) associated with build-out of the Specific Plan, VCC, and Entrada planning areas would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

As described above, the lower elevations of the Project area subject to the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas do not support suitable denning habitat for the black bear and its activities on site probably are limited to occasional foraging, movement, and dispersal. Substantial habitat would remain in the High Country SMA and Salt Creek area following construction of RMDP facilities and

build-out. Implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas would not substantially affect this species. The combined direct and indirect permanent impacts on habitat therefore would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Black bears are only expected to occur in the Project area during dispersal between large core habitat areas. Because the black bear is highly mobile, it would be expected to leave/avoid construction zones. It is highly unlikely, therefore, that RMDP-related construction activities would result in direct injury or mortality of individual adult black bears, although there is a small possibility this could occur. Implementation of the SCP would not directly affect this species. Thus, implementation of the RMDP and the SCP would not substantially adversely affect this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Because direct permanent and temporary impacts (Impacts to Individuals) would be very unlikely, they would be adverse but not significant.

Indirect Permanent Impacts

Black bears are only expected to occur in the Project area during dispersal between large core habitat areas. Because the black bear is highly mobile, it would be expected to leave/avoid construction zones. It is highly unlikely, therefore, that build-out of the Specific Plan, VCC, and Entrada planning areas would result in direct injury or mortality of individual adult black bears. Thus, build-out of the Specific Plan, VCC, and Entrada planning areas would not substantially adversely affect this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Because indirect permanent impacts (Impacts to Individuals) would be very unlikely, they would be adverse but not significant.

Secondary Impacts

Increased human activity, nighttime lighting, and noise related to short-term construction activities associated with implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas could alter the dispersal behavior of the black bear between the mountain ranges to the north and south of the Project area. Implementation of the SCP would not

affect this species. Bears could be attracted to trash and garbage and construction waste if left in unsecured containers.

Long-term development-related increases in vehicle traffic, noise, nighttime lighting, and human presence, especially at bridges and road crossings, could alter the movement behavior of the black bear between the mountain ranges to the north and south and could also lead to more frequent adverse encounters with humans and collisions with vehicles. Pet, stray, and feral dogs associated with increased human presence could also harass bears moving through the area.

These short-term and long-term secondary impacts would result in a substantial adverse impact to the habitat use and movement patterns of this species in the Project area (significance criterion 4). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Similar to Alternative 2, Alternatives 3 through 7 would not result in direct permanent or temporary loss of suitable denning habitat for the black bear. Areas affected by the RMDP probably are only occasionally used by black bears for foraging, movement, and dispersal, and loss of habitat in these areas would not substantially affect this species. Substantial habitat would remain in the High Country SMA and Salt Creek area following construction of RMDP facilities. Therefore, direct permanent and temporary impacts (Loss of Habitat) associated with implementation of the RMDP and the SCP would be adverse but not significant for Alternatives 3 through 7.

Indirect Permanent Impacts

Similar to Alternative 2, Alternatives 3 through 7 would not result in indirect permanent loss of suitable denning habitat for the black bear. Areas affected by build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas probably are only occasionally used by black bears for foraging, movement, and dispersal, and loss of habitat in these areas would not substantially affect this species. Substantial habitat would remain in the High Country SMA and Salt Creek area following build-out. Therefore, indirect permanent impacts (Loss of Habitat) resulting from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would be adverse but not significant for Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would be similar to Alternative 2: no impacts to suitable denning habitat for the black bear would occur and areas affected by the RMDP and build-out probably are only occasionally used by black bears for foraging, movement, and dispersal. Substantial habitat would remain in the High Country SMA and Salt Creek area following construction of RMDP facilities and build-out. Therefore, the combined direct and indirect permanent impacts (Loss of Habitat) associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would be adverse but not significant for Alternatives 3 through 7

Impacts to Individuals

The potential for impacts to individual black bears as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Therefore, impacts to individual black bears occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be highly unlikely, and therefore would be adverse but not significant.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as increased human activity, traffic collisions, noise, and nighttime lighting. Therefore, impacts to individual black bears due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in significant secondary impacts to individual American black bears. Bears that occasionally forage on site, or move or disperse through the Project area would be vulnerable to encounters with humans and pet, stray, and feral dogs and increased vehicle

collisions, and their behavior may be altered by lighting and noise associated both the construction activities and long-term development. Trash, garbage, and other debris associated with construction may attract bears, increasing their risk of negative encounters with humans.

The primary mitigation strategy to reduce long-term secondary impacts to a level less than significant is the permanent preservation, restoration and enhancement, and management of 6,700 acres in the River Corridor SMA, High Country SMA, and Salt Creek area that will provide adequate movement and dispersal habitat for black bear through the Project area and limit the risk of negative encounters with humans. Restoration and enhancement activities, including a naturally vegetated transition area along the River Corridor SMA and restoration at the large culverted crossing of SR-126 west of the Specific Plan area, will increase native vegetation cover and provide additional protection for the black bear as it moves through the Project area. This large open space system connects the Santa Susana Mountains in the south to the Los Padres National Forest north of the Santa Clara River *via* the High Country SMA, Salt Creek area, and River Corridor SMA (**Figures 4.5-3** and **4.5-22**). This regional habitat connection will allow the black bear to disperse through the Project area without having to contact residential, commercial, and industrial areas, thus avoiding secondary effects, such as noise and nighttime lighting. Lighting effects at the natural open space–urban interface will also be controlled by requiring downcast lighting along the interface. The large, contiguous areas of natural land, along with wildlife undercrossings of SR-126 (**Figure 4.5-32**), therefore, will provide habitat linkages and wildlife corridors to support movement between larger core habitat areas north and south of the Project area. Negative encounters between black bears and humans and pet, stray, and feral dogs in open spaces areas will be controlled through restrictions on recreational activities and through direct controls on stray and feral dogs.

During construction, trash, garbage, and other debris that could attract bears to construction sites will be secured.

All specific mitigation measures for the American black bear are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-161 SECONDARY IMPACTS – AMERICAN BLACK BEAR

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures that will mitigate secondary impacts to the black bear. The primary focus of these mitigation measures is to provide adequate habitat in the open space system for the black bear and to reduce impacts related to increased human activity that could inhibit movement by the black bear through the region.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 relate to habitat restoration in the River Corridor SMA and provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development and human activity on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side of bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation and allow the black bear to move unconstrained through the Project region (**Figure 4.5-3**).

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-17 and SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the River Corridor SMA and High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only on developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and oak tree replacement occur as

described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

SP-4.6-56 requires that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for impacts from habitat fragmentation, including reduction in wildlife corridors and habitat linkages and increased human activity. A measure is also provided to control for bear attractants during construction, including trash, garbage, and other debris.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. BIO-19 includes a provision to enhance the existing agricultural undercrossing and agricultural land at the base of Salt Creek to facilitate wildlife movement between the north side of SR-126 and the Salt Creek area. This enhancement would include dedication of a portion of the agricultural field north of SR-126 and planting of trees and/or scrub habitat north and south of the existing undercrossing of the highway.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active

intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-22 states that the Oak Resource Management Plan shall incorporate the findings of the Draft Newhall Ranch Mitigation Feasibility Report (Dudek 2007A) and areas identified as being suitable for oak woodland enhancement and creation shall be used for mitigation.

BIO-59 specifies that a wildlife movement corridor plan shall be prepared and implemented. The plan will include design criteria for road crossings and methods to encourage passage, such as lighting, bubblers, and vegetation planting. Signs shall be installed along roadways, indicating potential wildlife crossings where mountain lions and mule deer are likely to cross. These wildlife crossing signs and undercrossings for mountain lion and mule deer will also serve black bear.

BIO-63 will be implemented to mitigate impacts by pet, stray, and feral dogs. This mitigation measure requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral dogs in open space areas.

BIO-70 will be implemented to control for bear attractants during construction, including trash, garbage, and other debris. This general mitigation measure primarily describes features and construction notes to protect biological resources. The relevant element of this mitigation measure is that the operator will install and use fully covered trash receptacles to contain all food, food scraps, food wrappers, beverage containers, and other miscellaneous trash.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to black bear will be reduced to a level that would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

MOUNTAIN LION (SPECIALLY PROTECTED MAMMAL)

Life History

The mountain lion (*Puma concolor*) is a widespread species that occupies a latitudinal range of 100° in North and South America and is found in nearly all habitats from the northern limit of the Canadian forests to Patagonia in South America (NatureServe 2007). It is primarily limited to the mountainous regions of the western United States and Canada but has small, disjunct populations in southern Florida and the Upper Peninsula of Michigan (NatureServe 2007). Globally, it is considered to be secure in its range, but it may be locally threatened in some areas because of hunting pressure, lack of prey, and other anthropogenic factors (NatureServe 2007). Its range throughout California extends from deserts to humid forests in the Coast Ranges and from sea level to 3,050 meters (10,000 feet) AMSL, but mountain lions do not inhabit xeric regions of the Mojave and Colorado deserts. They are most abundant in habitats that support their primary prey, mule deer, and their seasonal movements tend to follow migrating deer herds.

Mountain lions prefer habitats that provide cover, such as thickets in brush and timber in woodland vegetation (Zeiner *et al*. 1990B). They also utilize caves and other natural cavities for cover and breeding. They require extensive areas of riparian vegetation and brushy stages of various habitats, with interspersions of irregular terrain, rocky outcrops, and tree–brush edges. Mountain lions build their dens in natural cavities such as caves and sometimes in thickets. A study of diurnal bedding habitat in northeast Oregon suggests that mountain lions also need both vertical and horizontal cover components, such as rocks and downed logs, to feel secure enough to bed (Akenson *et al*. 1996). They are active year-round and are solitary crepuscular hunters (active early morning and evening), although they are frequently active nocturnally and occasionally during the day. Mule deer make up 60% to 80% of their diet, but mountain lions also prey on raccoons, rabbits, rodents, porcupines, coyotes, and occasionally livestock.

Home ranges of mountain lions are quite variable in relation to season, sex, and resources. The home ranges of adult male mountain lions often span well over 100 square miles (*e.g.*, Loft 1996). In the Santa Ana Mountains of Orange County, Padley (1989, 1996) found that annual home ranges varied from 32 to 86 square miles, with a mean of 43 square miles, and that home ranges were stable from year to year, which Padley suggested may be related to the abundance of mule deer populations. Mountain lions mutually avoid each other, but are not known to actively defend their territory.

Females generally give birth every other year (Zeiner *et al.* 1990B). Cubs are weaned at about 40 days and remain with their mothers for an average of 15 months and sometimes up to 26 months. Dispersal by juvenile mountain lions in the Santa Ana Mountains is initiated by the mother abandoning her cub at about 18 months of age at the edge of her range, whereupon the cub disperses to the part of the urban–wildland interface farthest from its natal range and uses temporary home ranges near this interface (Beier 1996). Beier (1996) also observed dispersing

individuals using corridors along well-covered travel routes, an underpass, areas lacking artificial lighting, and areas with low residential densities (less than one dwelling unit per 16 hectares (39.5 acres)). A total of 60% of the females did not disperse from their natal range, whereas all males did. Females dispersed on average 7.7 miles and males dispersed on average 62.8 miles.

The mountain lion is categorized as highly mobile with regard to its ability to move through the landscape, in particular through corridors and linkages (Singleton and Lehmkuhl 1999; Dudek 2008C). Wildlife movement corridors and linkages are critical for mountain lions due to their large home ranges and the need for access to water sources. Wildlife corridors and landscape linkages serve to ameliorate habitat fragmentation and isolation by permitting travel, migration, and mating opportunities (Beier and Loe 1992). While they use a variety of suitable natural habitats, they tend to avoid urban areas. A study in the Santa Ana Mountains analyzed the travel paths of radio-tagged mountain lions (Dickson *et al*. 2005) and showed that mountain lions frequented canyon bottoms and gentle slopes disproportionately more than ridgelines and steep slopes. They prefer riparian vegetation for diurnal use and nocturnal travel, which may indicate their preference for canyon bottoms. The Conservation Biology Institute (CBI 2003) monitored wildlife movement in San Diego County and found that mountain lions pass through fairly restricted areas. Although bridge underpasses and natural overpasses are the desired crossings of roads, mountain lions in southern California, for example, are known to use box culverts less than 15 by 15 feet to pass under freeways (Beier 1995). It is also notable that Florida panthers use underpasses as low as seven feet in height under a divided highway (Foster and Humphrey 1995), indicating that mountain lions will move through fairly constrained passages if necessary.

The main threat to the mountain lion in southern California is urban development and its associated roads, utilities, and facilities and the resulting decrease and fragmentation of habitat available for the mountain lion. The large areas of contiguous open foraging habitats required by this species are becoming increasingly scarce. Urban development also increases the proximity of mountain lions to residences and consequently increases the frequency of human encounters with mountain lions, often resulting in killing of the lion, as well as mortality of mountain lions from vehicle collisions. Human presence also may have adverse effects on mountain lion behavior by altering their range use and foraging activities (Van Dyke *et al*. 1986).

Survey Results

Mountain lions have been documented within and adjacent to the Project area during focused surveys in 2004 for mammals by Impact Sciences (2005). They were observed at scent/track stations four times in riparian willow habitat (Impact Sciences 2005) and also observed in the High Country SMA in 2005 (Dudek and Associates 2006B). Mountain lions were not observed during spotlight surveys by Impact Sciences (2005). Specific locations for mountain lions in the Project area were not provided by Impact Sciences (2005), but it is assumed that mountain lions could occur anywhere in the Project area where deer also occur. A mountain lion was also

observed in 2008 in upper Middle Canyon (Huntley 2008). The entire Project area, at approximately 14,300 acres (22 square miles), is probably not large enough to encompass the entire home range of a mountain lion. Even assuming some level of home range overlap between and within sexes, it is unlikely that the Project area would support more than two or three individuals at any given time.

The mountain lion uses riparian, woodland, and upland habitats in the Project area. Primary habitats contain some cover for this species and include alluvial scrub, southern cottonwood–willow riparian, Mexican elderberry, giant reed, mulefat scrub, southern coast live oak riparian forest, southern willow scrub, shrub tamarisk, big sagebrush scrub, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, coastal scrub alliances and associations, big sagebrush–California buckwheat, coast live oak woodland, valley oak woodland, valley oak/grass, mixed oak woodland, and California walnut woodland. A total of 8,581 acres of suitable habitat is present in the Project area.

Because of its broad habitat use, the mountain lion is assumed to freely range throughout the Project area. An important issue, therefore, is to what extent the proposed Project would constrain use of the site and movement between large protected open space areas in the region. **Figure 4.5-22** shows regional linkages adapted from South Coast Wildlands (Penrod *et al*. 2006) that would accommodate mountain lion. The north–south linkage design for this species is generally located west of the Project area but incorporates the Salt Creek area and High Country SMA open space areas as well as the River Corridor SMA. **Figure 4.5-31** shows more local habitat linkages and available crossings of the Santa Clara River. There are two linkages that the mountain lion would likely use: Salt Creek Canyon, which serves as a southeast-to-northwest habitat linkage from the Salt Creek area and High Country SMA through the Fillmore Greenbelt to the Los Padres National Forest, and the Santa Susana Mountains Corridor, which serves as a generally east-to-west habitat linkage from High Country SMA to the Ventura County S.O.A.R. Open Area to the west and the public lands to the east. There are three wildlife crossings of SR-126 in Ventura County and three crossings of SR-126 within the Project area, at San Martinez Grande Canyon, Chiquito Canyon, and Castaic Creek. While all three of the latter crossings are of adequate size and configuration to convey movement, they are also well east of the regional corridors depicted in **Figure 4.5-22** and would be bound by development upon build-out. Mountain lions would have to travel close to urban areas to use these crossings. These crossings would likely have less movement than the three locations in Ventura County that line up more directly with the linkages shown in **Figure 4.5-22**.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of

Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 146 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.7% of these communities on site (**Figure 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat). A total of 63 acres would be directly temporarily impacted.

Habitat use by mountain lions is expected to track the distribution of mule deer in the Project area. Because mule deer use tributaries to the Santa Clara River with water and cover, and these tributaries would be affected by the RMDP, at least temporarily displacing deer, mountain lions would be affected as well. However, construction would be phased such that alternative resource areas would remain available to both species. The relatively small permanent loss of habitat and temporary impacts as a result of the construction/grading activities therefore would not have a substantial adverse effect on the mountain lion; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 2,077 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 24.2% of these communities on site (**Figures 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat).

A relatively large amount and percentage of on-site riparian and upland vegetation providing habitat for the mountain would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. The mountain lion is an uncommon species and declining in southern California. It has been observed in the Project area and probably currently uses much of the existing Project area for foraging, movement, and dispersal. This loss of habitat is expected to alter the use and distribution of the mountain

lion on site, both as a result of direct loss of habitat and the effect of habitat loss on the distribution of mule deer. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from 24.2% of currently occupied habitat, thus reducing its range on site. The loss of habitat could also substantially interfere with its movement across the site between core habitat areas to the north and south (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,223 acres (25.0%). Because of the large amount and percentage of habitat loss, the combined direct and indirect impacts to suitable habitat would have a substantial adverse effect on the distribution of the mountain lion on site, thus substantially restricting its range on site and potentially interfering with its movement across the site between core habitat areas to the north and south (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because the mountain lion is highly mobile, it would be expected to leave and/or avoid construction zones. It is unlikely that RMDP-related construction activities would result in direct injury or mortality of individual adult mountain lions, although there is some risk of collision with fast-moving construction equipment and vehicles. Adult or juvenile mountain lions occurring in the RMDP would likely be foraging or moving through the area. In addition, mountain lions typically den in more rocky areas with caves or cavities suitable for dens that are more likely found in the upland habitats of High Country SMA than the habitats found within the Project area; however, the species has been known to den in dense vegetation. Therefore, it is unlikely that RMDP-related construction activities would result in injury or mortality of very young mountain lions still confined to natal dens. Implementation of the SCP would not directly impact this species. Although foraging and movement may be somewhat altered, injury or mortality of individuals during RMDP-related construction activities would be unlikely. Construction activities would not have a substantial direct effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the

species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

Because the mountain lion is highly mobile, it would be expected to leave and/or avoid construction zones during build-out of the Specific Plan, VCC, and Entrada planning areas. It is unlikely that construction activities would result in direct injury or mortality of individual adult mountain lions, although there is some risk of collision with fast-moving construction equipment and vehicles. However, the upland portions of the Specific Plan area that would be developed have the potential to support mountain lion dens. If an active mountain lion den occurred within or in proximity to an area proposed for grading, injury or mortality could occur to young/fetal cubs as a result of den disturbance. The loss of young/fetal cubs would have a substantial adverse effect on this species (significance criterion 1). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term noise and human presence associated with construction and/or grading activities for the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas may alter the foraging behavior and movement patterns of mountain lions in the immediate vicinity of these activities. However, because this species typically forages and moves at night (although some activity may occur at dusk and dawn), the effects of these short-term construction-related activities on mountain lions are expected to be minimal, although it may avoid lighted construction areas. Implementation of the SCP would not affect this species.

Long-term secondary impacts associated with urban development include nighttime illumination of areas adjacent to open space that could disrupt foraging and movement behavior; increased incidence of vehicle collisions at new and expanded roadways; increased encounters with humans and pet, stray, and feral dogs; and the use of rodenticides to control small mammals that are prey for mountain lions (*e.g.*, ground squirrels and rabbits), which may reduce the prey populations and possibly cause secondary poisoning. The build-out of the Specific Plan, VCC, and Entrada planning areas would also result in habitat fragmentation and isolation of habitat on site currently used. The wildlife corridors and habitat linkages that mountain lions currently use to travel to and from the Santa Clara River corridor, the Los Padres National Forest to the north, the Santa Susana Mountains to the south, the Ventura S.O.A.R. Open Area to the west, and the public lands to the east would be reduced. Decreasing the extent of the wildlife corridors and linkages may bring mountain lions closer to residential areas and roads during their movements between core habitat areas.

These short-term and long-term secondary impacts could permanently restrict the range of the mountain lion and reduce its population on site (significance criteria 1, 4, and 7). Secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the mountain lion (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 126 acres (1.5%) of permanent loss and 67 acres of temporary loss;
- Alternative 4 – 128 acres (1.5%) of permanent loss and 60 acres of temporary loss;
- Alternative 5 – 143 acres (1.7%) of permanent loss and 72 acres of temporary loss;
- Alternative 6 – 121 acres (1.4%) of permanent loss and 69 acres of temporary loss; and
- Alternative 7 – 57 acres (0.7%) of permanent loss and 91 acres of temporary loss.

Compared to Alternative 2, which would result in 146 acres (1.7%) of permanent loss and 63 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 through 6 would be somewhat less overall and the temporary loss of habitat under Alternatives 3 through 6 would not be substantially different. The difference between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would result in fewer permanent impacts and more temporary impacts to suitable habitat for the mountain lion compared to the other alternatives.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is similar in magnitude compared to Alternative 2, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and the Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the mountain lion (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 1,949 acres (22.7%) of permanent loss;
- Alternative 4 – 1,894 acres (22.1%) of permanent loss;
- Alternative 5 – 1,844 acres (21.5%) of permanent loss;
- Alternative 6 – 1,565 acres (18.2%) of permanent loss; and
- Alternative 7 – 1,399 acres (16.3%) of permanent loss.

Compared to Alternative 2, which would result in 2,077 acres (24.2%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7 and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would reduce impacts to suitable habitat for the mountain lion compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large amount and percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the mountain lion occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the mountain lion:

- Alternative 3 – 2,075 acres (24.2%) of permanent loss;
- Alternative 4 – 2,021 acres (23.6%) of permanent loss;

- Alternative 5 – 1,986 acres (23.1%) of permanent loss;
- Alternative 6 – 1,686 acres (19.6%) of permanent loss; and
- Alternative 7 – 1,455 acres (17.0%) of permanent loss.

Compared to Alternative 2, which would result in 2,223 acres (25.9%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7. There would also be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7 and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 that would result in reduced impacts to suitable habitat for the mountain lion compared to the other alternatives. Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for the mountain lion occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial and therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual mountain lions as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Adults would likely leave and/or avoid construction areas, but there would be some risk of injury or mortality from collisions with fast-moving construction equipment or vehicles. Impacts to individual mountain lions occurring as a result of implementation of the RMDP and the SCP under Alternatives 3 through 7 would be adverse but not significant. There is a greater risk of injury or mortality of young/fetal cubs as a result of den disturbance due to construction activities in the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas because there is greater potential for denning habitat in these areas. These impacts would be significant, absent mitigation under Alternatives 3 through 7.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-

term effects due to factors such as increased human activity, increased incidence of traffic collisions, and nighttime lighting. Therefore, the loss or degradation of suitable habitat and the impacts to mountain lions due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to mountain lion: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Significant impacts to individuals could occur if natal dens are present in the Specific Plan area and are disturbed during construction. This could include the destruction of dens from vegetation clearing and grading, which could result in injury or mortality of individuals from direct contact with equipment or entombment. Impacts may also include behavioral disturbances due to increased human activity, noise, ground vibration, and lighting, which could cause the female to abandon an active natal den or could disrupt foraging activities. To reduce these impacts, the applicant will conduct pre-construction surveys for natal dens within the construction footprint and within a 2,000-foot buffer around the construction site. If a natal den is found, no construction-related activities shall occur within the buffer zone until the cubs are reared.

The combined permanent loss of suitable habitat for the mountain lion resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 1,455 acres (17.0%) under Alternative 7 to 2,223 acres (25.9%) under Alternative 2. This would be a substantial loss of suitable habitat and would reduce the size and distribution of the mountain lion population in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable habitat to support the mountain lion in the Project vicinity. Implementation of these mitigation measures will result in protection, restoration and enhancement, and management of approximately 5,129 acres of suitable habitat for the mountain lion. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**). Native vegetation restoration and enhancement in these areas will provide additional protective cover for mountain lions.

With respect to secondary effects, mountain lions using habitat in close proximity to construction zones may be disturbed by construction activities, including increased human activity, noise, ground vibration, and lighting, which may alter essential behavioral patterns, such as foraging and rearing of young. The protection of mountain lion natal dens with young, as well as controls on lighting, will help avoid and reduce these construction-related secondary impacts. Potential

long-term effects of development include habitat fragmentation; increased human activity; pet, stray, and feral dogs; lighting; increased vehicle collisions; and use of rodenticides, which may reduce prey and potentially cause secondary poisoning. The large open space system composed of the River Corridor SMA, the High Country SMA, and the Salt Creek area will provide adequate protected open space that will in part offset these impacts. The open space system connects the Santa Susana Mountains in the south to the Los Padres National Forest north of the Santa Clara River *via* the High Country SMA, Salt Creek area, and River Corridor SMA (**Figures 4.5-3** and **4.5-22**). This regional habitat connection will allow mountain lions to use and move through the Project area without having to contact residential, commercial, and industrial areas, thus reducing secondary effects, such as noise and nighttime lighting. Lighting effects at the natural open space–urban interface will also be reduced by requiring downcast lighting along the interface. The large, contiguous areas of natural land, along with wildlife undercrossings of SR-126 (**Figure 4.5-32**), therefore, will provide habitat linkages and wildlife corridors to support movement between larger core habitat areas north and south of the Project area. Several specific mitigation measures will also be implemented to control human activities in open space areas, including restrictions on recreational activities and homeowner education. Pets will be leashed, and stray and feral dogs will be otherwise controlled in or adjacent to open space areas. Rodenticides will be controlled through an integrated pest management (IPM) plan. Vehicle collisions will be reduced through placement of signs indicating where along roads mountain lions are likely to cross and road undercrossings will be built in accordance with current wildlife corridors used by this species. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

All specific mitigation measures for mountain lion are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-162 IMPACTS TO INDIVIDUALS – MOUNTAIN LION

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan EIR did not identify mitigation measures to avoid, minimize, or mitigate the loss of mountain lion natal dens.

Measures Recommended by EIS/EIR

This EIS/EIR recommends BIO-60 to avoid impacts to mountain lion natal dens. BIO-60 requires a survey for mountain lion natal dens 30 days prior to construction activities. The survey shall include the construction footprint and the area within 2,000 feet of the Project disturbance boundaries. If a natal den is found, an appropriate setback from the den shall be established until

it is determined by a qualified biologist in consultation with CDFG that the cubs have been successfully reared or the mountain lions have left the area.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to mountain lion natal dens would not be significant for Alternatives 2, 3, 4, 5, 6, and 7 because no impacts would occur.

IMPACT 4.5-163 LOSS OF HABITAT – MOUNTAIN LION

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the mountain lion through protection, restoration and enhancement, and management of habitat.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figures 4.5-3** and **4.5-22**).

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-28 states that mitigation banking for riparian habitats in the High Country SMA is subject to state and federal regulations and permits; mitigation for oak resources is subject to the Oak Resources Management Plan; and mitigation banking for Mexican elderberry scrub is be subject to the approval of the County Forester.

SP-4.6-17 and SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting,

fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the River Corridor SMA and High Country SMA.

Mitigation Measure SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and oak tree replacement occur as described in SP-4.6-48. Mitigation Measure SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Measures Recommended by EIS/EIR

The EIS/EIR recommends the following mitigation measures to reduce and mitigate the loss of mountain lion habitat through protection, restoration and enhancement, and management of habitat.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active

intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-22 states that the Oak Resource Management Plan shall incorporate the findings of the Draft Newhall Ranch Mitigation Feasibility Report (Dudek 2007A) and areas identified as being suitable for oak woodland enhancement and creation shall be used for mitigation.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the mountain lion will be reduced to a level that would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-164 SECONDARY IMPACTS – MOUNTAIN LION

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will mitigate secondary impacts to the mountain lion, including habitat fragmentation, increased human and pet activity, and nighttime illumination of areas adjacent to open space that could disrupt foraging and movement behavior.

SP-4.6-1 through SP-4.6-16, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, SP-4.6-48, and SP-4.6-63, as described above, will be implemented to mitigate for habitat fragmentation and increased human and pet activity through protection, restoration and enhancement, and management of habitat.

SP-4.6-17 and SP-4.6-29 through SP-4.6-32, as described above, will be implemented to control public activities in the River Corridor SMA and High Country SMA.

In addition, SP-4.6-18 and SP-4.6-19 will benefit the mountain lion through design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage

public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side of bank stabilization and development.

SP-4.6-33 will be implemented to mitigate potential adverse edge effects by permitting construction of buildings and other structures only on developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 will be implemented to control nighttime illumination by requiring that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to reduce secondary impacts, including habitat fragmentation; increased encounters by mountain lions with humans and pet, stray, and feral dogs; the use of rodenticides to control small mammals that are pre for the mountain lion (*e.g.*, ground squirrels and rabbits) that may reduce the prey populations and possibly cause secondary poisoning; and increased incidence of vehicle collisions at new and expanded roadways.

BIO-1 through BIO-16 and BIO-19 through BIO-22, as described above, will be implemented to mitigate for the effects of habitat fragmentation and increased public activity through the preservation, restoration and enhancement, and management of habitat. BIO-19 includes a provision to enhance the existing agricultural undercrossing and agricultural land at the base of Salt Creek to facilitate wildlife movement between the north side of SR-126 and the Salt Creek area. This enhancement would include dedication of a portion of the agricultural field north of SR-126 and planting of trees and/or scrub habitat north and south of the existing undercrossing of the highway.

BIO-59 will be implemented to reduce the chance of vehicle collisions. This measure specifies that a wildlife movement corridor plan shall be prepared and implemented. The plan will include design criteria for road crossings and methods to encourage passage, such as lighting, bubblers, and vegetation planting. Signs shall be installed along roadways, indicating potential wildlife crossings where mountain lions and mule deer are likely to cross.

BIO-63 will be implemented to control for pet, stray, and feral dogs. This measure requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral dogs in open space areas.

BIO-64 will be implemented to address the use of pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, the secondary impacts to mountain lion will be reduced to a level that would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

MULE DEER (CDFG TRUST RESOURCE)

Life History

The mule deer (*Odocoileus hemionus*) is a common species with a widespread distribution throughout the western United States and Canada and south into mainland and Baja California, Mexico (Hall 1981). It occurs throughout most of California, except in deserts and intensively farmed areas without cover (Zeiner *et al.* 1990B). Globally, it is considered to be secure in its range, but it may be locally threatened in some areas because of cattle-grazing pressure or other sources of habitat degradation (NatureServe 2007).

Throughout its range, the mule deer uses coniferous and deciduous forests, riparian habitats, desert shrub, coastal scrub, chaparral, and grasslands with shrubs. It is often associated with successional vegetation, especially near agricultural lands (NatureServe 2007). It uses forested cover for protection from the elements and open expanses for feeding (Wilson and Ruff 1999). Mule deer fawn in a variety of habitats that have available water and abundant forage, including moderately dense shrubs and forests, dense herbaceous stands, and higher-elevation riparian and mountain shrub vegetation.

Mule deer are primarily crepuscular, but may be active day or night; their patterns seem to be influenced by abrupt changes or extremes in precipitation, temperature, and relative humidity. The mule deer's diet varies with the season, quality of food, and abundance of food. They forage on new growth of various shrubs. They also forage on forbs, acorns, and a few grasses (NatureServe 2007; Wilson and Ruff 1999). In the spring, they feed primarily on forbs and grasses; in summer and winter, they require shrubs; and in the fall, they rely heavily on acorns where available.

Mule deer can be resident in an area or migrate. In mountainous regions of California, mule deer often migrate to lower elevations during the winter and back to higher elevations in the summer. In milder climates, they usually are not migratory, but local movements may occur in relation to precipitation, and presumably, resource availability (NatureServe 2007). The home ranges of a doe and fawn group vary between 0.2 to 1.9 square miles, but generally are less than one square mile. Bucks have larger home ranges and travel longer distances, varying from 18 to 60 square miles. Does may defend small areas from other deer and predators when they are caring for newborns, which typically are born in the spring and weaned by about 16 weeks (Wilson and Ruff 1999). Bucks are generally solitary but may form small feeding herds in the spring and summer and tend to avoid each other during mating season in the fall.

Mule deer have broad habitat use patterns and use steep slope and ridgelines to avoid predators. They will also travel close to urban. The CBI (2003) wildlife movement study in San Diego County found that mule deer pass through fairly restricted areas. Although open bridges and

bridge overpasses are desired for crossings of roads, mule deer also use box culverts as long as they can see to the other side of the culvert.

Mule deer are still common throughout most of their range. However, some local populations may be threatened with extirpation due to habitat loss and fragmentation and associated anthropogenic impacts, such as increased vehicle collisions; harassment by dogs; and competition for food resources with cattle, sheep, and wild pigs (NatureServe 2007; Zeiner *et al.* 1990B). As noted above, although still relatively common, this species may be declining in southern California.

Survey Results

Mule deer were documented within and adjacent to the Project area during focused surveys in 2004 for mammals by Impact Sciences (2005). Mule deer were most frequently observed in agriculture and coastal scrub, but also in chaparral, riparian willow, and mulefat scrub. In addition to the Impact Sciences (2005) study, mule deer were also observed in the High Country SMA in 2005 (Dudek and Associates 2006B) and in the Entrada development area in 2000 (Haglund and Baskin 2000) and 2006 (Dudek and Associates 2006E).

Mule deer use riparian, woodland, and upland shrub habitats in the Project area, and they often occur along the edges of habitat mosaics where they forage. Primary habitats contain some cover for mule deer and include alluvial scrub, southern cottonwood–willow riparian, Mexican elderberry, giant reed, mulefat scrub, southern coast live oak riparian forest, southern willow scrub, shrub tamarisk, big sagebrush scrub, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, coastal scrub alliances and associations, big sagebrush–California buckwheat, coast live oak woodland, valley oak woodland, valley oak/grass, mixed oak woodland, and California walnut woodland. A total of 8,581 acres of suitable habitat is present in the Project area.

Because of its broad habitat use, the mule deer is assumed to freely range throughout the Project area. An important issue, therefore, is to what extent the proposed Project would constrain use of the site and movement between large protected open space areas in the region. **Figure 4.5-22** shows regional linkages adapted from South Coast Wildlands (Penrod *et al*. 2006) that would accommodate mule deer. The north–south linkage design for this species is generally located west of the Project area but incorporates the Salt Creek area and High Country SMA open space areas as well as the River Corridor SMA. **Figure 4.5-31** shows more local habitat linkages and available crossings of the Santa Clara River. There are two linkages that mule deer would likely use: Salt Creek Canyon, which serves as a southeast-to-northwest habitat linkage from the Salt Creek area and High Country SMA through the Fillmore Greenbelt to the Los Padres National Forest, and the Santa Susana Mountains Corridor, which serves as a generally east-to-west habitat linkage from High Country SMA to the Ventura County S.O.A.R. Open Area to the west and the public lands to the east. There are three wildlife crossings of SR-126 in Ventura County

and three crossings of SR-126 within the Project area, at San Martinez Grande Canyon, Chiquito Canyon, and Castaic Creek. While all three of the latter crossings are of adequate size and configuration to convey movement, they are also well east of the regional corridors depicted in **Figure 4.5-22** and would be bound by development upon build-out. Mule deer would have to travel close to urban areas to use these crossings. These crossings would likely have less movement than the three locations in Ventura County that line up more directly with the linkages shown in **Figure 4.5-22**.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 146 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.7% of these communities on site (**Figure 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat). A total of 63 acres would be directly temporarily impacted.

Tributaries that provide water sources, forage, and cover for mule deer would be affected at various times during construction of RMDP facilities. Construction would be phased such that alternative resource areas would remain available to this species, but it would be at least temporarily displaced from areas under active construction. Because the mule deer is still widespread and generally common throughout its range, however, the relatively small permanent loss of habitat and temporary impacts as a result of the construction/grading activities would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 2,077 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 24.2% of these communities on site (**Figures 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat).

Although the mule deer is still widespread and generally common, a relatively large amount and percentage of on-site riparian, woodland, and upland shrub vegetation providing habitat for the species would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. While this loss of habitat is expected to alter the range use and distribution of the mule deer on site, this species is still widespread and relatively common throughout its range. In addition, there would substantial habitat remaining in the High Country SMA, Salt Creek area, and River Corridor SMA after build-out. This loss of habitat therefore would not have a substantial adverse effect on this species, substantially affect its distribution in the Project region, or substantially interfere with its movement across the site between core habitat areas to the north and south (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,223 acres (25.0%). While this combined loss of habitat is expected to alter the range use and distribution of the mule deer on site, this species is still widespread and relatively common throughout its range. In addition, there would substantial habitat remaining in the High Country SMA, Salt Creek area, and River Corridor SMA after implementation of the RMDP and build-out. This loss of habitat therefore would not have a substantial adverse effect on this species, substantially affect its distribution in the Project region, or substantially interfere with its movement across the site between core habitat areas to the north and south (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because the mule deer is highly mobile, it generally would be expected to leave and/or avoid construction zones. However, occasional collisions between mule deer and faster-moving construction equipment and other vehicles may occur, resulting in injury or

mortality of individuals. Implementation of the SCP would not directly impact this species. Because the mule deer is still widespread and relatively common in its range, however, the occasional injury or mortality of individuals resulting from collisions during RMDP-related construction activities would not have a substantial direct effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

Similar to direct impacts, occasional collisions between mule deer and faster-moving construction equipment and other vehicles may occur during construction activities associated with build-out of the Specific Plan, VCC, and Entrada planning areas, resulting in injury or mortality of individuals. Because the mule deer is still widespread and relatively common in its range, however, the occasional injury or mortality of individuals resulting from collisions would not have a substantial direct effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

Short-term noise, dust, and human presence associated with construction and/or grading activities for the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas may alter the foraging behavior and movement patterns of the mule deer in the immediate vicinity of these activities. Daytime activity by mule deer near construction areas is most likely to be affected, while nocturnal activity probably would be relatively unaffected, although deer may avoid lighted areas. Implementation of the SCP would not affect this species.

Long-term secondary impact on mule deer associated with urban development include nighttime illumination of areas adjacent to open space that could disrupt foraging and movement behavior; increased incidence of vehicle collisions at new and expanded roadways; and increased encounters by mule deer with humans and pet, stray, and feral dogs. The build-out of the Specific Plan, VCC, and Entrada planning areas would also result in habitat fragmentation and isolation of habitat on site. The wildlife corridors and habitat linkages that mule deer currently use to travel to and from the Santa Clara River corridor, the Los Padres National Forest to the north, the Santa Susana Mountains to the south, the Ventura S.O.A.R. Open Area to the west, and the public lands to the east would be reduced. Decreasing the extent of the wildlife corridors

and linkages for mule deer may bring them closer to residential areas and roads during their movements between core habitat areas.

These short-term and long-term secondary impacts could permanently restrict the range of mule deer and reduce its population on site. However, because this species is still widespread and relatively common in its range, and substantial suitable habitat would remain in the Project vicinity in the High Country SMA, Salt Creek area, and River Corridor SMA after implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas, these secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the mule deer (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 126 acres (1.5%) of permanent loss and 67 acres of temporary loss;
- Alternative 4 – 128 acres (1.5%) of permanent loss and 60 acres of temporary loss;
- Alternative 5 – 143 acres (1.7%) of permanent loss and 72 acres of temporary loss;
- Alternative 6 – 121 acres (1.4%) of permanent loss and 69 acres of temporary loss; and
- Alternative 7 – 57 acres (0.7%) of permanent loss and 91 acres of temporary loss.

Compared to Alternative 2, which would result in 146 acres (1.7%) of permanent loss and 63 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 through 6 would be somewhat less overall and the temporary loss of habitat under Alternatives 3 through 6 would not be substantially different. The difference between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would result in fewer permanent impacts and more temporary impacts to suitable habitat for the mule deer compared to the other alternatives.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is similar in magnitude compared to Alternative 2, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and the Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for mule deer (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 1,949 acres (22.7%) of permanent loss;
- Alternative 4 – 1,894 acres (22.1%) of permanent loss;
- Alternative 5 – 1,844 acres (21.5%) of permanent loss;
- Alternative 6 – 1,565 acres (18.2%) of permanent loss; and
- Alternative 7 – 1,399 acres (16.3%) of permanent loss.

Compared to Alternative 2, which would result in 2,077 acres (24.2%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7 and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would reduce impacts to suitable habitat for the mule deer compared to the other alternatives.

Alternatives 3 through 7 would have reduced impacts compared to Alternative 2. Also, because the mule deer is still widespread and relatively common in its range and because substantial habitat would remain in the Project vicinity in the High Country SMA, Salt Creek area, and River Corridor SMA following build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas, these impacts would not have a substantial adverse effect on this species. The indirect permanent loss of suitable habitat for the mule deer occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and

Entrada planning areas would result in the following impacts to suitable habitat for the mule deer:

- Alternative 3 – 2,075 acres (24.2%) of permanent loss;
- Alternative 4 – 2,021 acres (23.6%) of permanent loss;
- Alternative 5 – 1,986 acres (23.1%) of permanent loss;
- Alternative 6 – 1,686 acres (19.6%) of permanent loss; and
- Alternative 7 – 1,455 acres (17.0%) of permanent loss.

Compared to Alternative 2, which would result in 2,223 acres (25.9%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7. There would also be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7 and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 that would result in reduced impacts to suitable habitat for the mule deer compared to the other alternatives. In addition, because the mule deer is still widespread and relatively common in its range and because substantial habitat would remain in the Project vicinity in the High Country SMA, Salt Creek area, and River Corridor SMA following implementation of the RMDP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas, these impacts would not have a substantial adverse effect on this species. The combined direct and indirect permanent loss of suitable habitat for the mule deer occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Impacts to Individuals

The potential for impacts to individual mule deer, including injury or mortality as a result of collision with fast-moving construction equipment or vehicles, as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Because this species is widespread and relatively common in its range, impacts to individual mule deer occurring as a result of implementation of the RMDP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Secondary Impacts

Short-term and long-term secondary impacts on mule deer could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects. Short-term effects could include noise, dust, and increased human activity that could affect its daytime activity and nighttime lighting that could affect its nocturnal activity. Long-term effects include increased human activity, increased incidence of traffic collisions, nighttime lighting, and encounters with pet, stray, and feral dogs. However, because this species is still widespread and relatively common in its range and because substantial habitat will be available in the High Country SMA, Salt Creek area, and River Corridor SMA after implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas these short-term and long-term secondary effects would be adverse but not significant for Alternatives 3 through 7.

Mitigation Strategy and Summary

No mitigation is required for impacts to the mule deer because all impacts were determined to be adverse but not significant. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of upland and riparian habitat areas in the River Corridor SMA, High Country SMA, and Salt Creek area that will form a large, contiguous open space system of approximately 6,300 acres, of which more than 5,000 acres are suitable habitat for the mule deer. Riparian and oak woodland restoration and enhancement in this protected open space will provide additional cover for this species. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, lighting, and increased human activity during construction, because individuals will have access to breeding and foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral dogs; and lighting; will be mitigated through a variety of measures.

SAN FERNANDO VALLEY SPINEFLOWER (FC, CE, CNPS LIST 1B.1)

Life History

The San Fernando Valley spineflower (SFVS) (*Chorizanthe parryi* var. *fernandina*) is a low-growing herbaceous annual. Germination occurs following the onset of late-fall and winter rains. Its numbers vary widely from year to year and, in years of poor rainfall, only very few plants may be found. It flowers and sets seed between April and June, depending on rainfall and temperature. Its flowers are minute (only a few millimeters long). The flower bases, including the developing seeds, are within spiny urn-shaped "involucres," also only a few millimeters long. The mature seeds remain inside the involucres, which may serve in their dispersal. Historically, SFVS was known from several occurrences in and around the San Fernando Valley and one site in Orange County (CNPS 2009). As of 1993, all those sites had been presumed extirpated, and the plant presumed extinct (Hickman 1993). In 1999, SFVS was rediscovered in Ventura County, and in 2000 it was rediscovered at Newhall Ranch. Currently, SFVS is known from only these two locations: Laskey Mesa in the Upper Las Virgenes Canyon Open Space in Ventura County, and the Project area in Los Angeles County. These two SFVS locations are approximately 17 miles apart. The Laskey Mesa area is on the southern edge of the Simi Hills near the City of Calabasas in an area formally known as Ahmanson Ranch.

At the two current known locations, SFVS generally occurs within sparsely vegetated grassland and scrub communities and associated ecotones. At Laskey Mesa, SFVS is described as occurring along the interface between California sagebrush scrub and grassland habitats. This observed distribution may be the result of past dryland farming of the mesa top, which would have removed any SFVS growing in the farmed area (CDFG 2001A). Due to past farming and livestock grazing practices, it is not known whether Laskey Mesa was native grassland, coastal scrub, or a mix of both prior to European contact. At the Project site, the majority of SFVS sites occur within California sagebrush scrub and California annual grassland but also occur on sites that were recently subjected to terracing and grubbing for agricultural purposes, but which were not planted with actual crops or were planted with crops in the recent past. SFVS occurs at sites within openings in coast live oak woodland, undifferentiated chaparral, and alluvial scrub. Sparsely vegetated areas with low overall cover of herbaceous vegetation and some bare ground are typical of occupied SFVS sites at Ahmanson Ranch and the Project site, although SFVS has also been observed in areas of dense annual grasses.

The majority of information regarding the pollination biology of SFVS is from the results of studies carried out at Ahmanson Ranch by Jones *et al.* (2002). Five types of arthropods were found to be responsible for more than 75% of visits to SFVS flowers: two species of native ants (*Dorymyrmex pyramicus* and *Solenopsis xyloni*), European honeybee (*Apis mellifera*), and two beetle species (*Dastyinae* sp. and *Zabrotes* sp.). No specific information on seed dispersal is available, but, in the field, involucres have been observed to attach to human skin, clothing, and

shoes, suggesting potential for involucres containing seed to be carried away from the parent plant if they lodge on humans or other animals. Native ants may also play a role in the dispersal of SFVS (LaPierre and Wright 2000).

In addition to the direct loss of individuals, SFVS is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after various human-caused environmental changes, such as repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are known secondary effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives, possibly including SFVS. Exotic plants can also alter hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development.

An increase in the abundance of domestic cats and dogs from adjacent Specific Plan, VCC, and Entrada planning areas could indirectly affect the SFVS through the reduction of populations of native rodents that may act as SFVS seed-dispersal agents. In addition, the introduction of Argentine ants could adversely affect SFVS populations because these ants are capable of out-competing and displacing native ants and other arthropod species that may provide important ecological functions for SFVS, including pollination and seed dispersal, as well as for other native plant species (Holway *et al.* 2002). The extent to which Argentine ants may directly impact the SFVS has not been studied directly and remains uncertain, but the impact is assumed to be adverse. Studies by Jones *et al.* (2004) found reduced seed set in SFVS where pollinators were excluded (*i.e.*, preventing cross-pollination among plants, and limiting seed production to only self-pollination events). Their work suggests that open and uninhibited pollination results in the production of considerably more seed, and that native pollinators are important to SFVS reproduction.

Survey Results

Following the rediscovery of SFVS at Ahmanson Ranch, biologists working with Sapphos Environmental Consulting conducted a directed search for SFVS that included historical localities, suitable habitat areas within the historical range of SFVS, and suitable habitat areas near the existing population at Laskey Mesa. A total of seven historical locations and 21 other locations were surveyed with negative results in 1999 and 2000 (Sapphos 2001).

In 2000, URS surveyed portions of the Specific Plan area to the south of and along the Santa Clara River corridor (URS 2002). SFVS was detected at sites along Grapevine Mesa and in the vicinity of Airport Mesa (URS 2002). FL*x* and Katherine Rindlaub found SFVS within the Entrada planning area in 2000 (FL*x* 2004C). Observations of SFVS in 2002, 2003, 2004, 2005,

2006, and 2007 (Dudek and Associates 2002A, 2002B, 2002C, 2004B, 2004C, 2004E, 2004F, 2004G, 2004H, 2006F, 2006G, 2006H, 2006I, 2006J, 2006K; Dudek 2007F, 2007G, 2007H; FL*x* 2004B, 2005, 2006A) were made during surveys that focused on the identification and location of special-status plant species and during field efforts to census and map SFVS occurrences on the Project site.

FL*x* observed SFVS in May 2001 at San Martinez Grande within the Specific Plan area. In May 2002, FL*x* observed SFVS in the central, eastern, and southern portions of Airport Mesa within the Specific Plan area (FL*x* 2002A). In each year from 2002 through 2007, SFVS has been observed in four general areas within the Specific Plan area: Airport Mesa, Grapevine Mesa, Potrero Canyon, and San Martinez Grande Canyon (Dudek and Associates 2002A, 2004C, 2004F, 2006F, 2006I; Dudek 2007F) (**Figures 4.5-25** through **4.5-28**). SFVS has been observed from 2002 through 2007 on the western side of the VCC planning area, just east of Hasley Canyon (Dudek and Associates 2002C, 2004B, 2004G, 2006H, 2006K; Dudek 2007H) (**Figure 4.5-29,** San Fernando Valley Spineflower Occurrences – Valencia Commerce Center). This species has also been observed from 2002 through 2007 in several areas at the Entrada planning area, including the southeastern portion of the site, the central area in and beside the wash, and the western portion of the site adjacent to the Six Flags Magic Mountain Amusement Park on the south side and west side (Dudek and Associates 2002B, 2004E, 2004H, 2006G, 2006J; Dudek 2007G; FL*x* 2004B, 2005, 2006A) (**Figure 4.5-30,** San Fernando Valley Spineflower Occurrences – Entrada). SFVS was observed in the Entrada site fireworks area in 2004, 2005, and 2006 (FL*x* 2004B, 2005, 2006A).

On the Project site, SFVS occurrences exist predominantly on slopes with a south-facing aspect within openings in sparsely vegetated habitat characterized as open California sagebrush scrub and associations, California annual grasslands, or at the edge of agricultural fields on mesas. Characteristic site conditions include a low cover of grasses, herbs, and shrubs and a visible component of bare ground. Vegetative cover in the area of SFVS occurrences ranged from 5% to 100%, but was most commonly between 60% and 80%. Most of the observed SFVS were found on soils mapped by the USDA (1969) as slightly eroded to eroded Castaic–Balcom silty clay loam (30% to 50% slopes) or Terrace Escarpments. Plants in the vicinities of Grapevine Mesa and Airport Mesa were observed downslope of terrace surfaces capped by Zamora clay loam (2% to 9% slopes), with a few plants occurring on artificial fill or alluvium derived from adjacent terrace deposits. SFVS at San Martinez Grande Canyon occurs primarily on old landslide debris (Seward 2002). The soil type for all mapped SFVS occurrences on the Project site consisted of sandy loams. Elevations at SFVS locations on site range from approximately 1,000 to 1,300 feet AMSL.

Table 4.5-57 presents the SFVS occurrence data and acres occupied within the Project site for each year surveyed. These data are depicted in **Figures 4.5-25** through **4.5-30**. In 2002, surveys estimated 7,814 individuals occupying 0.59 acre. In 2003, surveys estimated populations of

SFVS totaling 5,947,120 individuals occupying 16 acres. In 2004, the total population of SFVS was estimated to be 558,388 individuals occupying 5.33 acres. In 2005, the total population of SFVS was estimated to be 7,391,813 individuals occupying 11.45 acres. In 2006, the total population of SFVS was estimated to be 1,773,496 individuals occupying 8.49 acres. In 2007, the total population of SFVS was estimated to be 760 individuals occupying 0.12 acre. The surveys conducted for SFVS throughout the High Country SMA and Salt Creek area were negative. Approximately 0.25 acre of cumulative SFVS occupied area at Entrada lies within an existing utility easement. Approximately 0.33 acre of cumulative SFVS occupied area at Grapevine Mesa lies within an existing utility easement.

Table 4.5-57

The yearly fluctuations in SFVS data suggest that climatic conditions relate to SFVS abundance and area occupied. SFVS abundance and area occupied were dramatically lower in 2002, 2004, and 2007 compared to 2003 and 2005. Years 2002, 2004, and 2007 experienced below-average rainfall, but in 2003 rainfall was considered normal, according to the Western Regional Climate Center (2008). Winter 2004/spring 2005 rainfall was considered to be one of the wettest years on record; in winter 2005/spring 2006, rainfall was slightly below average but not as low as it was in 2002, 2004, and 2007, according to the Western Regional Climate Center (WRCC 2008). The wide annual fluctuations of SFVS on site suggest that the locations would be best characterized by the cumulative area occupied rather than by number of individuals (**Table 4.5-58**). Because several years of mapped occurrence data are available for SFVS, impacts to this species were evaluated by impacts to individuals rather than by loss of habitat.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Impacts to Individuals

Direct Permanent Impacts

Implementation of the proposed SCP and Candidate Conservation Agreement, along with issuance by CDFG of the associated section 2081(b) Incidental Take Permit, would result in impacts to SFVS populations within the RMDP and SCP Project area. The cumulative SFVS occurrence data, collected annually from 2002 through 2007, show 20.24 acres of area occupied by SFVS within the SCP area (*i.e*., the maximum occupied polygon boundaries). The number of individual SFVS plants on site varies considerably from year to year **(Table 4.5-57**). Potential impacts to this species are therefore primarily evaluated in terms of loss of cumulative area occupied by SFVS mapped between 2002 and 2007 rather than number of individuals.

Under the proposed SCP, 68.6% of the area occupied by SFVS within the SCP area would fall within designated spineflower preserves; 31.4% (6.4 acres) would remain outside the spineflower preserves and would be permanently lost. A summary of the conserved areas within each proposed spineflower preserve is included in **Table 4.5-58**. Spineflower preserves would be designated in the five core occurrence areas within the RMDP area and the Entrada planning area (**Figure 4.5-30**). The VCC planning area occurrence (approximately 4.2% of total cumulative area occupied by SFVS on site) would not have an associated spineflower preserve.

Table 4.5-58
Direct Impacts of the Proposed SCP
to SFVS Cumulative Occupied Area

Location	Total Acres	Acres Preserved	Percent Preserved	Acres Impacted	Percent Impacted
Airport Mesa	8.40	5.22	62.2%	3.17	37.8%
Grapevine Mesa	4.97	4.02	80.9%	0.95	19.1%
Potrero	1.93	1.32	68.7%	0.60	31.3%
San Martinez Grande	2.29	2.29	100%	0	0%
Entrada	1.81	1.03	56.8%	0.78	43.2%
VCC	0.85	0	0%	0.85	100%
Total	**20.24**	**13.88**	**68.6%**	**6.35**[1]	**31.4%**

[1] A small portion (0.37 acre) of this area lies within designated open space within the Airport Mesa, Grapevine Mesa, and Potrero areas. While this area does not fall within the impact footprint, it will not be managed or monitored. For purposes of this analysis this area is considered to be taken.

Under the proposed SCP, a series of spineflower preserves would be established and managed with the intent to maximize the likelihood of the long-term survival of the SFVS, the preservation of native habitats, biodiversity, and the corresponding biological functions and values (**Figure 4.5-139**, Alternative 2 Spineflower Preserve Areas with Adjacent Land Use). The proposed spineflower preserves would include habitat for potential SFVS pollinators and dispersal agents. Management of the spineflower preserves would include restoration of degraded and/or damaged SFVS habitats and the establishment of site-specific buffers included in the above acreage, aimed at neutralizing and controlling adverse edge effects from adjacent changes in land use. A spineflower preserve manager would be contracted with, and paid for by, Newhall Land to perform environmental monitoring, oversee the proposed spineflower preserve areas, and ensure that the monitoring and management activities outlined in the proposed SCP are carried out. The spineflower preserve manager would be a qualified biologist or land management entity/biological firm and would be responsible for submitting monitoring reports as required by the SCP. The spineflower preserve manager would have the authority to stop construction work where such work is damaging or would damage spineflower preserves.

The proposed system of spineflower preserves would protect 13.88 acres of area occupied by SFVS within the SCP area and would include buffer areas within the spineflower preserves, to attenuate any adverse edge effects from urban development on areas occupied by SFVS within the spineflower preserves. **Figure 4.5-140**, Typical Spineflower Preserve, schematically depicts a typical preserve with SFVS cumulative occupied area and buffer area. **Table 4.5-59** describes the set of buffer widths that would be implemented with approval of the proposed SCP.

Table 4.5-59
SFVS Buffer Widths, Proposed SCP

Preserve Location	Acres of Area Occupied by SFVS with Buffer of			
	80–100 ft	100–200 ft	200–300 ft	>300 ft
Airport Mesa	0.13	1.76	2.42	0.91
Grapevine Mesa	0.24	2.42	1.36	0
San Martinez Grande	<0.01	0.18	0.41	1.70
Potrero	0.11	0.75	0.46	0.01
Entrada	0.09	0.81	0.13	<0.01
Total by Percent	4.13%	42.59%	34.39%	18.90%

As shown in **Table 4.5-59**, implementation of the proposed SCP would create preserves in which spineflower occurrences are buffered from adjacent land uses by distances ranging in width from a minimum of 80 feet to more than 300 feet. No spineflower occurrences would be buffered by less than 80 feet. These buffer areas would be managed exclusively for SFVS preservation and conservation. No fuel modifications, hydrologic disturbances, foot trails, equestrian trails, or other recreational uses, or any other land uses inconsistent with spineflower management would be permitted within the buffer areas. The buffer width is measured from the edge of the mapped spineflower polygon to the nearest spineflower preserve boundary. Within the spineflower preserves, 95.9% of the SFVS cumulative occupied area would be buffered by at least 100 feet, and 18.9% of the SFVS cumulative occupied area would be more than 300 feet from the preserve edge. Management measures described in the SCP, in combination with these buffer widths, are intended to address various risk factors from adjacent changes in land use and provide for the long-term persistence of SFVS within the preserves.

Any SFVS occurrences outside of the proposed spineflower preserves would be taken incidental to build-out of the approved Specific Plan, VCC, and Entrada planning areas, and such take would be authorized by the proposed Incidental Take Permit under California Fish and Game Code section 2081.

Implementation of the proposed SCP and Candidate Conservation Agreement and subsequent build-out of the Specific Plan, VCC, and Entrada planning areas would permit the loss of approximately 31.4% of known SFVS cumulative occupied area on site, and that loss would occur with the subsequent build-out of the Specific Plan, VCC, and Entrada planning areas (**Figure 4.5-139**). This loss would be a substantial adverse effect on this species and would substantially reduce the number and restrict the range of this species (significance criteria 1 and 7). The loss would be mitigated in part through the designation and management of SFVS preserve areas to be monitored and managed for spineflower preservation for 50 years as described in the SCP. Even with preservation

and management as proposed, direct permanent and temporary impacts (Impacts to Individuals) would be significant and unavoidable.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC, and Entrada planning areas would not result in any additional impacts to SFVS as compared to impacts associated with implementation of the RMDP, SCP, and 2081 Permit (above). Build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on SFVS; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) to SFVS would not be significant because no additional impacts would occur.

Combined Direct and Indirect Permanent Impacts

Under Alternative 2, issuance of the 2081 Permit, implementation of the proposed SCP and Candidate Conservation Agreement and subsequent build-out of the Specific Plan, VCC, and Entrada planning areas would result in the combined direct and indirect loss of approximately 31.4% (6.4 acres) of known SFVS cumulative occupied area on site (**Figure 4.5-139**). This loss would be a substantial adverse effect to SFVS and would substantially reduce its number and restrict its range (significance criteria 1 and 7). The loss would be mitigated in part through the designation and management of SFVS preserve areas to be monitored and managed for spineflower preservation for 50 years as described in the SCP. Even with preservation and management as proposed, the combined direct and indirect permanent impacts (Impacts to Individuals) of Alternative 2 would be significant and unavoidable.

Secondary Impacts

Potential short-term and long-term secondary impacts resulting from the proposed Project to SFVS cumulative occupied area within the proposed preserve areas include hydrologic alterations and water quality impacts; accidental clearing, trampling, and grading; runoff, sedimentation, erosion and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant and animal species; increased human activity and trampling and soil compaction; and increased risk of fire. The potential loss of SFVS as a result of these secondary impacts would constitute a substantial adverse effect on this species as well as a substantial reduction in its number and a reduction in the range of SFVS (significance criteria 1 and 7). Secondary impacts would be significant, absent mitigation.

ALTERNATIVE 3 THROUGH 7

Impacts to Individuals

Direct Permanent Impacts

Implementation of the proposed SCP and Candidate Conservation Agreement, along with issuance by CDFG of the associated section 2081(b) Incidental Take Permit, and subsequent build-out of the Specific Plan, VCC, and Entrada planning areas would result in the following direct impacts to individual SFVS (**Figures 4.5-141** through **4.5-145**, Alternative 3 through 7 Spineflower Preserve Areas with Adjacent Land Use):

- Alternative 3 – permanent loss of 4.54 acres (22.5%) of cumulative spineflower occurrence area;
- Alternative 4 – permanent loss of 3.53 acres (17.5%) of cumulative spineflower occurrence area;
- Alternative 5 – permanent loss of 3.18 acres (15.8%) of cumulative spineflower occurrence area;
- Alternative 6 – permanent loss of 2.32 acres (11.5%) of cumulative spineflower occurrence area; and
- Alternative 7 – permanent loss of 0.36 acre (1.8%) of cumulative spineflower occurrence area.

Compared to Alternative 2, which would result in the direct permanent loss of 6.35 acres (31.4%) of known SFVS cumulative occupied area, the permanent loss of SFVS cumulative occupied area under Alternatives 3 through 7 would be somewhat less for each subsequent alternative. These differences are primarily due to the increase in the number and size of spineflower preserves to be monitored and managed for spineflower preservation for 50 years as described in the SCP.

Although Alternatives 3 through 7 would have reduced direct impacts (*i.e.,* removal of cumulative occupied area) compared to Alternative 2, these impacts would still be substantially adverse for all alternatives. The direct permanent loss of SFVS as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for loss of individual SFVS plants as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through

7 would be the same as for Alternative 2 (*i.e.*, no additional impacts to SFVS, as compared to impacts associated with implementation of the RMDP and the SCP, would occur) (**Figures 4.5-141** through **4.5-145**). No loss of individual SFVS would be attributed to these Project components because the losses would result directly from issuance of the 2081 Permit. Indirect impacts (Impacts to Individuals) would not be significant because no indirect impacts would occur.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would be the same as the direct permanent impacts (above). The combined direct and indirect permanent loss of SFVS occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts would occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as the introduction of non-native, invasive plant and animal species; hydrologic alterations and water quality impacts; altered fire patterns (frequency, seasonality, or intensity; and increased human activity and trampling and soil compaction. The loss of individual SFVS plants due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to SFVS: (1) impacts to individuals, and (2) secondary impacts to individuals and suitable habitat outside the Project footprint.

Preserve management is described fully in the SCP and incorporates the mitigation measures summarized below. The direct impacts of implementing the SCP, issuing the 2081 Permit, and subsequent build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be mitigated in part (Alternative 2) or in full (Alternatives 3 through 7) through preserve set-aside and management; enhancement of degraded habitats within the SFVS preserves to allow for natural expansion of cumulative occupied area; and active efforts to expand, restore, or create SFVS occurrences within the preserve areas. In addition, preserve

management would minimize secondary effects to the preserve areas by managing buffer areas between SFVS occurrences and preserve boundaries. Alternative 2 would preserve and manage about 68% of known SFVS cumulative occupied area on the Project site. Under Alternatives 3 through 7, SFVS preserve areas would be somewhat larger for each subsequent alternative.

The implementation of mitigation measures to avoid, minimize, and mitigate impacts to individuals, will establish a system of spineflower preserves to be placed into permanent conservation easements and will provide for a long-term monitoring and management program that will ensure the persistence of the SFVS within the Project area. The proposed system of spineflower preserves will protect 13.88 acres (68.6%) of area occupied by SFVS within the SCP area for Alternative 2, 15.61 acres (77.5%) for Alternative 3, 16.61 acres (82.5%) for Alternative 4, 16.96 acres (84.2%) for Alternative 5, 17.82 acres (88.5%) for Alternative 6, and 19.70 acres (98.2%) for Alternative 7.

Management of the spineflower preserves under each alternative will include restoration and enhancement of degraded and/or damaged SFVS habitats. A spineflower preserve manager will be contracted and funded by Newhall Land to perform environmental monitoring, oversee the proposed spineflower preserve areas, and ensure that the monitoring and management activities outlined in the proposed SCP and previously incorporated mitigation measures are carried out. These mitigation measures include the installation of short-term and long-term fencing and signage, limitations on road construction near the spineflower preserves, limitations to prevent unauthorized access to the spineflower preserves, limitations to activities within adjacent FMZs, response strategies to wildfire events as presented in the Emergency Fire Response Plan, and regular and ongoing consultation to be maintained with the County and CDFG in connection with ongoing agricultural operations. To the extent that project-related direct and indirect significant impacts to SFVS cannot be avoided or substantially lessened through establishment of the Newhall Ranch spineflower preserve(s) and through other avoidance, minimization, or other compensatory mitigation measures, a translocation and reintroduction program may be implemented. The system of spineflower preserves, along with the long-term monitoring and management program and the translocation and reintroduction program, will allow the SFVS to persist on site in perpetuity.

The secondary impacts of implementing the SCP; issuing the 2081 Permit; and subsequent build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be mitigated in full for Alternatives 2 through 7. Under each of the alternatives the potential short-term secondary impacts, such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; and hydrologic alterations, will be avoided and minimized by providing open space connections and setbacks for the spineflower preserves; providing guidelines for grading and construction activities near the spineflower preserves and for restoration activities within the spineflower preserves; by retaining a qualified biologist during all grading and construction activities within

and near the spineflower preserves; by protecting the preserve areas during grading and construction activities with temporary fencing and signage, water control measures, and stormwater flow redirection; and by providing erosion control plans, dust control, and an overall Project SWPPP within and near the spineflower preserves. Long-term secondary impacts to SFVS, such as the introduction of non-native, invasive plant and animal species; increased human activity, trampling, and soil compaction; hydrologic alterations and water quality impacts; and increased fire frequency/extent/intensity, will be avoided and minimized by providing open space connections and setbacks for the spineflower preserves; providing guidelines for ongoing agricultural activities; restricting access to the spineflower preserves; supplying permanent signage and fencing around the spineflower preserves; restricting the plants to be planted in and around the spineflower preserves; and requiring the development of a fire management plan, including guidelines for fuel modification activities within the spineflower preserves, and providing an emergency fire response plan and response strategies for wildfire or mass movement (*e.g.*, landslides, slope sloughing, or other geologic events) within the spineflower preserves.

Both short-term and long-term secondary impacts to SFVS will be mitigated to less than significant by implementing these mitigation measures, by establishing a system of spineflower preserves to protect the core occurrences of SFVS in the Project area under Alternatives 3 through 7, and by implementing management and monitoring within an adaptive management framework to maintain or enhance the protected SFVS occurrences within the five spineflower preserves. To the extent that secondary impacts to SFVS cannot be avoided or substantially lessened through establishment of the Newhall Ranch spineflower preserve(s) and other avoidance, minimization, or other compensatory mitigation measures, a translocation and reintroduction program may be implemented.

The implementation of these mitigation measures, along with the establishment of a system of spineflower preserves and the implementation of a long-term monitoring and management plan will mitigate to less than significant all secondary impacts to the spineflower preserve areas and the SFVS within the spineflower preserves. The ways in which the specific threats to the SFVS will be avoided and minimized are discussed in greater detail below.

Non-Native, Invasive Plant Species

To address potential impacts associated with the introduction of non-native plants into spineflower preserve areas, the proposed SCP and associated mitigation measures mentioned above contain restrictions intended to reduce the use of invasive, exotic plants within the Specific Plan, VCC, and Entrada planning areas. Plant palettes proposed for use on landscaped slopes, street medians, park sites, and other public landscaped and FMZ areas within 100 feet of spineflower preserves shall be reviewed by the spineflower preserve manager or a qualified biologist to ensure that the proposed landscape plants will not naturalize and cause maintenance

or vegetation community degradation in the spineflower preserve and buffer areas. Container plants to be installed within public areas within 200 feet of the spineflower preserves shall be inspected by the spineflower preserve manager or a qualified biologist for the presence of disease, weeds, and pests, including Argentine ants. Plants with pests, weeds, or diseases shall be rejected. In addition, landscape plants shall not be on the California Invasive Plant Council's (Cal-IPC) California Invasive Plant Inventory (most recent version) or on the list of Invasive Ornamental Plants provided in **Appendix B** of the SCP (Dudek 2007E). The current Cal-IPC list can be obtained from the Cal-IPC website (Cal-IPC 2006).

According to the Conservation Biology Institute (CBI) SFVS buffer study (CBI 2000) prepared for Ahmanson Ranch, and applicable here, the combined effectiveness of measures intended to minimize the effects of invasive plant species on spineflower preserves would be low when the buffer is less than 50 feet wide, moderate with a buffer between 80 and 100 feet wide, and high in situations where buffer width exceeds 200 feet. Because the proposed SCP will provide a minimum buffer of 80 feet, and a buffer greater than 100 feet in width for 95.9% and greater than 200 feet for 53.3% of the area occupied by SFVS within the spineflower preserves for Alternative 2, a buffer greater than 100 feet in width for 95.7% and greater than 200 feet for 54.7% of the area occupied by SFVS within the spineflower preserves for Alternative 3, a buffer greater than 100 feet in width for 94.7% and greater than 200 feet for 54.0% of the area occupied by SFVS within the spineflower preserves for Alternative 4, a buffer greater than 100 feet in width for 94.9% and greater than 200 feet for 51.9% of the area occupied by SFVS within the spineflower preserves for Alternative 5, a buffer greater than 100 feet in width for 98.8% and greater than 200 feet for 89.6% of the area occupied by SFVS within the spineflower preserves for Alternative 6, and a buffer greater than 100 feet in width for 97.8% and greater than 200 feet for 89.9% of the area occupied by SFVS within the spineflower preserves for Alternative 7, the measures proposed to minimize effects from invasive plant species around spineflower preserves should be moderately to highly effective.

Non-Native, Invasive Animal Species

To discourage introduction of non-native animal species, and Argentine ants in particular, into spineflower preserve areas, the proposed SCP and associated mitigation measures mentioned above will require that container plants to be installed within 200 feet of the spineflower preserves be inspected by the spineflower preserve manager for the presence of pests, including Argentine ants, and for disease, prior to delivery to the site and also during delivery. Plants with pests, weeds, or diseases will be rejected.

Although implemented for public safety and the protection of property and not specifically for management of the spineflower preserves, FMZs located at the interface between natural or spineflower preserve areas and urban development will also help to reduce impacts associated with non-native animals entering the spineflower preserves, as these zones will serve as a

vegetated setback between spineflower preserves and urban areas. Using native or non-invasive, non-native, drought-resistant plants to the extent possible in the FMZ will minimize the amount of irrigation required to maintain the vegetation, thus maintaining a xeric habitat in the spineflower preserve areas and buffers that will be less conducive to the establishment of Argentine ant populations.

Argentine ants are of special concern as a potential threat to the SFVS. The goal of management is to preclude the invasion of Argentine ants into the spineflower preserves and their associated buffers. Controls will be implemented using an Integrated Pest Management (IPM) approach and will likely require a combination of methods. The primary management strategy focuses on prevention by maintaining an inhospitable habitat condition in the buffer between the development edge and the spineflower preserve. Argentine ants are sensitive to moisture gradients and are more likely to invade mesic areas and avoid xeric areas. Menke and Holway (2006) noted that the abundance of Argentine ants changes dramatically across soil moisture gradients. They suggest that interception and diversion of urban runoff from naturally xeric areas could restrict invasions by Argentine ants and that "even small reductions in urban runoff may act to limit Argentine ants in areas that are otherwise too dry" (Menke and Holway 2006). Thus, a "dry zone" between urban and natural habitats, where there is naturally little moisture, may act a barrier for Argentine ants and inhibit them from invading the natural areas.

The following project design features and management measures will be implemented to prevent the invasion of Argentine ants in the spineflower preserves:

1. Providing "dry zones" between urban development and SFVS populations, where typical soil moistures are maintained at levels below about 10% soil saturation, which will deter the establishment of nesting colonies of Argentine ants; and by providing dry zone buffers of sufficient width to reduce the potential for Argentine ant activity within core habitat areas;
2. Ensuring that landscape container plants installed within 200 feet of spineflower preserves are ant-free to reduce the chance of colonies establishing in areas close to the spineflower preserves;
3. Maintaining natural hydrologic conditions in the spineflower preserves through the Project design features for roadways, French drains, irrigation systems, underground utilities, drainage pipes and fencing, storm drains, and any other BMP measures that apply to surface water entering the spineflower preserve areas. Measures intended to maintain the existing hydrology of the spineflower preserves are discussed in more detail in the subsection, *Changes in Hydrology*, below; and
4. Using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

Although the Project design features described above will help control Argentine ant invasion into the spineflower preserves, there is still a potential for invasions to occur where typical soil moisture increases above about 10% saturation. Invasions by Argentine ants, if they occur, are reversible under appropriate conditions. Menke and Holway (2006) demonstrated that Argentine ant abundance systematically declined in experimentally irrigated areas over a few months once the irrigation was terminated. If soil moisture can be restored to 10% saturation or less, Argentine ant abundances will decrease. In areas where Argentine ant invasions have occurred, soil moisture will be required to be reduced to 10% saturation or less.

The threat of Argentine ants and the associated control measures are discussed in more detail in the document *Relationship of Argentine Ant to Conserved San Fernando Valley Spineflower Populations*, attached as **Appendix C** of the SCP (Dudek 2007E).

The proposed SCP, which incorporates the aforementioned mitigation measures, will require quarterly monitoring for Argentine ants along the urban–open space interface at sentinel locations where invasions could occur (*e.g.*, where moist microhabitats that attract Argentine ants may be created) following the completion and occupancy of a development area. Based on a study by Suarez *et al.* (2001), Argentine ant populations disperse at a rate of approximately 15 to 270 meters (approximately 49 to 886 feet) per year; therefore, quarterly monitoring for Argentine ants should be adequate to detect incipient invasions. A qualified biologist shall determine the monitoring locations. Ant pitfall traps will be placed in these sentinel locations and operated on a quarterly basis to detect invasion by Argentine ants. If Argentine ants are detected during monitoring, the qualified biologist shall distinguish between foraging ants versus nesting ants and implement appropriate direct control measures immediately to help prevent the invasion from worsening. These direct controls may include but would not be limited to nest/mound insecticide treatment, focused broadcast application of insecticides over large infested areas, or available natural control methods being developed. A general reconnaissance of the infested area will also be conducted to identify and correct the possible source of the invasion, such as uncontrolled urban runoff, leaking pipes, and collected water.

According to the CBI SFVS buffer study (CBI 2000), the combined effectiveness of measures intended to minimize the effects of invasive animals on spineflower preserves would be low with a buffer less than 50 feet wide and would be moderate with a buffer between 80 and 300 feet wide. The study did not identify any buffer width at which these management measures would be considered highly effective. Because the proposed SCP will provide a minimum buffer of 80 feet and a buffer greater than 100 feet in width for 95.9% and greater than 200 feet for 53.3% of the area occupied by SFVS within the spineflower preserves for Alternative 2, a buffer greater than 100 feet in width for 95.7% and greater than 200 feet for 54.7% of the area occupied by SFVS within the spineflower preserves for Alternative 3, a buffer greater than 100 feet in width for 94.7% and greater than 200 feet for 54.0% of the area occupied by SFVS within the spineflower preserves for Alternative 4, a buffer greater than 100 feet in width for 94.9% and

greater than 200 feet for 51.9% of the area occupied by SFVS within the spineflower preserves for Alternative 5, a buffer greater than 100 feet in width for 98.8% and greater than 200 feet for 89.6% of the area occupied by SFVS within the spineflower preserves for Alternative 6, and a buffer greater than 100 feet in width for 97.8% and greater than 200 feet for 89.9% of the area occupied by SFVS within the spineflower preserves for Alternative 7, the measures proposed to minimize effects from non-native, invasive animals around spineflower preserves should be moderately effective.

Vegetation Clearing

No vegetation clearing will be permitted within spineflower preserves, with the exception of habitat management activities for the benefit and the maximum preservation of SFVS populations. No development-associated FMZs shall be allowed in the spineflower preserve areas. Controlled burning may be allowed in the future within the Newhall Ranch spineflower preserve areas and buffers, provided that it is based upon a burn plan prepared by the SFVS preserve manager and approved by the County of Los Angeles Fire Department and CDFG. Annual maintenance of FMZs will be exclusively outside the preserve boundaries. Removal of undesirable non-native plants and other activities in SFVS preserve buffer areas that ensure the long-term survival of SFVS, will be the responsibility of the spineflower preserve manager. The Homeowners Association (HOA) will be responsible for any fuel modification that occurs in designated FMZs.

In addition, spineflower preserve temporary fencing shall be shown on construction plans and installed prior to initiating construction clearing and grubbing activities within 200 feet of spineflower preserves. The spineflower preserve manager or a qualified biologist shall monitor fence installation. Clearing for fence installation shall be minimized to what is necessary to install the fence, and where possible shall leave the roots of native plants in place to allow re-growth. As necessary, native vegetation will be restored and weed management shall be performed following fence installation to ensure that temporarily cleared native plant areas do not become weed dominated after installation.

According to the CBI SFVS buffer study (CBI 2000) prepared for Ahmanson Ranch, and applicable here, the combined effectiveness of measures intended to minimize the effects of vegetation clearing on spineflower preserves would be low when the buffer is less than 50 feet wide, moderate with a buffer between 80 and 100 feet wide, and high in situations where buffer width exceeds 200 feet. Because the proposed SCP would provide a minimum buffer of 80 feet, and a buffer greater than 100 feet in width for 95.9% and greater than 200 feet for 53.3% of the area occupied by SFVS within the spineflower preserves for Alternative 2, a buffer greater than 100 feet in width for 95.7% and greater than 200 feet for 54.7% of the area occupied by SFVS within the spineflower preserves for Alternative 3, a buffer greater than 100 feet in width for 94.7% and greater than 200 feet for 54.0% of the area occupied by SFVS within the spineflower

preserves for Alternative 4, a buffer greater than 100 feet in width for 94.9% and greater than 200 feet for 51.9% of the area occupied by SFVS within the spineflower preserves for Alternative 5, a buffer greater than 100 feet in width for 98.8% and greater than 200 feet for 89.6% of the area occupied by SFVS within the spineflower preserves for Alternative 6, and a buffer greater than 100 feet in width for 97.8% and greater than 200 feet for 89.9% of the area occupied by SFVS within the spineflower preserves for Alternative 7, the measures proposed to minimize effects from vegetation clearing around spineflower preserves should be moderately to highly effective.

Trampling

The proposed SCP and associated mitigation measures mentioned above will require the installation of fencing and signage to minimize trampling of SFVS populations. Fencing shall be installed along the outside edge of the spineflower preserve and buffer areas adjacent to proposed developments, parks, golf courses, or other "active land uses" to prevent unauthorized access. Specific areas that are adequately protected by steep terrain (1.5:1 or steeper) and/or dense vegetation may not require fencing but will require signage. The determination of the need for fencing in these areas shall be subject to the approval of the spineflower preserve manager or a qualified biologist. If monitoring determines that slope and/or vegetation does not effectively deter unauthorized access, additional fencing may be required to be added by the spineflower preserve manager or a qualified biologist. Fencing is not required in areas bordered by large parcels of conserved natural open space areas, or the Santa Clara River corridor, as installing fencing in these areas would be unnecessary and damaging to existing vegetation and wildlife corridors.

Fencing must extend a minimum of four feet above grade and include wood-doweled split rail fencing; exterior grade, heavy duty, vinyl three-railed fencing; three-strand non-barbed wire; or similar. Fencing installed adjacent to native vegetation communities and natural open space areas will allow for the passage of animals.

Outdoor all-weather signs measuring approximately 12 by 16 inches shall be posted on all spineflower preserve access gates and along spineflower preserve fencing at approximately 800 feet on center, except adjacent to road crossings, where signs will be posted. The placement will take topography into account, emphasizing placement on ridgelines where they will be visible to emergency fire personnel and others. Signs shall state in English and Spanish that the area is a biological preserve that hosts a state-listed endangered and federal candidate plant species and that trespassing is prohibited (in accordance with Newhall Ranch Specific Plan Program EIR Mitigation Measure SP-4.6-68). Signs shall indicate that fuel modification and management work is not allowed within the spineflower preserve or buffer areas. Signage at trailheads shall describe the spineflower preserve, its purpose, and the applicable rules of conduct within the spineflower preserve. The signage shall state that people not abiding by these rules or who

damage the protected species will be subject to prosecution, including fines and/or imprisonment. All signage shall include emergency contact information and shall be reviewed and approved by the spineflower preserve manager or a qualified biologist.

According to the CBI SFVS buffer study (CBI 2000), the combined effectiveness of measures intended to minimize the effects of trampling on spineflower preserves would be moderate when the buffer is less than 50 feet wide and would be high in situations where buffer width exceeds 80 feet. Because the proposed SCP would provide a minimum buffer of 80 feet, and a buffer greater than 100 feet in width for 95.9% and greater than 200 feet for 53.3% of the area occupied by SFVS within the spineflower preserves for Alternative 2, a buffer greater than 100 feet in width for 95.7% and greater than 200 feet for 54.7% of the area occupied by SFVS within the spineflower preserves for Alternative 3, a buffer greater than 100 feet in width for 94.7% and greater than 200 feet for 54.0% of the area occupied by SFVS within the spineflower preserves for Alternative 4, a buffer greater than 100 feet in width for 94.9% and greater than 200 feet for 51.9% of the area occupied by SFVS within the spineflower preserves for Alternative 5, a buffer greater than 100 feet in width for 98.8% and greater than 200 feet for 89.6% of the area occupied by SFVS within the spineflower preserves for Alternative 6, and a buffer greater than 100 feet in width for 97.8% and greater than 200 feet for 89.9% of the area occupied by SFVS within the spineflower preserves for Alternative 7, the measures proposed to minimize effects from trampling should be highly effective.

Changes in Hydrology

The proposed SCP and associated mitigation measures mentioned above require that pre-development hydrology conditions be maintained in the spineflower preserve areas. Project-specific design measures will be implemented in order to minimize changes in surface water flows to the spineflower preserve areas. Roadways will be constructed with slopes that convey water flows within the roadway easements and away from spineflower preserve areas. French drains will be installed along the edge of any roadways and fill slopes that drain toward the spineflower preserve areas. Where manufactured slopes drain toward the spineflower preserve(s), a temporary irrigation system will be installed to the satisfaction of the County in order to establish the vegetation on the slope area(s). This system shall continue only until the slope vegetation is established and self sustaining. Underground utilities will not be located within or through the spineflower preserve areas. Drainage pipes installed within the spineflower preserve areas away from SFVS populations to convey surface or subsurface water away from the populations will be aligned to avoid the spineflower preserve areas to the maximum extent practicable. Fencing or other structural type barriers that will be installed to reduce intrusion of people or domestic animals into the spineflower preserve areas shall incorporate footing designs that minimize moisture collection.

Storm drain outfalls from proposed development areas shall only be installed within spineflower preserve areas where necessary to retain pre-construction hydrologic conditions within the spineflower preserves, sustain existing riparian and wetland vegetation communities, and/or allow for the restoration of currently disturbed areas to the native riparian/alluvial vegetation community. Additionally, storm drains will not be permitted to daylight at the bottom of slopes within spineflower preserve areas. When located in a spineflower preserve area, storm drains must meet the following criteria:

1. Storm drains must not impact SFVS either directly or indirectly;
2. Storm drains may only daylight at the bottom of slopes within spineflower preserve areas; and
3. Under no circumstances shall storm drains daylight onto steeply sloped areas or other areas that would cause erosion.

Any surface water entering a spineflower preserve area from development areas is required to pass through BMP measures, which will be described in the SWPPP. Storm drain outlets must contain adequate energy dissipaters to prevent downstream erosion and stream channel down-cutting. In addition, storm drain outlets must be designed based on pre- and post-construction hydrologic studies (in accordance with Newhall Ranch Specific Plan Program EIR Mitigation Measure SP-4.6-69). Storm drains and permanent structural BMP measures shall be designed by a licensed civil engineer. Required BMPs, where applicable, shall be incorporated into the facility design and shall be subject to approval by the spineflower preserve manager or a qualified biologist. Long-term maintenance of storm drain BMPs will be the responsibility of the designated maintenance entity.

According to the CBI SFVS buffer study (CBI 2000), the combined effectiveness of measures intended to minimize the effects of artificially increased water supply on spineflower preserves would be low when the buffer is less than 50 feet wide, moderate with a buffer between 80 and 100 feet wide, and high in situations where buffer width exceeds 200 feet. Because the proposed SCP would provide a minimum buffer of 80 feet, and a buffer greater than 100 feet in width for 95.9% and greater than 200 feet for 53.3% of the area occupied by SFVS within the spineflower preserves for Alternative 2, a buffer greater than 100 feet in width for 95.7% and greater than 200 feet for 54.7% of the area occupied by SFVS within the spineflower preserves for Alternative 3, a buffer greater than 100 feet in width for 94.7% and greater than 200 feet for 54.0% of the area occupied by SFVS within the spineflower preserves for Alternative 4, a buffer greater than 100 feet in width for 94.9% and greater than 200 feet for 51.9% of the area occupied by SFVS within the spineflower preserves for Alternative 5, a buffer greater than 100 feet in width for 98.8% and greater than 200 feet for 89.6% of the area occupied by SFVS within the spineflower preserves for Alternative 6, and a buffer greater than 100 feet in width for 97.8% and greater than 200 feet for 89.9% of the area occupied by SFVS within the spineflower preserves

for Alternative 7, the measures proposed to minimize effects from hydrologic changes around spineflower preserves should be moderately to highly effective.

Chemical Pollutants

The proposed SCP and associated mitigation measures mentioned above provide for the establishment of buffers around portions of the delineated spineflower preserve(s) not connected to Open Area, the River Corridor SMA, or the High Country SMA land use designations; these buffers will serve to attenuate the effects of any chemical contamination originating in surrounding developed areas. In addition, the SCP and associated mitigation measures contain provisions for erosion control plans, dust control plans, and an overall Project SWPPP intended to prevent erosion, sedimentation, or runoff caused by development from affecting the spineflower preserve locations. These provisions will be included on construction plans and will be reviewed by the spineflower preserve manager, or a qualified biologist, prior to construction within 200 feet of spineflower preserves. Any surface water entering a spineflower preserve area from development areas is required to pass through BMP measures, which will be described in the SWPPP.

According to the CBI SFVS buffer study (CBI 2000), the combined effectiveness of measures intended to minimize the effects of chemical pollutants on spineflower preserve areas would be low when the buffer is less than 15 feet wide, moderate with a buffer between 30 and 50 feet wide, and high in situations where buffer width exceeds 80 feet. Because the proposed SCP will provide a minimum buffer of 80 feet, and a buffer greater than 100 feet in width for 95.9% and greater than 200 feet for 53.3% of the area occupied by SFVS within the spineflower preserves for Alternative 2, a buffer greater than 100 feet in width for 95.7% and greater than 200 feet for 54.7% of the area occupied by SFVS within the spineflower preserves for Alternative 3, a buffer greater than 100 feet in width for 94.7% and greater than 200 feet for 54.0% of the area occupied by SFVS within the spineflower preserves for Alternative 4, a buffer greater than 100 feet in width for 94.9% and greater than 200 feet for 51.9% of the area occupied by SFVS within the spineflower preserves for Alternative 5, a buffer greater than 100 feet in width for 98.8% and greater than 200 feet for 89.6% of the area occupied by SFVS within the spineflower preserves for Alternative 6, and a buffer greater than 100 feet in width for 97.8% and greater than 200 feet for 89.9% of the area occupied by SFVS within the spineflower preserves for Alternative 7, the measures proposed to minimize effects from chemical pollutants entering spineflower preserves should be highly effective.

Increased Fire Frequency

The proposed SCP and associated mitigation measures mentioned above will permit the use of limited fuel modification activities within the spineflower preserves, which will be restricted to selective thinning with hand tools to allow the maximum preservation of SFVS populations. No other fuel modification or clearance activities shall be allowed in the Newhall Ranch spineflower

preserve areas. All FMZs associated with the adjacent development shall be located outside of proposed spineflower preserves. Controlled burning may be allowed in the future within the Newhall Ranch spineflower preserve areas and buffers, provided that it is based upon a burn plan approved by the County of Los Angeles Fire Department and CDFG. The plant palette authorized for use in FMZs within 100 feet of spineflower preserves shall be reviewed by the spineflower preserve manager or a qualified biologist to ensure that the proposed landscape plants will not naturalize and cause maintenance or vegetation community degradation in the spineflower preserve and buffer areas. By locating FMZs at the interface between spineflower preserve areas and proposed development, these zones will serve the dual purpose of providing fire protection and additional SFVS buffer area.

In the event that a spineflower preserve or a portion of a spineflower preserve burns in a wildfire, the spineflower preserve manager and Newhall Land shall promptly review the site and determine what action, if any, should be taken. The primary anticipated post-fire spineflower preserve management activity involves monitoring the site and controlling annual weeds that may invade burned areas following a fire event, especially when such weeds that were not previously present or not present in similar densities present an imminent threat to the survival of SFVS populations. If fire-control lines or other forms of bulldozer damage occur in the spineflower preserves, these areas will be repaired and revegetated to pre-burn conditions or better. An Emergency Fire Response Plan will be prepared (in accordance with Newhall Ranch Specific Plan Program EIR Mitigation Measure SP-4.6-72) prior to the establishment of the spineflower preserves and approved by CDFG and Los Angeles County Fire Department.

Management responses to wildfire and/or geologic events will be informed by the results of adaptive management activities related to non-native plants, fire suppression, fire exclusion, and the disruption of the natural soil-disturbance regime. In general, however, a burned site will be left to recover naturally from wildfire or geologic events. The coastal scrub habitat types within the spineflower preserves are well adapted to recover from wildfires unless the fire frequency is artificially increased (Holland 1986). Therefore, burned areas shall not be seeded or sprayed with soil stabilizer, straw, or hay. The latter two items are usually contaminated with various problematic weed seeds and often include noxious weed seed. It should be noted that several species of weeds not considered to be noxious by the USDA may be considered a noxious weed in natural spineflower preserve areas and, if introduced, would be very expensive to control/eradicate. In addition, active post-fire revegetation and soil stabilization efforts interfere with natural post-fire successional species and vegetation development stages that should be allowed to occur in order for the habitat to properly recover and regenerate.

Erosion-control devices, including seeding, straw wattles, and soil tackifiers, should be avoided following a fire event for the aforementioned reasons. An exception to this would be fires that occur at a higher-than-average frequency, which may artificially accelerate erosion processes. This situation is to be evaluated by the spineflower preserve manager. Imminent and

unavoidable threats to human health, safety, and welfare represent another exception to this passive management approach in post-fire conditions. Fire frequencies have a tendency to increase at the urban–wildland interface. If the spineflower preserves are subject to a greater-than-natural fire frequency, the guidelines outlined herein shall be followed to help ensure that the spineflower preserves recover to a natural state.

According to the CBI SFVS buffer study (CBI 2000), the combined effectiveness of measures intended to minimize the effects of increased fire frequency on spineflower preserve areas would be low when the buffer is less than 50 feet wide and would be moderate in situations where buffer width exceeds 80 feet. The study did not identify a buffer width sufficient for these measures to achieve a high level of effectiveness because wildfires are more unpredictable and difficult to control. Because the proposed SCP will provide a minimum buffer of 80 feet, and a buffer greater than 100 feet in width for 95.9% and greater than 200 feet for 53.3% of the area occupied by SFVS within the spineflower preserves for Alternative 2, a buffer greater than 100 feet in width for 95.7% and greater than 200 feet for 54.7% of the area occupied by SFVS within the spineflower preserves for Alternative 3, a buffer greater than 100 feet in width for 94.7% and greater than 200 feet for 54.0% of the area occupied by SFVS within the spineflower preserves for Alternative 4, a buffer greater than 100 feet in width for 94.9% and greater than 200 feet for 51.9% of the area occupied by SFVS within the spineflower preserves for Alternative 5, a buffer greater than 100 feet in width for 98.8% and greater than 200 feet for 89.6% of the area occupied by SFVS within the spineflower preserves for Alternative 6, and a buffer greater than 100 feet in width for 97.8% and greater than 200 feet for 89.9% of the area occupied by SFVS within the spineflower preserves for Alternative 7, the measures proposed to minimize effects of wildfires on spineflower preserves should be moderately effective.

The establishment of the system of spineflower preserves, along with the long-term monitoring and management measures, described above, will mitigate to less than significant all secondary impacts to the spineflower preserve areas and SFVS individuals within the preserves.

All specific mitigation measures for SFVS are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures, as well as in the SCP.

IMPACT 4.5-165 IMPACTS TO INDIVIDUALS – SAN FERNANDO VALLEY SPINEFLOWER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to avoid, minimize, or mitigate the loss of SFVS individuals.

Focused Surveys

SP-4.6-53 requires current, updated, site-specific surveys for rare, threatened, or endangered plant or animal species determined to be on a site for which any subdivision map proposing construction has been submitted. These surveys were conducted from 2002 to 2007, as described above, in accordance with the requirements set forth in Mitigation Measure SP-4.6-59, which requires consultation with CDFG at specific milestones. These two measures help to minimize impacts to SFVS. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Spineflower Mitigation Area Overlay

SP-4.6-65 requires the applicant to design subdivision maps that are responsive to the characteristics of the SFVS and other endangered plant species and to agree to the identified special study areas.

Spineflower Preserves

SP-4.6-66 requires that direct impacts to known SFVS populations within the Specific Plan area be avoided or minimized through the establishment of one or more on-site spineflower preserves delineated in consultation with the County and CDFG and configured to ensure the continued existence of the species in perpetuity.

SP-4.6-80 specifies that the applicant shall establish an appropriately sized preserve area at San Martinez Canyon to protect the spineflower population at San Martinez Canyon.

Connectivity, Reserve Design and Buffers

SP-4.6-67 requires that indirect impacts associated with the interface between the preserved spineflower populations and planned development be avoided or minimized by establishing open space connections with the Open Area, River Corridor SMA, or High Country SMA and establishing buffers around portions of the spineflower preserve(s) not connected to Open Area, the River Corridor SMA, or the High Country SMA; open space connection and buffers shall be revegetated to mitigate for temporary disturbance due to grading.

Preserve Protection/Fencing

SP-4.6-68 requires temporary orange fencing and prohibitive signage around spineflower preserves, open space connections, and buffer areas adjacent to areas impacted by proposed development prior to and during all phases of construction. The areas behind the temporary fencing shall not be used for storage associated with construction activities. Following the final phase of construction, permanent fencing shall be installed on the spineflower preserve boundary.

Preserve Protection/Hydrologic Alterations

SP-4.6-69 addresses indirect impacts resulting from changes to hydrology at the interface between the spineflower preserves and planned development, requiring that they be avoided or mitigated. This standard will be met through the demonstration that the storm drain system achieves pre-development hydrologic conditions for the spineflower preserve(s).

Road Construction Measures

SP-4.6-70 specifies the redesign or realignment of roads to avoid or substantially lessen direct impacts to SFVS populations and to achieve the standards set forth in Mitigation Measures SP-4.6-66 and SP-4.6-67. Roadways and road rights-of-way shall not be constructed in any spineflower preserves or buffer locations.

Engineering, Design and Grading Modifications

SP-4.6-71 states that direct impacts to SFVS populations shall be further assessed at the subdivision map level. To avoid or substantially lessen impacts to SFVS populations, development footprints, roadway alignments, and project-specific grading may be adjusted to achieve spineflower preserve and connectivity/preserve design/buffer standards.

Fire Management Plan

SP-4.6-72 requires that a fire management plan be developed to avoid and minimize impacts to SFVS and to protect and manage the spineflower preserves and buffers. Fuel modification activities within the spineflower preserves will be restricted to selective thinning with hand tools.

Water Flow Diversion and Management

SP-4.6-73 states that the subdivision map shall implement project-specific design measures to minimize changes in surface water flows to the spineflower preserves.

Reassessment Requirement

SP-4.6-76 states that the applicant shall reassess the impacts to SFVS populations using subdivision mapping data, baseline data from the Newhall Ranch Final EIR, and data from updated plant surveys in conjunction with the first Newhall Ranch subdivision map submittal. If the reassessment results in the identification of new or additional impacts, the mitigation measures set forth in this program or a Fish and Game Code section 2081 permit shall be required.

Newhall Ranch Monitoring and Management

SP-4.6-77 directs the applicant to prepare a monitoring and management plan in consultation with CDFG for the impacts to SFVS populations. This plan shall be in place when the spineflower preserve(s) and connectivity/preserve design/buffers are established The plan shall include monitoring, reporting, and management.

Translocation/Reintroduction Program

SP-4.6-78 requires implementation of a translocation and reintroduction program in consultation with CDFG to mitigate for direct impacts at a 4:1 ratio and indirect impacts at 1:1 ratio when project-related direct and indirect impacts to SFVS cannot be avoided or lessened.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to avoid, minimize, or mitigate direct and indirect impacts due to loss of SFVS individuals.

Establishment and Oversight of Spineflower Preserves

BIO-23 and BIO-24 provide for the placement of the spineflower preserve areas into a permanent conservation easement and provide for the management of the spineflower preserve areas.

Restoration and Enhancement of Spineflower Preserves

BIO-25 describes restoration of disturbed portions of the spineflower preserves through revegetation with native plant communities. Areas that have greater than 30% absolute cover by weeds will be restored to have at least 70% absolute cover by native species. Cal-IPC List A and B plants that are present within the spineflower preserves will be controlled.

Emergency Fire Response Plan

BIO-26 requires preparation of an emergency fire response plan prior to the establishment of the spineflower preserves and approval by CDFG and Los Angeles County Fire Department. In the event that a spineflower preserve or a portion of a spineflower preserve burns in a wildfire or suffers from mass movements (*e.g.*, landslides, slope sloughing, or other geologic events), the spineflower preserve manager and Newhall Land shall promptly review the site and determine what action, if any, should be taken.

Preserve Protection/Access

BIO-35 through BIO-37 provide guidelines for the installation of permanent fencing and signage for the spineflower preserves. All portions of the spineflower preserves shall be closed with the

exception of pre-identified existing dirt roads and utility easements. Fencing shall be installed along the outside edge of the spineflower preserve and buffer areas, although specific areas adequately protected by steep terrain (1.5:1 or steeper) and/or dense vegetation may not require fencing but will require signage. Outdoor all-weather signs (12 by 16 inches) shall be posted on spineflower preserve access gates and adjacent to road crossings, and along spineflower preserve fencing at 800-foot intervals.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, direct impacts to SFVS individuals under Alternative 2 will remain significant. Implementation of Alternative 2 creates significant unavoidable impacts.

After mitigation, direct impacts due to the loss of SFVS individuals will be adverse but not significant for Alternatives 3, 4, 5, 6, and 7 because the percentage of preserved SFVS cumulative occupied area would be expanded, and the protected unoccupied acreage would be expanded.

IMPACT 4.5-166 SECONDARY IMPACTS – SAN FERNANDO VALLEY SPINEFLOWER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate secondary impacts to SFVS.

Focused Surveys

SP-4.6-53 requires current, updated, site-specific surveys for rare, threatened, or endangered plant or animal species determined to be on a site for which any subdivision map proposing construction has been submitted. These surveys were conducted from 2002 to 2007, as described above, in accordance with the requirements set forth in Mitigation Measure SP-4.6-59, which requires consultation with CDFG at specific milestones. These two measures help to minimize impacts to SFVS.

Spineflower Mitigation Area Overlay

SP-4.6-65 requires the applicant to design subdivision maps that are responsive to the characteristics of SFVS and other endangered plant species and to agree to the identified special study areas.

Spineflower Preserves

SP-4.6-66 requires that direct impacts to known SFVS populations within the Specific Plan area be avoided or minimized through the establishment of one or more on-site spineflower preserves delineated in consultation with the County and CDFG and configured to ensure the continued existence of the species in perpetuity.

SP-4.6-80 specifies that the applicant shall establish an appropriately sized preserve area at San Martinez Canyon to protect the spineflower population at San Martinez Canyon.

Connectivity, Preserve Design, and Buffers

SP-4.6-67 requires that indirect impacts associated with the interface between the preserved spineflower populations and planned development be avoided or minimized by establishing open space connections with the Open Area, River Corridor SMA, or High Country SMA and establishing buffers around portions of the spineflower preserve(s) not connected to Open Area, the River Corridor SMA, or the High Country SMA; open space connection and buffers shall be revegetated to mitigate for temporary disturbance due to grading.

Preserve Protection/Fencing

SP-4.6-68 requires temporary orange fencing and prohibitive signage around spineflower preserves, open space connections, and buffer areas adjacent to areas impacted by proposed development prior to and during all phases of construction. The areas behind the temporary fencing shall not be used for storage associated with construction activities. Following the final phase of construction, permanent fencing shall be installed on the spineflower preserve boundary.

Preserve Protection/Hydrologic Alterations

SP-4.6-69 addresses indirect impacts resulting from changes to hydrology at the interface between the spineflower preserves and planned development, requiring that they be avoided or mitigated. This standard will be met through the demonstration that the storm drain system achieves pre-development hydrologic conditions for the spineflower preserve(s).

Road Construction Measures

SP-4.6-70 specifies the redesign or realignment of roads to avoid or substantially lessen direct impacts to SFVS populations and to achieve the standards set forth in Mitigation Measures SP-4.6-66 and SP-4.6-67. Roadways and road rights-of-way shall not be constructed in any spineflower preserves or buffer locations.

Engineering, Design and Grading Modifications

SP-4.6-71 states that direct impacts to SFVS populations shall be further assessed at the subdivision map level. To avoid or substantially lessen impacts to SFVS populations, development footprints, roadway alignments, and project-specific grading may be adjusted to achieve spineflower preserve and connectivity/preserve design/buffer standards.

Fire Management Plan

SP-4.6-72 requires that a fire management plan be developed to avoid and minimize impacts to SFVS and to protect and manage the spineflower preserves and buffers. Fuel modification activities within the spineflower preserves will be restricted to selective thinning with hand tools.

Water Flow Diversion and Management

SP-4.6-73 states that the subdivision map shall implement project-specific design measures to minimize changes in surface water flows to the spineflower preserves.

Biological Monitor

SP-4.6-74 requires that an experienced biologist/botanist monitor grading and fence/utility installation activities that involve earth movement adjacent to the spineflower preserves biweekly, to avoid incidental take of conserved plant species and to avoid disturbance of the preserves.

Construction Impact Avoidance Measures

SP-4.6-75 requires implementation of water control, stormwater flow redirection, and treatment of exposed, graded slopes during all construction phases to avoid and minimize indirect impacts to the spineflower preserves.

Reassessment Requirement

SP-4.6-76 states that the applicant shall reassess the impacts to SFVS populations using subdivision mapping data, baseline data from the Newhall Ranch Final EIR (County of Los Angeles 2003A), and data from updated plant surveys in conjunction with the first Newhall Ranch subdivision map submittal. If the reassessment results in the identification of new or additional impacts, the mitigation measures set forth in this program or a Fish and Game Code section 2081 permit shall be required.

Newhall Ranch Monitoring and Management

SP-4.6-77 directs the applicant to prepare a monitoring and management plan in consultation with CDFG for the impacts to SFVS populations. This plan shall be in place when the

spineflower preserve(s) and connectivity/preserve design/buffers are established. The plan shall include monitoring, reporting, and management.

Translocation/Reintroduction Program

SP-4.6-78 requires implementation of a translocation and reintroduction program in consultation with CDFG to mitigate for direct impacts at a 4:1 ratio and indirect impacts at a 1:1 ratio when project-related direct and indirect impacts to SFVS cannot be avoided or lessened.

Ongoing Agricultural Activities

SP-4.6-79 requires the applicant to engage in regular consultation with the County and CDFG in connection with its ongoing agricultural operations to avoid or minimize significant direct impacts to the spineflower, and to provide 30 days advance written notice to the County and CDFG of the proposed conversion of its ongoing rangeland operations on Newhall Ranch to more intensive agricultural uses.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to avoid, minimize, or mitigate short-term and long-term secondary impacts.

Establishment and Oversight of Spineflower Preserves

BIO-23 and BIO-24 provide for the placement of the spineflower preserve areas into a permanent conservation easement and provide for the management of the spineflower preserve areas.

Restoration and Enhancement of Spineflower Preserves

BIO-25 describes restoration of disturbed portions of the spineflower preserves through revegetation with native plant communities. Areas that have greater than 30% absolute cover by weeds will be restored to have at least 70% absolute cover by native species. Cal-IPC List A and B plants that are present within the spineflower preserve will be controlled.

Emergency Fire Response Plan

BIO-26 requires preparation of an emergency fire response plan prior to the establishment of the spineflower preserves and approval by CDFG and Los Angeles County Fire Department. In the event that a spineflower preserve or a portion of a spineflower preserve burns in a wildfire or suffers from mass movements (*e.g.*, landslides, slope sloughing, or other geologic events), the spineflower preserve manager and Newhall Land shall promptly review the site and determine what action, if any, should be taken.

Prevention of Construction-Related Impacts/Temporary Fencing

BIO-27 and BIO-31 provide guidelines for temporary fencing design, installation, monitoring, and repair.

Spineflower preserve temporary fencing—three-strand non-barbed-wire fence or bright orange U.V.-stabilized polyethylene construction "snow" fencing, attached to metal t-posts that extend at least four feet above grade or equivalent—shall be shown on construction plans and installed prior to initiating construction clearing and grubbing activities within 200 feet of spineflower preserves. Impacts to native vegetation will be minimized and native vegetation will be restored as necessary. Appropriate BMPs shall be installed at the edge of development-manufactured slopes when the spineflower preserve is within 200 feet and downslope of proposed development.

Prevention of Construction-related Impacts

BIO-28 through BIO-30 and BIO-33 minimize construction-related impacts in spineflower preserves by requiring "environmental education sessions," incorporating dust control, erosion control, and water quality plans (as required in the Project SWPPP) into construction plans and requiring weekly construction monitoring for all construction activities within 200 feet of spineflower preserve areas.

Preserve Protection/Invasive Plants and Animals

BIO-34 requires plant palettes proposed for use within 100 feet of a spineflower preserve to be reviewed by the spineflower preserve manager or a qualified biologist to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants to be installed within 200 feet of the spineflower preserves shall be inspected by the spineflower preserve manager or a qualified biologist for the presence of disease, weeds, and pests, including Argentine ants.

Preserve Protection/Access

BIO-35 through BIO-37 provide guidelines for the installation of permanent fencing and signage for the spineflower preserves. All portions of the spineflower preserves shall be closed, with the exception of pre-identified existing dirt roads and utility easements. Fencing shall be installed along the outside edge of the spineflower preserve and buffer areas, although specific areas adequately protected by steep terrain (1.5:1 or steeper) and/or dense vegetation may not require fencing but will require signage. Outdoor all-weather signs (12 by 16 inches) shall be posted on spineflower preserve access gates and adjacent to road crossings, and along spineflower preserve fencing at 800-foot intervals.

Preserve Protection/Hydrology

BIO-38 and BIO-39 specify storm drain requirements and limitations within spineflower preserve areas in order to retain pre-construction hydrologic conditions within spineflower preserves, and require that any surface water entering a spineflower preserve from the development areas pass through BMP measures as described in the SWPPP.

Argentine Ants

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrologic conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface, where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants will occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to SFVS will be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

INTENTIONALLY LEFT BLANK

UNDESCRIBED EVERLASTING (NO CURRENT STATUS)

Life History

White rabbit-tobacco (*Gnaphalium leucocephalum*, or *Pseudognaphalium leucocephalum*) is a perennial herb occurring in southeastern Arizona, southern New Mexico, much of mainland Mexico, and (in some reports) as far east as Texas. According to published and online sources in California, it also occurs in southwestern California from San Luis Obispo County south to San Diego County and Baja California, generally at relatively low elevations but sometimes to about 6,900 feet elevation AMSL (Munz 1974; Hickman 1993; Nesom 2006; CNPS 2009; Consortium of California Herbaria 2007; Lazar and Bittman 2006). Several botanists, including Andrew C. Sanders of U.C. Riverside (Sanders 2007) believe that the plants in southern California are distinct from those farther east and should be considered a separate species due to several differences in plant structure (stature, pubescence, and phyllary characters; Dudek and Associates 2004C) and its geographic distribution. The California occurrences are hundreds of miles disjunct from the eastern occurrences (it does not occur in the Sonoran or Mojave deserts between the two areas). The California plants have not been formally described in botanical literature as a distinct species or subspecies, but this EIS/EIR treats them as an undescribed species (*Gnaphalium* sp. *nova*) based on differences in plant structure.

CPNS (2009) and CDFG (2009) treat this species as white rabbit-tobacco, including it on CNPS List 2.2 and CDFG ranking G4/S2S3.2. If a future publication confirms that the California populations are distinct from species' occurrences in Arizona, New Mexico, and mainland Mexico, then the undescribed species would meet criteria for inclusion on CNPS List 1B.2.

A search of three herbaria (U.C. Riverside, Rancho Santa Ana Botanic Garden, and the San Diego Natural History Museum) by Dudek biologist Marc Doalson revealed that 14 collections of this plant have been made in Ventura, Orange, Riverside, Los Angeles, and San Diego counties. Eight collections date from 1901 to 1987 (1901, 1918, 1922, 1928, 1931, 1959, 1985, and 1987). There are six more recent collections dating from 1994 to 2003 (1994, two from 1995, 1997, and two from 2003). Many are from somewhat vague localities, such as "San Fernando Valley" and "Pasadena." Modern collections have come mostly from the Santa Ana Mountains region and especially Temescal Wash in western Riverside County, with several collections from adjacent San Diego County (Dudek and Associates 2004C). In addition to the herbaria specimens, the undescribed everlasting has been observed in 2003, 2004, 2005, and 2007 along Castaic Creek and the Santa Clara River (Dudek and Associates 2004A, 2004H, 2006F; Causey 2007) and in 2004 and 2005 in Hasley Canyon in Los Angeles County (Dudek and Associates 2004G, 2006H).

The undescribed everlasting is a short-lived perennial herb. An individual plant persists over several years as a woody rootstock. New stems and leaves are produced during winter and

spring, followed by flowering stems. Its blooming period lasts from July through December (CNPS 2009).

The undescribed everlasting occurs in relatively open, sandy alluvial soils, often being found on the benches along major washes in river wash habitat among sparse cover of non-wetlands species such as scalebroom, big sagebrush or California buckwheat. It generally is not found in streamside habitat where willows, mulefat or other riparian species tend to shade out understory herbs. In general, it is found on stable alluvial deposits above the level of the active channel. These benches may be scoured by infrequent high river flows, but tend to remain in place on a time scale of several years to a few decades or more, even during most floods. On a longer time scale, larger floods sometimes scour and rework broad areas of the floodplain, eroding the margins of alluvial benches and re-depositing the material in new sites.

Undescribed everlasting seeds are very small and light, with a plume-like awns adapted for wind dispersal. Many seeds fall in the immediate vicinity of parent plants so that its populations persist at occupied sites. But some seeds can be dispersed to new, unoccupied habitat elsewhere in the river wash. This dispersal mechanism allows the species to establish new occurrences where river hydrology creates suitable habitat at new sites.

In addition to the direct loss of individuals, undescribed everlasting is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives such as the undescribed everlasting. Exotic plants can also alter hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development.

Survey Results

Observations of the undescribed everlasting species in 2003, 2004, and 2005 (Dudek and Associates 2004C, 2004F, 2004G, 2006F, 2006H; FL*x* 2004B) were made during surveys that focused on the identification and location of special-status plant species. Observations of the undescribed everlasting species in 2007 (Causey 2007) were made during surveys that focused on the identification and location of the undescribed everlasting species.

Focused surveys were conducted in spring and summer of 2002 through 2005, timed to be coincident with the annual blooming period for early blooming annual species. An additional survey for this species was conducted in 2007 in areas known to previously support undescribed everlasting. This survey period would overlap with the blooming period of white-headed

cudweed, which lasts from July through December (CNPS 2009). This species has definitive habitat requirements, and the surveys focused on suitable habitat. In addition, this is a conspicuous plant with a distinctive odor, and senescent or juvenile stems would have been observed during the non-blooming period.

The undescribed everlasting is almost always associated with alluvial soils, often found on the benches along major washes; therefore, it is anticipated that occurrences of this species may shift over time on site. Sandy alluvial land occurs mostly on floodplains along the Santa Clara River and its tributaries. The large storm events of 2005 and associated large flows within Castaic Creek and the Santa Clara River resulted in extensive scouring and/or removal of the terraces and benches on which the plants previously occurred along the west bank of Hasley Canyon; however, that flood event did not remove the other occurrences on site. The limited surveys covering alluvial soils and washes within the River Corridor SMA portion of the Specific Plan area in other years, and below-average rainfall in 2004, may have affected the observations of this species. Given the number of surveys conducted for this species on site in the context of storm event cycles, the cumulative survey results are representative of the distribution of this species on site.

Two main occurrences and a number of smaller occurrences of this undescribed species were documented within the Specific Plan area during the 2003, 2004, 2005, and 2007 field seasons (Dudek and Associates 2004C, 2004F, 2006F; Causey 2007; FL*x* 2004B) (**Figure 4.5-7,** RMDP/SCP – Special-Status Plant Species Occurrences, and **Figures 4.5-13** through **4.5-15,** River Corridor SMA – Special-Status Species Occurrences). These occurrences are primarily on secondary alluvial benches in the Santa Clara River near the mouth of Long Canyon and where Castaic Creek and the Santa Clara River converge, south of SR-126. In both the Specific Plan and VCC planning areas, the vegetation around these plants consists of sparsely vegetated open river wash. **Table 4.5-60** provides a summary of occurrence data for the undescribed everlasting that occur within the Specific Plan and VCC planning areas. Because several years of mapped occurrence data are available for the undescribed everlasting, impacts to this species were evaluated by impacts to individuals rather than by loss of habitat.

Table 4.5-60
Occurrence Data for the Undescribed Everlasting that Occurs within the Specific Plan and VCC Planning Areas

	Undescribed Everlasting Individuals Observed			
Location	**2003**	**2004**	**2005**	**2007**
Specific Plan Area	530	712	805	85
High Country SMA	–	–	–	–
Salt Creek Area	–	–	–	–
RMDP (Specific Plan Area + High Country SMA + Salt Creek Area)	530	712	805	85
VCC	–	270	65	350
Entrada	–	–	–	–
TOTAL	**530**	**982**	**870**	**435**

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Impacts to Individuals

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the direct loss of 7 individuals. Based on the results of field surveys conducted within the Project area for special-status plants from 2002 through 2005, there is only a low probability that undocumented undescribed everlasting occurrences, consisting of relatively few plants, may exist in other portions of the Project area, possibly including areas to be disturbed by construction. Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the VCC planning area would result in the indirect permanent loss of 350 of the undescribed everlasting observed in 2007 (**Figure 4.5-146,** Alternative 2 Impacts to RMDP/SCP Special-Status Plants). Because no undescribed everlasting plants were observed within the Entrada planning area, build-out of the Entrada planning area is not anticipated to impact any undescribed everlasting plants. Although build-out of the Specific Plan area would not result in the loss of any documented individuals, because the undescribed everlasting is a floodplain species, the location of individuals may change prior to construction commencing. If individual locations were to change, build-out of the Specific Plan area could result in the loss of undescribed everlasting individuals. Loss of undescribed everlasting individuals within the VCC planning area and the potential loss within the Specific Plan area would be considered a substantial adverse effect on this species and would substantially reduce the number and restrict the range of this species (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of the undescribed everlasting individuals resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 357 individuals. The loss of the undescribed everlasting occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would be considered a substantial adverse effect on this species and would substantially reduce the number and restrict the range of this species on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts to this plant associated with implementation of the RMDP and the SCP and build-out of the Specific Plan area include short-term secondary impacts such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust; and long-term impacts such as introduction of non-native, invasive plant species; increased human activity, trampling, and soil compaction; and hydrologic alterations and water quality impacts. No undescribed everlasting plants would remain at the VCC planning area at the time of build-out, and no undescribed everlasting plants were observed within the Entrada planning area; therefore, build-out of the VCC and Entrada planning areas is not anticipated to impact any undescribed everlasting plants. The potential loss of this undescribed everlasting species as a result of these secondary impacts within the Specific Plan area would constitute a substantial adverse effect on this species and

could substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). Secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Impacts to Individuals

Direct Permanent and Temporary Impacts

The direct loss of 7 individual undescribed everlasting plants as a result of implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar to impacts under Alternative 2 (impacts to 7 individuals). Based on the results of field surveys conducted within the Project area for special-status plants from 2002 through 2005, there is only a low probability that undocumented undescribed everlasting occurrences, consisting of relatively few plants, may exist in other portions of the Project area, possibly including areas to be disturbed by construction. The relative risk of impacts to undocumented undescribed everlasting would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. The direct permanent and temporary loss (Impacts to Individuals) of undescribed everlasting occurring as a result of implementation of the RMDP and the SCP would be significant, absent mitigation, for Alternatives 3 through 7.

Indirect Permanent Impacts

Under Alternative 3, build-out of the Specific Plan and VCC planning areas would result in the same indirect permanent impacts to undescribed everlasting as under Alternative 2 (loss of 350 undescribed everlasting individual) (**Figures 4.5-147** through **4.5-151**, Alternatives 3 through 7 Impacts to RMDP/SCP Special-Status Plants). Based on the results of field surveys conducted within the Project area for special-status plants from 2002 through 2005, there is only a low probability that undocumented undescribed everlasting occurrences, consisting of relatively few plants, may exist in other portions of the Project area, possibly including areas to be disturbed by construction. The indirect permanent loss of undescribed everlasting plants (Impacts to Individuals) as a result of build-out of the Specific Plan and VCC planning areas would be significant, absent mitigation, for Alternative 3. Because no undescribed everlasting plants were observed within the Entrada planning area, build-out of the Entrada planning area is not anticipated to impact any undescribed everlasting plants under Alternative 3.

Under Alternatives 4 through 7, build-out of the Specific Plan would not result in indirect permanent impacts to undescribed everlasting, a reduction compared to Alternative 2 (Alternative 2 results in the indirect loss of 350 undescribed everlasting individuals due to build-out of the VCC planning area; build-out of the VCC planning area is not a

component of Alternatives 4 through 7). Because surveys were conducted within the Project area for special-status plants from 2002 through 2005, and specifically for the undescribed everlasting in 2007, there is a low probability that undocumented undescribed everlasting occurrences, consisting of relatively few plants, exist in other portions of the Project area, possibly including areas to be disturbed by construction. The relative risk of impacts to undocumented undescribed everlasting would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. The indirect permanent loss of undescribed everlasting plants (Impacts to Individuals) as a result of build-out of the Specific Plan and VCC planning areas would not be significant for Alternatives 4 through 7 because no impacts would occur. Because no undescribed everlasting plants were observed within the Entrada planning area, build-out of the Entrada planning area is not anticipated to impact any undescribed everlasting plants under Alternatives 4 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts for Alternative 3 resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the loss of 357 undescribed everlasting individuals, similar to Alternative 2 (357 individuals). The combined direct and indirect permanent impacts for Alternatives 4 through 7 resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas would result in the loss of 7 individuals, a reduction compared to Alternative 2 (357 individuals). Because surveys were conducted within the Project area for special-status plants from 2002 through 2005, and specifically for the undescribed everlasting in 2007, there is a low probability that undocumented undescribed everlasting occurrences, consisting of relatively few plants, exist in other portions of the Project area, possibly including areas to be disturbed by construction. The relative risk of impacts to undocumented undescribed everlasting would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. The combined direct and indirect loss of the undescribed everlasting occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would be considered a substantial adverse effect on this species and would substantially reduce the number and restrict the range of this species on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and VCC (Alternative 3 only) planning

areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. Because no undescribed everlasting plants were observed within the Entrada planning area, build-out of the Entrada planning area is not anticipated to impact any undescribed everlasting plants under Alternatives 3 through 7.The loss of individual undescribed everlasting and the effect on its habitat due to secondary impacts within the Specific Plan area resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and VCC planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to the undescribed everlasting: (1) impacts to individuals, and (2) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals would occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment. The combined permanent loss of undescribed everlasting individuals would be 350 for Alternatives 2 and 3, and no loss of individuals for Alternatives 4 through 7. The combined permanent loss of 357 individuals would have a substantial adverse effect on this species and would substantially reduce the number and restrict the range of this species. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Focused surveys to be conducted prior to the commencement of grading/construction activities within suitable habitat for the undescribed everlasting will ensure that any individual plants that may have germinated in new sites or may not have been documented by previous field surveys would be located. Follow-up measures would require Newhall Land either to avoid those plants or to mitigate any impacts to them. Avoidance measures, and, if necessary, the salvage of seeds and/or transplantation of individuals identified within the disturbance area to an appropriate receptor site within the River Corridor SMA where long-term preservation is provided, shall be implemented as outlined within the undescribed everlasting mitigation and monitoring plan. In addition, mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA in a natural state by restricting access and prohibiting grazing, agriculture, and recreation within the River Corridor SMA, as well as providing for the restoration and enhancement of habitat within the River Corridor SMA, will mitigate the direct and indirect loss of and/or harm to undescribed everlasting.

Short-term secondary impacts, such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust;

and hydrologic alterations and water quality impacts, would be minimized by providing guidelines for grading and construction activities; by retaining a qualified biologist during all grading and construction activities; by providing erosion control plans, dust control, and an overall Project SWPPP; by preventing pollutants from entering flowing streams and storm flows; by providing guidelines for stream diversion; and by requiring that the Specific Plan conform to all provisions of required NPDES permits and water quality permits required by the RWQCB. Long-term secondary impacts to the undescribed everlasting, such as the introduction of non-native, invasive plant species and increased human activity, trampling, and soil compaction, would be minimized by providing revegetation plans for the River Corridor SMA placing restrictions on plant palettes proposed for use on landscaped slopes; by restricting access to, grazing within, and recreational usage of the River Corridor SMA; and by providing for transition areas along the River Corridor SMA.

All specific mitigation measures for the undescribed everlasting species are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-167 IMPACTS TO INDIVIDUALS – UNDESCRIBED EVERLASTING

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to avoid, minimize, and/or mitigate the loss of the undescribed everlasting.

The undescribed everlasting is associated with the Santa Clara River and Castaic Creek and, where this species occurs in jurisdictional areas, the following mitigation measures will apply.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-47a permits mitigation banking within the River Corridor SMA, High Country SMA, and Open Area, subject to requirements for riparian habitats, oak resources, and Mexican elderberry scrub.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In addition to the restoration and avoidance mitigation measures described above, the undescribed everlasting will benefit from the following preservation and management mitigation measures. SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to reduce the loss of and harm to the undescribed everlasting.

To mitigate for the removal of individuals during construction, BIO-75 requires pre-construction focused surveys for the undescribed species of everlasting within suitable habitat for the species. The surveys shall be conducted up to one year prior to commencement of construction activities. Should the species be documented within the Project boundary, avoidance measures shall be implemented to minimize impacts to individual plants wherever feasible. These measures shall include minor adjustments to the boundaries/location of haul routes and other Project features. If, due to Project design constraints, avoidance of all plants is not possible, then further measures, described in BIO-76, shall be implemented to salvage seeds and/or transplant individual plants. BIO-76 states that prior to the issuance of grading permits, the applicant shall develop an Undescribed Everlasting Mitigation and Monitoring Plan to be implemented if surveys conducted in accordance with BIO-75 are positive. The Plan shall provide for replacement of individual plants to be removed at a minimum 1:1 ratio, within suitable habitat at a site where no future construction-related disturbance will occur. The Plan shall specify requirements for the selection of the mitigation site; methods for harvesting seeds or salvaging and transplantation of individual plants; site preparation procedures; a schedule and action plan to maintain and monitor the mitigation area; criteria and performance standards; measures to exclude unauthorized entry into the mitigation areas; and contingency measures.

In addition to mitigation measures requiring replacement of individual plants, the undescribed everlasting is associated with jurisdictional areas along the Santa Clara River and Castaic Creek and, where this species occurs in jurisdictional areas, the following mitigation measures will apply. BIO-1 through BIO-16 include requirements for the development and implementation of mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of

success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts associated with the loss of individuals of the undescribed everlasting species would be adverse but not significant for alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-168 SECONDARY IMPACTS – UNDESCRIBED EVERLASTING

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to the undescribed everlasting.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-20, which states that any grading activities within or adjacent to the River Corridor SMA shall have grading perimeters clearly marked and inspected prior to grading. The Project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources**.**

In order to avoid and minimize impacts due to hydrologic alterations and water quality impacts, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measure 4.6-58, which requires conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In order to avoid and minimize impacts due to the introduction of non-native, invasive plant species, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-7 and SP-4.6-19:

SP-4.6-7 requires that revegetation plans for the River Corridor SMA include guidelines for the maintenance of the mitigation site during the establishment of plantings, control of non-native plants, maintenance of the irrigation system, and replacement of plants, if necessary

SP-4.6-19 requires that transition areas be in areas where there is no steep grade separation; that native riparian plants be incorporated into landscaping where feasible; that roads and bridges be designed to discourage access to River Corridor SMA; that bank stabilization be composed of ungrouted rock; and that a minimum 100-foot-wide buffer be provided between top river-side of bank stabilization and development.

In order to avoid and minimize impacts due to increased human activity and trampling and the compaction of soils, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-17, SP-4.6-18 and SP-4.6-19, and SP-4.6-24:

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-24 states that the River Corridor SMA conservation and public access easement shall prohibit grazing and agriculture and shall restrict recreational use to the established trail system.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA in a natural state. These measures include SP-4.6-1 through SP-4.6-16 and SP-4.6-63, SP-4.6-17, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-47a, and SP-4.6-55 and SP-4.6-58:

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area.

Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

SP-4.6-47a permits mitigation banking within the River Corridor SMA, High Country SMA, and Open Area, subject to requirements for riparian habitats, oak resources, and Mexican elderberry scrub.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate secondary impacts to the undescribed everlasting.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, as well as from hydrologic alterations and water quality impacts, this EIS/EIR identifies Mitigation Measures BIO-45 and BIO-52:

BIO-45 defines the timing and design of stream diversion bypass channels and dewatering activities and related restrictions to ensure that proper construction, operation, and abandonment diversion or dewatering will occur.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements, conduct meetings with contractor describing the importance of restricting work to the restricted areas, discuss procedures for minimizing harm to or harassment of wildlife, review the construction area in the field with the contractor in accordance with the final grading plan, conduct a final field review of staking, be present during initial vegetation clearing and grading, and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to further avoid and minimize impacts from dust, runoff, and sedimentation, erosion, and chemical and toxic compound pollution, this EIS/EIR identifies Mitigation Measures BIO-70 and BIO-71:

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction, as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 requires dust control measures for development areas to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control plans shall comply with SCAQMD Rule 403 (SCAQMD 2005), and chemical dust suppression shall not be utilized within 100 feet of known special-status plant communities.

Short-term secondary impacts associated with runoff, sedimentation, erosion, and chemical and toxic compound pollution and with hydrologic alterations and water quality impacts would also be mitigated by implementation of Mitigation Measure BIO-49, which prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, this EIS/EIR identifies Mitigation Measure BIO-72, which specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

In order to avoid and minimize impacts from increased human activity and trampling, this EIS/EIR identifies Mitigation Measure BIO-73, which requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

In order to address both short-term and long-term secondary impacts to this species, this EIS/EIR identifies Mitigation Measure BIO-75 and BIO-76:

To mitigate for the removal of individuals during construction, BIO-75 requires pre-construction focused surveys for the undescribed species of everlasting within suitable habitat for the species. The surveys shall be conducted up to one year prior to commencement of construction activities. Should the species be documented within the Project boundary, avoidance measures shall be

implemented to minimize impacts to individual plants wherever feasible. These measures shall include minor adjustments to the boundaries/location of haul routes and other Project features. If, due to Project design constraints, avoidance of all plants is not possible, then further measures, described in BIO-76, shall be implemented to salvage seeds and/or transplant individual plants. BIO-76 states that prior to the issuance of grading permits, the applicant shall develop an Undescribed Everlasting Mitigation and Monitoring Plan to be implemented if surveys conducted in accordance with BIO-75 are positive. The Plan shall provide for replacement of individual plants to be removed at a minimum 1:1 ratio, within suitable habitat at a site where no future construction-related disturbance will occur. The Plan shall specify requirements for the selection of the mitigation site; methods for harvesting seeds or salvaging and transplantation of individual plants; site preparation procedures; a schedule and action plan to maintain and monitor the mitigation area; criteria and performance standards; measures to exclude unauthorized entry into the mitigation areas; and contingency measures.

Each potential secondary impact would also be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA in a natural state. These measures include Mitigation Measures BIO-1 through BIO-16 and BIO-73:

BIO-1 through BIO-16 include requirements for the development and implementation of mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the undescribed everlasting species would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

UNDESCRIBED SUNFLOWER (NO CURRENT STATUS)

Life History

In June 2002, undescribed sunflower (*Helianthus* sp. *nova*) plants were observed growing in a seep area south of the Santa Clara River between Middle Canyon and San Jose Flats (Dudek and Associates 2002A) (**Figure 4.5-14,** River Corridor SMA – Special-Status Species Occurrences; **Figure 4.5-23,** Middle Canyon Spring– Vicinity Map; **Figure 4.5-24,** Middle Canyon Spring– Existing Conditions). A specimen was collected and sent to the herbarium at the University of California at Berkeley, where it was determined to be Los Angeles sunflower (*Helianthus nuttallii* ssp. *parishii*) by Dr. John Strother (Errter 2002). Los Angeles sunflower was last seen in 1937 and was presumed to be extinct (CNPS 2007). Then the plant specimen (and other specimens) was then sent to Dr. Loren Rieseberg and Dr. Charles Heiser at the University of Indiana and was identified as Nuttall's sunflower (*Helianthus nuttallii* ssp. *nuttallii*), which is a more common sunflower species. Based on pollen electron microscopy and chromosome counts, it is likely that the undescribed sunflower species in question is a hybrid between *H. nuttallii* and California sunflower (*H. californicus*) or an intermediate evolutionary step between the two species (Porter and Fraga 2004). Dr. David Keil, editor of the sunflower family for the upcoming revised edition of the Jepson Manual, plans to publish a formal description of the plant, treating it as a new species (Keil 2006). Upon publication and formal recognition, the undescribed sunflower would immediately meet criteria for listing as threatened or endangered under state and federal Endangered Species Acts.

Currently, very little is known about the ecology of this sunflower. This rhizomatous perennial grows in water-saturated soil and gravel along the margin of a slight rise within the Middle Canyon Spring, which drains into the south side of the Santa Clara River just upstream of its confluence with Castaic Creek. During surveys conducted by Dudek in September 2002, the ground was cool and completely wet, during the driest year in recorded history; therefore, the area is likely to be wet all year long (Dudek and Associates 2002A). This sunflower grows to a height of 10 to 16 feet, rising above surrounding vegetation, and remains in the sun throughout most of the day. Honey bees, cabbage white butterflies, and damselflies were observed visiting these flowers in 2002 (Dudek and Associates 2002A). The blooming period of the related Nuttall's sunflower is July through September, and for California sunflower is June through October (Munz 1974). The undescribed sunflower has been observed to bloom in August and September (Dudek and Associates 2002A).

Because this species is only known to occur in one location, and that is within Middle Canyon Spring, which is supported by groundwater, it would seem that a major threat to the undescribed sunflower would include any changes to groundwater hydrology that could impact groundwater and surface water quantity and quality at the spring. Proposed development could remove native vegetation upslope, increase runoff from roads and other paved surfaces, and result in an increase

in ornamental landscaping and lawns, all of which ultimately lead to increased irrigation. In addition to the immediate adverse effects that would occur to the sunflower as a result of changes in the hydrology of the spring, these consequences can result in increased erosion and transport of surface matter into known undescribed sunflower populations. Altered erosion, increased surface flows, and underground seepage could allow for the establishment of non-native plants. Non-native plant species, which compete for light, water, and nutrients, have also been found to invade native vegetation communities and to become established after repeated burnings, clearing of vegetation, or trampling or following periods of drought and overgrazing—possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of native species such as the undescribed sunflower.

Survey Results

Observations of the undescribed sunflower species in 2002 (Dudek and Associates 2002A) were made during surveys that focused on the identification and location of special-status plant species. Ten individual undescribed sunflower individuals were observed growing in three to five rhizomatous groups. The undescribed sunflower was observed again in 2004 (FL*x* 2004A).

Focused surveys were conducted in the spring and summer of 2002 through 2007, timed to coincide with the annual blooming period for early-blooming annual species. The surveys typically began in April and extended through August. The precise blooming period for the undescribed sunflower is not known, and different *Helianthus* species bloom at a wide variety of periods throughout the year. The blooming periods of the related Nuttall's sunflower and California sunflower both occur in mid summer (USDA 2007 and USDI 2007, respectively) and partially overlapped with some of the survey periods. The extension of the undescribed sunflower's blooming period beyond the field survey season may have affected observations of this species. This species has definitive habitat requirements, and the surveys focused on suitable habitat. In addition, this is a large, conspicuous plant, and senescent or juvenile stems would have been observed during the non-blooming period.

Surveys conducted by Dudek from 2003 through 2007 did not include the Middle Canyon Spring. Only surveys conducted by FL*x* in 2004 (FL*x* 2004A), a year of below-average rainfall (October 2003–September 2004; WRCC 2007), comprehensively covered the River Corridor SMA and the Middle Canyon Spring. The lack of surveys conducted at Middle Canyon Spring in other years and the below-average rainfall in 2004 may have affected the observations of this species. Because several years of mapped occurrence data are available for the undescribed sunflower, impacts to this species were evaluated by impacts to individuals rather than by loss of habitat

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Impacts to Individuals

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would not result in the direct loss of individuals of the undescribed sunflower species, which is only known to occur within the Middle Canyon Spring. The spring is within a portion of the River Corridor SMA. No undescribed sunflower individuals or habitat are expected to occur within the RMDP or the SCP development area. A span bridge, abutment, and flood control modification within the Middle Canyon drainage would be installed adjacent to the spring as part of the RMDP. Implementation of the RMDP and the SCP would not result in a substantial adverse effect on this species and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). Direct permanent and temporary impacts (Impacts to Individuals) would not be significant because impacts are not expected to occur.

Indirect Permanent Impacts

This species is only known to occur within the Middle Canyon Spring and no undescribed sunflower individuals or habitat occur within the Specific Plan development area; therefore, build-out of the Specific Plan area would not result in the loss of any undescribed sunflower plants. This species has not been observed within the VCC and Entrada planning areas; therefore, build-out of the VCC and Entrada planning areas is not anticipated to result in the loss of any undescribed sunflower plants. Build-out of the Specific Plan, VCC, and Entrada planning areas would not result in a substantial adverse effect on this species and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would not be significant because no impacts would occur.

Combined Direct and Indirect Permanent Impacts

This species is only known to occur within the Middle Canyon Spring and no undescribed sunflower individuals or habitat occur within the RMDP and SCP development area or the Specific Plan development area. None of these individuals would be directly or indirectly lost as a result of implementing the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas. Implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would not result in a substantial adverse effect on this species (even if a few plants were to be located in the development area prior to construction), and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Impacts to Individuals) to this species would not be significant because impacts are not expected to occur as the undescribed sunflower has not been identified in the Project development area.

Secondary Impacts

Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and the build-out of the Specific Plan, VCC, and Entrada planning areas include short-term and long-term impacts. Potential short-term impacts resulting from construction-related activities include accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; and hydrologic alterations and water quality impacts. Potential long-term impacts resulting from the build-out of the Specific Plan development area include the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. No undescribed sunflower plants have been observed within the VCC and Entrada planning areas; therefore, no loss of undescribed sunflower is expected to occur due to build-out of these developments. The potential loss of this undescribed sunflower species as a result of these secondary impacts would constitute a substantial adverse effect on this species and could substantially reduce the number and restrict the range of this species (significance criteria 1 and 7). Secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Impacts to Individuals

Direct Permanent and Temporary Impacts and Indirect Permanent Impacts

The potential for loss of individual undescribed sunflower plants as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would

essentially be similar to Alternative 2 impacts (no known occurrences would be impacted). The undescribed sunflower is only known to occur within the Middle Canyon Spring within the River Corridor SMA portion of the RMDP site. None of these individuals would be directly lost by implementation of the RMDP or the SCP, or build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas. Direct temporary and permanent and indirect permanent impacts (Impacts to Individuals) would not be significant because impacts are not expected to occur.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would essentially be similar to Alternative 2 impacts (no known occurrences would be impacted). The undescribed sunflower is only known to occur within the Middle Canyon Spring within the River Corridor SMA portion of the RMDP site. None of these individuals would be directly lost by implementation of the RMDP or the SCP, or build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas. Combined direct and indirect permanent impacts (Impacts to Individuals) would not be significant because impacts are not expected to occur.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. GSI (2008) concluded that based on an evaluation of current hydrogeologic conditions and modeled post-development conditions the future spring hydrology and water quality would not be substantially altered; however, for purposes of this analysis minor hydrologic changes (increase or decrease in groundwater supply to the spring) were considered as a potential impact. The loss of individual undescribed sunflower and the effects on its habitat due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

This species would not be subject to direct or indirect impacts by the proposed Project. Construction activities would not occur in habitat occupied by this species. The Project would

result in significant secondary impacts to individuals and suitable habitat outside the Project footprint.

The applicant will implement several mitigation measures to avoid, minimize, and mitigate secondary impacts to individuals and associated habitat. Short-term secondary impacts, such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; and hydrologic alterations and water quality impacts would be minimized by providing guidelines for grading and construction activities; by retaining a qualified biologist during all grading and construction activities, by providing erosion control plans, dust control, and an overall Project SWPPP; by providing guidelines for stream diversion; by preventing pollutants from entering flowing streams and storm flows; by requiring that the Specific Plan conform to all provisions of required NPDES permits and water quality permits required by the RWQCB, and by requiring temporary fencing and signage around the Middle Canyon Spring during all phases of construction adjacent to the spring. Long-term secondary impacts to the undescribed sunflower, such as the introduction of non-native, invasive plant species and increased human activity, trampling, and soil compaction, would be minimized to a level that is adverse but not significant by: providing revegetation plans for the River Corridor SMA; placing restrictions on plant palettes proposed for use on landscaped slopes; restricting access to, grazing within, and recreational usage of the River Corridor SMA; and providing for transition areas along the River Corridor SMA.

As described above, a number of factors may affect the long-term viability of the undescribed sunflower. In order to address both short-term and long-term secondary impacts to this species, the applicant will prepare a plan that identifies measures to maintain the undescribed sunflower species. The plan (outlined in BIO-77 below) will provide guidelines for collecting additional data on existing site conditions, developing a construction monitoring program and a post-development monitoring program, developing threshold parameters that activate consultation with CDFG and adaptive management measures for water quality and water quantity issues, excluding unauthorized entry into the spring, and contingency measures. BIO-77 identifies interim thresholds to trigger immediate consultation with CDFG, and any actions, if needed, to offset potential effect, should data indicate a deviation of more than 10% from the existing condition. The plan shall be subject to the approval of CDFG prior to disturbance within 100 feet of flowing water in the Middle Canyon drainage and/or 200 feet of Middle Canyon Spring.

Additionally, both short-term and long-term secondary impacts will be minimized through revegetation, restoration, and enhancement plans designed to provide for the long-term maintenance of the River Corridor SMA in a natural state and through the implementation of the plan.

All specific mitigation measures for the undescribed sunflower are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-169 SECONDARY IMPACTS – UNDESCRIBED SUNFLOWER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to the undescribed sunflower.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-20, which states that any grading activities within or adjacent to the River Corridor SMA shall have grading perimeters clearly marked and inspected prior to grading. The Project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources**.**

In order to avoid and minimize impacts due to hydrologic alterations and water quality impacts, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measure 4.6-58, which requires conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In order to avoid and minimize impacts due to the introduction of non-native, invasive plant species, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-7 and SP-4.6-19:

SP-4.6-7 requires that revegetation plans for the River Corridor SMA include guidelines for the maintenance of the mitigation site during the establishment of plantings, control of non-native plants, maintenance of the irrigation system, and replacement of plants, if necessary.

SP-4.6-19 requires that transition areas be in areas where there is no steep grade separation, that native riparian plants be incorporated into landscaping where feasible, that roads and bridges be designed to discourage access to River Corridor SMA, that bank stabilization be composed of ungrouted rock, and that a minimum 100-foot-wide buffer be provided between top river-side of bank stabilization and development.

In order to avoid and minimize impacts due to increased human activity, trampling, and the compaction of soils, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-17, SP-4.6-18 and SP-4.6-19, and SP-4.6-24:

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-24 states that the River Corridor SMA conservation and public access easement shall prohibit grazing and agriculture and shall restrict recreational use to the established trail system.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA in a natural state. These measures include SP-4.6-1 through SP-4.6-16 and SP-4.6-63, SP-4.6-17, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-47a, and SP-4.6-55 and SP-4.6-58:

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

SP-4.6-47a permits mitigation banking within the River Corridor SMA, High Country SMA, and Open Area, subject to requirements for riparian habitats, oak resources, and Mexican elderberry scrub.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate secondary impacts to the undescribed sunflower.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, as well as from hydrologic alterations and water quality impacts, this EIS/EIR identifies Mitigation Measures BIO-45, BIO-52, and BIO-74:

BIO-45 defines the timing and design of stream diversion bypass channels and dewatering activities and related restrictions to ensure that proper construction, operation, and abandonment diversion or dewatering will occur.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements, conduct meetings with contractor describing the importance of restricting work to the restricted areas, discuss procedures for minimizing harm to or harassment of wildlife, review the construction area in the field with the contractor in accordance with the final grading plan, conduct a final field review of staking, be present during initial vegetation clearing and grading, and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-74 requires installation of temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to construction within 200 feet of the spring and, if applicable, within 100 feet of flowing water in the Middle Canyon drainage. Permanent fencing and signage shall be erected along the bordering subdivision tract following construction. A qualified biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. Any upslope

runoff from construction areas will be directed away from the Middle Canyon Spring. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

In order to further avoid and minimize impacts from dust, runoff, sedimentation, erosion, and chemical and toxic compound pollution, this EIS/EIR identifies Mitigation Measures BIO-70 and BIO-71:

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 requires dust control measures for development areas to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control plans shall comply with SCAQMD Rule 403 (SCAQMD 2005), and chemical dust suppression shall not be utilized within 100 feet of known special-status plant communities.

Short-term secondary impacts associated with runoff, sedimentation, erosion, and chemical and toxic compound pollution and with hydrologic alterations and water quality impacts would also be mitigated by implementation of Mitigation Measure BIO-49, which prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, this EIS/EIR identifies Mitigation Measure BIO-72:

BIO-72 specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

In order to avoid and minimize long-term secondary impacts from increased human activity and trampling, this EIS/EIR identifies Mitigation Measures BIO-73 and BIO-74:

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-74 requires installation of temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to construction within 200 feet of the spring and, if applicable,

within 100 feet of flowing water in the Middle Canyon drainage. Permanent fencing and signage shall be erected along the bordering subdivision tract following construction. A qualified biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. Any upslope runoff from construction areas will be directed away from the Middle Canyon Spring. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

In order to address long-term secondary impacts to this species related to water quality and quantity, light from Commerce Center Drive bridge, and light and noise from vehicles, this EIS/EIR identifies Mitigation Measures BIO-77 and BIO-51:

BIO-77 describes preparation of a plan and measures to be implemented by the applicant to maintain the populations of the undescribed snail and sunflower species. The plan will provide guidelines for collecting data on existing site conditions, developing a construction monitoring program and a post-development monitoring program, developing threshold parameters that activate adaptive management measures for water quality and water quantity issues, excluding unauthorized entry into the spring, and contingency measures. The plan shall be subject to the approval of CDFG prior to disturbance within 100 feet of flowing water in the Middle Canyon drainage and/or 200 feet of Middle Canyon Spring.

BIO-51 will minimize impacts to natural areas and riparian resource, including the Middle Canyon Spring, from associated lighting and stormwater runoff associated with bridges (*i.e.*, Commerce Center Drive bridge) over the Santa Clara River. All lighting will be designed to be directed away from natural areas (pursuant to SP-4.6-56) using shielded lights, low sodium-vapor lights, bollard lights, or other available light and glare minimization methods. Bridges will be designed to minimize normal vehicular lighting from trespassing into natural areas using side walls a minimum of 24 inches high. All stormwater from the bridges will be directed to water treatment facilities for water quality treatment.

Secondary impacts would also be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA in a natural state. These measures include Mitigation Measures BIO-1 through BIO-16 and BIO-73:

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of

success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to previously undescribed sunflower species would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

ISLAND MOUNTAIN-MAHOGANY (CNPS LIST 4.3/S3.3)

Life History

Island mountain-mahogany (*Cercocarpus betuloides* var. *blancheae*) is a shrub or small tree of the Rose family that is endemic to California's Ventura and Los Angeles counties, including the Channel Islands (except San Clemente Island) (CNPS 2007; Hickman 1993). It is found primarily on dry rocky slopes and washes at elevations between 30 and 600 meters AMSL (Dole and Rose 1996). It is an evergreen shrub or shrubby tree, typically found in chaparral and closed-cone coniferous forests. It is fire-adapted and resprouts readily from rootstocks the growing season following a fire (Twisselmann 1995).

Island mountain-mahogany is distinguished from the more common birch-leaf mountain-mahogany by its larger leaves with more lateral veins, more flowers per inflorescence, and generally shorter style on mature fruits (Hickman 1993). It is a large and conspicuous shrub and can be identified year-round from its leaf characteristics. It generally blooms between February and May and produces seed during late summer (CNPS 2007; Hickman 1993). The flowers are wind pollinated, and seeds are dispersed by wind and small mammals. Seeds dispersed by wind can travel up to 450 feet from the parent plant (Gucker 2006).

In addition to the direct loss of individuals, island mountain-mahogany is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives such as the island mountain-mahogany. Exotic plants can also alter hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development.

Survey Results

Island mountain-mahogany was observed within the Entrada planning area in 2003, 2004, and 2005 (Dudek 2004E, 2004H, 2006G). Within the Specific Plan area, island mountain-mahogany was recorded annually from 2002 to 2006 (Dudek 2002A, 2004C, 2004F, 2006F, 2006I). Observations of this species were made within the Salt Creek area in 2003 (Dudek 2004I). This species has not been observed within the VCC planning area (Dudek 2002C, 2004B, 2004G, 2006H, 2006K, 2007H). Island mountain-mahogany was found primarily in chaparral at the base of north-facing slopes.

Because focused surveys were conducted in spring and summer (2001 through 2005), most occurred during and after the annual blooming period for island mountain-mahogany, which blooms from February to May (CNPS 2007). The surveys typically began in April and extended through August. This factor may have affected detection of this species. Surveys in 2006 and 2007 focused on the identification of San Fernando Valley spineflower only within known occurrences, reducing the total survey area and, consequently, the number of other documented special-status species observed; this could explain why island mountain-mahogany was recorded only within the Specific Plan area in 2006 and not at all in 2007. This species is a large shrub and was observed and identified during the blooming period and the non-blooming period.

Given the status of the species (CNPS List 4.3), the exact locations of individuals of this species within the Project area have not been mapped, but island mountain-mahogany is known to occur as an occasional component of chaparral vegetation communities within the Specific Plan and Entrada planning areas. Therefore, impacts to this species were evaluated by loss of habitat instead of impacts to individuals. A total of 2,286 acres of suitable habitat (chaparral vegetation communities) is present in the Project area (**Figures 4.5-11-A1** through **4.5-11-C2**, RMDP/SCP – Vegetation Communities and Land Covers, **Figure 4.5-20**, VCC SCP Site – Vegetation Communities and Land Covers, and **Figure 4.5-21**, Entrada RMDP/SCP Site – Vegetation Communities and Land Covers).

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP would result in the direct loss of 30 acres (1.3%) of suitable habitat for this species (within both the permanent and temporary footprints) out of 2,286 acres on site (**Figures 4.5-33-A1** through **4.5-33-D2**). No island mountain-mahogany individuals would be directly lost by implementation of the SCP. Although this species has a relatively low sensitivity ranking (California Heritage S3.3 ranking indicates no current threats known), the direct loss of island mountain-mahogany

occupying this habitat as a result of construction/grading activities would be considered a substantial adverse effect on this species and would constitute a substantial direct adverse effect on this species (significance criterion 1). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan and Entrada planning areas would result in the loss of approximately 519 acres (22.7%) of suitable habitat within these areas (**Figure 4.5-33-A1** through **4.5-33-D2**). Individual island mountain-mahogany plants occurring within suitable habitat would be lost as a result of build-out of these planning areas. Because this species has not been observed within the VCC planning area, build-out of the VCC planning area is not anticipated to impact any island mountain-mahogany plants. Although this species has a relatively low sensitivity ranking (California Heritage S3.3 ranking indicates no current threats known), the potential loss of island mountain-mahogany individuals and the effect on suitable habitat as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would not constitute a substantial adverse effect on this species (significance criterion 1). Indirect, permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas would total 549 acres (24.0%). Although this species has a relatively low sensitivity ranking (California Heritage S3.3 ranking indicates no current threats known), the combined direct and indirect permanent impacts to island mountain-mahogany individuals and suitable habitat would constitute a substantial adverse effect on this species (significance criterion 1). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas could occur to island mountain-mahogany. These include accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; hydrologic alterations and water quality impacts; the introduction of non-native, invasive plant species; increased human activity, trampling, and soil compaction; and increased risk of fire. Although this species has a relatively low sensitivity ranking (California Heritage S3.3 ranking indicates no current threats known)**,** the potential loss of island mountain-mahogany individuals and the effect on suitable habitat resulting from these secondary impacts would constitute a

substantial adverse effect on this species (significance criterion 1). Secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to suitable habitat for island mountain-mahogany (**Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 29 acres (1.3%) of permanent loss;
- Alternative 4 – 31 acres (1.4%) of permanent loss;
- Alternative 5 – 30 acres (1.3%) of permanent loss;
- Alternative 6 – 30 acres (1.3%) of permanent loss; and
- Alternative 7 – 34 acres (1.5%) of permanent loss.

Compared to Alternative 2, which would result in the direct loss of 30 acres, the direct loss of habitat under Alternatives 3 through 6 would not be substantially different. The difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in greater impacts along the adjacent uplands under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is not substantially different than overall habitat loss under Alternative 2, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan and Entrada planning areas would result in the following indirect impacts to suitable habitat for island mountain-mahogany (**Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 506 acres (22.1%) of permanent loss;
- Alternative 4 – 496 acres (21.7%) of permanent loss;
- Alternative 5 – 498 acres (21.8%) of permanent loss;

- Alternative 6 – 490 acres (21.4%) of permanent loss; and
- Alternative 7 – 379 acres (16.6%) of permanent loss.

Compared to Alternative 2, which would result in 519 acres (22.7%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternative 7 would have the least impact because there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that would reduce impacts to island mountain-mahogany suitable habitat.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the loss of habitat on site. The indirect permanent loss of suitable habitat for island mountain-mahogany occurring as a result of build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas would result in the following impacts to suitable habitat for island mountain-mahogany:

- Alternative 3 – 535 acres (23.4%) of permanent loss;
- Alternative 4 – 527 acres (23.1%) of permanent loss;
- Alternative 5 – 528 acres (23.1%) of permanent loss;
- Alternative 6 – 520 acres (22.7%) of permanent loss; and
- Alternative 7 – 413 acres (18.1%) of permanent loss.

Compared to Alternative 2, which would result in 549 acres (24.0%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 6 would not be substantially different compared with impacts associated with Alternative 2, as described above for the discussions of direct and indirect impacts. Reduced impacts would occur because of additional pullbacks from the Santa Clara River (and its tributaries), and other Project footprint reductions that would occur under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for island mountain-mahogany occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The loss of or degradation of suitable habitat and the loss of island mountain-mahogany individuals due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to island mountain-mahogany: (1) loss of habitat, and (2) secondary impacts to individuals and suitable habitat outside the Project footprint.

Loss of habitat (and associated impacts to occasional individual island mountain-mahogany plants) could occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment. The combined permanent loss of island mountain-mahogany habitat would range from 413 acres (18.1%) under Alternative 7 to 549 acres (24.0%) under Alternative 2. The combined permanent loss of this habitat would have a substantial adverse effect on this species. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. At least 1,486 acres of suitable habitat will be conserved in the High Country SMA and Salt Creek area where long-term preservation is provided. Mitigation measures for the preservation and management of the 4,205-acre High Country SMA would protect approximately 1,362 acres of suitable island mountain-mahogany habitat (Dudek 2007A) and would allow island mountain-mahogany to persist on site in perpetuity.

Short-term secondary impacts, such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; and hydrologic alterations and water quality impacts, would be minimized by providing guidelines for grading and construction activities; by retaining a qualified biologist during all grading and construction activities; by providing erosion control plans, dust control, and an overall Project SWPPP; by preventing pollutants from entering flowing streams and storm flows; by providing guidelines for stream diversion; and by requiring that the Specific Plan conform to all provisions of required NPDES permits and water quality permits required by the RWQCB. Long-term secondary impacts to island mountain-mahogany, such as the introduction of non-

native, invasive plant species; hydrologic alterations and water quality impacts; increased human activity, trampling, and soil compaction; and increased risk of fire, would be minimized by restricting access to, grazing within, and recreational usage of the High Country SMA; providing for transition areas along the High Country SMA; providing drainage guidelines; requiring conformance with NPDES and RWQCB permit provisions; requiring the implementation of a wildfire fuel modification plan (Dudek 2008A); placing restrictions on domestic animals in proximity to open space areas; providing trail signage and homeowner education; and placing restrictions on plant palettes proposed for use on landscaped slopes.

All specific mitigation measures for island mountain-mahogany are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-170 LOSS OF HABITAT – ISLAND MOUNTAIN-MAHOGANY

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to avoid, minimize, or mitigate the loss of habitat (chaparral vegetation communities) for island mountain-mahogany.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where chaparral vegetation communities occurs. Transition from the development edge to the natural area (where chaparral vegetation communities occur) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA, which supports 1,362 acres of chaparral vegetation communities.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two mitigation measures to reduce the loss of habitat (chaparral vegetation communities) for island mountain-mahogany.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA, both of which support chaparral vegetation communities and island mountain-mahogany occurrences. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-62 states that at least 1,900 acres of Open Area within the Specific Plan area shall be offered for dedication to a NLMO. These 1,900 acres of the Open Area will be left as natural vegetation.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, impacts associated with the loss of habitat for island mountain-mahogany would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-171 SECONDARY IMPACTS – ISLAND MOUNTAIN-MAHOGANY

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to island mountain-mahogany.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-32, SP-4.6-34, and SP-4.6-35:

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-34 and SP-4.6-35 establish that grading perimeters shall be clearly marked and inspected by the Project biologist prior to impacts occurring within or adjacent to the High Country SMA, and that the biologist shall work with the grading contractor to avoid inadvertent impacts to biological resources outside of the grading area.

Secondary impacts associated with accidental clearing, trampling, and grading would be further mitigated by implementation of Mitigation Measure SP-4.6-33, which permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where chaparral vegetation communities occur. Transition from the development edge to the natural area (where chaparral vegetation communities occur) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-33, which permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where chaparral vegetation communities occur. Transition from the development edge to the natural area (where chaparral vegetation communities occur) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

In order to avoid and minimize impacts from increased human activity and trampling, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-29 through SP-4.6-32, SP-4.6-33, and SP-4.6-39:

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where chaparral vegetation communities occur. Transition from the development edge to the natural area (where chaparral vegetation communities occur) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-39 states that the High Country SMA easements shall prohibit grazing within the High Country SMA, except for long-term resource management programs, and shall restrict recreation to the established trail system.

In order to avoid and minimize impacts from hydrologic and water quality–related impacts adjacent to and downstream of construction activities, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-44 and SP-4.6-45, which provide guidelines for major drainages (which are in proximity to chaparral vegetation communities), and SP-4.6-58, which requires conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In order to avoid and minimize impacts from increased fire frequency, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-31, SP-4.6-32, SP-4.6-33, and SP-4.6-49 through SP-4.6-52:

SP-4.6-31 prohibits hunting, fishing, and motor or off-trail bike riding within the High Country SMA.

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-49 through SP-4.6-52 describe wildfire fuel modification plans and fuel modification measures that will minimize the potential exposure of the development areas, Open Area, and SMAs (which contain chaparral vegetation communities) to fire hazards.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the High Country SMA and Salt Creek area in a natural state. These measures include SP-4.6-27, SP-4.6-29 through SP-4.6-32, SP-4.6-33, SP-4.6-36 through SP-4.6-42, and SP-4.6-55 and SP-4.6-58:

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. This will benefit chaparral vegetation communities located in proximity to drainages.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate short-term and long-term secondary impacts to a level that is adverse but not significant.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading, this EIS/EIR identifies Mitigation Measure BIO-52, which states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to avoid and minimize impacts from dust, runoff, sedimentation, erosion, and chemical and toxic compound pollution, this EIS/EIR identifies Mitigation Measures BIO-52, BIO-70, and BIO-71:

BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial

vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 requires dust control measures for development areas to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control plans shall comply with SCAQMD Rule 403 (SCAQMD 2005), and chemical dust suppression shall not be utilized within 100 feet of known special-status plant communities.

Short-term secondary impacts associated with runoff, sedimentation, erosion, and chemical and toxic compound pollution would be further mitigated by implementation of Mitigation Measure BIO-49, which prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, this EIS/EIR identifies Mitigation Measure BIO-72, which specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

In order to avoid and minimize impacts from increased human activity and trampling, this EIS/EIR identifies Mitigation Measure BIO-69, which requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

In order to avoid and minimize impacts from hydrologic and water quality-related impacts adjacent to and downstream of construction activities, this EIS/EIR identifies Mitigation Measures BIO-49 and BIO-52:

BIO-49 requires that pollutants from construction activities not be allowed to enter a flowing stream or be placed in locations that may be subjected to storm flows. This will benefit chaparral vegetation communities and any island mountain-mahogany located in proximity to drainages.

BIO-52, which states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to avoid and minimize impacts from increased fire frequency, this EIS/EIR identifies Mitigation Measure BIO-63, which requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the High Country SMA and Salt Creek area in a natural state. These measures include BIO-19 and BIO-69:

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA, both of which support chaparral vegetation communities and island mountain-mahogany occurrences. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to island mountain-mahogany would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

LATE-FLOWERED MARIPOSA LILY (CNPS LIST 1B.2/S2.2)

Life History

Late-flowered mariposa lily (*Calochortus weedii* var. *vestus*) is known to occur in Monterey, Santa Barbara, San Luis Obispo, and Ventura counties at elevations between 275 and 900 meters AMSL. It has been documented from the nearby Santa Susana Mountains in Ventura County, located to the west of the Project area (CNPS 2007). This bulbiferous herb is typically found in dry, open chaparral and coastal woodland (Hickman 1993) but is sometimes found in riparian woodland on serpentine soils (CNPS 2007). Late-flowered mariposa lily blooms between June and August (CNPS 2007). It is identified by its flower color (pale cream, purplish, or red-brown, usually with a central blotch and dark hairs on inner surface); squarish petals with a fringe on the margin; and slightly depressed nectar gland hidden by surrounding hairs but without hairs on the gland surface itself.

No species-specific pollination or seed dispersal data are available for late-flowered mariposa lily. Seed dispersal for *Calochortus* is limited, with no obvious adaptations for wind or animal dispersal; fruits are capsular and borne close to the ground, with relatively heavy, passively dispersed seeds that lack fleshiness, sticktights, or (except in one species) wings (Patterson and Givnish 2003). Typically, *Calochortus* flowers are generalists in terms of their pollinators, although bees have been observed to be the primary pollinator in some *Calochortus* species, such as Lyall's mariposa lily (*C. lyallii*) (Dilley *et al.* 2000; Miller 2000).

Perennial bulbs, including late-flowered mariposa lily, may persist below ground without producing flowers or even leaves during years of poor rainfall or other environmental causes. For example, bulbs tend to flower in higher numbers following wildfire, which introduces large quantities of mineral nutrients (as ash) into the soil. Dormant plants (those producing no aboveground growth in a given year) cannot be located by field botanists, and those producing only leaves are unlikely to be found during surveys because the leaves are inconspicuous and visually similar to grass leaves. Thus, numbers of plants observed above ground fluctuates much more widely than numbers of living bulbs in the soil. The number of plants censused even in a "good" year is a minimum estimate of the number of living bulbs in the soil.

In addition to the direct loss of individuals, late-flowered mariposa lily is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives such as the late-flowered mariposa lily.

Exotic plants can also alter hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development.

Survey Results

Late-flowered mariposa lily was observed on steep ridges and slopes in chaparral in the High Country SMA in 2003 (Dudek and Associates 2004I) (**Figure 4.5-17**, High Country SMA and Salt Creek Area – Special-Status Species Occurrences).

All surveys were conducted during and after the blooming season for late-flowered mariposa lily, which occurs from June through August (CNPS 2007). As mentioned above in the Life History section, only a fraction of *Calochortus* plants flower in any given year, and the non-flowering individuals are generally not as visible. It is therefore not possible to estimate what portion was observed. In addition, surveys in the Project development area in 2006 and 2007 focused on the identification of San Fernando Valley spineflower only within known occurrences, reducing the total survey area and, subsequently, the number of other documented special-status species observed. However, given the repeated surveys within the Specific Plan, VCC, and Entrada planning areas, it is assumed that the majority of late-flowered mariposa lily plants on site was observed.

Late-flowered mariposa lily occurrences were mapped utilizing aerial photography and topographic maps. Professional judgment and experience were used to delineate these polygons based on the detectability of the species, topography, and vegetation. This and other perennial special-status plants were mapped at a 10- to 20-meter (32.8- to 65.6-foot) scale due to their population dynamics (including seed dispersal and pollination range), observability, habit, habitat limitations, and mapping accuracy.

Because weather conditions—primarily rainfall—largely determine whether late-flowered mariposa lily blooms in a given year, these factors likely affected the detection of this species. There was a less-than-average amount of rainfall in the 2001-2002, 2003-2004, and 2005-2006 rain seasons (WRCC 2008), and, during the 2006-2007 rain season (October 2006–September 2007), the Piru 2 ESE weather station in Los Angeles County experienced its driest year in recorded history, with 4.1 inches of rain—less than one-quarter of the normal mean amount (17.40 inches) (WRCC 2008). While the amount of rainfall varied during the survey years, the 2002-2003 and 2004-2005 rain seasons were above average, and the cumulative survey results are representative of the distribution of this species on site.

Within the RMDP and SCP sites, late-flowered mariposa lily was found only in the High Country SMA. An estimated number of approximately 150 individuals occupying two locations was observed (Dudek and Associates 2004I). Because several years of mapped occurrence data are available for late-flowered mariposa lily, impacts to this species were evaluated by impacts to individuals rather than by loss of habitat

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Impacts to Individuals

Direct Permanent and Temporary Impacts

At least 150 late-flowered mariposa lily plants in two locations are known from the Project area occur within the High Country SMA portion of the RMDP and SCP site. None of these individuals would be directly lost by implementation of the RMDP or the SCP. Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented late-flowered mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. Implementation of the RMDP and the SCP would not result in a substantial adverse effect on this species (even if a few plants were to be located in the development area prior to construction), and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). Direct impacts (Impacts to Individuals) to this species would not be significant because impacts are not expected to occur as late-flowered mariposa lily has not been identified in the Project development area.

Indirect Permanent Impacts

Within the Specific Plan area, 150 late-flowered mariposa lily individuals were observed in the High Country SMA, outside of the Specific Plan area development footprint. This species was not observed within the VCC or Entrada planning areas. Therefore, build-out of the Specific Plan, VCC, and Entrada planning areas would not result in the loss of known late-flowered mariposa lily plants (**Figure 4.5-146,** Alternative 2 Impacts to RMDP/SCP Special-Status Plants). Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented late-flowered mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be

disturbed by construction. Build-out of the Specific Plan, VCC, and Entrada planning areas would not result in a substantial adverse effect on this species, and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) to this species would not be significant because impacts are not expected to occur as late-flowered mariposa lily has not been identified in the Project development area.

Combined Direct and Indirect Permanent Impacts

The 150 late-flowered mariposa lily plants known from the Project area occur only within the High Country SMA portion of the RMDP site. None of these individuals would be directly or indirectly lost as a result of implementing the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas. Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented late-flowered mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. Implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would not result in a substantial adverse effect on this species (even if a few plants were to be located in the development area prior to construction), and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Impacts to Individuals) to this species would not be significant because impacts are not expected to occur as late-flowered mariposa lily has not been identified in the Project development area.

Secondary Impacts

Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and the build-out of the Specific Plan, VCC, and Entrada planning areas include hydrologic alterations and water quality impacts; accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; increased risk of fire; and increased human activity, trampling, and compaction of soils. Within the RMDP/SCP study area, late-flowered mariposa lily is located only in the High Country SMA, outside of the impact footprint for the RMDP/SCP and for the Specific Plan, VCC, and Entrada planning areas. The late-flowered mariposa lily occurrences are located several thousands of feet from the nearest residential development in the proposed Potrero Village and are not expected to experience secondary impacts from residential development. Both locations of late-flowered mariposa lily are located within 300 feet of the proposed trails in the High Country SMA, making these individuals susceptible to trampling or plant collecting by recreational visitors in the High Country SMA. However, because this species has an underground bulb, even if a plant were

trampled or a flower were picked, individuals would likely not be lost. Therefore, the potential loss of late-flowered mariposa lily and the effect on its habitat as a result of these secondary impacts would not constitute a substantial adverse effect on this species or cause a substantial reduction in the number or a reduction in the range of this species (significance criteria 1 and 7). Secondary impacts would be adverse, but not significant.

ALTERNATIVES 3 THROUGH 7

Impacts to Individuals

Direct Permanent and Temporary Impacts and Indirect Permanent Impacts

The 150 late-flowered mariposa lily plants known from the Project area occur only within the High Country SMA portion of the RMDP site. None of these individuals would be directly lost by implementation of the RMDP or the SCP or build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas (**Figures 4.5-147** through **4.5-151**, Alternatives 3 through 7 Impacts to RMDP/SCP Special-Status Plants). The potential for impacts to individual late-flowered mariposa lily plants as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would essentially be the same as for Alternative 2. Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented late-flowered mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. The relative risk of impacts to undocumented late-flowered mariposa lily would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Direct and indirect impacts (Impacts to Individuals) to this species would not be significant because impacts are not expected to occur as late-flowered mariposa lily has not been identified in the Project development area.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would be similar to Alternative 2. The 150 late-flowered mariposa lily plants known from the Project area occur only within the High Country SMA portion of the RMDP site. None of these individuals would be directly lost by implementation of the RMDP or the SCP, or build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas. Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented late-flowered mariposa lily occurrences, consisting of

relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. The relative risk of impacts to undocumented late-flowered mariposa lily would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Combined direct and indirect permanent impacts (Impacts to Individuals) would not be significant because impacts are not expected to occur.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The impacts to individual late-flowered mariposa lily and the effect on its habitat due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 would be adverse, but not significant.

Mitigation Strategy and Summary

This species would not be subject to significant direct, indirect, or secondary impacts by the proposed Project. Construction activities would not occur in habitat occupied by this species. Although no mitigation is required, late-flowered mariposa lily will benefit from previously incorporated Mitigation Measures SP-4.6-53 and SP-4.6-59, which state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required. In addition, the 150 known late-flowered mariposa lily plants would be conserved in the High Country SMA.

MAINLAND CHERRY (LOCALLY REGULATED)

Life History

Mainland cherry (*Prunus ilicifolia* ssp. *ilicifolia*) is a sclerophyllous, broad-leaved shrub or shrubby tree found throughout the central and southern Coast Ranges and from Napa County southward to Baja California (Hickman 1993; McMurray 1990). It is a shrub of the Rose family. In southern California, it is a component of mesic chaparral below 1,600 meters (5,905 feet) AMSL within foothill woodland, chaparral, and coastal scrub communities (McMurray 1990; Dole and Rose 1996). In mature chaparral communities, holly-leafed cherry will occur as a dominant woody species in relatively moist, cool sites, such as eroded channels, arroyos, depressions, washes, and the toes and shoulders of slopes (McMurray 1990; Dole and Rose 1996). The species is able to establish as a widespread component of fire-prone environments because of vigorous resprouting. Population expansion and seedling establishment primarily occur during extended fire-free periods because seedlings can develop in gaps created by the death of shorter-lived species (McMurray 1990).

Mainland cherry blooms between March and May (CalFlora 2008), but it is a conspicuous shrub and it can be recognized year-round by its leaf characteristics. This species is pollinated by insects, including bees (Plants for a Future 2007; California Gardens 2007). The fruit is eaten, and presumed dispersed, by birds and mammals, including bear and coyote (California Gardens 2007).

In addition to the direct loss of individuals, mainland cherry is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives such as the mainland cherry. Exotic plants can also alter hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development.

Survey Results

Within the Specific Plan area, mainland cherry was recorded in 2001, 2002, 2003, 2004, 2005, and 2006 within undifferentiated chaparral, big sagebrush scrub, and river wash (Dudek and Associates 2002A, 2004C, 2004F, 2006F, 2006I; FL*x* 2002A). Observations of this species were made within the VCC planning area in 2003, 2004, 2005, and 2006 within undifferentiated chaparral, big sagebrush scrub, and river wash (Dudek and Associates 2004B, 2004G, 2006H, 2006K). Mainland cherry was observed within the Entrada planning area as an occasional

component of undifferentiated chaparral, big sagebrush scrub, and river wash in 2003, 2004, 2005, 2006, and 2007 (Dudek and Associates 2004E, 2004H, 2006G, 2006J; Dudek 2007F).

Focused surveys for special-status plant species were conducted in spring and summer 2001 through 2007, coincident with the annual blooming period for mainland cherry, which blooms from March through May (CalFlora 2008). The surveys typically began in April and extended through August. Surveys in 2006 and 2007 focused on the identification of San Fernando Valley spineflower only within known occurrences, reducing the total survey area and, subsequently, the number of other documented special-status species observed. This species is a large, conspicuous tree or shrub and was observed and identified during the blooming period and the non-blooming period.

This species was observed within the RMDP and SCP area in 2001, 2002, 2003, 2004, 2005, 2006, and 2007. Given the low sensitivity status of the species, the exact locations of individual mainland cherry shrubs were not mapped. Therefore, impacts to this species were evaluated by loss of habitat instead of impacts to individuals. A total of 424 acres of suitable habitat for mainland cherry (undifferentiated chaparral, big sagebrush scrub, and river wash) is present in the Project area (**Figures 4.5-11-A1** through **4.5-11-C2**, RMDP/SCP – Vegetation Communities and Land Covers, **Figure 4.5-20**, VCC SCP Site – Vegetation Communities and Land Covers, and **Figure 4.5-21**, Entrada RMDP/SCP Site – Vegetation Communities and Land Covers).

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP would result in the direct loss of 88 acres (20.8%) of suitable habitat for this species (within both the permanent and temporary footprints) out of 424 acres on site (**Figures 4.5-33-A1** through **4.5-33-D2**, Alternative 2 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). No suitable habitat would be directly lost by implementation of the SCP.

The loss of mainland cherry suitable habitat as a result of implementation of the RMDP would have a substantial adverse effect on a species designated as special-status by the County of Los Angeles and would, therefore, be a significant impact (significance criterion 1). Direct impacts to mainland cherry (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent loss of 81 acres (19.1%) of suitable habitat for mainland cherry within these areas (**Figures 4.5-33-A1** through **4.5-33-D2**, Alternative 2 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). Individual mainland cherry plants occurring within suitable habitat would be lost as a result of build-out of these planning areas. The potential loss of mainland cherry individuals and the effect on suitable habitat as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on a species designated as special-status by the County of Los Angeles and would, therefore, be a significant impact (significance criterion 1). Indirect permanent impacts to mainland cherry (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of mainland cherry suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 169 acres (39.9%). The combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on a species designated as special-status by the County of Los Angeles and would, therefore, be a significant impact (significance criterion 1). The combined direct and indirect permanent impacts to mainland cherry (Loss of Habitat) would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; hydrologic alterations and water quality impacts; the introduction of non-native, invasive plant species; increased human activity, trampling, and soil compaction; and increased risk of fire. The potential loss of mainland cherry and the effect on its habitat as a result of these secondary impacts would constitute a substantial adverse effect to this species (significance criterion 1). Secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to suitable habitat for mainland cherry (**Figures 4.5-34-A1** through **4.5-38-D2**, Alternatives 3 through 7 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities):

- Alternative 3 – 89 acres (21.0%) of permanent loss ;
- Alternative 4 – 83 acres (19.6%) of permanent loss ;
- Alternative 5 – 91 acres (21.5%) of permanent loss ;
- Alternative 6 – 78 acres (18.4%) of permanent loss ; and
- Alternative 7 – 62 acres (14.7%) of permanent loss.

Compared to Alternative 2, which would result in the direct loss of 88 acres (20.8%) of mainland cherry suitable habitat, the permanent and temporary loss of habitat under Alternatives 3 through 6 would not be substantially different. The difference between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in fewer permanent impacts and relatively more temporary impacts to mainland cherry suitable habitat under Alternative 7.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is generally similar to the loss under Alternative 2, these impacts would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to suitable habitat for mainland cherry (**Figures 4.5-34-A1** through **4.5-38-D2**, Alternatives 3 through 7 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communitie**s**):

- Alternative 3 – 63 acres (14.8%) of permanent loss;
- Alternative 4 – 48 acres (11.3%) of permanent loss;
- Alternative 5 – 48 acres (11.3%) of permanent loss;
- Alternative 6 – 24 acres (5.7%) of permanent loss; and
- Alternative 7 – 15 acres (3.5%) of permanent loss.

Compared to Alternative 2, which would result in 81 acres (19.1%) of indirect permanent loss of mainland cherry suitable habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4, 5, and 6 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under those alternatives. Alternative 7 would have the least impact because VCC would not be constructed and there would be additional pullbacks from the Santa Clara River and its tributaries, as well as other changes in the Project footprint that would reduce impacts to mainland cherry suitable habitat.

Although Alternatives 3 through 7 would all have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the loss of habitat on site. The indirect permanent loss of suitable habitat for mainland cherry occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for mainland cherry:

- Alternative 3 – 152 acres (35.8%) of permanent loss;
- Alternative 4 – 131 acres (30.9%) of permanent loss;
- Alternative 5 – 139 acres (32.8%) of permanent loss;
- Alternative 6 – 102 acres (24.1%) of permanent loss; and
- Alternative 7 – 77 acres (18.2%) of permanent loss.

Compared to Alternative 2, which would result in 169 acres (32.9%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts; as described above, impacts would be reduced because VCC would not be constructed under Alternatives 4 through 7, and additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions would occur under Alternative 7. Although Alternatives 3 through 7 would all have reduced impacts compared to Alternative 2, these impacts would still be adverse because of the loss of habitat on site. The combined direct and indirect permanent loss of suitable habitat for mainland cherry occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2, because each alternative has similar short-term construction activities and long-term effects due to factors such as increased runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The loss of or degradation of suitable habitat and the loss of mainland cherry individuals due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to mainland cherry: (1) loss of suitable habitat, and (2) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to habitat and associated individuals could occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment. The combined permanent loss of suitable habitat for the mainland cherry resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 77 acres (18.2%) under Alternative 7 to 169 acres (32.9%) under Alternative 2. The combined permanent loss of suitable habitat and associated individuals would have a substantial adverse effect on a species designated as special-status by the County of Los Angeles. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to habitat and associated individuals. Pre-construction surveys for mainland cherry will be conducted, and mainland cherry trees and shrubs will be replaced in conformance with the oak tree ordinance (*e.g.*, County of Los Angeles 1988) in effect at that time, and mainland cherry trees or shrubs outside riparian areas greater than one inch diameter at breast height (dbh) shall be replaced at a ratio of at least 2:1. The proposed mitigation, through guidelines supplied by the Oak Resources Management Plan and through the preservation and long-term management of the High Country SMA, River Corridor SMA, Salt Creek area, and Open Area, provides mitigation for the loss of tree resources in a manner that emphasizes: (1) restoring the natural regeneration capabilities of preserved woodlands in order to restore and improve forest diversity and value on a long-term basis and (2) creating new woodlands in areas that supported mainland cherry prior to development and in areas that will enhance wildlife movement and habitat functions. General procedures to avoid and minimize impacts to mainland cherry habitat and associated individuals during construction

will be implemented, and a qualified biologist will be present during construction in order to avoid inadvertent impacts to biological resources outside of the grading area, further reducing impacts to the species.

With respect to short-term secondary impacts, such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; and hydrologic alterations and water quality impacts, they will be minimized by providing guidelines for grading and construction activities; by retaining a qualified biologist during all grading and construction activities; by providing erosion control plans, dust control, and an overall Project SWPPP; by preventing pollutants from entering flowing streams and storm flows; by providing guidelines for stream diversion; and by requiring that the Specific Plan conform to all provisions of required NPDES permits and water quality permits required by the RWQCB. Long-term, residual secondary impacts to the mainland cherry, such as the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction, would be minimized by restricting access to, grazing within, and recreational usage of the River Corridor SMA and High Country SMA; providing for transition areas along the River Corridor SMA and High Country SMA; providing drainage guidelines; requiring conformance with NPDES and RWQCB permit provisions; requiring the implementation of a wildfire fuel modification plan (Dudek 2008A); placing restrictions on domestic animals in proximity to open space areas; providing trail signage and homeowner education; placing restrictions on plant palettes proposed for use on landscaped slopes; and providing revegetation plans for the River Corridor SMA.

All specific mitigation measures for mainland cherry are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-172 LOSS OF HABITAT – MAINLAND CHERRY

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to avoid, minimize, and/or mitigate the loss of habitat.

To mitigate for the loss of mainland cherry habitat during construction, SP-4.6-61 states that if the County determines that there may be mainland cherry on the property, a site-specific survey shall be conducted to determine its presence or absence, and any necessary mitigation measures shall be implemented. In the event that mainland cherry individuals are found during the survey, they will be replaced according to SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources, and applies these standards to mainland cherry, within the High Country SMA and Open Area, including: replacement trees shall be planted in conformance with

the current oak tree ordinance, trees planted shall be of local genetic stock, a resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

In addition to mitigation measures requiring site-specific surveys and replacement of individual trees, mainland cherry is associated with several jurisdictional tributaries to the Santa Clara River, and, where this species occurs in jurisdictional areas, the following mitigation measures will apply.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, and corrective measures) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-28 states that mitigation banking for riparian habitats in the High Country SMA is subject to state and federal regulations and permits, mitigation for oak resources is subject to the Oak Resources Management Plan, and mitigation banking for Mexican elderberry scrub is subject to the approval of the County Forester. SP-4.6-47a permits mitigation banking within the River Corridor SMA, High Country SMA, and Open Area, subject to requirements for riparian habitats, oak resources, and Mexican elderberry scrub.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub. SP-4.6-44 requires drainages with flows over 2,000 cfs in the Open Area to have soft bottoms. Bank protection will be ungrouted rock or buried bank stabilization except where other stabilization is required for public safety. SP-4.6-45 requires establishment of the alignments and widths of major drainages in the Open Area through drainage studies to be approved by the County at the time of subdivision map approval.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In addition to the restoration and avoidance mitigation measures described above, mainland cherry will benefit from the following preservation and management mitigation measures. SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

SP-4.6-26a identifies riparian revegetation and oak tree replacement opportunities in the High Country SMA and specifies mitigation requirements for each.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA.

SP-4.6-46 and SP-4.6-47 describe the dedication of the Open Area and provide acceptable usage guidelines.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to reduce the loss of habitat for mainland cherry.

In addition to mitigation measures described above requiring site-specific surveys and replacement of individual trees, mainland cherry is associated with several jurisdictional tributaries to the Santa Clara River, and, where this species occurs in jurisdictional areas, the following mitigation measures will apply.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-22 states that the Oak Resource Management Plan shall incorporate the findings of the Draft Newhall Ranch Mitigation Feasibility Report (Dudek 2007A), and areas identified as being suitable for oak resources (including mainland cherry) enhancement and creation shall be used for mitigation.

BIO-88 states that any southern California black walnut or mainland cherry trees or shrubs outside riparian areas greater than one inch dbh shall be replaced at a ratio of at least 2:1, using a minimum 15-gallon size specimen that measures at least one inch in diameter one foot above the base.

In addition to the restoration and avoidance mitigation measures described above, mainland cherry will benefit from the following preservation and management mitigation measures.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-62 states that at least 1,900 acres of Open Area within the Specific Plan area shall be offered for dedication to a NLMO. These 1,900 acres of the Open Area will be left as natural vegetation.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, impacts associated with the loss of habitat for mainland cherry would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-173 SECONDARY IMPACTS – MAINLAND CHERRY

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to mainland cherry.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-20, SP-4.6-32, SP-4.6-34, and SP-4.6-35:

SP-4.6-20 states that any grading activities within or adjacent to the River Corridor SMA shall have grading perimeters clearly marked and inspected prior to grading. The project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources**.**

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-34 and SP-4.6-35 establish that grading perimeters shall be clearly marked and inspected by the Project biologist prior to impacts occurring within or adjacent to the High Country SMA

and that the biologist shall work with the grading contractor to avoid inadvertent impacts to biological resources outside of the grading area.

Secondary impacts associated with accidental clearing, trampling, and grading would be further mitigated by implementation of Mitigation Measure SP-4.6-33, which permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

In order to avoid and minimize impacts from hydrologic and water quality–related impacts adjacent to and downstream of construction activities, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-44 and SP-4.6-45, which provide guidelines for major drainages, and SP-4.6-58, which requires conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-7, SP-4.6-19, SP-4.6-26a, SP-4.6-33, and SP-4.6-43:

SP-4.6-7 requires that revegetation plans for the River Corridor SMA include guidelines for the maintenance of the mitigation site during the establishment of plantings, control of non-native plants, maintenance of the irrigation system, and replacement of plants, if necessary

SP-4.6-19 requires that transition areas be in areas where there is no steep grade separation, that native riparian plants be incorporated into landscaping where feasible, that roads and bridges be designed to discourage access to River Corridor SMA, that bank stabilization be composed of ungrouted rock, and that a minimum 100-foot-wide buffer be provided between top river-side of bank stabilization and development.

SP-4.6-26a identifies riparian revegetation and oak tree replacement opportunities in the High Country SMA and specifies mitigation requirements for each.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

In order to avoid and minimize impacts from increased human activity and trampling, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-17, SP-4.6-18 and SP-4.6-19, SP-4.6-24, SP-4.6-29 through SP-4.6-32, SP-4.6-33, and SP-4.6-39:

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor, off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-24 states that the River Corridor SMA conservation and public access easement shall prohibit grazing and agriculture and shall restrict recreational use to the established trail system.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain planning areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-39 states that the High Country SMA easements shall prohibit grazing within the High Country, except for long-term resource management programs, and shall restrict recreation to the established trail system.

In order to avoid and minimize impacts from increased fire frequency, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-17, SP-4.6-31, SP-4.6-32, SP-4.6-33, and SP-4.6-49 through SP-4.6-52:

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to day time use. No hunting, fishing, motor or

off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-31 prohibits hunting, fishing, and motor or off-trail bike riding within the High Country SMA.

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-49 through SP-4.6-52 describe wildfire fuel modification plans and fuel modification measures that will minimize the potential exposure of the development areas, Open Area, and SMAs to fire hazards.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA, the High Country SMA, and Open Area in a natural state. These measures include SP-4.6-1 through SP-4.6-16 and SP-4.6-63, SP-4.6-17, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-26a, SP-4.6-27, SP-4.6-28, SP-4.6-29 through SP-4.6-32, SP-4.6-33, SP-4.6-36 through SP-4.6-42, SP-4.6-43, SP-4.6-46 and SP-4.6-47, SP-4.6-47a, and SP-4.6-55 and SP-4.6-58:

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, and corrective measures) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area.

Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

SP-4.6-26a identifies riparian revegetation and oak tree replacement opportunities in the High Country SMA and specifies mitigation requirements for each.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-28 states that mitigation banking for riparian habitats in the High Country SMA is subject to state and federal regulations and permits, mitigation for oak resources is subject to the Oak Resources Management Plan, and mitigation banking for Mexican elderberry scrub is subject to the approval of the County Forester.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA. SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

SP-4.6-46 and SP-4.6-47 describe the dedication of the Open Area and provide acceptable usage guidelines.

SP-4.6-47a permits mitigation banking within the River Corridor SMA, High Country SMA, and Open Area, subject to requirements for riparian habitats, oak resources, and Mexican elderberry scrub.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate short-term and long-term secondary impacts to a level that is adverse but not significant.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust; as well as from hydrologic alterations and water quality impacts, this EIS/EIR identifies Mitigation Measures BIO-45 and BIO-52:

BIO-45 defines the timing and design of stream diversion bypass channels and dewatering activities and related restrictions to ensure that proper construction, operation, and abandonment diversion or dewatering will occur.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to further avoid and minimize impacts from dust, runoff, sedimentation, erosion, and chemical and toxic compound pollution, this EIS/EIR identifies Mitigation Measures BIO-70 and BIO-71:

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction, as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 requires dust control measures for development areas to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control plans shall comply with SCAQMD Rule 403 (SCAQMD 2005), and chemical dust suppression shall not be utilized within 100 feet of known special-status plant communities.

Short-term secondary impacts associated with runoff, sedimentation, erosion, and chemical and toxic compound pollution and with hydrologic alterations and water quality impacts would also be mitigated by implementation of Mitigation Measure BIO-49, which prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, this EIS/EIR identifies Mitigation Measure BIO-72, which specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

In order to avoid and minimize impacts from increased human activity and trampling, this EIS/EIR identifies Mitigation Measures BIO-69 and BIO-73:

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

Each potential secondary impact would also be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA, the High Country SMA, and Open Area in a natural state. These measures include BIO-1 through BIO-16, BIO-62, BIO-69, and BIO-73:

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-

lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-62 states that at least 1,900 acres of Open Area within the Specific Plan area shall be offered for dedication to a NLMO. These 1,900 acres of the Open Area will be left as natural vegetation.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to mainland cherry would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

OAK TREES (LOCALLY REGULATED)

Life History

Five oak species or hybrid forms occur on the Newhall Ranch Project site. Four of them are tree species and one is a shrub. None of these oak species is rare or has special conservation status with the CDFG (2009) or CNPS (2009). Oaks, however, are recognized for aesthetic, historic, and habitat values (Starrs 2002), and oak trees or oak woodlands are protected by a variety of statutes and policies in California, including the County of Los Angeles Oak Tree Ordinance (CLAOTO).

Oak forests and woodlands provide food, cover, and nesting or denning habitat for many animal species (Block 1990; Pavlik *et al.* 1991). Oaks are the most evident plants, but the forests and woodlands are made up of diverse assemblages of understory shrubs, vines, herbs, grasses, and parasites (*e.g.*, mistletoe). Standing dead trees and fallen logs provide essential habitat elements. Acorns, fruits of other species, leaves, insects, seeds, mushrooms, and other fungi all provide food for wildlife. Oak woodlands and forests provide thermal cover for large mammals, including deer, and escape cover for many other animals. Oak canopies and foliage provide perching, roosting, and nesting sites for many bird species. Cavities in the limbs or trunks of oak trees are used as nesting and denning sites by birds and mammals. Dead oak trees provide nest sites for woodpeckers (which build nesting cavities) and "secondary cavity nesters," which use old woodpecker nests. Woodpeckers and many secondary cavity nesters feed largely on insects, perhaps preventing large-scale insect outbreaks from killing off forest stands. Barrett (1980) lists at least 20 mammal species of this region that use oaks for food, cover, or both. Verner (1980) identified 110 birds that use oak habitats in California during breeding season.

Oaks are wind pollinated and do not form showy flowers. Their male flowers are minute, arranged in conspicuous pendulous catkins, often releasing copious pollen in spring. The female flowers are also minute and initially are inconspicuous in leaf axils. They become conspicuous after pollination, as the acorns develop. Acorn maturation may take one or two years, depending on species (Hickman 1993). Many oaks have a tendency to produce "mast" fruit (*i.e.*, produce copious acorn crops in some years, and very few acorns in others).

Coast Live Oak (*Quercus agrifolia*)

Coast live oaks are endemic to California and northern Mexico and occur along the Coast, Transverse, and Peninsular ranges in California, and the Sierra de Juarez and Sierra San Pedro Martir ranges in Mexico, from southern Mendocino County, California, south to Canada El Piquillo, Baja California (Minnich 1987; Pavlik *et al.* 1991; Steinberg and Howard 1992). They are found on many soil types in valleys and woodlands, and in mixed-evergreen forests below about 1,500 meters elevation (Hickman 1993).

Coast live oaks are evergreens, growing to about 25 meters tall, and have widely ridged, furrowed, checkered dark gray trunk bark. The leaf blades are variable in size, shape, and margin patterns, usually oblong to round with a rounded to spine-toothed tip. Leaf margins are sometimes weakly spine-toothed. The upper leaf surface is dull green and usually strongly convex (Dole and Rose 1996). On the undersides, the leaves are irregularly veined, with tufts of brownish hairs where lateral veins join the midvein (Steinberg and Howard 1992); this character is generally diagnostic for coast live oak. Male and female inflorescences generally appear in early spring, while new leaves are immature. The acorn matures in one year (Dole and Rose 1996; Hickman 1993). The cup is obconic with thin scales. The nut is ovoid with a pointed tip (Hickman 1993). Coast live oaks are slow-growing long-lived (125 to 250 years) trees, and do not mature until about age 60 to 80 years (Griffin 1977).

Scrub Oak (*Quercus berberidifolia*)

Scrub oaks are found through the outer Coast, Transverse, and Peninsular ranges, from Tehama County to northern Baja California (Pavlik *et al.* 1991), and are common throughout much of their range. They are generally found in well-drained soils, in chaparral or with other oak species in mixed woodlands (Allen-Diaz *et al.* 2007; Keeley and Davis 2007), on dry slopes between about 300 and 1,500 meters AMSL (Hickman 1993). Scrub oaks are evergreen, growing to about three meters tall, and have smooth to chunky grayish bark. The leaf blades are variable in size and shape. The upper surfaces are generally flat or somewhat convex or wavy, and dull olive green. The lower surfaces are pale, dull gray- or yellow-green, covered by minute closely appressed hairs (not visible without magnification) (Hickman 1993). The flowers generally appear in early spring while new leaves are immature. The acorns mature in one year (Dole and Rose 1996; Hickman1993). The acorn cup is hemispheric with tubercled scales; the nut is ovoid with an obtuse to acute tip (Hickman 1993).

Valley Oak (*Quercus lobata*)

Valley oaks are endemic to California and occur from Shasta County south through the Central Valley and lower-elevation foothills and valleys of the Sierra Nevada and Coast Ranges to Los Angeles County (Pavlik *et al*. 1991; Howard 1992). They are found primarily in bottomland soils on slopes, valleys, and savannahs below about 1,700 meters AMSL (Hickman 1993), usually on silty loam, clay loam, and sandy clay loam soils typical of floodplains and valley floors.

Valley oaks are characteristic, stately-looking deciduous trees growing up to about 35 meters tall. They have deeply checkered, light grayish bark. The leaves are broad and lobed. The upper leaf surface is dull green with minute hairs. Catkins emerge from March to April and produce acorns during the fall (Howard 1992). The acorns mature in one year (Dole and Rose 1996; Hickman 1993). The acorn cups are hemispheric with tubercled scales; the nuts are long-conic with tapered to pointed tips (Hickman 1993).

Valley oaks are long-lived trees, but many stands are apparently not regenerating at high enough rates to replace natural mortality, especially on dry sites and on grazing lands (Griggs 1990; Allen-Diaz *et al.* 2007). The lack of regeneration is due to poor seedling establishment, largely due to wholesale changes in woodland understory ecology, from native shrubs and herbs to non-native grasses and forbs (Pavlik *et al.* 1991).

Alvord Oak (*Quercus* x *alvordiana*)

Alvord oak is an oak species of hybrid origin, involving blue oak (*Q. douglasii*) and Tucker's oak (*Q. john-tuckeri*) (Nixon and Muller 1997). Alvord oak is a semi-deciduous shrub to small tree, usually less than about 10 feet tall. Its distribution is mainly the interior Coast Ranges and Tehachapi Mountains (Hickman 1993) and Liebre Mountains (Boyd 1999). The Project site is evidently at or near its southernmost distribution. It is recognized by its semi-deciduous life history, leaf shape, and fine structure of the minute leaf hairs (Roberts 1995). This Fagaceae species is found on dry slopes and hills between 400 and 1,300 meters AMSL. Catkins emerge in spring and produce acorns during the fall that mature in one year (Pavlik *et al.* 1991; Hickman 1993). Alvord oak specimens collected at the Project site were identified by John Tucker of the U.C. Davis Tucker Herbarium.

Interior Live Oak (*Quercus wislizeni*)

Interior live oaks are endemic to California and northern Mexico, from Siskiyou and Shasta counties south along the foothills of the Sierra Nevada and inner Coast Ranges into northern Baja California (Tirmenstein 1989). They are found on a variety of soils including well-drained, fine-grained to cobbly or gravelly sandy loams, or skeletal soils, in interior canyons, slopes, valleys, chaparral, and mixed evergreen forests and woodlands below about 2,000 meters AMSL (Hickman 1993; White and Sawyer 1994).

Where they occur on valley floors, interior live oaks may grow to about 22 meters tall but often occur as smaller trees or shrubs in chaparral and dense forest stands. They have checkered, furrowed, grayish bark. They are evergreens. The leaf blades are strongly variable in size, shape, and margin patterns. Their upper surfaces are smooth and shiny, dark green, and the lower surfaces are slightly yellow-green and also smooth and shiny (Tirmenstein 1989). This characteristic distinguishes interior live oak from other evergreen oaks, including the shrubby species, throughout the region.

Flowers and fruit begin production from March to May. The acorns mature in two years (Dole and Rose 1996; Hickman 1993). The hemispheric cup has thin scales, while the nut is cylindrical-ovoid to obconic (Hickman 1993).

The primary threats to individual oak trees on construction sites are typically the result of physical injuries or changes caused by machinery involved with the development process.

Potential impacts to oak trees include root damage, soil excavation and compaction, grade changes, loss of canopy, and trunk wounds, among others. Other threat factors associated with urban development include human-caused alterations and hydrologic changes. Potential impacts due to the increase in human presence include firewood harvesting, hiking/recreational use, green waste/debris deposition, and increased susceptibility to diseases. These activities cause denuded growing environments from soil compaction, seedling trampling, exotic species introduction, littering, vandalism, and deliberate or accidental wildfire ignition. Changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff) can also threaten oak trees. Altered erosion, increased surface flows, and underground seepage can allow for the establishment of non-native, invasive plants, which can increase fire frequency, extent, and intensity. Altered hydrology also can change the soil environment by enabling soil pathogens to thrive in warm seasons when soil is normally dry (Swiecki 1990; Swiecki and Bernhardt 1996).

Diseases include oak mistletoe (*Phoradendron villosum*), hedgehog fungus (*Hericium erinaceus*), and sunscald (Swiecki and Bernhardt 1996). Additionally, a variety of oak diseases and blights are associated with modified water regimes, especially from irrigation: oak anthracnose (*Apiognomonia errabunda* and *Cryptocline cinerescens*), white rot of sapwood caused by *Hypoxylon thouarsianum*, basidiocarps (*Lactiporus gilbertsonii*), phytophthora root rot (*Phytophthora spp.*), and oak root fungus (*Armillaria mellea*) (Swiecki and Bernhardt 1996). In northern California, several oak species have suffered high mortality caused by a pathogenic fungus, termed "sudden oak death" (*Phytophthora ramorum*) (Swain 2002), but risk of its spreading to southern California is apparently low (Sonoma State University Geographic Information Center 2004).

Altered fire regime due to increased human use may affect oak ecology in a variety of ways; perhaps increasing weed abundance (Pavlik *et al.* 1991) or perhaps facilitating seedling establishment (Allen-Diaz *et al.* 2007). Mature oak trees are very long-lived, even after repeated burning. Most species (excluding coast live oak) are top-killed by even low-intensity fires (Plumb 1980). Following fire, they resprout from basal burls. This pattern is comparable to the "postfire obligate resprouter" life history Keeley and Davis (2007) described for numerous chaparral shrubs. Among these species, fire mortality is low, but repeated over-frequent wildfires would eventually exhaust stored carbohydrates and kill well-established burls.

Survey Results

Oak tree surveys have been conducted within the portions of the study area (including a 200-foot buffer) where development would occur, while the number of oak trees to be preserved within protected areas (*e.g.*, High Country and River Corridor SMAs, and the Salt Creek area) has been estimated (Impact Sciences 2006B, 2006C, 2006D; Land Design Consultants 2007; Dudek 2007D). Trees within the development portion of the Specific Plan, VCC, and Entrada planning areas were mapped using a global positioning system (GPS). Tree stands (tree groupings)

outside of these areas, in undisturbed or preserved areas, were delineated on aerial images and evaluated in the field *via* a sampling protocol and later statistically analyzed for population estimates.

In summary, trees with minimum trunk diameters (eight inches for single trunks or a combined 12 inches for two stems on a multi-stemmed tree) were inventoried. Additionally, trees with trunks of five inches or larger diameter were recorded from specific areas in consideration of the Oak Woodlands Conservation Act (Pub. Resources Code, § 21083.4), the state law applicable to County oak woodland impact analysis (for counties without an oak ordinance in substantial conformance with the state law). Based on the tree inventory data available to Dudek, the number of trees in the five- to seven-inch range is not substantial within the Newhall Land property.

In total, 3,766 trees were inventoried and assessed within the GPS inventory areas (**Table 4.5-61**, Species Distribution for Oak Trees within the GPS Inventory Areas (Heritage Oaks)). The majority of the trees throughout the GPS inventory areas are native coast live oak trees. Present at lower, but substantial, levels are valley oak trees. The trees are scattered throughout the property but consistent with the species' preferences: the coast live oaks are primarily associated with drainage bottoms, north-facing slopes, and along secondary drainages on non-north-facing slopes; the valley oaks are strongly associated with open grassland areas on gentler slopes and valley bottoms.

Table 4.5-61
Species Distribution for Oak Trees within the GPS Inventory Areas (Heritage Oaks)

	Proposed Project Areas						
Species	**Entrada Planning Area**	**Valencia Commerce Center**	**Homestead Village**	**Landmark Village**	**Potrero Village**	**Mission Village**	**Total**
coast live oak	0	0	1,789	3	997	501	3,290
valley oak	59	29	4	0	248	75	415
Alvord oak	0	3	2	0	0	0	5
scrub oak	10	0	28	0	0	18	56
Total	**69 (8)**	**32 (1)**	**1,823 (156)**	**3 (2)**	**1,245 (159)**	**594 (51)**	**3,766 (377)**

Preserved trees outside the GPS inventory areas in the large dedicated open space areas of the River Corridor SMA, High Country SMA, and Salt Creek area were estimated with sampling and regression analysis. Henrickson estimated 156 oak trees are present in the River Corridor SMA (County of Los Angeles 1999). Preserved tree populations within the High Country SMA and Salt Creek area were estimated in 2007. The estimated number of oak trees in the High Country SMA is 13,732 and in the Salt Creek area is 5,640, occurring primarily on north-facing slopes and in ravines and drainage bottoms (Dudek 2007D).

Together, the surveys of the inventory areas and the estimates of preserved trees outside these areas identified 23,294 oak trees potentially regulated by CLAOTO (County of Los Angeles 1988) and California Public Resources Code section 21083. The vast majority of the oaks on site are coast live oak (*Quercus agrifolia;* 16,626), but valley oak (*Q. lobata*; 3,302), scrub oak (*Q. berberidifolia*; 56*)*, interior live oak (*Q. wislizeni*; 1), and Alvord oak (*Q.* × *alvordiana*; 5) also occur. The 156 trees estimated to be in the River Corridor SMA were not identified to the species level. The remaining 3,148 trees are classified as mixed oaks. Impacts to, and mitigation for, oak woodland and oak/grass vegetation communities are discussed in detail in **Subsection 4.5.5.2.3.2**, Impacts to Vegetation Communities and Land Covers. Because the oak species were mapped so extensively on site, impacts to these species were evaluated by impacts to individuals rather than by loss of habitat.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Impacts to Individuals

Direct Permanent and Temporary Impacts

Loss of individual oak trees on construction sites is typically the result of physical injuries or changes caused by machinery involved with the development process. In addition to the removal of individual trees, potential impacts to oak trees include root damage, soil excavation and compaction, grade changes, loss of canopy, and trunk wounds, among others.

Of the approximately 23,294 regulated oak trees within the RMDP and SCP site, it is estimated that approximately 220 trees (0.9%), including 32 heritage oaks as defined by CLAOTO, would be lost or damaged (within both the permanent and temporary footprints) to allow for construction of RMDP facilities (**Figure 4.5-152**, Alternative 2 Impacts to RMDP/SCP Oak Trees). This represents a loss of habitat elements (*e.g.*, acorn production, nesting sites, shade cover) for a variety of wildlife species. The majority of the regulated oak trees that would be lost or damaged by implementation of the RMDP

and SCP occur within CDFG and/or Corps jurisdictional riparian areas. No individuals would be directly lost by implementation of the SCP.

This loss would constitute a substantial direct adverse effect on these oak species and would be a substantial reduction in the number or range of these oak species (significance criteria 1 and 7). This loss would also conflict with CLAOTO, and would constitute a significant impact on regulated trees (significance criterion 5). Direct permanent and temporary impacts are significant, absent mitigation.

Indirect Permanent Impacts

The remedial grading required for build-out of the Specific Plan area would result in impacts to 1,087 of the 17,397 protected oak trees, including 181 heritage oaks, representing 6.3% of the total population of ordinance and heritage oaks within the Specific Plan area. Build-out of the VCC planning area would result in the loss of 31 ordinance oak trees, none of which are heritage oaks, representing 96.9% of the ordinance and heritage oaks within that planning area. Build-out of the Entrada planning area would result in the loss of 32 oak trees, none of which are heritage oaks, representing 46.4% of the total population of ordinance and heritage oaks within that planning area (**Figure 4.5-152**, Alternative 2 Impacts to RMDP/SCP Oak Trees). This represents a loss of habitat elements (*e.g.*, acorn production, nesting sites, shade cover) for a variety of wildlife species. In addition to the removal of individual trees, potential impacts to oak trees include root damage, soil excavation and compaction, grade changes, loss of canopy, and trunk wounds, among others. The loss of these trees would constitute a substantial adverse effect on these oak species and would substantially reduce the number or restrict the range of these oak species (significance criteria 1 and 7). This loss would also conflict with CLAOTO and would constitute a significant impact on regulated trees (significance criterion 5). Indirect permanent impacts would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of individual oak trees resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 1,370 (5.9%) trees, including 213 heritage oak trees. This represents a loss of habitat elements (*e.g.*, acorn production, nesting sites, shade cover) for a variety of wildlife species. In addition to the removal of individual trees, potential impacts to oak trees include root damage, soil excavation and compaction, grade changes, loss of canopy, and trunk wounds, among others. The combined direct and indirect impacts to oak trees would have a substantial adverse effect on these oak species and would substantially reduce the number or restrict the range of these oak species (significance criteria 1 and 7). This loss would also conflict with CLAOTO and would

constitute a significant impact on regulated trees (significance criterion 5). The combined direct and indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and the build-out of the Specific Plan, VCC, and Entrada planning areas include accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; increased human activity that may result in littering, vandalism, and increased susceptibility to diseases, and trampling and soil compaction, and an increased risk of fire. Because of the widespread presence of these oak species on site in proximity to proposed development areas, short-term and long-term secondary impacts are expected to occur to these oak species. The impacts to oak trees as a result of these secondary impacts would constitute a substantial direct adverse effect on these oak species and could substantially reduce the number or restrict the range of these oak species (significance criteria 1 and 7). This potential loss would also conflict with CLAOTO and would constitute a significant impact on regulated trees (significance criterion 5). Secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Impacts to Individuals

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to individual oak trees (**Figures 4.5-153** through **4.5-157,** Alternatives 3 through 7 Impacts to RMDP/SCP Oak Trees)**:**

- Alternative 3 – permanent loss of 226 (1.0%) oak trees, including 32 heritage oak trees;
- Alternative 4 – permanent loss of 219 (0.9%) oak trees, including 32 heritage oak trees;
- Alternative 5 – permanent loss of 338 (1.5%) oak trees, including 39 heritage oak trees;
- Alternative 6 – permanent loss of 271 (1.2%) oak trees, including 65 heritage oak trees; and
- Alternative 7 – permanent loss of 304 (1.3%) oak trees, including 82 heritage oak trees.

Compared to Alternative 2, which would result in the direct permanent loss of 220 (0.9%) oak trees, including 32 heritage oak trees, the permanent loss of oak trees under Alternatives 3 through 7 would not be substantially different due to changes in the Project footprint. The majority of the regulated oak trees that would be lost or damaged by implementation of the RMDP and SCP occur within CDFG and/or Corps jurisdictional riparian areas.

Because the direct permanent loss (Impacts to Individuals) of oak trees occurring as a result of implementation of the RMDP and the SCP under Alternatives 3 through 7 is not substantially different than overall loss of individuals under Alternative 2, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to individual oak trees (**Figures 4.5-153** through **4.5-157,** Alternatives 3 through 7 Impacts to RMDP/SCP Oak Trees):

- Alternative 3 – permanent loss of 914 (3.9%) oak trees, including 164 heritage oak trees;
- Alternative 4 – permanent loss of 860 (3.7%) oak trees, including 162 heritage oak trees;
- Alternative 5 – permanent loss of 880 (3.8%) oak trees, including 159 heritage oak trees;
- Alternative 6 – permanent loss of 579 (2.5%) oak trees, including 96 heritage oak trees; and
- Alternative 7 – permanent loss of 541 (2.3%) oak trees, including 74 heritage oak trees.

Compared to Alternative 2, which would result in the permanent loss of 1,150 (4.9%) individual oak trees, including 181 heritage oak trees, Alternatives 3 through 7 would impact fewer oak trees. Reduced impacts would occur because there would be additional pullbacks from the Santa Clara River and its tributaries, and other changes in the Project footprint that would reduce impacts to oak trees. Additionally, no development would occur within the VCC planning area under Alternatives 4 through 7.

Because the indirect permanent loss (Impacts to Individuals) of oak trees occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 is not substantially different than loss of individuals

under Alternative 2, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to individual oak trees:

- Alternative 3 – permanent loss of 1,140 (4.9%) oak trees, including 196 heritage trees;
- Alternative 4 – permanent loss of 1,079 (4.6%) oak trees, including 194 heritage trees;
- Alternative 5 – permanent loss of 1,218 (5.2%) oak trees, including 198 heritage trees;
- Alternative 6 – permanent loss of 850 (3.6%) oak trees, including 161 heritage trees; and
- Alternative 7 – permanent loss of 845 (3.6%) oak trees, including 156 heritage trees.

Compared to Alternative 2, which would result in the permanent loss of 1,370 (5.9%) oak trees, including 213 heritage oak trees, Alternatives 3 through 7 would result in reduced impacts, as described above for the discussions of direct and indirect permanent impacts. The reduced impacts would be due to successively greater pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions that would reduce impacts to oak trees. Additionally, no development would occur within the VCC planning area under Alternatives 4 through 7. The combined direct and indirect permanent loss of individual oak trees occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity,

trampling, and soil compaction. Because of the widespread presence of these oak species on site in proximity to proposed development areas, short-term and long-term secondary impacts are expected to occur to these oak species. Impacts to individual oak trees due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to oak trees: (1) impacts to individuals, and (2) secondary impacts to individuals outside the Project footprint.

Impacts to individual oak trees could occur as a result of physical injuries or changes caused by machinery involved with the development process. In addition to the removal of individual trees, potential impacts to oak trees include root damage, soil excavation and compaction, grade changes, loss of canopy, and trunk wounds, among others. The combined permanent loss of individual oak trees resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 845 trees (3.6%), including 156 heritage oak trees, under Alternative 7 to 1,370 trees (5.9%), including 213 heritage oak trees, under Alternative 2. The combined permanent loss of individuals would constitute a substantial adverse effect on these oak species and would substantially reduce the number or restrict the range of these oak species. This loss would also conflict with CLAOTO and would constitute a significant impact on regulated trees. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals and associated habitat. General procedures to avoid and minimize impacts to oak trees during construction will be implemented and a qualified biologist will be present during construction in order to avoid inadvertent impacts to biological resources outside of the grading area, further reducing impacts to the species.

The proposed mitigation encompasses a three-part strategy that incorporates (1) planting replacement trees, per the requirements of CLAOTO and previously incorporated Mitigation Measure SP-4.6-48; (2) additional replacement ratios recommended in this EIS/EIR for impacts to oak trees and oak woodlands where they occur within stream channels falling under CDFG and Corps jurisdiction, per sections 1600 and 404 (BIO-2); and (3) additional measures recommended in this EIS/EIR for tree replacement or woodland restoration/enhancement to mitigate for oak trees and woodland occurring in uplands, outside CDFG and Corps jurisdiction (BIO-22).

The Project's impacts to oak trees and oak woodlands are related but are not identical. Losses of oak trees are to be mitigated by planting replacement trees (per the requirements of CLAOTO, BIO-22b, and previously incorporated Mitigation Measure SP-4.6-48), supplementing those

numbers with additional replacement trees as described in BIO-22c (for upland oak trees) and BIO-2.

This EIS/EIR requires additional oak woodland replacement at a ratio ranging from 2:1 to 3:1 for any oak woodland lost within jurisdictional streambeds (BIO-2) and at a ratio of 1:1 for woodland acreages lost outside of jurisdictional areas (BIO-22d). For impacts to upland oak woodlands, Newhall Land may enhance existing degraded woodland areas, at the increased ratio of 2:1.

All oak trees to be planted for CLAOTO compliance will be subject to species and performance criteria as specified in CLAOTO (see BIO-22b). Where CLAOTO replacement trees are planted in natural open areas such as the High Country SMA and Salt Creek areas, the planting areas will be planted and managed as natural woodlands, to include other characteristic woodland species and to provide habitat for a broader variety of wildlife than is possible in close proximity to development.

In addition, this EIS/EIR requires replacement of oak trees at a ratio of 0.5:1 for oak trees with dbh of 8 to 35 inches, and at a ratio of 2.5:1 for oak trees with dbh of 36 or more inches lost or impacted in uplands (BIO-22c). These trees are in addition to the CLAOTO requirement described above. These additional trees may also be incorporated into woodland habitat enhancement or creation.

This oak mitigation strategy will be outlined in an Oak Resource Management Plan, to be prepared by the applicant and submitted for approval to CDFG and County of Los Angeles, and implemented upon approval. The Plan shall identify areas suitable for oak woodland enhancement and creation. The Plan shall distinguish between oaks to be planted in compliance with CLAOTO (BIO-22b) and the additional measures required by this EIS/EIR (BIO-2 for woodlands in jurisdictional streambeds; and BIO-22c and 22d for upland areas).

The Oak Resource Management Plan shall include measures to create or enhance woodlands as follows: (1) locations and acreages of mitigation sites where woodland creation or enhancement will; (2) a description of proposed cover and number of native trees, shrubs and grasses per acre to be established. This description shall be based on comparable intact woodlands in the area of impact or elsewhere within the RMDP planning area, consistent with conditions of the proposed mitigation site; (3) site preparation measures to include (as appropriate) topsoil treatment, soil decompaction, erosion control, weed grow/kill cycle, or as otherwise approved by the agencies; (4) methods for the removal of non-native plants (*e.g.*, mowing, weeding, raking, herbicide application, or burning); (5) a plant palette listing all species, including sizes, planting densities, or seeding rates, to be based on target vegetation; (6) the source of all plant propagules (seed, potted nursery stock, *etc.*) and the quantity and species of seed or potted stock of all plants to be introduced or planted into the mitigation areas; (7) temporary irrigation, protection from herbivores, fertilizer, weeding, *etc*.; (8) a schedule and action plan to maintain and monitor the

enhancement/restoration areas, to include at minimum, qualitative annual monitoring for revegetation success and site degradation due to erosion, trespass, or animal damage for a period no less than 5 years total and no less than 2 years after removal of irrigation (if any); (9) where sites are near trails or other access points, measures such as fencing, signage, or security patrols to exclude unauthorized entry into the mitigation areas shall be implemented as needed; (10) tree protection standards to be implemented for individual trees or woodlands adjacent to development activity; (11) success criteria as stated in BIO-22b and BIO-22d; and (12) contingency measures, such as replanting, erosion control, irrigation system repair, or understory re-seeding, to be implemented if habitat improvement/restoration efforts do not meet the success criteria stated in the plan. The Oak Resource Management Plan would reduce impacts to oak trees by replacing trees and enhancing oak woodland habitat in the Project area.

As described in the Draft Newhall Ranch Mitigation Feasibility Study (Dudek 2007A), potential mitigation sites for three oak vegetation communities—valley oak/grass, coast live oak woodland, and valley oak woodland—were identified in the High Country SMA and Salt Creek area (**Figure 4.5-158**, Newhall Land – Potential Oak Mitigation Sites). A comprehensive evaluation identified approximately 111 acres considered suitable for creating specific oak vegetation communities, including 87 acres of valley oak/grass, 10 acres of coast live oak woodland, and 0.4 acre of valley oak woodland.

In addition to oak habitat mitigation, individual oak trees will be planted in several areas within the High Country SMA and Salt Creek area. In general, potential oak mitigation sites considered were sites mapped as oak vegetation communities (*e.g.*, coast live oak woodland, valley oak woodland, or valley oak/grass) that were sparse and could support additional oaks or sites that were disturbed (agricultural land, California annual grassland, or disturbed land) that could support individual oak trees. Approximately 111 acres were identified as suitable in a comprehensive evaluation (Dudek 2007A). Where individual oak trees would be lost within jurisdictional riparian areas, those impacts would be mitigated in accordance with jurisdictional riparian mitigation requirements of the previously incorporated mitigation measures and the mitigation measures recommended by this EIS/EIR (in particular BIO-2). Mitigation for individual oak trees will be incorporated as appropriate into individual Subnotification Conceptual Wetlands Mitigation Plans for wetlands and adjacent uplands areas along the River Corridor SMA and Open Areas (along tributaries to the Santa Clara River).

Regarding short-term secondary impacts, such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; and hydrologic alterations and water quality impacts will be minimized by providing guidelines for grading and construction activities; by retaining a qualified biologist during all grading and construction activities; by providing erosion control plans, dust control, and an overall Project SWPPP; by preventing pollutants from entering flowing streams and storm flows; by providing guidelines for stream diversion; and by requiring that the Specific Plan conform to

all provisions of required NPDES permits and water quality permits required by the RWQCB. Long-term, residual secondary impacts to the oak trees, such as the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction will be minimized by additional measures restricting access to, grazing within, and recreational usage of the River Corridor SMA and High Country SMA; providing for transition areas along the River Corridor SMA and High Country SMA; providing drainage guidelines; requiring conformance with NPDES and RWQCB permit provisions; requiring the implementation of a wildfire fuel modification plan (Dudek 2008A); placing restrictions on domestic animals in proximity to open space areas; providing trail signage and homeowner education; placing restrictions on plant palettes proposed for use on landscaped slopes; and providing revegetation plans for the River Corridor SMA.

All specific mitigation measures for oak trees are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-174 IMPACTS TO INDIVIDUALS – OAK TREES

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to avoid, minimize, and/or mitigate the loss of oak trees.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where

feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-28 states that mitigation banking for riparian habitats in the High Country SMA is subject to state and federal regulations and permits, mitigation for oak resources is subject to the Oak Resources Management Plan, and mitigation banking for Mexican elderberry scrub is subject to the approval of the County Forester.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

SP-4.6-44 and SP-4.6-45 provide guidelines for major drainages.

SP-4.6-46 and SP-4.6-47 describe the dedication of the Open Area and provide acceptable usage guidelines.

SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with

the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

SP-4.6-49 through SP-4.6-52 describe wildfire fuel modification plans and fuel modification measures that will minimize the potential exposure of the development areas, Open Area, and SMAs to fire hazards.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to reduce the loss of and/or harm to oak trees.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-22 requires the preparation and implementation of an Oak Resource Management Plan. The Plan shall identify areas suitable for oak woodland enhancement and creation. The Plan shall distinguish between oaks to be planted in compliance with CLAOTO (BIO-22b) and the additional measures required by this EIS/EIR (BIO-2 for woodlands in jurisdictional streambeds; and BIO-22c and 22d for upland areas). The Oak Resource Management Plan would reduce impacts to oak trees by replacing and enhancing oak woodland in the Project area.

BIO-62 states that at least 1,900 acres of Open Area within the Specific Plan area shall be offered for dedication to a NLMO. These 1,900 acres of the Open Area will be left as natural vegetation.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts associated with the impacts to oak trees would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-175 SECONDARY IMPACTS – OAK TREES

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to oak trees.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-20, SP-4.6-32, SP-4.6-34 and SP-4.6-35:

SP-4.6-20 states that any grading activities within or adjacent to the River Corridor SMA shall have grading perimeters clearly marked and inspected prior to grading. The Project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources**.**

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-34 and SP-4.6-35 establish that grading perimeters shall be clearly marked and inspected by the Project biologist prior to impacts occurring within or adjacent to the High Country SMA and that the biologist shall work with the grading contractor to avoid inadvertent impacts to biological resources outside of the grading area.

Secondary impacts associated with accidental clearing, trampling, and grading would be further mitigated by implementation of Mitigation Measure SP-4.6-33, which permits construction of

buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

In order to avoid and minimize impacts from hydrologic and water quality–related impacts adjacent to and downstream of construction activities, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-44 and SP-4.6-45, which provide guidelines for major drainages, and SP-4.6-58, which requires conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-7, SP-4.6-19, SP-4.6-26a, SP-4.6-33, and SP-4.6-43:

SP-4.6-7 requires that revegetation plans for the River Corridor SMA include guidelines for the maintenance of the mitigation site during the establishment of plantings, control of non-native plants, maintenance of the irrigation system, and replacement of plants, if necessary.

SP-4.6-19 requires that transition areas be in areas where there is no steep grade separation, that native riparian plants be incorporated into landscaping where feasible, that roads and bridges be designed to discourage access to the River Corridor SMA, that bank stabilization be composed of ungrouted rock, and that a minimum 100-foot-wide buffer be provided between top river-side of bank stabilization and development.

SP-4.6-26a identifies riparian revegetation and oak tree replacement opportunities in the High Country SMA and specifies mitigation requirements for each.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

In order to avoid and minimize impacts from increased human activity and trampling, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-17, SP-4.6-18 and SP-4.6-19, SP-4.6-24, SP-4.6-29 through SP-4.6-32, SP-4.6-33, and SP-4.6-39:

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-24 states that the River Corridor SMA conservation and public access easement shall prohibit grazing and agriculture and shall restrict recreational use to the established trail system.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-39 states that the High Country SMA easements shall prohibit grazing within the High Country SMA, except for long-term resource management programs, and shall restrict recreation to the established trail system.

In order to avoid and minimize impacts from increased fire frequency, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-17, SP-4.6-31, SP-4.6-32, SP-4.6-33, and SP-4.6-49 through SP-4.6-52:

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-31 prohibits hunting, fishing, and motor or off-trail bike riding within the High Country SMA.

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-49 through SP-4.6-52 describe wildfire fuel modification plans and fuel modification measures that will minimize the potential exposure of the development areas, Open Area, and SMAs to fire hazards.

Each potential secondary impact will be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA, the High Country SMA, and Open Area in a natural state. These measures include SP-4.6-1 through SP-4.6-16 and SP-4.6-63, SP-4.6-17, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-26a, SP-4.6-27, SP-4.6-28, SP-4.6-29 through SP-4.6-32, SP-4.6-33, SP-4.6-36 through SP-4.6-42, SP-4.6-43, SP-4.6-46 and SP-4.6-47, SP-4.6-47a, and SP-4.6-55 and SP-4.6-58:

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where

feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

SP-4.6-26a identifies riparian revegetation and oak tree replacement opportunities in the High Country SMA and specifies mitigation requirements for each.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-28 states that mitigation banking for riparian habitats in the High Country SMA is subject to state and federal regulations and permits, mitigation for oak resources is subject to the Oak Resources Management Plan, and mitigation banking for Mexican elderberry scrub is subject to the approval of the County Forester.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA. Mitigation Measure SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

SP-4.6-46 and SP-4.6-47 describe the dedication of the Open Area and provide acceptable usage guidelines.

SP-4.6-47a permits mitigation banking within the River Corridor SMA, High Country SMA, and Open Area, subject to requirements for riparian habitats, oak resources, and Mexican elderberry scrub.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate short-term and long-term secondary impacts to a level that is adverse but not significant.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust; as well as from hydrologic alterations and water quality impacts, this EIS/EIR identifies Mitigation Measures BIO-45 and BIO-52:

BIO-45 defines the timing and design of stream diversion bypass channels and dewatering activities and related restrictions to ensure that proper construction, operation, and abandonment diversion or dewatering will occur.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements, conduct meetings with contractor describing the importance of restricting work to the restricted areas, discuss procedures for minimizing harm to or harassment of wildlife, review the construction area in the field with the contractor in accordance with the final grading plan, conduct a final field review of staking, be present during initial vegetation clearing and grading, and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to further avoid and minimize impacts from accidental clearing, trampling, and grading, this EIS/EIR identifies Mitigation Measure BIO-42, which requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities. Fencing shall extend to the root protection zone.

In order to further avoid and minimize impacts from dust, runoff, sedimentation, erosion, and chemical and toxic compound pollution, this EIS/EIR identifies Mitigation Measures BIO-70 and BIO-71:

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species

adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 requires dust control measures for development areas to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control plans shall comply with SCAQMD Rule 403 (SCAQMD 2005) and chemical dust suppression shall not be utilized within 100 feet of known special-status plant communities.

Short-term secondary impacts associated with runoff, sedimentation, erosion and chemical and toxic compound pollution, and with hydrologic alterations and water quality impacts will also be mitigated by implementation of Mitigation Measure BIO-49, which prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, this EIS/EIR identifies Mitigation Measure BIO-72, which specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

In order to avoid and minimize impacts from increased human activity and trampling, this EIS/EIR identifies Mitigation Measures BIO-69 and BIO-73:

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

In order to avoid and minimize impacts from increased fire frequency, this EIS/EIR identifies Mitigation Measure BIO-63, which requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

Each potential secondary impact will be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA, the High Country SMA, and Open Area in a natural state. These measures include BIO-1 through BIO-16, BIO-42, BIO-62, BIO-69, and BIO-73:

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-42 requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities. Fencing shall extend to the root protection zone.

BIO-62 states that at least 1,900 acres of Open Area within the Specific Plan area shall be offered for dedication to a NLMO. These 1,900 acres of the Open Area will be left as natural vegetation.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to oak trees would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

OAK-LEAVED NEMOPHILA (CNPS LIST 4.3/S3.3)

Life History

Oak-leaved nemophila (*Nemophila parviflora* var. *quercifolia)* is known to occur from Tuolumne County south through Kern County at elevations between 700 and 2,200 meters AMSL (CNPS 2007; University and Jepson Herbaria 2007). This species of the waterleaf family (Hydrophyllaceae) is an understory plant found primarily in forests, on slopes, and in ravines (Hickman 1993). The annual herb inhabits cismontane woodlands and lower montane coniferous forests and generally blooms from May to June (CNPS 2007).

In addition to the direct loss of individuals, oak-leaved nemophila is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives such as the oak-leaved nemophila. Exotic plants can also alter hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development.

Survey Results

During field surveys for this project, the first known specimen from Los Angeles County and the Transverse Ranges was collected in Long Canyon, on the Project site, at about 300 meters elevation. Observations of oak-leaved nemophila were made in 2003 and 2004 (Dudek and Associates 2004C, 2004F) and in 2005 (University and Jepson Herbaria 2009). This species was observed growing in the understory of oak woodland on gentle, northeast facing slopes.

Focused surveys were conducted in spring and summer 2002 through 2006, coincident with the annual blooming period for oak-leaved nemophila, which blooms from May through June (CNPS 2007). The surveys typically began in April and extended through August. Surveys in 2006 and 2007 focused on the identification of San Fernando Valley spineflower only within known occurrences, reducing the total survey area and, subsequently, the number of other documented special-status species observed; this could explain why oak-leaved nemophila was not recorded in 2006 and 2007.

Given the status of the species (CNPS List 4.3), the exact locations of individuals of this species within the Project area have not been mapped. However, this species was found in an oak woodland east of Grapevine Mesa (Dudek and Associates 2004C, 2004F) and in an oak woodland at the northeast end of Long Canyon in 2005 (University and Jepson Herbaria 2009)

within the Specific Plan area. Oak-leaved nemophila is assumed to occur as an occasional component of oak woodlands within the Specific Plan area. Therefore, impacts to this species were evaluated by loss of habitat instead of impacts to individuals. A total of 1,468 acres of suitable habitat is present in the Project area (**Figures 4.5-11-A1** through **4.5-11-C2**, RMDP/SCP – Vegetation Communities and Land Covers, **Figure 4.5-20**, VCC SCP Site – Vegetation Communities and Land Covers, and **Figure 4.5-21**, Entrada RMDP/SCP Site – Vegetation Communities and Land Covers).

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP would result in the direct loss of 11 acres (0.7%) of suitable habitat for this species (within both the permanent and temporary footprints) out of 1,468 acres on site (**Figures 4.5-33-A1** through **4.5-33-D2**, Alternative 2 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). No individuals would be directly lost by implementation of the SCP. Although this species has a relatively low sensitivity ranking (California Heritage S3.3 ranking indicates no current threats known), the direct loss of oak-leaved nemophila occupying this habitat as a result of construction/grading activities would be considered a substantial adverse effect on this species and would substantially reduce the number or restrict the range of the species (significance criteria 1 and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan area would result in the permanent loss of 85 acres (5.8%) of suitable habitat for this species (**Figures 4.5-33-A1** through **4.5-33-D2**, Alternative 2 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). No suitable habitat would be lost as a result of build-out of the VCC and Entrada planning areas. It is possible that individual oak-leaved nemophila plants within this suitable habitat would be

lost as a result of build-out of the Specific Plan area. Although this species has a relatively low sensitivity ranking (California Heritage S3.3 ranking indicates no current threats known), the potential loss of oak-leaved nemophila as a result of build-out of the Specific Plan area would be considered a substantial adverse effect on this species and would substantially reduce the number or restrict the range of the species (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan area would total 96 acres (6.5%). No suitable habitat would be lost as a result of build-out of the VCC and Entrada planning areas. Although this species has a relatively low sensitivity ranking (California Heritage S3.3 ranking indicates no current threats known), the combined direct and indirect permanent impacts to oak-leaved nemophila suitable habitat would have a substantial adverse effect on this species and would substantially reduce the number or restrict the range of the species (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan area include accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; hydrologic alterations and water quality impacts; the introduction of non-native, invasive plant species; increased human activity, trampling, and soil compaction; and increased risk of fire. There would be no secondary impacts associated with build-out of the VCC and Entrada planning areas. Although this species has a relatively low sensitivity ranking (California Heritage S3.3 ranking indicates no current threats known), the potential loss of oak-leaved nemophila and its suitable habitat resulting from these secondary impacts would not constitute a substantial adverse effect on this species and would not substantially reduce the number or restrict the range of the species (significance criteria 1 and 7). Secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to suitable habitat for oak-leaved nemophila (**Figures 4.5-34-A1** through **4.5-38-D2**, Alternatives 3 through 7 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities):

- Alternative 3 – 11 acres (0.7%) of permanent loss;
- Alternative 4 – 10 acres (0.7%) of permanent loss;
- Alternative 5 – 14 acres (1.0%) of permanent loss;
- Alternative 6 – 19 acres (1.3%) of permanent loss; and
- Alternative 7 – 19 acres (1.3%) of permanent loss.

Compared to Alternative 2, which would result in 11 acres (0.7%) of permanent loss and 1.4 acre of temporary loss, the permanent and temporary loss of habitat under Alternatives 3 through 5 would not be substantially different. The difference between Alternatives 6 and 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternatives 6 and 7, which would result in greater loss of oak woodlands adjacent to the Santa Clara River and its tributaries.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is not substantially different than overall habitat loss under Alternative 2, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan area would result in the following indirect impacts to suitable habitat for oak-leaved nemophila (**Figures 4.5-34-A1** through **4.5-38-D2**, Alternatives 3 through 7 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). No suitable habitat would be lost as a result of build-out of the VCC and Entrada planning areas.

- Alternative 3 – 66 acres (4.5%) of permanent loss;
- Alternative 4 – 65 acres (4.4%) of permanent loss;

- Alternative 5 – 66 acres (4.5%) of permanent loss;
- Alternative 6 – 41 acres (2.8%) of permanent loss; and
- Alternative 7 – 44 acres (3.0%) of permanent loss.

Compared to Alternative 2, which would result in 85 acres (5.8%) of indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 3 through 7 would impact fewer acres than Alternative 2 because of reductions in the Project footprint.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, impacts for Alternatives 3 through 7 would still be substantially adverse because of the loss of habitat on site. The indirect permanent loss of suitable habitat for oak-leaved nemophila occurring as a result of build-out of the Specific Plan area under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan area would result in the following impacts to suitable habitat for oak-leaved nemophila. No suitable habitat would be lost as a result of build-out of the VCC and Entrada planning areas.

- Alternative 3 – 77 acres (5.2%) of permanent loss;
- Alternative 4 – 75 acres (5.1%) of permanent loss;
- Alternative 5 – 80 acres (5.4%) of permanent loss;
- Alternative 6 – 60 acres (4.0%) of permanent loss; and
- Alternative 7 – 63 acres (4.2%) of permanent loss.

Compared to Alternative 2, which would result in 96 acres (6.5%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would not be substantially different compared with impacts associated with Alternative 2. Reduced impacts would occur because of reductions in the Project footprint for Alternatives 3 through 6, and additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 that reduce impacts to oak-leaved nemophila. The combined direct and indirect permanent loss of suitable habitat for oak-leaved nemophila occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan area under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan area under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. There would be no secondary impacts associated with build-out of the VCC and Entrada planning areas. The loss of or degradation of suitable habitat and the loss of individual oak-leaved nemophila due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan area under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to oak-leaved nemophila: (1) loss of habitat, and (2) secondary impacts to individuals outside the Project footprint.

Loss of habitat (and associated impacts to occasional individual oak-leaved nemophila plants) could occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment. The combined permanent loss of oak-leaved nemophila habitat would range from 63 acres (4.2%) under Alternative 7 to 96 acres (6.5%) under Alternative 2. The combined permanent loss of this habitat would have a substantial adverse effect on this species. This loss would also conflict with CLAOTO and would constitute a significant impact on regulated trees. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals and associated habitat. At least 833 acres of suitable habitat will be conserved in the High Country SMA and Salt Creek area where long-term preservation and management will be provided.

Short-term secondary impacts, such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; and hydrologic alterations and water quality impacts, would be minimized by providing guidelines for grading and construction activities; by retaining a qualified biologist during all grading and construction activities; by providing erosion control plans, dust control, and an overall Project SWPPP; by preventing pollutants from entering flowing streams and storm flows; by providing guidelines for stream diversion; and by requiring that the Specific Plan conform to all provisions of required NPDES permits and water quality permits required by the RWQCB. Long-term secondary impacts to oak-leaved nemophila, such as the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; increased human activity, trampling, and soil compaction; and increased risk of fire, would be minimized by restricting access to, grazing within, and recreational usage of the High Country SMA; providing

for transition areas along the High Country SMA; providing drainage guidelines; requiring conformance with NPDES and RWQCB permit provisions; requiring the implementation of a wildfire fuel modification plan (Dudek 2008A); placing restrictions on domestic animals in proximity to open space areas; providing trail signage and homeowner education; and placing restrictions on plant palettes proposed for use on landscaped slopes.

All specific mitigation measures for oak-leaved nemophila are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-176 LOSS OF HABITAT – OAK-LEAVED NEMOPHILA

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures which will avoid, minimize, and/or mitigate the loss of habitat (oak woodland vegetation communities) for oak-leaved nemophila.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where oak woodland vegetation communities occurs. Transition from the development edge to the natural area (where oak woodland vegetation communities occur) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA, which supports 566 acres of oak woodland vegetation communities.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or

endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to avoid, minimize, and/or mitigate the loss of habitat (oak woodland vegetation communities) for oak-leaved nemophila. BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA, both of which support oak woodland vegetation communities. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-62 states that at least 1,900 acres of Open Area within the Specific Plan area shall be offered for dedication to a NLMO. These 1,900 acres of the Open Area will be left as natural vegetation.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts associated with the loss of habitat for oak-leaved nemophila would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-177 SECONDARY IMPACTS – OAK–LEAVED NEMOPHILA

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to oak-leaved nemophila.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-32, SP-4.6-34, and SP-4.6-35:

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-34 and SP-4.6-35 establish that grading perimeters shall be clearly marked and inspected by the Project biologist prior to impacts occurring within or adjacent to the High Country SMA, and that the biologist shall work with the grading contractor to avoid inadvertent impacts to biological resources outside of the grading area.

Secondary impacts associated with accidental clearing, trampling, and grading would be further mitigated by implementation of Mitigation Measure SP-4.6-33, which permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where oak woodland vegetation communities occur. Transition from the development edge to the natural area (where oak woodland vegetation communities occur) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-33, which permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where oak woodland vegetation communities occur. Transition from the development edge to the natural area (where oak woodland vegetation communities occur) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

In order to avoid and minimize impacts from increased human activity and trampling, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-29 through SP-4.6-32, SP-4.6-33, and SP-4.6-39:

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where oak woodland vegetation communities occur. Transition from the development edge to the natural area (where oak woodland vegetation communities occur) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-39 states that the High Country SMA easements shall prohibit grazing within the High Country SMA, except for long-term resource management programs, and shall restrict recreation to the established trail system.

In order to avoid and minimize impacts from hydrologic and water quality–related impacts adjacent to and downstream of construction activities, the Newhall Ranch Specific Plan Program

EIR identified Mitigation Measures SP-4.6-44 and SP-4.6-45, which provide guidelines for major drainages (which are in proximity to oak woodland vegetation communities), and SP-4.6-58, which requires conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In order to avoid and minimize impacts from increased fire frequency, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-31, SP-4.6-32, SP-4.6-33, and SP-4.6-49 through SP-4.6-52:

SP-4.6-31 prohibits hunting, fishing, and motor or off-trail bike riding within the High Country SMA.

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-49 through SP-4.6-52 describe wildfire fuel modification plans and fuel modification measures that will minimize the potential exposure of the development areas, Open Area, and SMAs (which contain oak woodland vegetation communities) to fire hazards.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the High Country SMA and Salt Creek area in a natural state. These measures include SP-4.6-27, SP-4.6-29 through SP-4.6-32, SP-4.6-33, SP-4.6-36 through SP-4.6-42, and SP-4.6-55 and SP-4.6-58:

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition

from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. This will benefit oak woodland vegetation communities located in proximity to drainages.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate short-term and long-term secondary impacts to a level that is adverse but not significant.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading, this EIS/EIR identifies Mitigation Measure BIO-52, which states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to avoid and minimize impacts from dust, runoff, sedimentation, erosion, and chemical and toxic compound pollution, this EIS/EIR identifies Mitigation Measures BIO-52, BIO-70, and BIO-71:

BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 requires dust control measures for development areas to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control plans shall comply with SCAQMD Rule 403 (SCAQMD 2005), and chemical dust suppression shall not be utilized within 100 feet of known special-status plant communities.

Short-term secondary impacts associated with runoff, sedimentation, erosion, and chemical and toxic compound pollution would be further mitigated by implementation of Mitigation Measure BIO-49, which prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, this EIS/EIR identifies Mitigation Measure BIO-72, which specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

In order to avoid and minimize impacts from increased human activity and trampling, this EIS/EIR identifies Mitigation Measure BIO-69, which requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

In order to avoid and minimize impacts from hydrologic and water quality-related impacts adjacent to and downstream of construction activities, this EIS/EIR identifies Mitigation Measures BIO-49 and BIO-52:

BIO-49 prohibits requires that pollutants from construction activities not be allowed to enter a flowing stream or be placed in locations that may be subjected to storm flows. This will benefit oak woodland vegetation communities and any oak-leaved nemophila located in proximity to drainages.

BIO-52, which states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the

importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to avoid and minimize impacts from increased fire frequency, this EIS/EIR identifies Mitigation Measure BIO-63, which requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the High Country SMA and Salt Creek area in a natural state. These measures include BIO-19 and BIO-69:

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA, both of which support oak woodland vegetation communities. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to oak-leaved nemophila would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

OJAI NAVARRETIA (CNPS LIST 1B.1/S2)

Life History

Ojai navarretia (*Navarretia ojaiensis*) was documented within the Project area during the 2003 field season, at which time the species was undescribed. The species was first described in 2007 as Ojai navarretia (Johnson 2007). While distinct from each of the following taxa, Ojai navarretia is undoubtedly closely related to Jared's navarretia (*N. jaredii*), downy pincushion plant (*N. pubescens*), and Piute mountains navarretia (*N. setiloba*). In 2003, when Ojai navarretia was first observed within the Project area, it was observed that Ojai navarretia differs from Jared's navarretia in that Ojai navarretia has a purple spot on the edge of the corolla tube, there are papillae in the tube, and the stems are not white hairy. It differs from downy pincushion plant in that Ojai navarretia has a purple spot and papillae in the tube, the bracts are slightly wider, and the flowers are smaller and whitish as opposed to larger and purple. It differs from Piute mountains navarretia in that the Ojai navarretia has a purple spot, narrower bracts, and a smaller flower (Dudek and Associates 2004I). The Ojai navarretia occurrences were noted in grasslands and in openings in California sagebrush (Dudek and Associates 2004A) and sparsely vegetated valley needle grasslands (Dudek and Associates 2004I). Soils where the Ojai navarretia occurs are all clay soils (Dudek and Associates 2004I). This species was observed on gentle to moderate north-facing slopes (Dudek and Associates 2004I) to growing on all but east-facing slopes and generally on relatively flat soil to slopes up to 40° (Dudek and Associates 2004A).

Ojai navarretia is described as a tap-rooted annual, low and spreading to erect. The stems are hairy or fuzzy and sometimes glandular; the base stem color is yellow-green suffused with purple or red. The plant blooms May through July. The white flowers are funnelform in shape with a purple spot. The fruit is a yellow capsule that splits open to release solitary seed. The plant is known from approximately 10 occurrences in Santa Clarita Valley (including within the Salt Creek area of the RMDP and SCP area, and the Ventura Homestead site located immediately to the west of the RMDP and SCP area), Ojai Valley, and the Santa Susana Mountains on dry, clay soils in openings in chaparral, coastal scrub, and native perennial grasslands (Johnson 2007; CNPS 2009).

In addition to the direct loss of individuals, Ojai navarretia is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives such as the Ojai navarretia. Exotic plants can also alter

hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development.

Survey Results

Ojai navarretia was only observed in the Salt Creek area in 2003. The Ojai navarretia occurrences were located on clay soils in grasslands, openings in California sagebrush, and sparsely vegetated valley needle grasslands. This species was observed on all but east-facing slopes, and generally on relatively flat soil to slopes up to 40° (Dudek and Associates 2004A, 2004I) (**Figure 4.5-17**, High Country SMA and Salt Creek Area – Special-Status Species Occurrences).

All surveys were conducted (2002 through 2007) during and after the blooming season for Ojai navarretia, which occurs from May through July (Johnson 2007; CNPS 2009). The surveys typically began in April and extended through August. Surveys in the Project development area in 2002 through 2005 focused on the identification of special-status plants. Surveys in the Project development area in 2006 and 2007 focused on the identification of San Fernando Valley spineflower only within known occurrences, reducing the total survey area and, subsequently, the number of other documented special-status species observed. However, given the repeated surveys within the Specific Plan, VCC, and Entrada planning areas, it is assumed that the majority of Ojai navarretia plants on site was observed. This species has definitive habitat requirements and the surveys focused on suitable habitat (see above).

Ojai navarretia occurrences were mapped utilizing aerial photography and topographic maps. Professional judgment and experience were used to delineate these polygons based on the detectability of the species, topography, and vegetation.

Because weather conditions—primarily rainfall—may determine whether this species blooms in a given year, these factors likely affected the detection of Ojai navarretia. There was a less-than-average amount of rainfall in the 2001-2002, 2003-2004, and 2005-2006 rain seasons (WRCC 2008), and, during the 2006-2007 rain season (October 2006-September 2007), the Piru 2 ESE weather station in Los Angeles County experienced its driest year in recorded history, with 4.1 inches of rain—less than one-quarter of the normal mean amount (17.40 inches) (WRCC 2008). While the amount of rainfall varied during the survey years, the 2002-2003 and 2004-2005 rain seasons were above average, and the cumulative survey results are representative of the distribution of this species on site.

Two occurrences of the Ojai navarretia species (totaling approximately 60,000 individuals) were made between April and July 2003 (Dudek and Associates 2004I) during surveys that focused on the identification and location of special-status plant species. Because several years of surveys were conducted for Ojai navarretia and occurrences were mapped, impacts to this species were evaluated by impacts to individuals rather than by loss of habitat

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Impacts to Individuals

Direct Permanent and Temporary Impacts

At least 60,000 Ojai navarretia plants occurred in two locations within the Salt Creek area of the RMDP site in 2003. Neither of these mapped occurrences would be directly lost by implementation of the RMDP and the SCP. Because surveys were conducted within the Project area for special-status plants from 2002 through 2005, there is a low probability that undocumented Ojai navarretia occurrences, consisting of relatively few plants, exist in other portions of the Project area, possibly including areas to be disturbed by construction. Implementation of the RMDP and the SCP would not result in a substantial adverse effect on this species (even if a few plants were to be located in the development area prior to construction), and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). No direct impacts (Impacts to Individuals) are expected to occur; therefore, impacts would not be significant.

Indirect Permanent Impacts

Within the Specific Plan area, 60,000 Ojai navarretia individuals were observed in the Salt Creek area, outside of the Specific Plan development area. This species was not observed within the VCC and Entrada planning areas. Build-out of the Specific Plan, VCC, and Entrada planning areas would not result in the indirect permanent loss of Ojai navarretia individuals (**Figure 4.5-17,** High Country SMA and Salt Creek Area – Special-Status Species Occurrences). Because surveys were conducted within the Project area for special-status plants from 2002 through 2005, there is a low probability that undocumented Ojai navarretia occurrences, consisting of relatively few plants, exist in other portions of the Project area, possibly including areas to be disturbed by construction. Build-out of the Specific Plan, VCC, and Entrada planning areas would not result in a substantial adverse effect on this species (even if a few plants were to be

located in the development area prior to construction), and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). No indirect permanent impacts (Impacts to Individuals) are expected to occur; therefore, impacts would not be significant.

Combined Direct and Indirect Permanent Impacts

The 60,000 Ojai navarretia plants known from the Project area occur within the Salt Creek area portion of the RMDP site. None of these individuals would be directly or indirectly lost as a result of implementing the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas. Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented Ojai navarretia occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. Implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would not result in a substantial adverse effect on this species (even if a few plants were to be located in the development area prior to construction), and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Impacts to Individuals) to this species would not be significant because impacts are not expected to occur as Ojai navarretia has not been identified in the Project development area.

Secondary Impacts

Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and the build-out of the Specific Plan, VCC, and Entrada planning areas include hydrologic alterations and water quality impacts; accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; increased risk of fire; increased human activity, trampling, and soil compaction. Within the RMDP and SCP study area, Ojai navarretia is located only in the Salt Creek area, outside of the impact footprint for the RMDP and the SCP and for the Specific Plan, VCC, and Entrada planning areas, and more than 1,000 feet from the nearest recreational trail. The potential for secondary impacts to affect the known occurrences of this species as a result of the implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas is extremely limited and would likely be associated with inadvertent wildfire. This impact would not constitute a substantial adverse effect on this species or cause a substantial reduction in the number or a reduction in the range of this species (significance criteria 1 and 7). Secondary impacts would not be significant because impacts are not expected.

ALTERNATIVES 3 THROUGH 7

Impacts to Individuals

Direct Permanent and Temporary Impacts and Indirect Permanent Impacts

The 60,000 Ojai navarretia plants known from the Project area occur within the Salt Creek area portion of the RMDP site. None of these individuals would be directly lost by implementation of the RMDP or the SCP or build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas. The potential for impacts to individual Ojai navarretia plants as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2 impacts (no known occurrences would be impacted). Because surveys were conducted within the Project area for special-status plants from 2002 through 2005, there is a low probability that undocumented Ojai navarretia occurrences, consisting of relatively few plants, exist in other portions of the Project area, possibly including areas to be disturbed by construction. The relative risk of impacts to undocumented Ojai navarretia would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Direct and indirect impacts (Impacts to Individuals) would not be significant because impacts are not expected to occur.

Combined Direct and Indirect Permanent Impacts

The 60,000 Ojai navarretia plants known from the Project area occur within the Salt Creek area portion of the RMDP site. None of these individuals would be directly or indirectly lost as a result of implementing the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas. Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented Ojai navarretia occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. Implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would not result in a substantial adverse effect on this species (even if a few plants were to be located in the development area prior to construction), and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Impacts to Individuals) to this species would not be significant because impacts are not expected to occur as Ojai navarretia has not been identified in the Project development area.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The impacts to individual Ojai navarretia and effects on its habitat due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be significant because impacts are not expected to occur.

Mitigation Strategy and Summary

This species would not be subject to significant direct, indirect or secondary impacts by the proposed Project. Construction activities would not occur in habitat occupied by this species. Although no mitigation is required, Ojai navarretia will benefit from previously incorporated Mitigation Measures SP-4.6-53 and SP-4.6-59, which state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required. In addition, the 60,000 known Ojai navarretia individuals would be conserved in the Salt Creek area.

PARISH'S SAGEBRUSH (LOCALLY REGULATED)

Life History

Parish's sagebrush (*Artemisia tridentata* ssp. *parishii)* is not a CNPS special-status species but is considered sensitive by the County of Los Angeles (County of Los Angeles 2003A). It is one of several recognized subspecies of *Artemisia tridentata*, a widespread and characteristic shrub throughout much of western North America. At the Newhall Ranch site, Parish's sagebrush occurs in stands with the more common big sagebrush (*Artemisia tridentata* ssp. *tridentata*) subspecies. According to The Jepson Manual (Hickman 1993), the differentiating characteristics between the two subspecies are as follows: drooping inflorescence branches with hairy achenes (*i.e.*, the matured flower ovaries with seeds inside) in Parish's sagebrush, inflorescence branches erect to spreading with glandular achenes in common big sagebrush. Parish's sagebrush occurs along coastal ranges in Baja California and southern California, extending inland to regions south of the Great Basin (Shultz 2006A, 2006B). It occurs in sandy soils of valleys and foothills. It is considered regionally rare by local botanists (Meyer 2007). Parish's sagebrush blooms from October through November (Munz 1974).It appears that these two subspecies hybridize, as the full range of characteristics (drooping and erect inflorescence branches and hairy and glandular fruit) were found among the collected specimens at Landmark Village within the RMDP and SCP area in November 2005 (Dudek and Associates 2006C). There were sagebrush plants with drooping inflorescence branches (Parish's sagebrush) and erect inflorescence branches (common big sagebrush) that co-occur there, so collections of both were made. After analyzing the characteristics of numerous samples, including examining the fruits under a microscope, it was determined that both subspecies occur there. The characteristics were generally consistent among individual plants that seemed to fit into either Parish's sagebrush or common big sagebrush (*i.e.*, a plant with drooping inflorescence branches and hairy fruit had drooping inflorescence branches and hairy fruit throughout the plant). However, plants that appeared to be hybrids sometimes had mixed characters throughout.

In addition to the direct loss of individuals, Parish's sagebrush is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives such as Parish's sagebrush. Exotic plants can also alter hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development.

Survey Results

Parish's sagebrush was observed within big sagebrush scrub along riparian corridors in the RMDP and SCP area (Dudek and Associates 2006C) and in Salt Creek (Dudek and Associates 2006B). This species has not been observed within the VCC planning area (Dudek and Associates 2002C, 2004B, 2004G, 2006H, 2006K; Dudek 2007H). This species was not observed in the Entrada planning area (Dudek and Associates 2002B, 2004E, 2004H, 2006E, 2006G, 2006J; Dudek 2007G), but there is moderate potential that Parish's sagebrush occurs within big sagebrush scrub in the study area. When observed, Parish's sagebrush was found primarily intermixed with common big sagebrush.

Because focused surveys were conducted in spring and summer (2001 through 2005), most occurred after the annual blooming period for Parish's sagebrush, which blooms October through November (Munz 1974). Surveys in 2006 and 2007 focused on the identification of San Fernando Valley spineflower only within known occurrences, reducing the total survey area and, consequently, the number of other documented special-status species observed; this could be an explanation for why Parish's sagebrush was recorded within the Specific Plan area in 2006 and not at all in 2007. The surveys typically began in April and extended through August. However, big sagebrush is identifiable to the species year round. The mapped big sagebrush scrub would likely include all of the on-site distribution of Parish's sagebrush.

Big sagebrush is the dominant species in big sagebrush scrub on site. The exact locations of individuals of the Parish's sagebrush subspecies within the Project area have not been mapped, but Parish's sagebrush is known to occur as a component of big sagebrush scrub within the Project area. In November 2005, Dudek collected samples from a variety of sagebrush plants at Landmark Village within the RMDP and SCP area to determine what percentage of Parish's sagebrush individuals were present within big sagebrush scrub. At that location, there were sagebrush plants with drooping inflorescence branches (Parish's sagebrush) and erect inflorescence branches (common big sagebrush) that co-occur there, so collections of both were made. After analyzing the characteristics of numerous samples, including examining the fruits under a microscope, it was determined that both subspecies occur there, as do hybrids of the subspecies (Dudek and Associates 2006C). Parish's sagebrush, which is considered special status by the County of Los Angeles, grows intermixed within the common big sagebrush subspecies, which has no special status. Therefore, impacts to Parish's sagebrush were evaluated by loss of habitat instead of impacts to individuals. A total of 93 acres of suitable habitat (big sagebrush scrub) is present in the Project area. (**Figures 4.5-11-A1** through **4.5-11-C2**, RMDP/SCP – Vegetation Communities and Land Covers, **Figure 4.5-20**, VCC SCP Site – Vegetation Communities and Land Covers, and **Figure 4.5-21**, Entrada RMDP/SCP Site – Vegetation Communities and Land Covers).

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP would result in the direct permanent loss of 24 acres (25.8%) and the direct temporary loss of 5.2 acres of suitable habitat on site out of approximately 93 acres on site (**Figures 4.5-33-A1** through **4.5-33-D2**, Alternative 2 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). Potential impacts to individual Parish's sagebrush plants within big sagebrush scrub could occur. No individuals would be directly lost by implementation of the SCP. The loss of Parish's sagebrush as a result of implementation of the RMDP would constitute a substantial direct adverse effect on this species (significance criterion 1). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan and Entrada planning areas would result in the indirect permanent loss of 47 acres (50.5%) of big sagebrush scrub within the Project area (**Figures 4.5-33-A1** through **4.5-33-D2**, Alternative 2 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). Given these impacts, it is foreseeable that individual Parish's sagebrush plants would be lost as a result of build-out of the Specific Plan and Entrada planning areas. This would constitute a substantial adverse effect on this species (significance criterion 1). No impacts related to the build-out of the VCC planning area are expected. Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas would total 71 acres (76.3%). No impacts related to the build-out of the

VCC planning area are expected. The combined direct and indirect impacts to suitable habitat and associated loss of Parish's sagebrush plants would have a substantial adverse effect on this species (significance criterion 1). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas include accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; hydrologic alterations and water quality impacts; the introduction of non-native, invasive plant species; increased human activity, trampling, and soil compaction; and increased risk of fire. No impacts related to build-out of the VCC planning area are expected. The potential loss of Parish's sagebrush and the effect on its habitat as a result of these secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas would constitute a substantial adverse effect on this species and would conflict with local policies and ordinances protecting biological resources (significance criterion 1). Secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for Parish's sagebrush:

- Alternative 3 – 22 acres (23.7%) of permanent loss and 6.2 acres of temporary loss;
- Alternative 4 – 22 acres (23.7%) of permanent loss and 5.1 acres of temporary loss;
- Alternative 5 – 22 acres (23.7%) of permanent loss and 6.6 acres of temporary loss;
- Alternative 6 – 16 acres (17.1%) of permanent loss and 6.5 acres of temporary loss; and
- Alternative 7 – 2.6 acres (2.8%) of permanent loss and 21 acres of temporary loss.

Compared to Alternative 2, which would result in 24 acres (25.8%) of permanent direct loss and 5.2 acres of temporary loss, the permanent and temporary loss of habitat under Alternatives 3 through 6 would not be substantially different (**Figures 4.5-34-A1** through

4.5-38-D2, Alternatives 3 through 7 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). The difference between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts under that alternative.

Because the overall direct loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is not substantially different than overall habitat loss under Alternative 2, these impacts would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for Parish's sagebrush. No impacts related to build-out of the VCC planning area are expected under Alternatives 3 through 7.

- Alternative 3 – 34 acres (36.6%) of permanent loss;
- Alternative 4 – 32 acres (34.4%) of permanent loss;
- Alternative 5 – 35 acres (37.6%) of permanent loss;
- Alternative 6 – 17 acres (17.8%) of permanent loss; and
- Alternative 7 – 9.3 acres (10.0%) of permanent loss.

Compared to Alternative 2, which would result in 47 acres (50.5%) of permanent indirect loss of habitat, Alternatives 3 through 7 would have reduced impacts (**Figures 4.5-34-A1** through **4.5-38-D2**, Alternatives 3 through 7 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). Alternatives 3 through 6 would impact relatively fewer acres than Alternative 2 because of reductions in the Project footprint. Alternative 7 would have the least impact because there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that would reduce impacts to Parish's sagebrush.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the loss of habitat on site. The indirect permanent loss of suitable habitat for Parish's sagebrush occurring as a result of build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas

would result in the following impacts to suitable habitat for Parish's sagebrush. No impacts related to build-out of the VCC planning area are expected under Alternatives 3 through 7.

- Alternative 3 – 56 acres (60.2%) of permanent loss;
- Alternative 4 – 54 acres (58.1%) of permanent loss;
- Alternative 5 – 57 acres (61.3%) of permanent loss;
- Alternative 6 – 32 acres (34.8%) of permanent loss; and
- Alternative 7 – 12 acres (12.8%) of permanent loss.

Compared to Alternative 2, which would result in 71 acres (76.3%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts, as described above for the discussions of direct and indirect impacts. Reduced impacts would occur because of reductions in the Project footprint under Alternatives 3 through 6; additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions would occur under Alternative 7. The combined direct and indirect permanent loss of suitable habitat for Parish's sagebrush occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. No impacts related to build-out of the VCC planning area are expected under Alternatives 3 through 7. The loss of or degradation of suitable habitat and the loss of individual Parish's sagebrush due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to Parish's sagebrush: (1) loss of suitable habitat, and (2) secondary impacts to individuals and suitable habitat outside the Project footprint. Impacts to habitat and associated individuals could occur during construction as a

result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment. The combined permanent loss of suitable habitat for Parish's sagebrush resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 12 acres (12.8%) under Alternative 7 to 71 acres (76.3%) under Alternative 2. The combined permanent loss of habitat would constitute a substantial adverse effect on the habitat of this species and would substantially reduce the number or restrict the range of this species. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to habitat and associated individuals, which are typically associated with big sagebrush scrub along riparian corridors. The Project applicant will implement a series of mitigation measures designed to replace, restore, enhance, and maintain natural riparian communities in the Santa Clara River or its tributaries; and create new riparian communities in areas that currently support degraded or exotic vegetation. For riparian vegetation communities, this includes the direct replacement of riparian communities at a minimum 1:1 ratio for all permanently affected habitats in order to achieve the same functions and services that were lost through implementation of the proposed Project. Restoration shall be in kind and at a 1:1 replacement ratio for new vegetation communities if the replacement vegetation is installed two years in advance of the removal of existing vegetation communities. If the replacement vegetation communities cannot be installed prior to the two-year period, the restoration ratios would increase to ensure the replacement of lost functions and services. Mitigation designed to restore, enhance, or replace temporarily disturbed riparian vegetation communities focuses on achieving the required percent coverage and tree growth performance criteria for the proposed target species, as well as native species recruitment and reproduction. Mitigation measures will provide for the long-term maintenance of the River Corridor SMA, High Country SMA, and Open Area in a natural state by restricting access to and prohibiting grazing, agriculture, and recreation within these areas; providing for the restoration and enhancement of habitat within these areas; and through the open space dedication of these areas.

Short-term secondary impacts, such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; and hydrologic alterations and water quality impacts, would be minimized by providing guidelines for grading and construction activities; by retaining a qualified biologist during all grading and construction activities; by providing erosion control plans, dust control, and an overall Project SWPPP; by preventing pollutants from entering flowing streams and storm flows; by providing guidelines for stream diversion; and by requiring that the Specific Plan conform to all provisions of required NPDES permits and water quality permits required by the RWQCB. Long-term, residual secondary impacts to the Parish's sagebrush, such as the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction would be minimized by restricting access to, grazing within, and recreational usage of the River Corridor SMA and High Country SMA; providing for transition areas along the River Corridor SMA and High Country SMA; providing

drainage guidelines; requiring conformance with NPDES and RWQCB permit provisions; requiring the implementation of a wildfire fuel modification plan (Dudek 2008A); placing restrictions on domestic animals in proximity to open space areas; providing trail signage and homeowner education; placing restrictions on plant palettes proposed for use on landscaped slopes; and providing revegetation plans for the River Corridor SMA.

All specific mitigation measures for Parish's sagebrush are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-178 LOSS OF HABITAT – PARISH'S SAGEBRUSH

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to avoid, minimize, and/or mitigate the loss of habitat for Parish's sagebrush.

In order to mitigate for impacts to riparian resources, the following mitigation measures will be implemented. SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-26a identifies riparian revegetation and oak tree replacement opportunities in the High Country SMA, and specifies mitigation requirements for each. SP-4.6-28 states that mitigation banking for riparian habitats in the High Country SMA is subject to state and federal regulations and permits, mitigation for oak resources is subject to the Oak Resources Management Plan, and mitigation banking for Mexican elderberry scrub is subject to the approval of the County Forester. SP-4.6-47a permits mitigation banking within the River Corridor SMA, High Country SMA, and Open Area, subject to requirements for riparian habitats, oak resources, and Mexican elderberry scrub. SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In addition to restoration mitigation measures described above, Parish's sagebrush will benefit from the following preservation and management mitigation measures. SP-4.6-21 through SP-

4.6-26 describe the open space dedication of the River Corridor SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA. Mitigation Measures SP-4.6-46 and SP-4.6-47 describe the dedication of the Open Area and provide acceptable usage guidelines.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to reduce the loss of habitat for Parish's sagebrush.

In addition to the riparian resource mitigation measures described above, the following mitigation measures will mitigate for impacts to riparian resources. BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

In addition to the restoration mitigation measures described above, Parish's sagebrush will benefit from the following preservation and management mitigation measure. BIO-62 states that at least 1,900 acres of Open Area within the Specific Plan area shall be offered for dedication to an NLMO. These 1,900 acres of the Open Area will be left as natural vegetation.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, impacts associated with the loss of habitat for Parish's sagebrush would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-179 SECONDARY IMPACTS – PARISH'S SAGEBRUSH

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to Parish's sagebrush.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-20, SP-4.6-32, SP-4.6-34, and SP-4.6-35:

SP-4.6-20 states that any grading activities within or adjacent to the River Corridor SMA shall have grading perimeters clearly marked and inspected prior to grading. The Project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources**.**

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-34 and SP-4.6-35 establish that grading perimeters shall be clearly marked and inspected by the Project biologist prior to impacts occurring within or adjacent to the High Country SMA, and that the biologist shall work with the grading contractor to avoid inadvertent impacts to biological resources outside of the grading area.

Secondary impacts associated with accidental clearing, trampling, and grading would be further mitigated by implementation of Mitigation Measure SP-4.6-33, which permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

In order to avoid and minimize impacts from hydrologic and water quality-related impacts adjacent to and downstream of construction activities, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-44 and SP-4.6-45, which provide guidelines for major drainages, and SP-4.6-58, which requires conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-7, SP-4.6-19, SP-4.6-26a, SP-4.6-33, and SP-4.6-43:

SP-4.6-7 requires that revegetation plans for the River Corridor SMA include guidelines for the maintenance of the mitigation site during the establishment of plantings, control of non-native plants, maintenance of the irrigation system, and replacement of plants, if necessary.

SP-4.6-19 requires that transition areas be in areas where there is no steep grade separation, that native riparian plants be incorporated into landscaping where feasible, that roads and bridges be designed to discourage access to the River Corridor SMA, that bank stabilization be composed of ungrouted rock, and that a minimum 100-foot-wide buffer be provided between top river-side of bank stabilization and development.

SP-4.6-26a identifies riparian revegetation and oak tree replacement opportunities in the High Country SMA and specifies mitigation requirements for each.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

In order to avoid and minimize impacts from increased human activity and trampling, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-17, SP-4.6-18 and SP-4.6-19, SP-4.6-24, SP-4.6-29 through SP-4.6-32, SP-4.6-33, and SP-4.6-39:

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-24 states that the River Corridor SMA conservation and public access easement shall prohibit grazing and agriculture and shall restrict recreational use to the established trail system.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-39 states that the High Country SMA easements shall prohibit grazing within the High Country SMA, except for long-term resource management programs, and shall restrict recreation to the established trail system.

In order to avoid and minimize impacts from increased fire frequency, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-17, SP-4.6-31, SP-4.6-32, SP-4.6-33, and SP-4.6-49 through SP-4.6-52:

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-31 prohibits hunting, fishing, and motor or off-trail bike riding within the High Country SMA.

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-49 through SP-4.6-52 describe wildfire fuel modification plans and fuel modification measures that will minimize the potential exposure of the development areas, Open Area, and SMAs to fire hazards.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA, the High Country SMA, and Open Area in a natural state. These measures include SP-4.6-1

through SP-4.6-16 and SP-4.6-63, SP-4.6-17, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-26a, SP-4.6-27, SP-4.6-28, SP-4.6-29 through SP-4.6-32, SP-4.6-33, SP-4.6-36 through SP-4.6-42, SP-4.6-43, SP-4.6-46 and SP-4.6-47, SP-4.6-47a, and SP-4.6-55 and SP-4.6-58:

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

SP-4.6-26a identifies riparian revegetation and oak tree replacement opportunities in the High Country SMA and specifies mitigation requirements for each.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-28 states that mitigation banking for riparian habitats in the High Country SMA is subject to state and federal regulations and permits, mitigation for oak resources is subject to the Oak Resources Management Plan, and mitigation banking for Mexican elderberry scrub is subject to the approval of the County Forester.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA. Mitigation Measure SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

SP-4.6-46 and SP-4.6-47 describe the dedication of the Open Area and provide acceptable usage guidelines.

SP-4.6-47a permits mitigation banking within the River Corridor SMA, High Country SMA, and Open Area, subject to requirements for riparian habitats, oak resources, and Mexican elderberry scrub.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate short-term and long-term secondary impacts to a level that is adverse but not significant.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust; as well as from hydrologic alterations and water quality impacts, this EIS/EIR identifies Mitigation Measures BIO-45 and BIO-52:

BIO-45 defines the timing and design of stream diversion bypass channels and dewatering activities and related restrictions to ensure that proper construction, operation, and abandonment diversion or dewatering will occur.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to further avoid and minimize impacts from dust, runoff, sedimentation, erosion, and chemical and toxic compound pollution, this EIS/EIR identifies Mitigation Measures BIO-70 and BIO-71:

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 requires dust control measures for development areas to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control plans shall comply with SCAQMD Rule 403 (SCAQMD 2005) and chemical dust suppression shall not be utilized within 100 feet of known special-status plant communities.

Short-term secondary impacts associated with runoff, sedimentation, erosion and chemical and toxic compound pollution and with hydrological alterations and water quality impacts would also be mitigated by implementation of Mitigation Measure BIO-49, which prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, this EIS/EIR identifies Mitigation Measure BIO-72, which specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

In order to avoid and minimize impacts from increased human activity and trampling, this EIS/EIR identifies Mitigation Measures BIO-69 and BIO-73:

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA, the High Country SMA, and Open Area in a natural state. These measures include BIO-1 through BIO-16, BIO-62, BIO-69, and BIO-73:

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-62 states that at least 1,900 acres of Open Area within the Specific Plan area shall be offered for dedication to an NLMO. These 1,900 acres of the Open Area will be left as natural vegetation.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to Parish's sagebrush would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

PEIRSON'S MORNING-GLORY (CNPS LIST 4.2/S3.2)

Life History

Peirson's morning-glory (*Calystegia peirsonii*) is endemic to Los Angeles County in the northern San Gabriel Mountains and adjacent Mojave Desert (Antelope Valley). Its geographic range is relatively narrow, but it is widespread and locally common in the Liebre Mountains northeast of the Project area (Boyd 1999). It is in the morning-glory family (Convolvulaceae). It is found primarily on rocky slopes at elevations between 30 and 1,500 meters AMSL. It is a weakly climbing rhizomatous perennial, typically found in chaparral, coastal scrub, chenopod scrub, cismontane woodland, lower montane coniferous forest, and grasslands. It generally blooms between April and June (CNPS 2007; Hickman 1993).

Peirson's morning-glory grows to about 0.4 meter in height. The leaf and bractlet size, shape, and position relative to the flower base are characteristic and important to identification. It hybridizes or intergrades with several related species where their geographic ranges overlap (Hickman 1993; Boyd 1999). Identifications are often difficult due to these intermediate plants.

No species-specific pollination or seed dispersal data are available for Peirson's morning-glory. However, a *Calystegia* study conducted in Japan revealed that bees were the primary pollinators, comprising 56.7% of the total visitor species (Ushimaru and Kikuzawa 1999).

In addition to the direct loss of individuals, Peirson's morning-glory is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives such as the Peirson's morning-glory. Exotic plants can also alter hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development.

Survey Results

Observations of Peirson's morning-glory in 2002, 2003, 2004, 2005, and 2006 (Dudek and Associates 2002A, 2002B, 2004B, 2004C, 2004E, 2004F, 2004G, 2004H, 2004I, 2006B, 2006F, 2006G, 2006H, 2006I, 2006K; FL*x* 2002A) were made during surveys that focused on the identification and location of special-status species.

Because focused surveys were conducted in spring and summer (2001 through 2005), most occurred during and after the annual blooming period for Peirson's morning-glory, which blooms

from April to June (CNPS 2007). The surveys typically began in April and extended through August. Surveys in 2006 and 2007 focused on the identification of San Fernando Valley spineflower only within known occurrences, reducing the total survey area and, consequently, the number of other documented special-status species observed; this could be an explanation for why Peirson's morning-glory was recorded within the Specific Plan and VCC planning areas in 2006 but not in 2007, and why this species was not recorded within the Entrada planning area in either 2006 or 2007.

While never abundant, Peirson's morning-glory is widespread on site and was observed on ridges and slopes, weakly climbing over chaparral, coastal scrub, and grasslands throughout the Specific Plan, VCC, and Entrada planning areas, and the High Country SMA and Salt Creek area. Given the low sensitivity status of the species, the exact locations of individuals of this species within the Project area have not been mapped. Therefore, impacts to this species were evaluated by loss of habitat instead of impacts to individuals. A total of 8,780 acres of suitable habitat (chaparral, coastal scrub, and grassland vegetation communities) is present in the Project area (**Figures 4.5-11-A1** through **4.5-11-C2**, RMDP/SCP – Vegetation Communities and Land Covers, **Figure 4.5-20**, VCC SCP Site – Vegetation Communities and Land Covers, and **Figure 4.5-21**, Entrada RMDP/SCP Site – Vegetation Communities and Land Covers).

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP would result in the direct loss of 95 acres (1.1%) of suitable habitat for this species (within both the permanent and temporary footprints) out of 8,780 acres of suitable habitat on site (**Figures 4.5-33-A1** through **4.5-33-D2**). No individuals would be directly lost by implementation of the SCP. The direct loss of Peirson's morning-glory plants occupying this habitat as a result of construction/grading activities would have a substantial adverse effect on a species considered threatened by

CDFG (S3.2) (significance criterion 1). Direct impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in the indirect permanent loss of 2,966 acres (33.8%) of suitable habitat within these development areas (**Figures 4.5-33-A1** through **4.5-33-D2**). It is possible that individual Peirson's morning-glory plants within these vegetation communities would be lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. Although the number of individuals potentially affected would be minimal, the direct loss of Peirson's morning-glory occupying this habitat as a result of construction/grading activities would have a substantial adverse effect on a species considered threatened by CDFG (S3.2) (significance criterion 1). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,061 acres (34.9%). Although the number of individuals potentially affected would be minimal, the direct loss of Peirson's morning-glory occupying this habitat as a result of construction/grading activities would have a substantial adverse effect on a species considered threatened by CDFG (S3.2) (significance criterion 1). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; hydrologic alterations and water quality impacts; the introduction of non-native, invasive plant species; increased human activity, trampling, and soil compaction; and increased risk of fire. Because of the widespread presence of this species on site in proximity to proposed development areas, short-term and long-term secondary impacts are expected to occur to this species. The potential loss of Peirson's morning-glory and the effect on its habitat as a result of the secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas would constitute a substantial adverse effect on a special-status species and would substantially reduce the number or restrict the range of an endangered, rare, or threatened species (significance criteria 1 and 7). Secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for Peirson's morning-glory (**Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 106 acres (1.2%) of permanent loss;
- Alternative 4 – 94 acres (1.1%) of permanent loss;
- Alternative 5 – 124 acres (1.4%) of permanent loss;
- Alternative 6 – 146 acres (1.7%) of permanent loss; and
- Alternative 7 – 136 acres (1.5%) of permanent loss.

Compared to Alternative 2, which would result in the direct loss of 95 acres (1.1%) of suitable habitat, the direct loss of habitat under Alternatives 3 through 6 would not be substantially different. The difference between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is not substantially different than overall habitat loss under Alternative 2, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for Peirson's morning-glory (**Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 2,798 acres (31.9%) of permanent loss;
- Alternative 4 – 2,692 acres (30.7%) of permanent loss;
- Alternative 5 – 2,612 acres (29.7%) of permanent loss;
- Alternative 6 – 2,347 acres (26.7%) of permanent loss; and
- Alternative 7 – 2,062 acres (23.5%) of permanent loss.

Compared to Alternative 2, which would result in 2,966 acres (33.8%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 6 would impact fewer acres than Alternative 3 because VCC would not be constructed. Alternative 7 would have the least impact because VCC would not be constructed and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that would reduce impacts to Peirson's morning-glory.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, impacts for Alternatives 3 through 7 would still be substantially adverse because of the loss of habitat on site. The indirect permanent loss of suitable habitat for Peirson's morning-glory occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for Peirson's morning-glory:

- Alternative 3 – 2,904 acres (33.1%) of permanent loss;
- Alternative 4 – 2,786 acres (31.7%) of permanent loss;
- Alternative 5 – 2,736 acres (31.2%) of permanent loss;
- Alternative 6 – 2,493 acres (28.4%) of permanent loss; and
- Alternative 7 – 2,198 acres (25.0%) of permanent loss.

Compared to Alternative 2, which would result in 3,061 acres (34.9%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts, as described above for the discussions of direct and indirect impacts. Reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, and additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions would occur under Alternative 7. The combined direct and indirect permanent loss of suitable habitat for Peirson's morning-glory occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The loss of or degradation of suitable habitat and the loss of individual Peirson's morning-glory due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to Peirson's morning-glory: (1) loss of habitat, and (2) secondary impacts to individuals and suitable habitat outside the Project footprint.

Loss of habitat (and associated impacts to occasional individual Peirson's morning-glory plants) could occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment. The combined permanent loss of Peirson's morning-glory habitat would range from 2,198 acres (25.0%) under Alternative 7 to 3,061 acres (34.9%) under Alternative 2. The combined permanent loss of this habitat would have a substantial adverse effect on this species. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. At least 3,668 acres of suitable habitat will be conserved in the High Country SMA and Salt Creek area where long-term preservation is provided. Mitigation measures for the preservation and management of the 4,205-acre High Country SMA would protect approximately 2,726 acres of suitable Peirson's morning-glory habitat (Dudek 2007A) and would allow Peirson's morning-glory to persist on site in perpetuity.

Short-term secondary impacts, such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; and hydrologic alterations and water quality impacts would be minimized by providing guidelines for grading and construction activities; by retaining a qualified biologist during all grading and construction activities; by providing erosion control plans, dust control, and an overall Project SWPPP; by preventing pollutants from entering flowing streams and storm flows; by providing guidelines for stream diversion; and by requiring that the Specific Plan conform to all provisions of required NPDES permits and water quality permits required by the RWQCB. Long-term secondary impacts to Peirson's morning-glory, such as the introduction of non-native,

invasive plant species; hydrologic alterations and water quality impacts; increased human activity, trampling, and soil compaction; and increased risk of fire, would be minimized by restricting access to, grazing within, and recreational usage of the High Country SMA; providing for transition areas along the High Country SMA; providing drainage guidelines; requiring conformance with NPDES and RWQCB permit provisions; requiring the implementation of a wildfire fuel modification plan (Dudek 2008A); placing restrictions on domestic animals in proximity to open space areas; providing trail signage and homeowner education; and placing restrictions on plant palettes proposed for use on landscaped slopes.

All specific mitigation measures for Peirson's morning-glory are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-180 LOSS OF HABITAT – PEIRSON'S MORNING GLORY

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to avoid, minimize, or mitigate the loss of habitat (chaparral, coastal scrub, and grassland vegetation communities) for Peirson's morning-glory.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where chaparral, coastal scrub, and grassland vegetation communities occurs. Transition from the development edge to the natural area (where chaparral, coastal scrub, and grassland vegetation communities occur) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High

Country SMA, which supports 2,726 acres of chaparral, coastal scrub, and grassland vegetation communities.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends four mitigation measures to reduce the loss of habitat (chaparral, coastal scrub, and grassland vegetation communities) for Peirson's morning-glory.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA, both of which support chaparral, coastal scrub, and grassland vegetation communities and Peirson's morning-glory occurrences. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-62 states that at least 1,900 acres of Open Area within the Specific Plan area shall be offered for dedication to a NLMO. These 1,900 acres of the Open Area will be left as natural vegetation.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, impacts associated with the loss of habitat for Peirson's morning-glory would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-181 SECONDARY IMPACTS – PEIRSON'S MORNING-GLORY

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to Peirson's morning-glory.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-32, SP-4.6-34, and SP-4.6-35:

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-34 and SP-4.6-35 establish that grading perimeters shall be clearly marked and inspected by the Project biologist prior to impacts occurring within or adjacent to the High Country SMA, and that the biologist shall work with the grading contractor to avoid inadvertent impacts to biological resources outside of the grading area.

Secondary impacts associated with accidental clearing, trampling, and grading would be further mitigated by implementation of Mitigation Measure SP-4.6-33, which permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where chaparral, coastal scrub, and grassland vegetation communities occur. Transition from the development edge to the natural area (where chaparral, coastal scrub, and grassland vegetation communities occur) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-33, which permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where chaparral, coastal scrub, and grassland vegetation communities occur. Transition from the development edge to the natural area (where chaparral, coastal scrub, and grassland vegetation communities occur) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

In order to avoid and minimize impacts from increased human activity and trampling, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-29 through SP-4.6-32, SP-4.6-33, and SP-4.6-39:

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where chaparral, coastal scrub, and grassland vegetation communities occur. Transition from the development edge to the natural area (where chaparral, coastal scrub, and grassland vegetation communities occur) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-39 states that the High Country SMA easements shall prohibit grazing within the High Country SMA, except for long-term resource management programs, and shall restrict recreation to the established trail system.

In order to avoid and minimize impacts from hydrologic and water quality-related impacts adjacent to and downstream of construction activities, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-44 and SP-4.6-45, which provide guidelines for major drainages (which are in proximity to chaparral, coastal scrub, and grassland vegetation communities), and SP-4.6-58, which requires conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In order to avoid and minimize impacts from increased fire frequency, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-31, SP-4.6-32, SP-4.6-33, and SP-4.6-49 through SP-4.6-52:

SP-4.6-31 prohibits hunting, fishing, and motor or off-trail bike riding within the High Country SMA.

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition

from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-49 through SP-4.6-52 describe wildfire fuel modification plans and fuel modification measures that will minimize the potential exposure of the development areas, Open Area, and SMAs (which contain chaparral, coastal scrub, and grassland vegetation communities) to fire hazards.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the High Country SMA and Salt Creek area in a natural state. These measures include SP-4.6-27, SP-4.6-29 through SP-4.6-32, SP-4.6-33, SP-4.6-36 through SP-4.6-42, and SP-4.6-55 and SP-4.6-58:

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. This will benefit chaparral, coastal scrub, and grassland vegetation communities located in proximity to drainages.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate short-term and long-term secondary impacts to a level that is adverse but not significant.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading, this EIS/EIR identifies Mitigation Measure BIO-52, which states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to avoid and minimize impacts from dust, runoff, sedimentation, erosion, and chemical and toxic compound pollution, this EIS/EIR identifies Mitigation Measures BIO-52, BIO-70, and BIO-71:

BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 requires dust control measures for development areas to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control plans shall comply with SCAQMD Rule 403 (SCAQMD 2005) and chemical dust suppression shall not be utilized within 100 feet of known special-status plant communities.

Short-term secondary impacts associated with runoff, sedimentation, erosion, and chemical and toxic compound pollution would be further mitigated by implementation of Mitigation Measure BIO-49, which prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, this EIS/EIR identifies Mitigation Measure BIO-72, which specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure

that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

In order to avoid and minimize impacts from increased human activity and trampling, this EIS/EIR identifies Mitigation Measure BIO-69, which requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

In order to avoid and minimize impacts from hydrologic and water quality-related impacts adjacent to and downstream of construction activities, this EIS/EIR identifies Mitigation Measures BIO-49 and BIO-52:

BIO-49 requires that pollutants from construction activities not be allowed to enter a flowing stream or be placed in locations that may be subjected to storm flows. This will benefit chaparral, coastal scrub, and grassland vegetation communities and any Peirson's morning-glory located in proximity to drainages.

BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to avoid and minimize impacts from increased fire frequency, this EIS/EIR identifies Mitigation Measure BIO-63, which requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the High Country SMA and Salt Creek area in a natural state. These measures include BIO-19, BIO-20, BIO-21, and BIO-69:

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA, both of which support chaparral, coastal scrub, and grassland vegetation communities and Peirson's morning-glory occurrences. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to Peirson's morning-glory would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

PLUMMER'S MARIPOSA LILY (CNPS LIST 1B.2/S3.2)

Life History

Plummer's mariposa lily (*Calochortus plummerae*) is known to occur in Riverside, San Bernardino, Orange, Los Angeles, and Ventura counties at elevations between 100 and 1,700 meters AMSL. Records exist for the south side of the Santa Susana Mountains and Simi Hills adjacent to the Project area. This bulbiferous herb is typically found in chaparral, coastal scrub, cismontane woodland, lower montane coniferous forest, and grassland, often on granitic and/or rocky soils, and blooms between May and July (CNPS 2007). It is identified by its (usually) toothed petal margins; petals covered with long yellow hairs inside; and its round, slightly depressed nectar gland at the base of each petal surrounded by hairs but without hairs on the nectary surface itself (Hickman 1993). No species-specific pollination or seed dispersal data are available for Plummer's mariposa lily. Seed dispersal for *Calochortus* is limited, with no obvious adaptations for wind or animal dispersal; fruits are capsular and borne close to the ground, with relatively heavy, passively dispersed seeds that lack fleshiness, sticktights, or (except in one species) wings (Patterson and Givnish 2003). Typically, *Calochortus* flowers are generalists in terms of their pollinators, although bees have been observed to be the primary pollinator in some *Calochortus* species, such as Lyall's mariposa lily (*C. lyallii*) (Dilley *et al.* 2000; Miller 2000).

Perennial bulbs, including Plummer's mariposa lily, may persist below ground without producing flowers or even leaves during years of poor rainfall or other environmental causes. For example, bulbs tend to flower in higher numbers following wildfire, which introduces large quantities of mineral nutrients (as ash) into the soil. Dormant plants (those producing no aboveground growth in a given year) cannot be located by field botanists, and those producing only leaves are unlikely to be found during surveys because the leaves are inconspicuous and visually similar to grass leaves. Thus, numbers of plants observed above ground fluctuates much more widely than numbers of living bulbs in the soil. The number of plants censused even in a "good" year is a minimum estimate of the number of living bulbs in the soil.

In addition to the direct loss of individuals, Plummer's mariposa lily is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives such as the Plummer's mariposa lily. Exotic plants can also alter hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development.

Survey Results

Plummer's mariposa lily was only observed in the High Country SMA on steep southwest-facing ridges and slopes in coastal scrub and grasslands. The plants were generally mapped in areas of high vegetative cover and a variety of soil types (*e.g.*, gravelly loam, sandy loam, and rocky clay) (Dudek and Associates 2006B) (**Figure 4.5-17**, High Country SMA and Salt Creek Area – Special-Status Species Occurrences).

All surveys were conducted (2002 through 2007) during and after the blooming season for Plummer's mariposa lily, which occurs from May through July (CNPS 2007). As mentioned above in the Life History section, only a fraction of *Calochortus* plants flower in any given year, and the non-flowering individuals are generally not as visible. It is therefore not possible to estimate what portion was observed. In addition, surveys in the Project development area in 2006 and 2007 focused on the identification of San Fernando Valley spineflower only within known occurrences, reducing the total survey area and, subsequently, the number of other documented special-status species observed. However, given the repeated surveys within the Specific Plan, VCC, and Entrada planning areas, it is assumed that the majority of Plummer's mariposa lily plants on site was observed.

Plummer's mariposa lily occurrences were mapped utilizing aerial photography and topographic maps. Professional judgment and experience were used to delineate these polygons based on the detectability of the species, topography, and vegetation. This and other perennial special-status plants were mapped at a 10- to 20-meter (32.8- to 65.6-foot) scale due to their population dynamics (including seed dispersal and pollination range), observability, habit, habitat limitations, and mapping accuracy.

Because weather conditions—primarily rainfall—largely determine whether this species blooms in a given year, these factors likely affected the detection of the Plummer's mariposa lily. There was a less-than-average amount of rainfall in the 2001-2002, 2003-2004, and 2005-2006 rain seasons (WRCC 2008), and, during the 2006-2007 rain season (October 2006-September 2007), the Piru 2 ESE weather station in Los Angeles County experienced its driest year in recorded history, with 4.1 inches of rain—less than one-quarter of the normal mean amount (17.40 inches) (WRCC 2008). While the amount of rainfall varied during the survey years, the 2002-2003 and 2004-2005 rain seasons were above average, and the cumulative survey results are representative of the distribution of this species on site.

Within the RMDP and SCP sites, Plummer's mariposa lily was found only in the High Country SMA. An estimated number of approximately 78 individuals occupying five locations was observed (Dudek and Associates 2006B). Because several years of mapped occurrence data are available for Plummer's mariposa lily, impacts to this species were evaluated by impacts to individuals rather than by loss of habitat.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see Subsection 4.5.5.2.2 for detailed analysis.

ALTERNATIVE 2

Impacts to Individuals

Direct Permanent and Temporary Impacts

At least 78 Plummer's mariposa lily plants occur in five locations within the High Country SMA portion of the RMDP and SCP site. None of these individuals would be directly lost by implementation of the RMDP and the SCP. Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented Plummer's mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. Implementation of the RMDP and the SCP would not result in a substantial adverse effect on this species (even if a few plants were to be located in the development area prior to construction), and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). Direct impacts (Impacts to Individuals) would not be significant because impacts are not expected to occur as Plummer's mariposa lily has not been identified in the Project development area.

Indirect Permanent Impacts

Within the Specific Plan area, 78 Plummer's mariposa lily individuals were observed in the High Country SMA, outside of the Specific Plan development area. This species was not observed within the VCC and Entrada planning areas. Therefore, build-out of the Specific Plan, VCC, and Entrada planning areas would not result in the loss of known Plummer's mariposa lily plants (**Figure 4.5-146,** Alternative 2 Impacts to RMDP/SCP Special-Status Plants). Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, **t**here is a low probability that undocumented Plummer's mariposa lily occurrences, consisting of relatively few plants, exist in the Specific Plan development area. Build-out of the Specific Plan, VCC, and Entrada planning areas would not result in a substantial adverse effect on this

species(even if a few plants were to be located in the development area prior to construction), and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would not be significant because impacts are not expected to occur as Plummer's mariposa lily has not been identified in the Project development area.

Combined Direct and Indirect Permanent Impacts

The 78 Plummer's mariposa lily plants known from the Project area occur only within the High Country SMA portion of the RMDP site. None of these individuals would be directly or indirectly lost as a result of implementing the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas. Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented Plummer's mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. Implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would not result in a substantial adverse effect on this species (even if a few plants were to be located in the development area prior to construction), and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Impacts to Individuals) to this species would not be significant because impacts are not expected to occur as Plummer's mariposa lily has not been identified in the Project development area.

Secondary Impacts

Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and the build-out of the Specific Plan, VCC, and Entrada planning areas include the introduction of non-native, invasive plant and animal species; vegetation clearing; trampling; the introduction of chemical pollutants; increased fire frequency; exposure to fugitive dust; contact with polluted runoff; and changes in hydrology. Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented Plummer's mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. Within the RMDP and SCP study area, Plummer's mariposa lily is located only in the High Country SMA, outside of the impact footprint for the RMDP and the SCP and for the Specific Plan, VCC, and Entrada planning areas. The potential for secondary impacts to affect the known occurrences of this species as a result of the implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas is extremely limited and would likely be associated with inadvertent wildfire. This impact would not constitute a substantial adverse effect on this species or cause a substantial reduction in the number or a reduction in the

range of this species (significance criteria 1 and 7). Secondary impacts would not be significant because impacts are not expected to occur as Plummer's mariposa lily has not been identified in the Project development area or within 300 feet of the Project development area.

ALTERNATIVES 3 THROUGH 7

Impacts to Individuals

Direct Permanent and Temporary Impacts and Indirect Permanent Impacts

The 78 Plummer's mariposa lily plants known from the Project area occur only within the High Country SMA portion of the RMDP site. None of these individuals would be directly lost by implementation of the RMDP or the SCP or build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas (**Figures 4.5-147** through **4.5-151**, Alternatives 3 through 7 Impacts to RMDP/SCP Special-Status Plants). The potential for impacts to individual Plummer's mariposa lily plants as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2. Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented Plummer's mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. The relative risk of impacts to undocumented Plummer's mariposa lily would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Direct and indirect impacts (Impacts to Individuals) would not be significant because impacts are not expected to occur as Plummer's mariposa lily has not been identified in the Project development area.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would be similar to Alternative 2. The 78 Plummer's mariposa lily plants known from the Project area occur only within the High Country SMA portion of the RMDP site. None of these individuals would be directly lost by implementation of the RMDP or the SCP, or build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas. Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented Plummer's mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. The relative risk of impacts to undocumented Plummer's mariposa lily would decrease proportionally with decreases in the size of the Project footprint under the different

alternatives. Combined direct and indirect permanent impacts (Impacts to Individuals) would not be significant because impacts are not expected to occur.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The impacts to individual Plummer's mariposa lily and the effect on its habitat due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 would not be significant because impacts are not expected to occur as Plummer's mariposa lily has not been identified in the Project development area.

Mitigation Strategy and Summary

This species would not be subject to significant direct, indirect or secondary impacts by the proposed Project. Construction activities would not occur in habitat occupied by this species. Although no mitigation is required, Plummer's mariposa lily will benefit from previously incorporated Mitigation Measures SP-4.6-53 and SP-4.6-59, which state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required. In addition, the 78 known Plummer's mariposa lily would be conserved in the High Country SMA.

SLENDER MARIPOSA LILY (CNPS LIST 1B.2/S1.1?)

Life History

Slender mariposa lily (*Calochortus clavatus* var. *gracilis*) is known to occur in the southern San Gabriel Mountains of eastern Los Angeles County and the Santa Susana Mountains in western Los Angeles and Ventura counties at elevations between about 360 and 1,000 meters AMSL. This bulb-forming herb is typically found in chaparral, coastal scrub, and grasslands, often on clay and/or rocky soils, and blooms from March through June. The lily has been documented to occur at the mouth of Pico Canyon and other canyons in the vicinity (USGS, Newhall quad; CDFG 2007A).

No species-specific pollination or seed dispersal data are available for slender mariposa lily. Seed dispersal for *Calochortus* is limited, with no obvious adaptations for wind or animal dispersal; fruits are capsular and borne close to the ground, with relatively heavy, passively dispersed seeds that lack fleshiness, sticktights, or (except in one species) wings (Patterson and Givnish 2003). Typically, *Calochortus* flowers are generalists in terms of their pollinators, although bees have been observed to be the primary pollinator in other *Calochortus* species, such as Lyall's mariposa lily (*C. lyallii*) (Dilley *et al.* 2000; Miller 2000).

Perennial bulbs, including slender mariposa lily, may persist below ground without producing flowers or even leaves during years of poor rainfall or other environmental causes. For example, bulbs tend to flower in higher numbers following wildfire, which introduces large quantities of mineral nutrients (as ash) into the soil. Dormant plants (those producing no aboveground growth in a given year) cannot be located by field botanists, and those producing only leaves are unlikely to be found during surveys because the leaves are inconspicuous and visually similar to grass leaves. Thus, numbers of plants observed above ground fluctuates much more widely than numbers of living bulbs in the soil. The number of plants censused even in a "good" year is a minimum estimate of the number of living bulbs in the soil.

In addition to the direct loss of individuals, slender mariposa lily is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives such as the slender mariposa lily. Exotic plants can also alter hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development. This plant may also be lost through collection by humans.

Survey Results

Slender mariposa lily were observed on the Project site during numerous field surveys (**Subsection 4.5.3.2**, Survey Methods). Focused field studies to census slender mariposa lily were completed in the years 2002 through 2006 (Dudek and Associates 2004C, 2004E, 2004F, 2004G, 2004H, 2004I, 2006B, 2006F, 2006G, 2006H, 2006I; FL*x* 2004B, 2005, 2006A), although the 2002 field work was conducted late in the season.

All surveys were conducted during and after the blooming season for slender mariposa lily, which occurs from March to June (CNPS 2007); therefore, some counts (especially in 2002) were reliant on finding plants in fruit, when they are less conspicuous. As mentioned above in the Life History section, only a fraction of *Calochortus* plants flower in any given year, and the non-flowering individuals are generally not as visible. Moreover, because fruiting individuals are much more cryptic than flowering plants, it is expected that the fruiting individuals observed were a subset of the plants that were in flower earlier; it is not possible to estimate what portion was observed. In addition, surveys in 2006 and 2007 focused on the identification of San Fernando Valley spineflower only within known occurrences, reducing the total survey area and, subsequently, the number of other documented special-status species observed. However, given the repeated surveys within the Specific Plan, VCC, and Entrada planning areas, it is assumed that the majority of slender mariposa lily plants and occupied habitat on site was observed and delineated.

Slender mariposa lily occurrences were mapped utilizing aerial photography and topographic maps. Professional judgment and experience were used to delineate these polygons based on the detectability of the species, topography, and vegetation. This and other perennial special-status plants were mapped at a 10- to 20-meter (32.8- to 65.6-foot) scale due to their population dynamics (including seed dispersal and pollination range), observability, habit, habitat limitations, and mapping accuracy.

Because weather conditions—primarily rainfall—largely determine whether this species blooms in a given year, these factors, along with a relatively late survey period in 2002, likely affected the detection of slender mariposa lily. Slender mariposa lily census numbers varied widely from year to year. At most sites, numbers were highest in 2003, and numbers were substantially lower in 2002 and 2004. There was a less-than-average amount of rainfall in the 2001-2002, 2003-2004 and 2005-2006 rain seasons (WRCC 2008), and during the 2006-2007 rain season (October 2006-September 2007), the Piru 2 ESE weather station in Los Angeles County experienced its driest year in recorded history, with 4.1 inches of rain—less than one-quarter of the normal mean amount (17.40 inches) (WRCC 2008). Although there was a less-than-average amount of rainfall in 2004, numbers of slender mariposa lily in the Specific Plan Development Area increased about 20-fold during the same year. Presumably, this is due to a wildfire in that area, which would have caused increased water and soil nutrient availability by eliminating competing plant cover and adding ash

to the soil that could compensate for below-average rainfall. While wildfire presumably affected the numbers of slender mariposa lily in 2004, and the amount of rainfall varied during the survey years, with the 2002-2003 and 2004-2005 rain seasons being above average, the cumulative survey results are representative of the distribution of this species on site.

Slender mariposa lily is locally abundant in some parts of the RMDP and SCP area. Within the Project area, it was typically observed in coastal scrub (with California sagebrush and California buckwheat scrub) and California annual grassland. Most occurrences were mapped in areas of high vegetative cover and a variety of soil types (*e.g.*, gravelly loam, silty loam, sandy loam, clay loam, and rocky clay). **Table 4.5-62**, Slender Mariposa Lily Individuals Observed, provides a summary of population data for slender mariposa lily that occur within VCC and Entrada planning areas, and the main geographic areas of the RMDP area. Because several years of mapped occurrence data are available for slender mariposa lily, impacts to this species were evaluated by impacts to individuals rather than by loss of habitat.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Impacts to Individuals

Direct Permanent and Temporary Impacts

At least 66,100 slender mariposa lily plants—the maximum number recorded in a given year (2004) (**Table 4.5-62**)—occur in 627 locations, occupying 205 acres throughout portions of the RMDP and SCP area. Of this total, 0.7 acre (0.3%) of cumulative occupied area (**Table 4.5-64**, Impacts to Slender Mariposa Lily Cumulative Occupied Area by Alternative), where 52 documented individuals—the maximum potentially impacted by implementation of the RMDP in any given year (2005) (**Table 4.5-65**, Impacts to Slender Mariposa Lily Individuals by Alternative), representing approximately 0.08% of the total plants on site—would be directly lost by construction of RMDP facilities (within both the permanent and temporary footprints) (**Figure 4.5-146**, Alternative 2 Impacts to RMDP/SCP Special-Status Plants). Because surveys were conducted within the Project area for special-status plants from 2002 through 2005, there is a low probability that undocumented slender mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, possibly including areas to be disturbed by construction. No individuals would be directly lost by implementation of the SCP. The loss of slender mariposa lily occurring as a result of implementation of the RMDP and the SCP would not be considered a substantial adverse effect on this species and these activities would not substantially reduce the number or restrict the range of this species (significance criteria 1 and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in the indirect permanent loss of slender mariposa lily plants (**Figure 4.5-146**, Alternative 2 Impacts to RMDP/SCP Special-Status Plants). For purposes of this analysis, impacts are assessed using the cumulative occupied area and the year in which the greatest number of individual lilies would be impacted (**Tables 4.5-64** and **4.5-65**). Build-out of the Specific Plan area would result in the loss of 37 acres (18.0%) of cumulative occupied area,

representing approximately 25,962 documented individual slender mariposa lily plants, representing 39.3% of the total plants within that planning area. Build-out of the VCC planning area would result in the loss of 2.9 acres (1.0%) of cumulative occupied area, representing approximately 504 documented slender mariposa lily individuals, representing 0.8% of the total individuals observed within that planning area. Build-out of the Entrada planning area would result in to the loss of 31 acres (15.2%) of cumulative occupied area, representing approximately 4,128 documented individual slender mariposa lily plants, representing 6.2% of the total individuals within that planning area. In total, the build-out of the Specific Plan, VCC, and Entrada planning areas would result in the indirect loss of 71 acres (35.0%) of cumulative occupied area, or 30,593 plants (46.3%). Because surveys were conducted within the Project area for special-status plants from 2002 through 2005, there is a low probability that undocumented slender mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. The loss of slender mariposa lily occurring as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would be considered a substantial adverse effect on this species and would substantially reduce the number and restrict the range of this species on site (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of slender mariposa lily cumulative occupied area and individuals resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 72 acres (35.0%) and 30,645 (46.4%) individuals, respectively. The loss of slender mariposa lily occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would be considered a substantial adverse effect on this species and would substantially reduce the number and restrict the range of this species on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include hydrologic alterations and water quality impacts; accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; increased risk of fire; and increased human activity, collecting, trampling, and soil compaction. For purposes of this analysis, it is assumed

that the effects of the secondary impacts (and the potential for loss of slender mariposa lily) would be greatest within 300 feet of development (CBI 2000). Under Alternative 2, there would be 33 acres (16.3%) of cumulative occupied area and 23,963 individuals (36.3%) within 300 feet of development (**Table 4.5-66** Slender Mariposa Lily Individuals within 300 Feet of Development by Alternative; **Table 4.5-67** Slender Mariposa Lily Cumulative Occupied Area within 300 Feet of Development by Alternative). The loss of or degradation of suitable habitat, the loss of individual slender mariposa lily, and periodic adverse impacts to their growth or reproductive success (*e.g.*, flower collecting) would be considered a substantial adverse effect on this species and would substantially reduce the number and a reduction in the range of this species on site (significance criteria 1 and 7). Secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Impacts to Individuals

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to slender mariposa lilies cumulative occupied area and individuals (within both the permanent and temporary footprints) (**Figures 4.5-147** through **4.5-151,** Alternatives 3 through 7 Impacts to RMDP/SCP Special-Status Plants):

- Alternative 3 – permanent loss of 0.7 acre (0.3%) cumulative occupied area and 52 (0.08%) slender mariposa lilies;
- Alternative 4 – permanent loss of 0.7 acre (0.3%) cumulative occupied area and 52 (0.08%) slender mariposa lilies;
- Alternative 5 – permanent loss of 0.7 acre (0.3%) cumulative occupied area and 51 (0.08%) slender mariposa lilies;
- Alternative 6 – permanent loss of 0.2 acre (0.1%) cumulative occupied area and 21 (0.03%) slender mariposa lilies; and
- Alternative 7 – permanent loss of 0.3 acre (0.2%) cumulative occupied area and 16 (0.02%) slender mariposa lilies.

Compared to Alternative 2, which would result in the permanent direct loss of 0.7 acre (0.3%) cumulative occupied area and 52 (0.08%) slender mariposa lilies, the permanent loss of slender mariposa lilies under Alternatives 3 through 5 would not be substantially different due to changes in the Project footprint. The difference between Alternatives 6 and 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternatives 6 and 7, and other modifications to the Project footprint that would further decrease impacts to slender mariposa lily under Alternative 7. Because surveys were conducted within the Project development area for special-status plants from 2002 through 2005, there is a low probability that undocumented slender mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. The relative risk of impacts to undocumented slender mariposa lily would decrease proportionally with decreases in the size of the Project footprint under the different alternatives.

Because the direct permanent loss (Impacts to Individuals) of slender mariposa lily occurring as a result of implementation of the RMDP and the SCP under Alternatives 3

through 7 is not substantially different than loss under Alternative 2, impacts for Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to individual slender mariposa lilies (**Figures 4.5-147** through **4.5-151,** Alternatives 3 through 7 Impacts to RMDP/SCP Special-Status Plants):

- Alternative 3 – permanent loss of 64 acres (31.5%) cumulative occupied area and 29,429 (44.5%) slender mariposa lilies;
- Alternative 4 – permanent loss of 61 acres (30.1%) cumulative occupied area and 28,926 (43.8%) slender mariposa lilies;
- Alternative 5 – permanent loss of 50 acres (24.6%) cumulative occupied area and 8,970 (13.6%) slender mariposa lilies;
- Alternative 6 – permanent loss of 49 acres (23.6%) cumulative occupied area and 28,521 (43.1%) slender mariposa lilies; and
- Alternative 7 – permanent loss of 54 acres (26.3%) cumulative occupied area and 8,798 (13.3%) slender mariposa lilies.

Compared to Alternative 2, which would result in the permanent loss of 71 acres (35.0%) cumulative occupied area and 30,593 (46.4%) slender mariposa lilies, Alternatives 3, 4, and 6 would not be substantially different. Alternatives 5 and 7 would have the least impact to individuals because there would be additional pullbacks from the Santa Clara River and its tributaries, increases in the footprints of the spineflower preserves, and other changes in the Project footprint, that would reduce impacts to slender mariposa lily. Additionally, no development would occur within the VCC planning area under Alternatives 4 through 7. Because surveys were conducted within the Project area for special-status plants from 2002 through 2005, there is a low probability that undocumented slender mariposa lily occurrences, consisting of relatively few plants, exist in other portions of the Project area, including areas to be disturbed by construction. The relative risk of impacts to undocumented slender mariposa lily would decrease proportionally with decreases in the size of the Project footprint under the different alternatives.

Because the indirect permanent loss (Impacts to Individuals) of slender mariposa lily occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 is not substantially different than

loss under Alternative 2, impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to individual slender mariposa lilies:

- Alternative 3 – permanent loss of 65 acres (31.5%) cumulative occupied area and 29,481 (44.6%) slender mariposa lilies;
- Alternative 4 – permanent loss of 62 acres (30.1%) cumulative occupied area and 28,978 (43.8%) slender mariposa lilies;
- Alternative 5 – permanent loss of 50 acres (24.6%) cumulative occupied area and 9,021 (13.3%) slender mariposa lilies;
- Alternative 6 – permanent loss of 49 acres (23.6%) cumulative occupied area and 28,546 (43.2%) slender mariposa lilies; and
- Alternative 7 – permanent loss of 54 acres (26.3%) cumulative occupied area and 8,814 (13.3%) slender mariposa lilies.

Compared to Alternative 2, which would result in the combined direct and indirect permanent loss of 72 acres (35.0%) cumulative occupied area and 30,645 (46.4%) slender mariposa lilies, Alternatives 3, 4, and 6 would not be substantially different, as described above for the discussions of direct and indirect impacts. The difference between Alternatives 5 and 7 and Alternative 2 impacts to individuals is primarily due to additional pullbacks from the Santa Clara River and its tributaries, increases in the footprints of the spineflower preserves, and other Project footprint reductions that would reduce impacts to slender mariposa lily under Alternative 7. Additionally, no development would occur within the VCC planning area under Alternatives 4 through 7. The combined direct and indirect permanent loss of individual slender mariposa lilies occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for

Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. For purposes of this analysis, it is assumed that the effects of the secondary impacts (and the potential for loss of slender mariposa lily) would be greatest within 300 feet of development. For Alternatives 3 through 7, slender mariposa lily cumulative occupied area and individuals within 300 feet of development include:

- Alternative 3 – 37 acres (18.0%) cumulative occupied area and 25,250 (38.2%) slender mariposa lilies;
- Alternative 4 – 36 acres (17.5%) cumulative occupied area and 25,064 (37.9%) slender mariposa lilies;
- Alternative 5 – 28 acres (13.6%) cumulative occupied area and 8,258 (12.5%) slender mariposa lilies;
- Alternative 6 – 30 acres (14.4%) cumulative occupied area and 24,157 (36.5%) slender mariposa lilies; and
- Alternative 7 – 25 acres (12.3%) cumulative occupied area and 10,351 (15.7%) slender mariposa lilies.

Compared to Alternative 2, which would result in 33 acres (16.3%) cumulative occupied area and 23,963 (36.3%) slender mariposa lilies within 300 feet of development, Alternatives 3, 4, and 6 would not be substantially different, as described above for the discussions of direct and indirect impacts. The difference between Alternatives 5 and 7 and Alternative 2 impacts to individuals is primarily due to additional pullbacks from the Santa Clara River and its tributaries, increases in the footprints of the spineflower preserves, and other Project footprint reductions that would reduce impacts to slender mariposa lily under Alternative 7. Additionally, no development would occur within the VCC planning area under Alternatives 4 through 7. The loss of or degradation of suitable habitat, the loss of individual slender mariposa lily, and periodic adverse impacts to their growth or reproductive success (*e.g.*, flower collecting) due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to slender mariposa lily: (1) impacts to individuals, and (2) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment. The combined permanent loss of slender mariposa lilies individuals would range from 8,814 (13.3%) under Alternative 7 to 30,645 (46.4%) under Alternative 2. The combined permanent loss of these individuals would have a substantial adverse effect on this species and would substantially reduce the number and restrict the range of this species. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. A slender mariposa lily habitat replacement/enhancement program is outlined within the Draft RMDP Slender Mariposa Lily Mitigation and Monitoring Plan (Dudek 2007I), which describes how the applicant will successfully restore/enhance slender mariposa lily habitat and re-establish slender mariposa lily locations at appropriate receptor sites within the High Country SMA, Salt Creek area, and San Martinez Grande area where opportunities for long-term preservation are provided. While implementation of the proposed Project would result in impacts to a maximum of 72 acres of cumulative occupied area are within the development footprint, the mitigation and monitoring program mitigates impacts to slender mariposa lily cumulative occupied area at a ratio of 1:1 through successfully restoring/enhancing slender mariposa lily habitat and re-establishing slender mariposa lily locations in the High Country SMA, Salt Creek area, and other sites as appropriate. A minimum of 133 acres of slender mariposa lily cumulative occupied area will be conserved in the RMDP and SCP Project boundaries. These conserved acres include 73 acres of occupied habitat in the Salt Creek area, 30 acres in the High Country SMA, and at least 28 acres in the San Martinez Grande area.

Short-term secondary impacts, such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; and hydrologic alterations and water quality impacts would be minimized by providing guidelines for grading and construction activities; by retaining a qualified biologist during all grading and construction activities; by providing erosion control plans, dust control, and an overall Project SWPPP; by preventing pollutants from entering flowing streams and storm flows; by providing guidelines for stream diversion; and by requiring that the Specific Plan conform to all provisions of required NPDES permits and water quality permits required by the RWQCB. Long-term secondary impacts to slender mariposa lily, such as the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; increased human activity, trampling, and soil compaction; and increased risk of fire would be minimized by restricting access to, grazing within, and recreational usage of the High Country SMA; providing for transition areas along the High Country SMA; providing drainage guidelines; requiring conformance with NPDES and RWQCB permit provisions; requiring the implementation of a wildfire fuel modification plan; placing restrictions on domestic animals in proximity to open space areas; by providing trail signage and homeowner education; and placing restrictions on plant palettes proposed for use on landscaped slopes.

All specific mitigation measures for slender mariposa lily are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-182 IMPACTS TO INDIVIDUALS – SLENDER MARIPOSA LILY

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to avoid, minimize, or mitigate the loss of slender mariposa lily.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where slender mariposa lily occurs. Transition from the development edge to the natural area (where slender mariposa lily occurs) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA, which supports 30 acres of slender mariposa lily cumulative occupied area.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two mitigation measures to reduce the loss of and/or harm to slender mariposa lily.

BIO-25 describes restoration of disturbed portions of the spineflower preserves through revegetation with native plant communities. Areas that have greater than 30% absolute cover by weeds will be restored to have at least 70% absolute cover by native species. Cal-IPC List A and B plants that are present within the spineflower preserves will be controlled. Those slender mariposa lily occurrences located within spineflower preserves would benefit from this restoration measure.

BIO-40 requires implementation of the Draft RMDP Slender Mariposa Lily Mitigation and Monitoring Plan (Dudek 2007I), subject to agency approval. The Draft RMDP Slender Mariposa Lily Mitigation and Monitoring Plan (Dudek 2007I) shall be revised and submitted to CDFG for review and approval prior to ground disturbance to occupied habitat. Upon approval, the plan will be implemented by the applicant or its designee. The revised plan will demonstrate the feasibility of enhancing or restoring slender mariposa lily habitat in selected areas to be managed as natural open space (*i.e.*, High Country SMA, Salt Creek area, spineflower preserves, or River Corridor SMA) without conflicting with other resource management objectives. Habitat replacement/enhancement will be at a ratio of 1:1 (acres restored/enhanced to acres impacted).

Approximately 103 acres of slender mariposa lily cumulative occupied area will be conserved and managed in the RMDP Project boundary, specifically within the High County SMA and Salt Creek. Additional cumulative occupied area will be conserved and managed in San Martinez Grande Canyon at a 1:1 ratio (acres conserved/managed to acres impacted) based on impacts to cumulative occupied area within the Entrada planning area, as a means to ensure regional biodiversity of the species. Up to an additional 28 acres of slender mariposa lily cumulative occupied area can be conserved and managed in the San Martinez Grande Canyon area for this purpose.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts associated with the loss of slender mariposa lily would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-183 SECONDARY IMPACTS – SLENDER MARIPOSA LILY

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to slender mariposa lily.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-32, SP-4.6-34, and SP-4.6-35:

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-34 and SP-4.6-35 establish that grading perimeters shall be clearly marked and inspected by the Project biologist prior to impacts occurring within or adjacent to the High Country SMA, and that the biologist shall work with the grading contractor to avoid inadvertent impacts to biological resources outside of the grading area.

Secondary impacts associated with accidental clearing, trampling, and grading would be further mitigated by implementation of Mitigation Measure SP-4.6-33, which permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where slender mariposa lily occurs. Transition from the development edge to the natural area (where slender mariposa lily occurs) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-33, which permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where slender mariposa lily occurs. Transition from the development edge to the natural area (where slender mariposa lily occurs) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

In order to avoid and minimize impacts from increased human activity and trampling, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-29 through SP-4.6-32, SP-4.6-33, and SP-4.6-39:

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or

off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary where slender mariposa lily occurs. Transition from the development edge to the natural area (where slender mariposa lily occurs) shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-39 states that the High Country SMA easements shall prohibit grazing within the High Country SMA, except for long-term resource management programs, and shall restrict recreation to the established trail system.

In order to avoid and minimize impacts from hydrologic and water quality-related impacts adjacent to and downstream of construction activities, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-44 and SP-4.6-45, which provide guidelines for major drainages (which are in proximity to slender mariposa lily occurrences), and SP-4.6-58, which requires conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In order to avoid and minimize impacts from increased fire frequency, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-31, SP-4.6-32, SP-4.6-33, and SP-4.6-49 through SP-4.6-52:

SP-4.6-31 prohibits hunting, fishing, and motor or off-trail bike riding within the High Country SMA.

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-49 through SP-4.6-52 describe wildfire fuel modification plans and fuel modification measures that will minimize the potential exposure of the development areas, Open Area, and SMAs (which contain slender mariposa lily occurrences) to fire hazards.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the High Country

SMA and Salt Creek area in a natural state. These measures include SP-4.6-27, SP-4.6-29 through SP-4.6-32, SP-4.6-33, SP-4.6-36 through SP-4.6-42, and SP-4.6-55 and SP-4.6-58:

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. This will benefit slender mariposa lily occurrences located in proximity to drainages.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate short-term and long-term secondary impacts to a level that is adverse but not significant.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading, this EIS/EIR identifies Mitigation Measure BIO-52, which states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading;

and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to avoid and minimize impacts from dust, runoff, sedimentation, erosion, and chemical and toxic compound pollution, this EIS/EIR identifies Mitigation Measures BIO-52, BIO-70, and BIO-71:

BIO-52, which states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 requires dust control measures for development areas to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control plans shall comply with SCAQMD Rule 403 (SCAQMD 2005) and chemical dust suppression shall not be utilized within 100 feet of known special-status plant communities.

Short-term secondary impacts associated with runoff, sedimentation, erosion, and chemical and toxic compound pollution would be further mitigated by implementation of Mitigation Measure BIO-49, which prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, this EIS/EIR identifies Mitigation Measure BIO-72, which specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

In order to avoid and minimize impacts from increased human activity and trampling, this EIS/EIR identifies Mitigation Measure BIO-69, which requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

In order to avoid and minimize impacts from hydrologic and water quality-related impacts adjacent to and downstream of construction activities, this EIS/EIR identifies Mitigation Measures BIO-49 and BIO-52:

BIO-49 prohibits requires that pollutants from construction activities not be allowed to enter a flowing stream or be placed in locations that may be subjected to storm flows. This will benefit slender mariposa lily occurrences located in proximity to drainages.

BIO-52, which states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to avoid and minimize impacts from increased fire frequency, this EIS/EIR identifies Mitigation Measure BIO-63, which requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the High Country SMA and Salt Creek area in a natural state. These measures include BIO-19, BIO-20, BIO-21, BIO-40, and BIO-69:

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA, both of which support slender mariposa lily occurrences. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The

functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-40 requires implementation of the Draft RMDP Slender Mariposa Lily Mitigation and Monitoring Plan (Dudek 2007I), subject to agency approval. The Draft RMDP Slender Mariposa Lily Mitigation and Monitoring Plan (Dudek 2007I) shall be revised and submitted to CDFG for review and approval prior to ground disturbance to occupied habitat. Upon approval, the plan will be implemented by the applicant or its designee. The revised plan will demonstrate the feasibility of enhancing or restoring slender mariposa lily habitat in selected areas to be managed as natural open space (*i.e.*, High Country SMA, Salt Creek area, spineflower preserves, or River Corridor SMA) without conflicting with other resource management objectives. Habitat replacement/enhancement will be at a ratio of 1:1 (acres restored/enhanced to acres impacted). A minimum of 133 acres of slender mariposa lily cumulative occupied area will be conserved in the RMDP and SCP Project boundaries. At least 28 of the 133 acres will be conserved in the San Martinez Grande Canyon area

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to slender mariposa lily would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

SOUTHERN CALIFORNIA BLACK WALNUT (CNPS LIST 4.2/S3.2)

Life History

Southern California black walnut (*Juglans californica* var. *californica*) is a low-growing deciduous hardwood tree or large shrub endemic to southern California. Southern California black walnut is known to occur within Los Angeles, Santa Barbara, Ventura, Orange, Riverside, San Bernardino, and San Diego counties (CNPS 2007). Swanson (1976) also notes the occurrence of this species within San Luis Obispo County, inland of Cambria. Within Orange County, this species is known to occur along the Santa Ana River and, within San Bernardino County, it occurs as far east as Yucaipa (Swanson 1976). Although southern California black walnut is fairly widespread, extant walnut-dominated woodlands and forests are limited to the Santa Clarita River drainage in the vicinity of Sulphur Mountain as well as small stands in the Simi Hills and Santa Susana Mountains, the north slope of the Santa Monica Mountains, the San Jose Hills, Puente Hills, and Chino Hills (Griffin and Critchfield 1972; Quinn 1989).

Southern California black walnut is found primarily on dry south- and west-facing slopes and within canyons at elevations between 50 and 900 meters AMSL (CNPS 2007; Hickman 1993; Dole and Rose 1996). It grows to 15 meters height. Mature trees may have a single trunk, or may be multiple-stemmed from the base, due to post-fire resprouting (Quinn 1989). It inhabits chaparral and cismontane woodlands with Miocene–Pliocene shale and coastal scrub with alluvial soils (NatureServe 2007; CNPS 2007). Southern California black walnut can tolerate high salinity and alkalinity along streams (Mullally 1992). It generally blooms from March to August and produces seed during fall (CNPS 2007). *Juglans* species are wind-pollinated (Bai *et al.* 2006). Seedlings mature rapidly in moist, sunny conditions. Mature walnut fruits are actively sought and subsequently stored, buried, or eaten by small rodents, including California ground squirrels (*Spermophilus beecheyi*) and western gray squirrels (*Sciurus griseus*) (Quinn 1989; Takahashi *et al.* 2007).

In addition to the direct loss of individuals, southern California black walnut is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives such as the southern California black walnut. Exotic plants can also alter hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development.

Survey Results

Occurrences of this species throughout the RMDP and SCP area have been observed in a variety of vegetation communities, sometimes as the dominant species of California walnut woodland, and sometimes as an uncommon component of undifferentiated chaparral, coastal scrub alliances and associations, and alluvial scrub, oak woodland (coast live oak woodland, mixed oak woodland and forest, valley oak woodland), and southern cottonwood–willow riparian forest.

Focused surveys for special-status plant species were conducted in spring and summer 2002 through 2005, coincident with the annual blooming period for southern California black walnut, which blooms from March through August (CNPS 2007). Surveys in 2006 and 2007 focused on the identification of San Fernando Valley spineflower only within known occurrences, reducing the total survey area and, consequently, the number of other documented special-status species observed; this could be an explanation for why southern California black walnut was not recorded within the Specific Plan, VCC, and Entrada planning areas in 2006 and 2007.

Given the low sensitivity status of the species (CNPS List 4.2), the exact locations of all individual southern California black walnut trees within the Project area have not been mapped. However, a total of 27 acres of California walnut woodland is present in the Project area in the High Country SMA and Salt Creek area (**Figures 4.5-11-A1** through **4.5-11-C2**, RMDP/SCP – Vegetation Communities and Land Covers). Therefore, impacts to this species were evaluated by loss of habitat instead of impacts to individuals.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and construction of permitted facilities would not result in any direct permanent or temporary impacts to the 27 acres of California walnut woodland on site. Individual southern California black walnut trees are uncommon in other vegetation communities, but implementation of the RMDP is expected to result in the

removal of occasional individual southern California black walnut trees that exist in vegetation communities other than California walnut woodland. Pre-construction surveys will identify any additional individual southern California black walnut trees within other vegetation communities that will be impacted within the RMDP development area. No individuals would be directly lost by implementation of the SCP. Implementation of the RMDP and the SCP would have a substantial adverse effect on a species designated as special-status by the County of Los Angeles and considered threatened by CDFG (S3.2) (significance criterion 1). Direct impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC, and Entrada planning areas would not result in any indirect permanent impacts to the 27 acres of California walnut woodland on site. Individual southern California black walnut trees are uncommon in other vegetation communities, but build-out of the Specific Plan, VCC, and Entrada planning areas is expected to result in the removal of occasional individual southern California black walnut trees that exist in vegetation communities other than California walnut woodland. Pre-construction surveys will identify any additional individual southern California black walnut trees within other vegetation communities that will be impacted within the Specific Plan, VCC, and Entrada planning areas. Such an impact would have a substantial adverse effect on a species designated as special-status by the County of Los Angeles and considered threatened by CDFG (S3.2) (significance criterion 1). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent and Temporary Impacts

Implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would not result in impacts to California walnut woodland on site. Individual southern California black walnut trees are uncommon in other vegetation communities, but implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas is expected to result in the removal of occasional individual southern California black walnut trees that exist in vegetation communities other than California walnut woodland. Pre-construction surveys will identify any additional individual southern California black walnut trees within other vegetation communities that will be impacted within the RMDP and SCP areas, and the Specific Plan, VCC, and Entrada planning areas. The combined direct and indirect loss of southern California black walnut individuals that exist in vegetation communities other than California walnut woodland would be considered a substantial adverse effect on a species designated as special-status by the County of Los Angeles and considered

threatened by CDFG (S3.2) (significance criterion 1). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include short-term impacts such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; hydrologic alterations and water quality impacts; and long-term impacts such as the introduction of non-native, invasive plant species; increased human activity, trampling, and soil compaction; and increased risk of fire. Southern California walnut individuals are uncommonly distributed in several vegetation communities on site, some of which are in proximity to proposed development areas; therefore, short-term and long-term secondary impacts are expected to occur to this species. California walnut woodland occurs in proximity to recreational trails in the High Country SMA and Salt Creek area.

The potential loss of southern California black walnut and the effect on its habitat as a result of these secondary impacts would constitute a substantial adverse effect on a species designated as special-status by the County of Los Angeles and considered threatened by CDFG (S3.2) (significance criterion 1). Secondary impacts (Loss of Habitat) would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts and Indirect Permanent Impacts

The potential for direct permanent and temporary and indirect permanent loss of habitat for southern California black walnut as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to loss under Alternative 2. The 27 acres of California walnut woodland known to occur within the High Country SMA portion of the RMDP and SCP site would not be impacted under Alternatives 3 through 7. Individual southern California black walnut trees are uncommon in other vegetation communities, but implementation of the RMDP and the SCP is expected to result in the removal of occasional individual southern California black walnut trees that exist in vegetation communities other than California walnut woodland. Pre-construction surveys will identify any additional individual southern California black walnut trees within other vegetation communities that will be impacted within the RMDP development area. Such an impact would have a substantial adverse effect on a species designated as special-

status by the County of Los Angeles and considered threatened by CDFG (S3.2). Direct permanent and temporary and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

Implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would not result in impacts to California walnut woodland on site under Alternatives 3 through 7. Individual southern California black walnut trees are uncommon in other vegetation communities, but implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas is expected to result in the removal of occasional individual southern California black walnut trees that exist in vegetation communities other than California walnut woodland. Pre-construction surveys will identify any additional individual southern California black walnut trees within other vegetation communities that will be impacted within the Specific Plan, VCC, and Entrada planning areas. The combined direct and indirect permanent loss of southern California black walnut individuals that exist in vegetation communities other than California walnut woodland would be considered a substantial adverse effect on a species designated as special-status by the County of Los Angeles and considered threatened by CDFG (S3.2). The combined direct and indirect permanent impacts (Loss of Habitat) under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. Southern California walnut individuals are uncommonly distributed in several vegetation communities on site, some of which are in proximity to proposed development areas; therefore, short-term and long-term secondary impacts are expected to occur to this species. California walnut woodland occurs in proximity to recreational trails in the High Country SMA and Salt Creek area. The loss of or degradation of suitable habitat and the loss of individual southern California black walnut (designated as special-status by the County of Los Angeles and considered threatened by CDFG (S3.2)) due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to southern California black walnut: (1) loss of suitable habitat, and (2) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to habitat and associated individuals could occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment. Although the proposed project would not result in the loss of suitable habitat for the southern California black walnut, it is anticipated that the proposed project would result in impacts to small pockets of southern California black walnut as these occur as occasional components of other vegetation communities. The combined permanent loss of suitable habitat and associated individuals would have a substantial adverse effect on a species designated as special-status by the County of Los Angeles. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to habitat and associated individuals. Pre-construction surveys for southern California black walnut will be conducted and southern California black walnut trees will be replaced in conformance with the oak tree ordinance (*e.g.*, County of Los Angeles 1988) in effect at that time, and southern California black walnut trees or shrubs outside riparian areas greater than one inch dbh shall be replaced at a ratio of at least 2:1. The proposed mitigation, through guidelines supplied by the Oak Resources Management Plan and through the preservation and long-term management of the High Country SMA, River Corridor SMA, Salt Creek area, and Open Area, provides mitigation for the loss of tree resources in a manner that emphasizes: (1) restoring the natural regeneration capabilities of preserved woodlands in order to restore and improve forest diversity and value on a long-term basis and (2) creating new woodlands in areas that supported southern California black walnut prior to development and in areas that will enhance wildlife movement and habitat functions. In addition, where southern California black walnut trees occur within riparian areas, the Project applicant will implement a series of mitigation measures designed to replace, restore, enhance, and maintain natural riparian communities in the Santa Clara River or its tributaries; and create new riparian communities in areas that currently support degraded or exotic vegetation. Mitigation designed to restore, enhance, or replace temporarily disturbed riparian vegetation communities focuses on achieving the required percent coverage and tree growth performance criteria for the proposed target species, as well as native species recruitment and reproduction. Mitigation measures will provide for the long-term maintenance of the River Corridor SMA, High Country SMA, and Open Area in a natural state by restricting access to and prohibiting grazing, agriculture, and recreation within these areas; providing for the restoration and enhancement of habitat within these areas; and through the open space dedication of these areas. General procedures to avoid and minimize impacts to southern California black walnut habitat and associated individuals during construction will be implemented, and a qualified biologist will be present during construction in order to avoid inadvertent impacts to biological resources outside of the grading area, further reducing impacts to the species.

Short-term secondary impacts, such as accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; and hydrologic alterations and water quality impacts will be minimized by providing guidelines for grading and construction activities; by retaining a qualified biologist during all grading and construction activities; by providing erosion control plans, dust control, and an overall Project SWPPP; by preventing pollutants from entering flowing streams and storm flows; by providing guidelines for stream diversion; and by requiring that the Specific Plan conform to all provisions of required NPDES permits and water quality permits required by the RWQCB. Long-term, secondary impacts to southern California black walnut, such as the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction, will be minimized by additional measures restricting access to, grazing within, and recreational usage of the River Corridor SMA and High Country SMA; providing for transition areas along the River Corridor SMA and High Country SMA; providing drainage guidelines; requiring conformance with NPDES and RWQCB permit provisions; requiring the implementation of a wildfire fuel modification plan (Dudek 2008A); placing restrictions on domestic animals in proximity to open space areas; providing trail signage and homeowner education; placing restrictions on plant palettes proposed for use on landscaped slopes; and providing revegetation plans for the River Corridor SMA.

All specific mitigation measures for southern California black walnut are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-184 LOSS OF HABITAT – SOUTHERN CALIFORNIA BLACK WALNUT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to avoid, minimize, and/or mitigate the loss of or southern California black walnut trees.

To mitigate for the removal of individuals during construction, SP-4.6-48 lists standards for the restoration and enhancement of oak resources and applies these standards to southern California black walnut, within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, a resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

In addition to mitigation measures requiring replacement of individual trees, southern California black walnut is associated with jurisdictional areas along the Santa Clara River and its tributaries

and, where this species occurs in jurisdictional areas, the following mitigation measures will apply.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-28 states that mitigation banking for riparian habitats in the High Country SMA is subject to state and federal regulations and permits, mitigation for oak resources is subject to the Oak Resources Management Plan, and mitigation banking for Mexican elderberry scrub is subject to the approval of the County Forester. SP-4.6-47a permits mitigation banking within the River Corridor SMA, High Country SMA, and Open Area, subject to requirements for riparian habitats, oak resources, and Mexican elderberry scrub.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub. SP-4.6-44 requires drainages with flows over 2,000 cfs in the Open Area to have soft bottoms. Bank protection will be ungrouted rock or buried bank stabilization except where other stabilization is required for public safety. SP-4.6-45 requires establishment of the alignments and widths of major drainages in the Open Area through drainage studies to be approved by the County at the time of subdivision map approval.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In addition to the restoration and avoidance mitigation measures described above, southern California black walnut will benefit from the following preservation and management mitigation measures.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

SP-4.6-26a identifies riparian revegetation and oak tree replacement opportunities in the High Country SMA and specifies mitigation requirements for each.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities

for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA.

SP-4.6-46 and SP-4.6-47 describe the dedication of the Open Area and provide acceptable usage guidelines.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to reduce the loss of and/or harm to southern California black walnut trees.

In addition to mitigation measures described above requiring replacement of individual trees, southern California black walnut is associated with jurisdictional areas along the Santa Clara River and its tributaries and, where this species occurs in jurisdictional areas, the following mitigation measures will apply.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-22 states that the Oak Resource Management Plan shall incorporate the findings of the Draft Newhall Ranch Mitigation Feasibility Report (Dudek 2007A), and areas identified as being suitable for oak resources (including southern California black walnut) enhancement and creation shall be used for mitigation.

BIO-88 states that any southern California black walnut or mainland cherry trees or shrubs outside riparian areas greater than one inch dbh shall be replaced at a ratio of at least 2:1, using a minimum 15-gallon size specimen that measures at least one inch in diameter one foot above the base.

In addition to the restoration and avoidance mitigation measures described above, southern California black walnut will benefit from the following preservation and management mitigation measures. BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-62 states that at least 1,900 acres of Open Area within the Specific Plan area shall be offered for dedication to an NLMO. These 1,900 acres of the Open Area will be left as natural vegetation.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, impacts associated with the loss of southern California black walnut trees would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-185 SECONDARY IMPACTS – SOUTHERN CALIFORNIA BLACK WALNUT

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate secondary impacts to southern California black walnut trees.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-20, SP-4.6-32, and SP-4.6-34 and SP-4.6-35:

SP-4.6-20 states that any grading activities within or adjacent to the River Corridor SMA shall have grading perimeters clearly marked and inspected prior to grading. The Project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources**.**

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-34 and SP-4.6-35 establish that grading perimeters shall be clearly marked and inspected by the Project biologist prior to impacts occurring within or adjacent to the High Country SMA and that the biologist shall work with the grading contractor to avoid inadvertent impacts to biological resources outside of the grading area.

Secondary impacts associated with accidental clearing, trampling, and grading will be further mitigated by implementation of Mitigation Measure SP-4.6-33, which permits construction of

buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

In order to avoid and minimize impacts from hydrologic and water quality-related impacts adjacent to and downstream of construction activities, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-44 and SP-4.6-45, which provide guidelines for major drainages, and SP-4.6-58, which requires conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-7, SP-4.6-19, SP-4.6-26a, SP-4.6-33, and SP-4.6-43:

SP-4.6-7 requires that revegetation plans for the River Corridor SMA include guidelines for the maintenance of the mitigation site during the establishment of plantings, control of non-native plants, maintenance of the irrigation system, and replacement of plants, if necessary.

SP-4.6-19 requires that transition areas be in areas where there is no steep grade separation; that native riparian plants be incorporated into landscaping where feasible; that roads and bridges be designed to discourage access to River Corridor SMA; that bank stabilization be composed of ungrouted rock; and that a minimum 100-foot-wide buffer be provided between top river-side of bank stabilization and development.

SP-4.6-26a identifies riparian revegetation and oak tree replacement opportunities in the High Country SMA and specifies mitigation requirements for each.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

In order to avoid and minimize impacts from increased human activity and trampling, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-17, SP-4.6-18 and SP-4.6-19, SP-4.6-24, SP-4.6-29 through SP-4.6-32, SP-4.6-33, and SP-4.6-39:

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-24 states that the River Corridor SMA conservation and public access easement shall prohibit grazing and agriculture and shall restrict recreational use to the established trail system.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-39 states that the High Country SMA easements shall prohibit grazing within the High Country SMA, except for long-term resource management programs, and shall restrict recreation to the established trail system.

In order to avoid and minimize impacts from increased fire frequency, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-17, SP-4.6-31, SP-4.6-32, SP-4.6-33, and SP-4.6-49 through SP-4.6-52:

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-31 prohibits hunting, fishing, and motor or off-trail bike riding within the High Country SMA.

SP-4.6-32 states that the trail system shall be designed and constructed to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-49 through SP-4.6-52 describe wildfire fuel modification plans and fuel modification measures that will minimize the potential exposure of the development areas, Open Area, and SMAs to fire hazards.

Each potential secondary impact will be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA, the High Country SMA, and Open Area in a natural state. These measures include SP-4.6-1 through SP-4.6-16 and SP-4.6-63, SP-4.6-17, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-26a, SP-4.6-27, SP-4.6-28, SP-4.6-29 through SP-4.6-32, SP-4.6-33, SP-4.6-36 through SP-4.6-42, SP-4.6-43, SP-4.6-46 and SP-4.6-47, SP-4.6-47a, SP-4.6-48, SP-4.6-49 through SP-4.6-52, and SP-4.6-55 and SP-4.6-58:

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where

feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

SP-4.6-26a identifies riparian revegetation and oak tree replacement opportunities in the High Country SMA and specifies mitigation requirements for each.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-28 states that mitigation banking for riparian habitats in the High Country SMA is subject to state and federal regulations and permits, mitigation for oak resources is subject to the Oak Resources Management Plan, and mitigation banking for Mexican elderberry scrub is subject to the approval of the County Forester.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA. SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary. Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones (FMZs) as set forth in Mitigation Measure SP-4.6-49.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the High Country SMA.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

SP-4.6-46 and SP-4.6-47 describe the dedication of the Open Area and provide acceptable usage guidelines.

SP-4.6-47a permits mitigation banking within the River Corridor SMA, High Country SMA, and Open Area, subject to requirements for riparian habitats, oak resources, and Mexican elderberry scrub.

SP-4.6-48 lists standards for the restoration and enhancement of oak resources (including southern California black walnut) within the High Country SMA and Open Area, including: replacement trees shall be planted in conformance with the current oak tree ordinance, trees planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

SP-4.6-49 through SP-4.6-52 describe wildfire fuel modification plans and fuel modification measures that will minimize the potential exposure of the development areas, Open Area, and SMAs to fire hazards.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate short-term and long-term secondary impacts to a level that is adverse but not significant.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust; as well as from hydrologic alterations and water quality impacts, this EIS/EIR identifies Mitigation Measures BIO-45 and BIO-52:

BIO-45 states that when work in a flowing stream is unavoidable, the entire stream flow shall be diverted around the work area by a means approved by CDFG. A temporary diversion channel shall be constructed using the least damaging method possible. The stream channel alignment shall be restored after construction, in consultation with CDFG.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In order to further avoid and minimize impacts from dust, runoff, sedimentation, erosion, and chemical and toxic compound pollution, this EIS/EIR identifies Mitigation Measures BIO-70 and BIO-71:

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 requires dust control measures for development areas to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control plans shall comply with SCAQMD Rule 403 (SCAQMD 2005), and chemical dust suppression shall not be utilized within 100 feet of known special-status plant communities.

Short-term secondary impacts associated with runoff, sedimentation, erosion, and chemical and toxic compound pollution and with hydrological alterations and water quality impacts will also be mitigated by implementation of Mitigation Measure BIO-49, which prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, this EIS/EIR identifies Mitigation Measure BIO-72, which specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

In order to avoid and minimize impacts from increased human activity and trampling, this EIS/EIR identifies Mitigation Measure BIO-69 and BIO-73:

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

Each potential secondary impact will be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA, the High Country SMA, and Open Area in a natural state. These measures include BIO-1 through BIO-16, BIO-19, BIO-22, BIO-62, BIO-69, and BIO-73:

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-22 states that the Oak Resource Management Plan shall incorporate the findings of the Draft Newhall Ranch Mitigation Feasibility Report (Dudek 2007A), and areas identified as being suitable for oak woodland enhancement and creation shall be used for mitigation.

BIO-62 states that at least 1,900 acres of Open Area within the Specific Plan area shall be offered for dedication to an NLMO. These 1,900 acres of the Open Area will be left as natural vegetation.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to southern California black walnut trees would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

SOUTHWESTERN SPINY RUSH (CNPS LIST 4.2/S3.2)

Life History

Southwestern spiny rush (*Juncus acutus* ssp. *leopoldii*) is a large herbaceous perennial with long, rigid, cylindrical grass-like leaves with sharp tips (spines) that grows in moist saline areas and blooms from May through June (CNPS 2007). This stout, robust species occurs in San Luis Obispo, Santa Barbara, Ventura, Los Angeles, Orange, and San Diego counties, extending southward into Baja California and perhaps also east into Imperial County and Arizona as well (CNPS 2007). This species is considered locally and regionally rare by local botanists and has been documented from 10 vouchered collections from Los Angeles County, half of which are on Santa Catalina Island (Magney and Hoskinson 2007). This species was observed in 2006 in Violin Canyon adjacent to the Angeles National Forest and Interstate-5 (I-5), south of Templin Highway and Paradise Ranch, eight miles north of Castaic, in Los Angeles County. Southwestern spiny rush was observed in 2007 near the western bank of Castaic Creek above the Castaic power plant. This species was observed in 2005 and 2006 in Piru Creek (below Frenchman's flat) and Oso Creek (Huntley 2009). Southwestern spiny rush was observed along Castaic Creek upstream of the confluence of Castaic Creek and Fish Creek, and this species is locally common in Grasshopper Canyon (Boyd 1999).

Southwestern spiny rush generally occurs at elevations lower than 900 meters AMSL (Hickman 1993). Near the coast, it is found primarily in mesic sites of coastal dune systems and coastal salt marshes. Farther inland, it occurs in meadows, alkaline seeps, marshes, and sometimes along stream channels (CNPS 2007; Hickman 1993; Reiser 1994; Boyd 1999).

In addition to the direct loss of individuals, southwestern spiny rush is vulnerable to several effects related to urbanization. Non-native plant species, which compete for light, water, and nutrients, have been found to invade native vegetation communities and become established after repeated burnings, changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff), use of chemical pollutants, clearing of vegetation, trampling, or following periods of drought and overgrazing, all of which are possible side effects of nearby human habitation. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of natives such as the southwestern spiny rush. Exotic plants can also alter hydrologic and biochemical cycles, alter seed bank characteristics, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development.

Survey Results

Southwestern spiny rush was observed on site along secondary channels and low terraces along the Santa Clara River.

The focused surveys conducted in spring and summer 2001 through 2006 were coincident with the annual blooming period for southwestern spiny rush, which blooms from May through June

(CNPS 2007). The surveys typically began in April and extended through August. Surveys in 2006 and 2007 focused on the identification of San Fernando Valley spineflower only within known occurrences, reducing the total survey area and, consequently, the likelihood of detection of other documented special-status species. This species has definitive habitat requirements and the surveys focused on suitable habitat. In addition, this is a large, spiny plant and was observed during the non-blooming period and the blooming period.

Observations of southwestern spiny rush were made on site within the River Corridor SMA in 2001, 2003, 2004, 2005, and 2006 (Dudek and Associates 2004C, 2004F, 2006F, 2006I; FL*x* 2002A, 2004A). Given the status of the species (CNPS List 4.2), the exact locations of individuals of this species within the Project area have not been mapped. Therefore, impacts to this species were evaluated by loss of habitat instead of impacts to individuals. A total of 187 acres of suitable habitat (bulrush–cattail wetland, coastal and valley freshwater marsh, and herbaceous wetland) is present in the Project area. (**Figures 4.5-11-A1** through **4.5-11-C2**, RMDP/SCP – Vegetation Communities and Land Covers, **Figure 4.5-20**, VCC SCP Site – Vegetation Communities and Land Covers, and **Figure 4.5-21**, Entrada RMDP/SCP Site – Vegetation Communities and Land Covers).

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP would result in the direct permanent loss of 2.8 acres (1.5%) and the temporary loss of 4.3 acres of suitable habitat on site (**Figures 4.5-33-A1** through **4.5-33-D2**, Alternative 2 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). No individuals would be directly lost by implementation of the SCP. Because of the relatively small permanent and temporary direct loss of suitable habitat and its relatively broad distribution in the Project region, the direct loss of southwestern spiny rush plants occupying this habitat as a result of construction/grading activities would not be considered a substantial adverse effect on this species and would not

substantially reduce the number or restrict the range of the species (significance criteria 1 and 7). Direct impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in the indirect permanent loss of approximately 1.1 acres (0.6%) of suitable habitat on site (**Figures 4.5-33-A1** through **4.5-33-D2**, Alternative 2 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). It is likely that individual southwestern spiny rush plants associated with these vegetation communities would be lost as a result of build-out of these planning areas. Because of the minimal amount of suitable habitat that would be affected and its relatively broad distribution in the Project region, this loss would not be considered a substantial adverse effect on this species and would not substantially reduce the number or restrict the range of the species (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3.8 acres (2.1%). Because of the minimal amount of suitable habitat that would be affected and its relatively broad distribution in the Project region, the combined direct and indirect permanent impacts to southwestern spiny rush individuals and its habitat would not have a substantial adverse effect on this species and would not substantially reduce the number or restrict the range of the species (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Secondary Impacts

Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. Because of this species' relatively broad distribution in the Project region, the potential loss of southwestern spiny rush and the effect on its habitat resulting from these secondary impacts would not constitute a substantial adverse effect on this species and would not substantially reduce the number or restrict the range of the species (significance criteria 1 and 7). Secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following permanent and temporary direct impacts to suitable habitat for southwestern spiny rush:

- Alternative 3 – 1.8 acres (1.0%) of permanent loss and 4.4 acres of temporary loss;
- Alternative 4 – 1.9 acres (1.0%) of permanent loss and 4.3 acres of temporary loss;
- Alternative 5 – 2.3 acres (1.2%) of permanent loss and 5.2 acres of temporary loss;
- Alternative 6 – 2.0 acres (1.0%) of permanent loss and 4.1 acres of temporary loss; and
- Alternative 7 – 0.5 acres (0.3%) of permanent loss and 3.3 acres of temporary loss.

Compared to Alternative 2, which would result in 2.8 acres (1.5%) of permanent loss and 4.3 acres of temporary loss, the permanent and temporary loss of habitat under Alternatives 3 through 6 would not be substantially different (**Figures 4.5-34-A1** through **4.5-38-D2**, Alternatives 3 through 7 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). The difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is not substantially different than overall habitat loss under Alternative 2, impacts for Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for southwestern spiny rush:

- Alternative 3 – 0.6 acre (0.3%) of permanent loss;
- Alternative 4 – 0.2 acre (0.1%) of permanent loss;

- Alternative 5 – 0.0 acre (0.0%) of permanent loss;
- Alternative 6 – 0.0 acre (0.0%) of permanent loss; and
- Alternative 7 – 0.0 acre (0.0%) of permanent loss.

Compared to Alternative 2, which would result in 1.1 acres (0.6%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts (**Figures 4.5-34-A1** through **4.5-38-D2**, Alternatives 3 through 7 Impacts to RMDP/SCP, VCC, and Entrada Vegetation Communities). Alternative 4 would impact a reduced impact compared to Alternative 3 because VCC would not be constructed. Alternatives 5 through 7 would have the least impact because VCC would not be constructed and there would be additional pullbacks from the Santa Clara River and its tributaries, and other changes in the Project footprint that would reduce impacts to southwestern spiny rush compared to other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the habitat loss on site. The indirect permanent loss of suitable habitat for southwestern spiny rush occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for southwestern spiny rush:

- Alternative 3 – 2.5 acres (1.3%) of permanent loss;
- Alternative 4 – 2.0 acres (1.1%) of permanent loss;
- Alternative 5 – 2.3 acres (1.2%) of permanent loss;
- Alternative 6 – 2.0 acres (1.0%) of permanent loss; and
- Alternative 7 – 0.5 acre (0.3%) of permanent loss.

Compared to Alternative 2, which would result in 3.8 acres (2.1%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts, as described above for the discussions of direct and indirect impacts. Reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7 and additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions would occur under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable

habitat for southwestern spiny rush occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as increased human activity, noise, roads, bridges, and lighting. The loss of or degradation of suitable habitat and the loss of individual southwestern spiny rush due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Mitigation Strategy and Summary

This species would not be subject to significant direct, indirect or secondary impacts by the proposed Project. Although no mitigation is required, southwestern spiny rush will benefit from previously incorporated Mitigation Measures SP-4.6-53 and SP-4.6-59, which state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

As this plant is associated with riparian areas, southwestern spiny rush will also benefit from previously incorporated measures SP-4.6-1 through SP-4.6-16 and SP-4.6-63, which provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, and corrective measures) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

Southwestern spiny rush will benefit from BIO-1 through BIO-16, which include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees,

exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

4.5.6 MITIGATION MEASURES

Eighty mitigation measures were identified in the Newhall Ranch Specific Plan Program EIR (County of Los Angeles 2003) for biological resources. These measures (SP-4.6-1 through SP-4.6-80) are included below in **Subsection 4.5.6.1**. Eighty-nine additional mitigation measures have been developed for this EIS/EIR and are included below in **Subsection 4.5.6.2**. These additional measures (BIO-1 through BIO-89) are consistent with and supplement those mitigation measures listed in the previously certified Newhall Ranch Specific Plan Program EIR (County of Los Angeles 2003).

4.5.6.1 Mitigation Measures Already Required by the Adopted Specific Plan

SP-4.6-1 The restoration mitigation areas located within the River Corridor SMA shall be in areas that have been disturbed by previous uses or activities. Mitigation shall be conducted only on sites where soils, hydrology, and microclimate conditions are suitable for riparian habitat. First priority will be given to those restorable areas that occur adjacent to existing patches (areas) of native habitat that support sensitive species, particularly Endangered or Threatened species. The goal is to increase habitat patch size and connectivity with other existing habitat patches while restoring habitat values that will benefit sensitive species.

SP-4.6-2 A qualified biologist shall prepare or review revegetation plans. The biologist shall also monitor the restoration effort from its inception through the establishment phase.

SP-4.6-3 Revegetation Plans may be prepared as part of a California Department of Fish and Game 1603 Streambed Alteration Agreement and/or a U.S. Army Corps of Engineers Section 404 Permit, and shall include:

- Input from both the Project proponent and resource agencies to assure that the Project objectives applicable to the River Corridor SMA and the criteria of this RMP are met.
- The identification of restoration/mitigation sites to be used. This effort shall involve an analysis of the suitability of potential sites to support the desired habitat, including a description of the existing conditions at the site(s) and such base line data information deemed necessary by the permitting agency.

SP-4.6-4 The revegetation effort shall involve an analysis of the site conditions such as soils and hydrology so that site preparation needs can be evaluated. The revegetation plan shall include the details and procedures required to prepare the restoration site for planting (*i.e.,* grading, soil preparation, soil stockpiling, soil amendments, *etc.*), including the need for a supplemental irrigation system, if any.

SP-4.6-5 Restoration of riparian habitats within the River Corridor SMA shall use plant species native to the Santa Clara River. Cuttings or seeds of native plants shall be gathered within the River Corridor SMA or purchased from nurseries with local supplies to provide good genetic stock for the replacement habitats. Plant species used in the restoration of riparian habitat shall be listed on the approved project plant palette (Specific Plan Table 2.6-1, Recommended Plant Species for Habitat Restoration in the River Corridor SMA) or as approved by the permitting State and Federal agencies.

SP-4.6-6 The final revegetation plans shall include notes that outline the methods and procedures for the installation of the plant materials. Plant protection measures identified by the project biologist shall be incorporated into the planting design/layout.

SP-4.6-7 The revegetation plan shall include guidelines for the maintenance of the mitigation site during the establishment phase of the plantings. The maintenance program shall contain guidelines for the control of non-native plant species, the maintenance of the irrigation system, and the replacement of plant species.

SP-4.6-8 The revegetation plan shall provide for monitoring to evaluate the growth of the developing habitat. Specific performance goals for the restored habitat shall be defined by qualitative and quantitative characteristics of similar habitats on the River (*e.g.*, density, cover, species composition, structural development). The monitoring effort shall include an evaluation of not only the plant material installed, but the use of the site by wildlife. The length of the monitoring period shall be determined by the permitting state and/or federal agency.

SP-4.6-9 Monitoring reports for the mitigation site shall be reviewed by the permitting State and/or Federal agency.

SP-4.6-10 Contingency plans and appropriate remedial measures shall also be outlined in the revegetation plan.

SP-4.6-11 Habitat enhancement as referred to in this document means the rehabilitation of areas of native habitat that have been moderately disturbed by past activities (*e.g.*, grazing, roads, oil and natural gas operations, *etc.*) or have been invaded by non-native plant species such as giant cane (*Arundo donax*) and tamarisk (*Tamarix* sp.).

SP-4.6-12 Removal of grazing is an important means of enhancement of habitat values. Without ongoing disturbance from cattle, many riparian areas will recover naturally. Grazing except as permitted as a long-term resource management activity will be removed

from the River Corridor SMA pursuant to the Long-Term Management Plan set forth in Section 4.6 of the Specific Plan EIR.

SP-4.6-13 To provide guidelines for the installation of supplemental plantings of native species within enhancement areas, a revegetation plan shall be prepared prior to implementation of mitigation (see guidelines for revegetation plans above). These supplemental plantings will be composed of plant species similar to those growing in the existing habitat patch (see Specific Plan Table 2.6-1).

SP-4.6-14 Not all enhancement areas will necessarily require supplemental plantings of native species. Some areas may support conditions conducive for rapid "natural" reestablishment of native species. The revegetation plan may incorporate means of enhancement to areas of compacted soils, poor soil fertility, trash or flood debris, and roads as a way of enhancing riparian habitat values.

SP-4.6-15 Removal of non-native species such as giant cane (*Arundo donax*), salt cedar or tamarisk (*Tamarix* sp.), tree tobacco (*Nicotiana glauca*), castor bean (*Ricans communis*), if included in a revegetation plan to mitigate impacts, shall be subject to the following standards:

- First priority shall be given to those habitat patches that support or have a high potential for supporting sensitive species, particularly Endangered or Threatened species.
- All non-native species removals shall be conducted according to a resource agency approved exotics removal program.
- Removal of non-native species in patches of native habitat shall be conducted in such a way as to minimize impacts to the existing native riparian plant species.

SP-4.6-16 Mitigation banking activities for riparian habitats will be subject to State and Federal regulations and permits. Mitigation banking for oak resources shall be conducted pursuant to the Oak Resources Replacement Program. Mitigation banking for elderberry scrub shall be subject to approval of plans by the County Forester.

SP-4.6-17 Access to the River Corridor SMA for hiking and biking shall be limited to the River trail system (including the Regional River Trail and various Local Trails) as set forth in this Specific Plan.

- The River trail system shall be designed to avoid impacts to existing native riparian habitat, especially habitat areas known to support sensitive species. Where impacts to riparian habitat are unavoidable, disturbance shall be minimized and mitigated as outlined above under Mitigation Measures 4.6-1 through 4.6-8.

- Access to the River Corridor SMA will be limited to day time use of the designated trail system.
- Signs indicating that no pets of any kind will be allowed within the River Corridor SMA, with the exception that equestrian use is permitted on established trails, shall be posted along the River Corridor SMA.
- No hunting, fishing, or motor or off-trail bike riding shall be permitted.
- The trail system shall be designed and constructed to minimize impacts on native habitats.

SP-4.6-18 Where development lies adjacent to the boundary of the River Corridor SMA a transition area shall be designed to lessen the impact of the development on the conserved area. Transition areas may be comprised of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Exhibits 2.6-4, 2.6-5, and 2.6-6 indicate the relationship between the River Corridor SMA and the development (disturbed) areas of the Specific Plan. The SMAs and the Open Area as well as the undisturbed portions of the development areas are shown in green. As indicated on the exhibits, on the south side of the river the River Corridor SMA is separated from development by the river bluffs, except in one location. The Regional River Trail will serve as transition area on the north side of the river where development areas adjoin the River Corridor SMA (excluding Travel Village).

SP-4.6-19 The following are the standards for design of transition areas:

- In all locations where there is no steep grade separation between the River Corridor SMA and development, a trail shall be provided along this edge.
- Native riparian plants shall be incorporated into the landscaping of the transition areas between the River Corridor SMA and adjacent development areas where feasible for their long-term survival. Plants used in these areas shall be those listed on the approved plant palette (Specific Plan Table 2.6-2 of the Resource Management Plan [Recommended Plants for Transition Areas Adjacent to the River Corridor SMA]).
- Roads and bridges that cross the River Corridor SMA shall have adequate barriers at their perimeters to discourage access to the River Corridor SMA adjacent to the structures.
- Where bank stabilization is required to protect development areas, it shall be composed of ungrouted rock, or buried bank stabilization as described in Section 2.5.2.a, except at bridge crossings and other locations where public health and safety requirements necessitate concrete or other bank protection.

- A minimum 100-foot-wide buffer adjacent to the Santa Clara River should be required between the top river side of bank stabilization and development within the Land Use Designations Residential Low Medium, Residential Medium, Mixed-Use and Business Park unless, through Planning Director review in consultation with the staff biologist, it is determined that a lesser buffer would adequately protect the riparian resources within the River Corridor, or that a 100-foot-wide buffer is infeasible for physical infrastructure planning. The buffer area may be used for public infrastructure, such as: flood control access; sewer, water and utility easements; abutments; trails and parks, subject to findings of consistency with the Specific Plan and applicable County policies.

SP-4.6-20 The following guidelines shall be followed during any grading activities that take place within the River Corridor SMA:

- Grading perimeters shall be clearly marked and inspected by the project biologist prior to grading occurring within or immediately adjacent to the River Corridor SMA.
- The project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources.

SP-4.6-21 Upon final approval of the Newhall Ranch Specific Plan, the Special Management Area designation for the River Corridor SMA shall become effective. The permitted uses and development standards for the SMA are governed by the Development Regulations, Chapter 3 of the Specific Plan.

SP-4.6-22 Upon completion of development of all land uses, utilities, roads, flood control improvements, bridges, trails, and other improvements necessary for implementation of the Specific Plan within the River Corridor in each subdivision allowing construction within or adjacent to the River Corridor, a permanent, non-revocable *conservation and public access easement* shall be offered to the County of Los Angeles pursuant to Mitigation Measure 4.6-23, below, over the portion of the River Corridor SMA within that subdivision.

SP-4.6-23 The River Corridor SMA *Conservation and Public Access Easement* shall be offered to the County of Los Angeles prior to the transfer of the River Corridor SMA ownership, or portion thereof to the management entity described in Mitigation Measure 4.6-26, below.

SP-4.6-24 The River Corridor SMA *Conservation and Public Access Easement* shall prohibit grazing, except as a long-term resource management activity, and agriculture within the River Corridor and shall restrict recreation use to the established trail system.

Agricultural land uses and grazing for purposes other than long-term resource management activities within the River Corridor shall be extended in the event of the filing of any legal action against Los Angeles County challenging final approval of the Newhall Ranch Specific Plan and any related project approvals or certification of the Final EIR for Newhall Ranch. Agricultural land uses and grazing for purposes other than long-term resource management activities within the River Corridor shall be extended by the time period between the filing of any such legal action and the entry of a final judgment by a court with appropriate jurisdiction, after exhausting all rights of appeal, or execution of a final settlement agreement between all parties to the legal action, whichever occurs first.

SP-4.6-25 The River Corridor SMA conservation and public access easement shall be consistent in its provisions with any other conservation easements to State or Federal resource agencies which may have been granted as part of mitigation or mitigation banking activities.

SP-4.6-26 Prior to the recordation of the River Corridor SMA *Conservation and Public Access Easement* as specified in Mitigation Measure 4.6-23, above, the land owner shall provide a plan to the County for the permanent ownership and management of the River Corridor SMA, including any necessary financing. This plan shall include the transfer of ownership of the River Corridor SMA to the Center for Natural Lands Management, or if the Center for Natural Lands Management is declared bankrupt or dissolved, ownership will transfer or revert to a *joint powers authority* consisting of Los Angeles County (4 members), the City of Santa Clarita (2 members), and the Santa Monica Mountains Conservancy (2 members).

SP-4.6-26a Two types of habitat restoration may occur in the High Country SMA: (1) riparian revegetation activities principally in Salt Creek Canyon; and (2) oak tree replacement in, or adjacent to, existing oak woodlands and savannahs.

- Mitigation requirements for riparian revegetation activities within the High Country SMA are the same as those for the River Corridor SMA and are set forth in Mitigation Measures 4.6-1 through 4.6-11 and 4.6-13 through 4.6-16, above.
- Mitigation requirements for oak tree replacement are set forth in Mitigation Measure 4.6-48, below.

SP-4.6-27 Removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs, is a principal means of enhancing habitat values in the creeks, brushland and woodland areas of the SMA. The removal of grazing in the High Country SMA is discussed below under (b) 4. Long Term Management. All enhancement activities for riparian habitat within the

High Country SMA shall be governed by the same provisions as set forth for enhancement in the River Corridor SMA. Specific Plan Table 2.6-3 of the Resource Management Plan provides a list of appropriate plant species for use in enhancement areas in the High Country SMA.

SP-4.6-28 Mitigation banking activities for riparian habitats will be subject to State and Federal regulations and permits. Mitigation banking for oak resources, shall be conducted pursuant to the Oak Resource Replacement Program. Mitigation banking for elderberry scrub shall be subject to approval of plans by the County Forester.

SP-4.6-29 Access to the High Country SMA will be limited to day time use of the designated trail system.

SP-4.6-30 No pets of any kind will be allowed within the High Country SMA, with the exception that equestrian use is permitted on established trails.

SP-4.6-31 No hunting, fishing, or motor or trail bike riding shall be permitted.

SP-4.6-32 The trail system shall be designed and constructed to minimize impacts on native habitats.

SP-4.6-33 Construction of buildings and other structures (such as patios, decks, *etc*.) shall only be permitted upon developed pads within Planning Areas OV-04, OV-10, PV-02, and PV-28 and shall not be permitted on southerly slopes facing the High Country SMA (Planning Area HC-01) or in the area between the original SEA 20 boundary and the High Country boundary. If disturbed by grading, all southerly facing slopes which adjoin the High Country SMA within those Planning Areas shall have the disturbed areas revegetated with compatible trees, shrubs and herbs from the list of plant species for south and west facing slopes as shown in Table 2.6-3, Recommended Plant Species For Use In Enhancement Areas In The High Country.

Transition from the development edge to the natural area shall also be controlled by the standards of wildfire fuel modification zones as set forth in Mitigation Measure 4.6-49. Within fuel modification areas, trees and herbs from Table 2.6-3 of the Resource Management Plan should be planted toward the top of slopes; and trees at lesser densities and shrubs planted on lower slopes.

SP-4.6-34 Grading perimeters shall be clearly marked and inspected by the project biologist prior to impacts occurring within or adjacent to the High Country SMA.

SP-4.6-35 The project biologist shall work with the grading contractor to avoid inadvertent impacts to biological resources outside of the grading area.

SP-4.6-36 Upon final approval of the Newhall Ranch Specific Plan, the Special Management Area designation for the High Country SMA shall become effective. The permitted uses and development standards for the SMA are governed by the Development Regulations, Chapter 3.

SP-4.6-37 The High Country SMA shall be offered for dedication in three approximately equal phases of approximately 1,400 acres each proceeding from north to south, as follows:

1. The first offer of dedication will take place with the issuance of the 2,000th residential building permit of Newhall Ranch;
2. The second offer of dedication will take place with the issuance of the 6,000th residential building permit of Newhall Ranch; and
3. The remaining offer of dedication will be completed by the 11,000th residential building permit of Newhall Ranch.
4. The Specific Plan applicant shall provide a quarterly report to the Departments of Public Works and Regional Planning which indicates the number of residential building permits issued in the Specific Plan area by subdivision map number.

SP-4.6-38 Prior to dedication of the High Country SMA, a *conservation and public access easement* shall be offered to the County of Los Angeles and a conservation and management easement offered to the Center for Natural Lands Management. The High Country SMA *Conservation and Public Access Easement* shall be consistent in its provisions with any other *conservation easement*s to State or Federal resource agencies which may have been granted as part of mitigation or mitigation banking activities.

SP-4.6-39 The High Country SMA conservation and public access easement shall prohibit grazing within the High Country, except for those grazing activities associated with the long-term resource management programs, and shall restrict recreation to the established trail system.

SP-4.6-40 The High Country SMA conservation and public access easement shall be consistent in its provisions with any other conservation easements to State or Federal resource agencies which may have been granted as part of mitigation or mitigation banking activities.

SP-4.6-41 The High Country SMA shall be offered for dedication in fee to a *joint powers authority* consisting of Los Angeles County (4 members), the City of Santa Clarita (2 members), and the Santa Monica Mountains Conservancy (2 members). The *joint powers authority* will have overall responsibility for recreation within and conservation of the High Country.

SP-4.6-42 An appropriate type of service or assessment district shall be formed under the authority of the Los Angeles County Board of Supervisors for the collection of up to $24 per single family detached dwelling unit per year and $15 per single family attached dwelling unit per year, excluding any units designated as Low and Very Low affordable housing units pursuant to Section 3.10, Affordable Housing Program of the Specific Plan. This revenue would be assessed to the homeowner beginning with the occupancy of each dwelling unit and distributed to the *joint powers authority* for the purposes of recreation, maintenance, construction, conservation and related activities within the *High Country Special Management Area*.

SP-4.6-43 Suitable portions of *Open Area* may be used for mitigation of riparian, *oak resources*, or elderberry scrub. Mitigation activities within *Open Area* shall be subject to the following requirements, as applicable.

- River Corridor SMA Mitigation Requirements, including: Mitigation Measures 4.6-1 through 4.6-11 and 4.6-13 through 4.6-16; and
- High Country SMA Mitigation Requirements, including: Mitigation Measures 4.6-27, 4.6-29 through 4.6-42, and
- Mitigation Banking — Mitigation Measure 4.6-16.

SP-4.6-44 Drainages with flows greater than 2,000 cfs will have soft bottoms. Bank protection will be of ungrouted rock, or buried bank stabilization as described in Section 2.5.2.a, except at bridge crossings and other areas where public health and safety considerations require concrete or other stabilization.

SP-4.6-45 The precise alignments and widths of major drainages will be established through the preparation of drainage studies to be approved by the County at the time of subdivision maps which permit construction.

SP-4.6-46 While Open Area is generally intended to remain in a natural state, some grading may take place, especially for parks, major drainages, trails, and roadways. Trails are also planned to be within Open Area.

SP-4.6-47 At the time that final subdivision maps permitting construction are recorded, the *Open Area* within the map will be offered for dedication to the Center for Natural Lands Management. Community Parks within *Open Area* are intended to be public parks. Prior to the offer of dedication of *Open Area* to the Center for Natural Lands Management, all necessary *conservation and public access easements*, as well as easements for infrastructure shall be offered to the County.

SP-4.6-47a Mitigation Banking will be permitted within the River Corridor SMA, the High Country SMA, and the *Open Area land use designations,* subject to the following requirements:

- Mitigation banking activities for riparian habitats will be subject to State and Federal regulations, and shall be conducted pursuant to the mitigation requirements set forth in Mitigation Measure 4.6-1 through 4.6-15 above.
- Mitigation banking for oak resources shall be conducted pursuant to 4.6-48, below.
- Mitigation banking for elderberry scrub shall be subject to approval of plans by the County Forester

SP-4.6-48 Standards for the restoration and enhancement of oak resources within the High Country SMA and the Open Area include the following (oak resources include oak trees of the sizes regulated under the County Oak Tree Ordinance, southern California black walnut trees, Mainland cherry trees, and Mainland cherry shrubs):

- To mitigate the impacts to oak resources that may be removed as development occurs in the Specific Plan Area, replacement trees shall be planted in conformance with the oak tree ordinance in effect at that time.
- Oak resource species obtained from the local gene pool shall be used in restoration or enhancement.
- Prior to recordation of construction-level final subdivision maps, an oak resource replacement plan shall be prepared that provides the guidelines for the oak tree planting and/or replanting. The Plan shall be reviewed by the Los Angeles Department of Regional Planning and the County Forester and shall include the following: site selection and preparation, selection of proper species including sizes and planting densities, protection from herbivores, site maintenance, performance standards, remedial actions, and a monitoring program.
- All plans and specifications shall follow County oak tree guidelines, as specified in the County Oak Tree Ordinance.

SP-4.6-49 To minimize the potential exposure of the development areas, Open Area, and the SMAs to fire hazards, the Specific Plan is subject to the requirements of the Los Angeles County Fire Protection District (LACFPD), which provides fire protection for the area. At the time of final subdivision maps permitting construction in development areas that are adjacent to Open Area and the High Country SMA, a wildfire fuel modification plan shall be prepared in accordance with the fuel

modification ordinance standards in effect at that time and shall be submitted for approval to the County Fire Department.

SP-4.6-50 The wildfire fuel modification plan shall depict a fuel modification zone the size of which shall be consistent with the County fuel modification ordinance requirements. Within the zone, tree pruning, removal of dead plant material and weed and grass cutting shall take place as required by the fuel modification ordinance.

SP-4.6-51 In order to enhance the habitat value of plant communities that require fuel modification, fire retardant plant species containing habitat value may be planted within the fuel modification zone. Typical plant species suitable for Fuel Modification Zones are indicated in Specific Plan Table 2.6-5 of the Resource Management Plan. Fuel modification zones adjacent to SMAs and Open Areas containing habitat of high value such as oak woodland and savannas shall utilize a more restrictive plant list, which shall be reviewed by the County Forester.

SP-4.6-52 The wildfire fuel modification plan shall include the following construction period requirements: (a) a fire watch during welding operations; (b) spark arresters on all equipment or vehicles operating in a high fire hazard area; (c) designated smoking and non-smoking areas; and (d) water availability pursuant to the County Fire Department requirements.

SP-4.6-53 If, at the time any subdivision map proposing construction is submitted, the County determines through an Initial Study, or otherwise, that there may be Rare, Threatened or Endangered, plant or animal species on the property to be subdivided, then, in addition to the prior surveys conducted on the Specific Plan site to define the presence or absence of sensitive habitat and associated species, current, updated site-specific surveys for all such animal or plant species shall be conducted in accordance with the consultation requirements set forth in Mitigation Measure 4.6-59 within those areas of the Specific Plan where such animal or plant species occur or are likely to occur.

The site-specific surveys shall include the unarmored three-spine stickleback, the arroyo toad, the Southwestern pond turtle, the California red-legged frog, the southwestern willow flycatcher, the least Bell's vireo, the San Fernando Valley spineflower and any other Rare, Sensitive, Threatened, or Endangered plant or animal species occurring, or likely to occur, on the property to be subdivided. All site-specific surveys shall be conducted during appropriate seasons by qualified botanists or qualified wildlife biologists in a manner that will locate any Rare, Sensitive, Threatened, or Endangered animal or plant species that may be present. To the extent there are applicable protocols published by either the United States Fish

and Wildlife Service or the California Department of Fish and Game, all such protocols shall be followed in preparing the updated site-specific surveys.

All site-specific survey work shall be documented in a separate report containing at least the following information: (a) project description, including a detailed map of the project location and study area; (b) a description of the biological setting, including references to the nomenclature used and updated vegetation mapping; (c) detailed description of survey methodologies; (d) dates of field surveys and total person-hours spent on the field surveys; (e) results of field surveys, including detailed maps and location data; (f) an assessment of potential impacts; (g) discussion of the significance of the Rare, Threatened or Endangered animal or plant populations found in the project area, with consideration given to nearby populations and species distribution; (h) mitigation measures, including avoiding impacts altogether, minimizing or reducing impacts, rectifying or reducing impacts through habitat restoration, replacement or enhancement, or compensating for impacts by replacing or providing substitute resources or environments, consistent with CEQA (*CEQA Guidelines* section 15370); (i) references cited and persons contacted; and (j) other pertinent information, which is designed to disclose impacts and mitigate for such impacts."

SP-4.6-54 Prior to development within or disturbance to occupied unarmored threespine stickleback habitat, a formal consultation with the USFWS shall occur.

SP-4.6-55 Prior to development or disturbance within wetlands or other sensitive habitats, permits shall be obtained from pertinent Federal and State agencies and the Specific Plan shall conform to the specific provisions of said permits. Performance criteria shall include that described in Mitigation Measures 4.6-1 through 4.6-16 and 4.6-42 through 4.6-47 for wetlands, and Mitigation Measures 4.6-27, 4.6-28, and 4.6-42 through 4.6-48 for other sensitive habitats.

SP-4.6-56 All lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

SP-4.6-57 Where bridge construction is proposed and water flow would be diverted, blocking nets and seines shall be used to control and remove fish from the area of activity. All fish captured during this operation would be stored in tubs and returned unharmed back to the river after construction activities were complete.

SP-4.6-58 To limit impacts to water quality the Specific Plan shall conform with all provisions of required NPDES permits and water quality permits that would be required by the State of California Regional Water Quality Control Board.

SP-4.6-59 Consultation shall occur with the County of Los Angeles ("County") and California Department of Fish and Game ("CDFG") at each of the following milestones:

1. Before Surveys. Prior to conducting sensitive plant or animal surveys at the Newhall Ranch subdivision map level, the applicant, or its designee, shall consult with the County and CDFG for purposes of establishing and/or confirming the appropriate survey methodology to be used.

2. After Surveys. After completion of sensitive plant or animal surveys at the subdivision map level, draft survey results shall be made available to the County and CDFG within sixty (60) calendar days after completion of the field survey work.

3. Subdivision Map Submittal. Within thirty (30) calendar days after the applicant, or its designee, submits its application to the County for processing of a subdivision map in the Mesas Village or Riverwood Village, a copy of the submittal shall be provided to CDFG. In addition, the applicant, or its designee, shall schedule a consultation meeting with the County and CDFG for purposes of obtaining comments and input on the proposed subdivision map submittal. The consultation meeting shall take place at least thirty (30) days prior to the submittal of the proposed subdivision map to the County.

4. Development/Disturbance and Further Mitigation. Prior to any development within, or disturbance to, habitat occupied by Rare, Threatened, or Endangered plant or animal species, or to any portion of the Spineflower Mitigation Area Overlay, as defined below, all required permits shall be obtained from both USFWS and CDFG, as applicable. It is further anticipated that the federal and state permits will impose conditions and mitigation measures required by federal and state law that are beyond those identified in the Newhall Ranch Final EIR (March 1999), the Newhall Ranch DAA (April 2001) and the Newhall Ranch Revised DAA (2002). It is also anticipated that conditions and mitigation measures required by federal and state law for project-related impacts on Endangered, Rare or Threatened species and their habitat will likely require changes and revisions to Specific Plan development footprints, roadway alignments, and the limits, patterns and techniques associated with project-specific grading at the subdivision map level.

SP-4.6-60 If at the time subdivisions permitting construction are processed, the County determines through an Initial Study that there may be elderberry scrub vegetation on the property being subdivided, then a site specific survey shall be conducted to define the presence or absence of such habitat and any necessary mitigation measures shall be determined and applied.

SP-4.6-61 If at the time subdivisions permitting construction are processed, the County determines through an Initial Study that there may be mainland cherry trees and/or mainland cherry shrubs on the property being subdivided, then a site specific survey shall be conducted to define the presence or absence of such habitat and any necessary mitigation measures shall be determined and applied.

SP-4.6-62 When a map revision or Substantial Conformance determination on any subdivision map or Conditional Use Permit would result in changes to an approved oak tree permit, then the oak tree report for that oak tree permit must be amended for the area of change, and the addendum must be approved by the County Forester prior to issuance of grading permits for the area of the map or CUP being changed.

SP-4.6-63 Riparian resources that are impacted by buildout of the Newhall Ranch Specific Plan shall be restored with similar habitat at the rate of one acre replaced for each acre lost.

SP-4.6-64 The operator of the golf course shall prepare a Golf Course Maintenance Plan which shall include procedures to control storm water quality and ground water quality as a result of golf course maintenance practices, including irrigation, fertilizer, pesticide and herbicide use. This Plan shall be prepared in coordination with the County biologist and approved by the County Planning Director prior to the issuance of a Certificate of Occupancy.

SP-4.6-65 In order to facilitate the conservation of the spineflower on the Newhall Ranch Specific Plan site, the applicant, or its designee, shall, concurrent with Specific Plan approval, agree to the identified special study areas shown below in **Figure 2.6-8**, Spineflower Mitigation Area Overlay. The applicant, or its designee, further acknowledges that, within and around the Spineflower Mitigation Area Overlay (**Figure 2.6-8**), changes will likely occur to Specific Plan development footprints, roadway alignments, and the limits, patterns and techniques associated with project-specific grading at the subdivision map level. The applicant, or its designee, shall design subdivision maps that are responsive to the characteristics of the spineflower and all other Endangered plant species that may be found on the Specific Plan site.

SP-4.6-66 Direct impacts to known spineflower populations within the Newhall Ranch Specific Plan area shall be avoided or minimized through the establishment of one or more on-site preserves that are configured to ensure the continued existence of the species in perpetuity. Preserve(s) shall be delineated in consultation with the County and CDFG, and will likely require changes and revisions to Specific Plan development footprints for lands within and around the Spineflower Mitigation Area Overlay (**Figure 2.6-8**).

Delineation of the boundaries of Newhall Ranch spineflower preserve(s) for the entire Specific Plan area shall be completed in conjunction with approval of the first Newhall Ranch subdivision map filed in either the Mesas Village, or that portion of Riverwood Village in which the San Martinez spineflower population occurs.

A sufficient number of known spineflower populations shall be included within the Newhall Ranch spineflower preserve(s) in order to ensure the continued existence of the species in perpetuity. The conservation of known spineflower populations shall be established in consultation with the County and CDFG, and as consistent with standards governing issuance of an incidental take permit for spineflower pursuant to Fish and Game Code Section 2081, subdivision (b).

In addition to conservation of known populations, spineflower shall be introduced in appropriate habitat and soils in the Newhall Ranch preserve(s). The creation of introduced populations shall require seed collection and/or top soil at impacted spineflower locations and nursery propagation to increase seed and sowing of seed. The seed collection activities, and the maintenance of the bulk seed repository, shall be approved in advance by the County and CDFG.

Once the boundaries of the Newhall Ranch spineflower preserve(s) are delineated, the project applicant, or its designee, shall be responsible for conducting a spineflower population census within the Newhall Ranch spineflower preserve(s) annually for 10 years. (These census surveys shall be in addition to the surveys required by Mitigation Measure 4.6-53, above.) The yearly spineflower population census documentation shall be submitted to the County and CDFG, and maintained by the project applicant, or its designee. If there are any persistent population declines documented in the annual population census reports, the project applicant, or its designee, shall be responsible for conducting an assessment of the ecological factor(s) that are likely responsible for the decline, and implement management activity or activities to address these factors where feasible. In no event, however, shall project-related activities jeopardize the continued existence of the Newhall Ranch spineflower populations. If a persistent population decline is documented, such as a trend in steady population decline that persists for a period of five consecutive years, or a substantial drop in population is detected over a 10-year period, spineflower may be introduced in consultation with CDFG in appropriate habitat and soils in the Newhall Ranch preserve(s), utilizing the bulk spineflower seed repository, together with other required management activity or activities. These activities shall be undertaken by a qualified botanist/biologist, subject to approval by the County and CDFG. The project applicant, or its designee, shall be responsible for the funding and implementation of the necessary management activity or activities, including monitoring, as approved by the County and CDFG.

Annual viability reports shall be submitted to the County and CDFG for 10 years following delineation of the Newhall Ranch spineflower preserve(s) to ensure long-term documentation of the spineflower population status within the Newhall Ranch preserve(s). In the event annual status reports indicate the spineflower population within the Newhall Ranch preserve(s) is not stable and viable 10 years following delineation of the spineflower preserve(s), the project applicant, or its designee, shall continue to submit annual status reports to the County and CDFG for a period of no less than an additional five years.

SP-4.6-67 Indirect impacts associated with the interface between the preserved spineflower populations and planned development within the Newhall Ranch Specific Plan shall be avoided or minimized by establishing open space connections with Open Area, River Corridor, or High Country land use designations. In addition, buffers (*i.e.*, setbacks from developed, landscaped or other use areas) shall be established around portions of the delineated preserve(s) not connected to Open Area, the River Corridor or the High Country land use designations. The open space connections and buffer configurations shall take into account local hydrology, soils, existing and proposed adjacent land uses, the presence of non-native invasive plant species, and seed dispersal vectors.

Open space connections shall be configured such that the spineflower preserves are connected to Open Area, River Corridor, or High Country land use designations to the extent practicable. Open space connections shall be of adequate size and configuration to achieve a moderate to high likelihood of effectiveness in avoiding or minimizing indirect impacts (*e.g.*, invasive plants, increased fire frequency, trampling, chemicals, *etc.*) to the spineflower preserve(s). Open space connections for the spineflower preserve(s) shall be configured in consultation with the County and CDFG. Open space connections for the spineflower preserve(s) shall be established for the entire Specific Plan area in conjunction with approval of the first Newhall Ranch subdivision map filed in either the Mesa Village, or that portion of the Riverwood Village in which the San Martinez spineflower location occurs.

For preserves and/or those portions of preserves not connected to Open Area, River Corridor, or High Country land use designations, buffers shall be established at variable distances of between 80 and 200 feet from the edge of development to achieve a moderate to high likelihood of effectiveness in avoiding or minimizing indirect impacts (*e.g.*, invasive plants, increased fire frequency, trampling, chemicals, *etc.*) to the spineflower preserve(s). The buffer size/configuration shall be guided by the analysis set forth in the "*Review of Potential Edge Effects on the San Fernando Valley Spineflower*," prepared by Conservation Biology Institute, January 19, 2000, and other sources of scientific information and analysis, which are available at the

time the preserve(s) and buffers are established. Buffers for the spineflower preserve(s) shall be configured in consultation with the County and CDFG for the entire Specific Plan area. Buffers for the spineflower preserve(s) shall be established in conjunction with approval of the first Newhall Ranch subdivision map filed in either the Mesa Village, or that portion of the Riverwood Village in which the San Martinez spineflower location occurs.

Roadways and road rights-of-way shall not be constructed in any spineflower preserve(s) and buffer locations on Newhall Ranch unless constructing the road(s) in such location is found to be the environmentally superior alternative in subsequently required tiered EIRs in connection with the Newhall Ranch subdivision map(s) process. No other development or disturbance of native habitat shall be allowed within the spineflower preserve(s) or buffer(s).

The project applicant, or its designee, shall be responsible for revegetating open space connections and buffer areas of the Newhall Ranch spineflower preserve(s) to mitigate temporary impacts due to grading that will occur within portions of those open space connections and buffer areas. The impacted areas shall be reseeded with a native seed mix to prevent erosion, reduce the potential for invasive non-native plants, and maintain functioning habitat areas within the buffer area. Revegetation seed mix shall be reviewed and approved by the County and CDFG.

SP-4.6-68 To protect the preserved Newhall Ranch spineflower populations, and to further reduce potential direct impacts to such populations due to unrestricted access, the project applicant, or its designee, shall erect and maintain temporary orange fencing and prohibitive signage around the Newhall Ranch preserve(s), open space connections and buffer areas, which are adjacent to areas impacted by proposed development prior to and during all phases of construction. The areas behind the temporary fencing shall not be used for the storage of any equipment, materials, construction debris or anything associated with construction activities.

Following the final phase of construction of any Newhall Ranch subdivision map adjacent to the Newhall Ranch spineflower preserve(s), the project applicant, or its designee, shall install and maintain permanent fencing along the subdivision tract bordering the preserve(s). Permanent signage shall be installed on the fencing along the preservation boundary to indicate that the fenced area is a biological preserve, which contains protected species and habitat, that access is restricted, and that trespassing and fuel modification are prohibited within the area. The permanent fencing shall be designed to allow wildlife movement.

The plans and specifications for the permanent fencing and signage shall be approved by the County and CDFG prior to the final phase of construction of any Newhall Ranch subdivision map adjacent to a Newhall Ranch spineflower preserve(s).

SP-4.6-69 Indirect impacts resulting from changes to hydrology (*i.e.*, increased water runoff from surrounding development) at the interface between spineflower preserve(s) and planned development within the Newhall Ranch Specific Plan shall be avoided or mitigated to below a level of significance.

Achievement of this standard will be met through the documented demonstration by the project applicant, or its designee, that the storm drain system achieves pre-development hydrological conditions for the Newhall Ranch spineflower preserve(s). To document such a condition, the project applicant, or its designee, shall prepare a study of the pre- and post-development hydrology, in conjunction with Newhall Ranch subdivision maps adjacent to spineflower preserve(s). The study shall be used in the design and engineering of a storm drain system that achieves pre-development hydrological conditions. The study must conclude that proposed grade changes in development areas beyond the buffers will maintain pre-development hydrology conditions within the preserve(s). The study shall be approved by the Planning Director of the County, and the resulting conditions confirmed by CDFG.

The storm drain system for Newhall Ranch subdivision maps adjacent to any spineflower preserves must be approved by the County prior to the initiation of any grading activities.

SP-4.6-70 Consistent with the Spineflower Mitigation Area Overlay reflected in Mitigation Measure 4.6-65, direct impacts to known Newhall Ranch spineflower populations associated with proposed road construction or modifications to existing roadways shall be further assessed for proposed road construction at the Newhall Ranch subdivision map level, in conjunction with the tiered EIR required for each subdivision map. To avoid or substantially lessen direct impacts to known spineflower populations, Specific Plan roadways shall be redesigned or realigned, to the extent practicable, to achieve the spineflower preserve and connectivity/preserve design/buffer standards set forth in Mitigation Measures 4.6-66 and 4.6-67. The project applicant, or its designee, acknowledges that that road redesign and realignment is a feasible means to avoid or substantially lessen potentially significant impacts on the now known Newhall Ranch spineflower populations. Road redesign or alignments to be considered at the subdivision map level include:

(a) Commerce Center Drive;

(b) Magic Mountain Parkway;

(c) Chiquito Canyon Road;

(d) Long Canyon Road;

(e) San Martinez Grande Road;

(f) Potrero Valley Road;

(g) Valencia Boulevard; and

(h) Any other or additional roadways that have the potential to significantly impact known Newhall Ranch spineflower populations.

Roadways and road rights-of-way shall not be constructed in any spineflower preserve(s) and buffer locations on Newhall Ranch, unless constructing the road(s) in such location is found to be the environmentally superior alternative in subsequently required tiered EIRs in connection with the Newhall Ranch subdivision map(s) process.

SP-4.6-71 Consistent with the Spineflower Mitigation Area Overlay reflected in Mitigation Measure 4.6-65, direct impacts to known Newhall Ranch spineflower populations shall be further assessed at the Newhall Ranch subdivision map level, in conjunction with the required tiered EIR process. To avoid or substantially lessen impacts to known spineflower populations at the subdivision map level, the project applicant, or its designee, may be required to adjust Specific Plan development footprints, roadway alignments, and the limits, patterns and techniques associated with project-specific grading to achieve the spineflower preserve and connectivity/preserve design/buffer standards set forth in Mitigation Measures 4.6-66 and 4.6-67 for all future Newhall Ranch subdivision maps that encompass identified spineflower populations.

SP-4.6-72 A Fire Management Plan shall be developed to avoid and minimize direct and indirect impacts to the spineflower, in accordance with the adopted Newhall Ranch Resource Management Plan (RMP), to protect and manage the Newhall Ranch spineflower preserve(s) and buffers.

The Fire Management Plan shall be completed by the project applicant, or its designee, in conjunction with approval of any Newhall Ranch subdivision map adjacent to a spineflower preserve.

The final Fire Management Plan shall be approved by the County of Los Angeles Fire Department through the processing of subdivision maps.

Under the final Fire Management Plan, limited fuel modification activities within the spineflower preserves will be restricted to selective thinning with hand tools to allow the maximum preservation of Newhall Ranch spineflower populations. No other fuel modification or clearance activities shall be allowed in the Newhall Ranch spineflower preserve(s). Controlled burning may be allowed in the future within the Newhall Ranch preserve(s) and buffers, provided that it is based upon a burn plan approved by the County of Los Angeles Fire Department and CDFG. The project applicant, or its designee, shall also be responsible for annual maintenance of fuel modification zones, including, but not limited to, removal of undesirable non-native plants, revegetation with acceptable locally indigenous plants and clearing of trash and other debris in accordance with the County of Los Angeles Fire Department.

SP-4.6-73 At the subdivision map level, the project applicant, or its designee, shall design and implement project-specific design measures to minimize changes in surface water flows to the Newhall Ranch spineflower preserve(s) for all Newhall Ranch subdivision maps adjacent to the preserve(s) and buffers, and avoid and minimize indirect impacts to the spineflower. Prior to issuance of a grading permit for each such subdivision map, the project applicant, or its designee, shall submit for approval to the County plans and specifications that ensure implementation of the following design measures:

(a) During construction activities, drainage ditches, piping or other approaches will be put in place to convey excess storm water and other surface water flows away from the Newhall Ranch spineflower preserve(s) and connectivity/preserve design/buffers, identified in Mitigation Measures 4.6-66 and 4.6-67;

(b) Final grading and drainage design will be developed that does not change the current surface and subsurface hydrological conditions within the preserve(s);

(c) French drains will be installed along the edge of any roadways and fill slopes that drain toward the preserve(s);

(d) Roadways will be constructed with slopes that convey water flows within the roadway easements and away from the preserve(s);

(e) Where manufactured slopes drain toward the preserve(s), a temporary irrigation system would be installed to the satisfaction of the County in order to establish the vegetation on the slope area(s). This system shall continue only until the slope vegetation is established and self sustaining;

(f) Underground utilities will not be located within or through the preserve(s). Drainage pipes installed within the preserve(s) away from spineflower populations to convey surface or subsurface water away from the populations will be aligned to avoid the preserve(s) to the maximum extent practicable; and

(g) Fencing or other structural type barriers that will be installed to reduce intrusion of people or domestic animals into the preserve(s) shall incorporate footing designs that minimize moisture collection.

SP-4.6-74 A knowledgeable, experienced botanist/biologist, subject to approval by the County and CDFG, shall be required to monitor the grading and fence/utility installation activities that involve earth movement adjacent to the Newhall Ranch spineflower preserve(s) to avoid the incidental take through direct impacts of conserved plant species, and to avoid disturbance of the preserve(s). The biological monitor will conduct biweekly inspections of the project site during such grading activities to ensure that the mitigation measures provided in the adopted Newhall Ranch Mitigation Monitoring Program (Biota section) are implemented and adhered to.

Monthly monitoring reports, as needed, shall be submitted to the County verifying compliance with the mitigation measures specified in the adopted Newhall Ranch Mitigation Monitoring Program (Biota section).

The biological monitor will have authority to immediately stop any such grading activity that is not in compliance with the adopted Newhall Ranch Mitigation Monitoring Program (Biota section), and to take reasonable steps to avoid the take of, and minimize the disturbance to, spineflower populations within the preserve(s).

SP-4.6-75 The following measures shall be implemented to avoid and minimize indirect impacts to Newhall Ranch spineflower populations during all phases of project construction:

(a) Water Control. Watering of the grading areas would be controlled to prevent discharge of construction water into the Newhall Ranch preserve(s) or on ground sloping toward the preserve(s). Prior to the initiation of grading operations, the project applicant, or its designee, shall submit for approval to the County an irrigation plan describing watering control procedures necessary to prevent discharge of construction water into the Newhall Ranch preserve(s) and on ground sloping toward the preserve(s).

(b) Storm Water Flow Redirection. Diversion ditches would be constructed to redirect storm water flows from graded areas away from the Newhall Ranch preserve(s). To the extent practicable, grading of areas adjacent to the preserve(s) would be limited to spring and summer months (May through September) when the probability of rainfall is lower. Prior to the initiation of grading operations, the project applicant, or its designee, would submit for approval to the County a storm water flow redirection plan that demonstrates the flow of storm water away from the Newhall Ranch spineflower preserve(s).

(c) Treatment of Exposed Graded Slopes. Graded slope areas would be trimmed and finished as grading proceeds. Slopes would be treated with soil stabilization measures to minimize erosion. Such measures may include seeding and planting, mulching, use of geotextiles and use of stabilization mats. Prior to the initiation of grading operations, the project applicant, or its designee, would submit for approval to the County the treatments to be applied to exposed graded slopes that would ensure minimization of erosion.

SP-4.6-76 In conjunction with submission of the first Newhall Ranch subdivision map in either Mesas Village or that portion of Riverwood Village in which the San Martinez spineflower location occurs, the project applicant, or its designee, shall reassess project impacts, both direct and indirect, to the spineflower populations using subdivision mapping data, baseline data from the Newhall Ranch Final EIR and data from the updated plant surveys (see Specific Plan EIR Mitigation Measure 4.6-53).

This reassessment shall take place during preparation of the required tiered EIR for each subdivision map. If the reassessment results in the identification of new or additional impacts to Newhall Ranch spineflower populations, which were not previously known or identified, the mitigation measures set forth in this program, or a Fish and Game Code section 2081 permit(s) issued by CDFG, shall be required, along with any additional mitigation required at that time.

SP-4.6-77 Direct and indirect impacts to the preserved Newhall Ranch spineflower populations shall require a monitoring and management plan, subject to the approval of the County. The applicant shall consult with CDFG with respect to preparation of the Newhall Ranch spineflower monitoring/management plan. This plan shall be in place when the preserve(s) and connectivity/preserve design/buffers are established (see Mitigation Measures 4.6-66 and 4.6-67). The criteria set forth below shall be included in the plan.

Monitoring. The purpose of the monitoring component of the plan is to track the viability of the Newhall Ranch spineflower preserve(s) and its populations, and to ensure compliance with the adopted Newhall Ranch Mitigation Monitoring Program (Biota section).

The monitoring component of the plan shall investigate and monitor factors such as population size, growth or decline, general condition, new impacts, changes in associated vegetation species, pollinators, seed dispersal vectors, and seasonal responses. Necessary management measures will be identified. The report results will be sent annually to the County, along with photo documentation of the assessed site conditions.

The project applicant, or its designee, shall contract with a qualified botanist/biologist, approved by the County, with the concurrence of CDFG, to conduct quantitative monitoring over the life of the Newhall Ranch Specific Plan. The botanist/biologist shall have a minimum of three years experience with established monitoring techniques and familiarity with southern California flora and target taxa. Field surveys of the Newhall Ranch spineflower preserve(s) will be conducted each spring. Information to be obtained will include: (a) an estimate of the numbers of spineflowers in each population within the preserve(s); (b) a map of the extent of occupied habitat at each population; (c) establishment of photo monitoring points to aid in documenting long-term trends in habitat; (d) aerial photographs of the preserved areas at five-year intervals; (e) identification of significant impacts that may have occurred or problems that need attention, including invasive plant problems, weed problems and fencing or signage repair; and (f) overall compliance with the adopted mitigation measures.

For a period of three years from Specific Plan re-approval, all areas of potential habitat on the Newhall Ranch site will be surveyed annually in the spring with the goal of identifying previously unrecorded spineflower populations. Because population size and distribution limits are known to vary depending on rainfall, annual surveys shall be conducted for those areas proposed for development in order to establish a database appropriate for analysis at the project-specific subdivision map level (rather than waiting to survey immediately prior to proceeding with the project-specific subdivision map process). In this way, survey results gathered over time (across years of varying rainfall) will provide information on ranges in population size and occupation. New populations, if they are found, will be mapped and assessed for inclusion in the preserve program to avoid impacts to the species.

Monitoring/Reporting. An annual report will be submitted to the County and CDFG by December 31st of each year. The report will include a description of the monitoring methods, an analysis of the findings, effectiveness of the mitigation program, site photographs, and adoptive management measures, based on the findings. Any significant adverse impacts, signage, fencing or compliance problems identified during monitoring visits will be reported to the County and CDFG for corrective action by the project applicant, or its designee.

Management. Based on the outcome of ongoing monitoring and additional project-specific surveys addressing the status and habitat requirements of the spineflower, active management of the Newhall Ranch spineflower preserve(s) will be required in perpetuity. Active management activities will be triggered by a downward population decline over 5 consecutive years, or a substantial drop in population over a 10-year period following County re-approval of the Specific Plan.

Examples of management issues that may need to be addressed in the future include, but are not limited to, control of exotic competitive non-native plant species, herbivory predation, weed control, periodic controlled burns, or fuel modification compliance.

After any population decline documented in the annual populations census following County re-approval of the Specific Plan, the project applicant, or its designee, shall be responsible for conducting an assessment of the ecological factor(s) that are likely responsible for the decline, and implement management activity or activities to address these factors where feasible. If a persistent population decline is documented, such as a trend in steady population decline persistent for a period of 5 consecutive years, or a substantial drop in population detected over a 10-year period, spineflower may be introduced in appropriate habitat and soils in the Newhall Ranch preserve(s), utilizing the bulk spineflower seed repository, together with other required management activity or activities. In connection with this monitoring component, the project applicant, or its designee, shall contract with a qualified botanist/biologist, approved by the County, to complete: (a) a study of the breeding and pollination biology of the spineflower, including investigation into seed physiology to assess parameters that may be important as management tools to guarantee self-sustainability of populations, which may otherwise have limited opportunity for germination; and (b) a population genetics study to document the genetic diversity of the Newhall Ranch spineflower population. The criteria for these studies shall be to develop data to make the Newhall Ranch spineflower management program as effective as possible. These studies shall be subject to approval by the County's biologist, with the concurrence of CDFG. These activities shall be undertaken by a qualified botanist/biologist, subject to approval by the County with the concurrence of CDFG. The project applicant, or its designee, shall be responsible for the funding and implementation of the necessary management activity or activities, as approved by the County and CDFG.

The length of the active management components set forth above shall be governed by attainment of successful management criteria set forth in the plan rather than by a set number of years.

SP-4.6-78 To the extent project-related direct and indirect significant impacts on spineflower cannot be avoided or substantially lessened through establishment of the Newhall Ranch spineflower preserve(s), and other avoidance, minimization, or other compensatory mitigation measures, a translocation and reintroduction program may be implemented in consultation with CDFG to further mitigate such impacts. Direct impacts (*i.e.*, take) to occupied spineflower areas shall be fully mitigated at a 4:1

ratio. Impacts to occupied spineflower areas caused by significant indirect effects shall be mitigated at a 1:1 ratio.

Introduction of new spineflower areas will be achieved through a combination of direct seeding and translocation of the existing soil seed bank that would be impacted by grading. Prior to any development within, or disturbance to, spineflower populations, on-site and off-site mitigation areas shall be identified and seed and top soil shall be collected. One-third of the collected seed shall be sent to the Rancho Santa Ana Botanical Garden for storage. One third of the seed shall be sent to the USDA National Seed Storage Lab in Fort Collins, Colorado for storage. One third shall be used for direct seeding of the on-site and off-site mitigation areas.

Direct seeding. Prior to the initiation of grading, the project applicant, or its designee, shall submit to the County a program for the reintroduction of spineflower on Newhall Ranch. The reintroduction program shall include, among other information: (a) location map with scale; (b) size of each introduction polygon; (c) plans and specifications for site preparation, including selective clearing of competing vegetation; (d) site characteristics; (e) protocol for seed collection and application; and (f) monitoring and reporting. The program shall be submitted to CDFG for input and coordination. The project applicant, or its designee, shall implement the reintroduction program prior to the initiation of grading. At least two candidate spineflower reintroduction areas will be created within Newhall Ranch and one candidate spineflower reintroduction area will be identified offsite. Both on-site and off-site reintroduction areas will be suitable for the spineflower in both plant community and soils, and be located within the historic range of the taxon. Success criteria shall be included in the monitoring/management plan, with criteria for the germination, growth, and production of viable seeds of individual plants for a specified period.

Although the reintroduction program is experimental at this stage, the County considers such a program to be a feasible form of mitigation at this juncture based upon available studies. Botanists/biologists familiar with the ecology and biology of the spineflower would prepare and oversee the reintroduction program.

Translocation. Prior to the initiation of grading, the project applicant, or its designee, shall submit to the County a translocation program for the spineflower. Translocation would salvage the topsoil of spineflower areas to be impacted due to grading. Salvaged spineflower soil seed bank would be translocated to the candidate spineflower reintroduction areas. The translocation program shall include, among other information: (a) location map with scale; (b) size of each translocation polygon; (c) plans and specifications for site preparation, including selective clearing of

competing vegetation; (d) site characteristics; (e) protocol for topsoil collection and application; and (f) monitoring and reporting. The translocation program shall be submitted to CDFG for input and coordination. Translocation shall occur within the candidate spineflower reintroduction areas onsite and offsite. Successful criteria for each site shall be included in the monitoring/management plan/with criteria for the germination and growth to reproduction of individual plants for the first year a specified period.

Although the translocation program is experimental at this stage, the County considers such a program to be a feasible form of mitigation at this juncture based upon available studies. Botanists/biologists familiar with the ecology and biology of the spineflower would prepare and oversee the translocation program.

SP-4.6-79 The project applicant, or its designee, shall engage in regular and ongoing consultation with the County and CDFG in connection with its ongoing agricultural operations in order to avoid or minimize significant direct impacts to the spineflower.

In addition, the project applicant, or its designee, shall provide 30 days advance written notice to the County and CDFG of the proposed conversion of its ongoing rangeland operations on Newhall Ranch to more intensive agricultural uses. The purpose of the advance notice requirement is to allow the applicant, or its designee, to coordinate with the County and CDFG to avoid or minimize significant impacts to the spineflower prior to the applicant's proposed conversion of its ongoing rangeland operations to more intensive agricultural uses. This coordination component will be implemented by or through the County's Department of Regional Planning and/or the Regional Manager of CDFG. Implementation will consist of the County and/or CDFG conducting a site visit of the proposed conversion area(s) within the 30-day period, and making a determination of whether the proposed conversion area(s) would destroy or significantly impact spineflower population in or adjacent to those areas. If it is determined that the conversion area(s) do not destroy or significantly impact spineflower populations, then the County and/or CDFG will authorize such conversion activities in the proposed conversion area(s). However, if it is determined that the conversion area(s) may destroy or significantly impact spineflower populations, then the County and/or CDFG will issue a stop work order to the applicant, or its designee. If such an order is issued, the applicant, or its designee, shall not proceed with any conversion activities in the proposed conversion area(s). However, the applicant, or the designee, may take steps to relocate the proposed conversion activities in an alternate conversion area(s). In doing so, the applicant, or its designee, shall follow the same notice and coordination provisions identified above. This conversion shall not include ordinary pasture maintenance and renovation or dry land farming operations consistent with rangeland management.

SP-4.6-80 Upon approval of tentative tract map(s) impacting the San Martinez portion of the Specific Plan site, the applicant shall work with the Department of Regional Planning staff and SEATAC to establish an appropriately sized preserve area to protect the spineflower population at San Martinez Canyon.

4.5.6.2 Additional Mitigation Measures Proposed by this EIS/EIR

BIO-1 Mitigation Measures SP-4.6-1 through SP-4.6-16 specify requirements for riparian mitigation conducted in the High Country SMA, Salt Creek area, and Open Area. The RMDP includes requirements for mitigation of both riparian and upland habitats (such as riparian adjacent big sagebrush scrub), and incorporates these Mitigation Measures (SP-4.6-1 through SP-4.6-16). A Comprehensive Mitigation Implementation Plan (CMIP) has been developed by Newhall Land that provides an outline of mitigation to offset impacts described in the RMDP. The CMIP demonstrates the feasibility of creating the required mitigation acreage from RMDP project impacts (see BIO-2).

Detailed wetlands mitigation plans, in accordance with the CMIP, shall be submitted to, and are subject to the approval of, the Corps and CDFG as part of the sub-notification letters for individual projects. Individual project submittals shall include applicable CMIP elements, complying with the requirements outlined below. The detailed wetlands mitigation plan shall specify, at a minimum, the following: (1) the location of mitigation sites; (2) site preparation, including grading, soils preparation, irrigation installation, (2a) the quantity (seed or nursery stock) and species of plants to be planted (all species to be native to region); (3) detailed procedures for creating additional vegetation communities; (4) methods for the removal of non-native plants; (5) a schedule and action plan to maintain and monitor the enhancement/restoration area; (6) a list of criteria by which to measure success of the mitigation sites (*e.g.*, percent cover and richness of native species, percent survivorship, establishment of self-sustaining native of plantings, maximum allowable percent of non-native species); (7) measures to exclude unauthorized entry into the creation/enhancement areas; and (8) contingency measures in the event that mitigation efforts are not successful. Individual project detailed wetlands mitigation plans shall also classify the biological value (as "high," "moderate," or "low") of the vegetation communities to be disturbed as defined in these conditions, or may be based on an agency-approved method (*e.g.*, Hybrid Assessment of Riparian Communities (HARC)). The biological value shall be used to determine mitigation replacement ratios required under BIO-2 and BIO-10. The detailed wetlands mitigation plans shall provide for the 3:1 replacement of any southern California black walnut to be removed from the riparian corridor for individual projects. The plan shall be subject to the approval of CDFG and the Corps and approved prior to

the impact to riparian resources. BIO-4 describes that the functions and values will be assessed for the riparian areas that will be removed, and BIO-2 and BIO-10 describe the replacement ratios for the habitats that will be impacted.

BIO-2 The permanent removal of CDFG jurisdictional riparian habitats in the river and tributaries shall be replaced by creating riparian habitats of similar functions and values (see BIO-4) on the Project site, or as allowed under BIO-10. Riparian habitat meeting success criteria (see BIO-6) two years in advance of the removal of riparian habitat at the construction site shall be in kind and at a 1:1 replacement ratio (except as indicated below). If replacement riparian habitat cannot meet the success criteria two years in advance of the Project, the ratios listed below in **Table 4.5-68** will apply.

Table 4.5-68
CDFG Jurisdictional Permanent Impacts Mitigation Ratios

Ratios Listed by Vegetation Types & Quality				
Vegetation Community	**Veg Code / ID**	**HIGH Reach Value* (Mit. Ratio)**	**MEDIUM Reach Value** (Mit. Ratio)**	**LOW Reach Value*** (Mit. Ratio)**
Southern Cottonwood–Willow Riparian Forrest	SCWRF	4:1	3:1	2:1
Southern Willow Scrub	SWS	3:1	2.5:1	2:1
Oak Woodland (Coast Live, Valley)	CLOW / VOW	3:1	2.5:1	2:1
Big Sagebrush Scrub	BSS	2.5:1	2:1	1.5:1
Mexican Elderberry Scrub	MES	2.5:1	2:1	1.5:1
Cismontane Alkaline Marsh	CAM	2.5:1	2:1	1.5:1
Coastal and Valley Fresh Water Marsh	CFWM	2:1	1.5:1	1:1
Mulefat Scrub	MFS	2:1	1.5:1	1.25:1
Arrowweed Scrub	AWS	2:1	1.5:1	1:1
California Sagebrush scrub, and CSB-dominated habitats	CSB, CSB-A, -BS, -CB, -CHP, and -PS	2:1	1.5:1	1:1
Herbaceous Wetland	HW	1.5:1	1.25:1	1:1
River Wash, emergent veg.	RW	1.5:1	1.25:1	1:1
Chaparral, Chamise Chaparral	CHP, CC	1.5:1	1.25:1	1:1
Coyote Brush Scrub	CYS	1.5:1	1.25:1	1:1
Eriodictyon Scrub	EDS	1.5:1	1.25:1	1:1
California Grass Lands	CGL	1:1	1:1	1:1
Agricultural / Disturbed / Developed	AGR / DL / DEV	1:1	1:1	1:1

Notes:
* HIGH reach value indicates a portion of the Santa Clara River or main tributary that scored above 0.79 Total Score utilizing the HARC methodology described in **Section 4.2**, Geomorphology and Riparian Resources, of this EIS/EIR.
** MEDIUM reach value indicates a portion of the Santa Clara River or main tributary that scored between 0.4 and 0.79 Total Score utilizing the HARC methodology described in **Section 4.2.**
*** LOW reach value indicates a portion of the Santa Clara River or main tributary that scored below 0.4 Total Score utilizing

Table 4.5-68
CDFG Jurisdictional Permanent Impacts Mitigation Ratios

the HARC methodology described in **Section 4.2.**
Ratios for Permanent Impacts to all classifications: Mitigation initiated two years prior to disturbance: 1:1 ratio; mitigation initiated less than two years after disturbance shall follow ratios in table above; mitigation initiated two to five years after disturbance shall add 0.5 to each value in the table above; and over five years, 1.0 is added to each value in the table above. (For example, initiation of mitigation of mulefat scrub three years after disturbance for a high habitat impact would be a ratio of 2.5:1, instead of 2:1 if initiated within two years of disturbance or 3:1 if initiated more than five years after disturbance.)
Ratios for Temporary Impacts to all classifications: Disturbance period less than two years, 1:1; two to five years, 1.5:1; over five years, 2:1, except for removal of southern cottonwood and oak woodlands, which shall be mitigated at 2:1 for High, 1.5:1 for Medium, and 1:1 for Low for all periods (except for pre-mitigated, which is 1:1).
Exotic/Invasive Species Removal, followed by restoration/revegetation, may be used to offset impacts above. Mitigation shall be credited at an acreage equivalent to the percentage of exotic vegetation at the restoration site. This means, for example, if a 10-acre area is occupied by 10% exotic species, restoration will be credited for 1 acre of impact. As appropriate and authorized by CDFG, reduced percentage credits may be applied for invasive removal with passive restoration (weeding and documentation of natural recruitment only).

BIO-3 Creation of new vegetation communities and restoration of impacted vegetation communities shall occur at suitable sites in or adjacent to the watercourses or in areas where bank stabilization would occur. The highest-priority vegetation community restoration sites are to be new riverbed and tributary areas created, or disturbed sites impacted, during the excavation of uplands for bank protection/stabilization activities. Restoration sites may also occur at locations outside the riverbed where there are appropriate hydrologic conditions to create a self-sustaining riparian vegetation community and where upland and riparian vegetation community values are absent or very low. All sites shall contain suitable hydrological conditions and surrounding land uses to ensure a self-sustaining functioning riparian vegetation community. Candidate restoration sites shall be described in the annual mitigation status report (BIO-12). Sites will be approved when the detailed wetlands mitigation plans are submitted to the Corps and CDFG as part of the sub-notification letters submitted for individual projects Status of the sites will be addressed as part of the annual mitigation status report and mitigation accounting form agency review. Each revegetation plan will include acreages, maps and site specific descriptions of the proposed revegetation site, including analysis of soils, hydrologic suitability, and present and future adjacent land uses.

BIO-4 Replacement vegetation communities shall be designed to replace the functions and values of the vegetation communities being removed. The replacement vegetation communities shall have similar dominant trees and understory shrubs and herbs (excluding exotic species) to those of the affected vegetation communities (see **Table 4.5-69** for example of recommended plant species for the River Corridor SMA and tributaries). In addition, the replacement vegetation communities shall be designed to

replicate the density and structure of the affected vegetation communities once the replacement vegetation communities have met the mitigation success criteria.

Table 4.5-69
Potential Plant Species for Vegetation Community Restoration in the River Corridor SMA and Tributaries

Trees	
red willow	*Salix laevigata*
arroyo willow	*Salix lasiolepis*
Fremont cottonwood	*Populus fremontii*
black cottonwood	*Populus balsamifera* ssp. *trichocarpa*
western sycamore	*Platanus racemosa*
Shrubs	
mulefat	*Baccharis salicifolia*
sandbar willow	*Salix exigua*
arrow weed	*Pluchea sericea*
Herbs	
mugwort	*Artemisia douglasiana*
western ragweed	*Ambrosia psilostachya*
cattail	*Typha latifolia*
bulrush	*Scirpus americanus*
prairie bulrush	*Scirpus maritimus*

Note: This is a recommended list. Other species may be found suitable based on site conditions and state and federal permits.

BIO-5 Average plant spacing shall be determined based on an analysis of vegetation communities to be replaced. The applicant shall develop plant spacing specifications for all riparian vegetation communities to be restored. Plant spacing specifications shall be reviewed and approved by the Corps and CDFG when restoration plans are submitted to the agencies as part of the sub-notification letters submitted to the Corps and CDFG for individual projects or as part of the annual mitigation status report and mitigation accounting form.

BIO-6 The revegetation site will be considered "complete" upon meeting all of the following success criteria. In a sub-notification letter, the applicant may request modification of success criteria on a project by project basis. Acceptance of such request will be at the discretion of CDFG and the Corps.

1. Regardless of the date of initial planting, any restoration site must have been without active manipulation by irrigation, planting, or seeding for a minimum of three years prior to Agency consideration of successful completion.

2. The percent cover and species richness of native vegetation shall be evaluated based on local reference sites established by CDFG and the Corps for the plant communities in the impacted areas.

3. Native shrubs and trees shall have at least 80% survivorship after two years beyond the beginning of the success evaluation start date. This may include natural recruitment.

4. Non-native species cover will be no more than 5% absolute cover through the term of the restoration.

5. Giant reed (*Arundo donax*), tamarisk (*Tamarix ramosissima*), perennial pepperweed (*Lepidium latifolium*), tree of heaven (*Ailanthus altissimus*), pampas grass (*Cortaderia selloana)* and any species listed on the California State Agricultural list, or Cal-IPC list of noxious weeds will not be present on the revegetation site as of the date of completion approval.

6. Using the HARC assessment methodology, the compensatory mitigation site shall meet or exceed the baseline functional scores of the impact area in jurisdictional waters of the United States. If the compensatory mitigation site cannot meet or exceed the baseline functional score of the impact area in jurisdictional waters of the United States, additional mitigation area would be required to compensate for the functional loss.

BIO-7 If at any time prior to Agency approval of the restoration area, the site is subject to an act of God (flood, fires, or drought)) the applicant shall be responsible for replanting the damaged area. The site will be subject to the same success criteria as provided for in BIO-6. Should a second act of God occur prior to Agency approval of the restoration area, the applicant shall coordinate with the Agencies and develop an alternative restoration strategy(ies) to meet success requirements. This may include restoration elsewhere in the River corridor or tributaries.

BIO-8 Temporary irrigation shall be installed as necessary for plant establishment. Irrigation shall continue as needed until the restoration site becomes self sustaining, regarding survivorship and growth. Irrigation shall be terminated in the fall to provide the least stress to plants.

BIO-9 As an alternative to the creation/restoration of vegetation communities to compensate for permanent removal of riparian vegetation communities, in the Santa Clara River, the applicant may control invasive exotic plant species within the Upper Santa Clara River Sub-Watershed for a portion of the Santa Clara River mitigation required under BIO-2. The applicant may perform this work or contribute "in-lieu fees" to the

Upper Santa Clara River Arundo/Tamarisk Removal Program to perform this work, if available. The weed control sites shall be selected in a coordinated, logical manner to ensure that giant reed and other invasive weeds are controlled to improve and expand wildlife and endangered species habitat; reduce flooding, erosion, and fire hazards; improve water quality; and potentially increase stream flow/water quantity in the RMDP watercourses. Removal areas shall be kept free of exotic plant species for five years after initial treatment. In areas where extensive exotic removal occurs, revegetation with native plants or natural recruitment shall be documented.

BIO-10 The exotics control program may utilize methods and procedures in accordance with the provisions in the Upper Santa Clara River Watershed Arundo/Tamarisk Removal Plan Final EIR, dated February 2006, or the applicant may propose alternative methods and procedures for Corps and CDFG review and approval pursuant to a sub-notification letter or annual mitigation status report submittal. Exotic plant species control will be credited at an acreage equivalent to the percentage of exotic vegetation at the restoration site. By example: a 10-acre site occupied by 10% exotic species will be credited for one acre of mitigation. The exotic weed control location will be documented on the annual mitigation status report and mitigation accounting form. If "in-lieu fees" are paid, it will be documented on the annual mitigation status report and mitigation accounting form, along with a reporting of the status of exotic vegetation treatment.

BIO-11 To provide an accurate and reliable accounting system for mitigation, the applicant utilizing the RMDP shall file a mitigation accounting form annually with the Corps and CDFG by April 1. This form shall document the amount of vegetation planted during the past year, any "in-lieu fees" paid for exotic invasive plant species control, the status of all mitigation credits to date, and any credits subtracted by projects implemented during the past year. The applicant, utilizing the RMDP, shall keep detailed records and provide a mitigation accounting form to the Corps and CDFG annually for review for the life of the permit, or until all credits have been used up for individual projects, and success criteria have been met. The Corps and CDFG shall provide concurrence within 60 days, including written verification for all restoration and weed removal sites that meet the specified performance criteria. Adequate proof of delivery of applicable reports would be required as well as subsequent notice to the Agencies requesting surety release.

BIO-12 An annual mitigation status report shall be submitted to the Corps and CDFG by April 1 of each year until satisfaction of success criteria identified in BIO-6. This report shall include any required plans for plant spacing, locations of candidate restoration and weed control sites or proposed "in-lieu fees," restoration methods, and vegetation community restoration performance standards. For active vegetation

community creation sites, the report shall include the survival, percent cover, and height of planted species; the number by species of plants replaced; an overview of the revegetation effort and its success in meeting performance criteria; the method used to assess these parameters; and photographs. For active exotics control sites, the report shall include an assessment of weed control; a description of the relative cover of native vegetation, bare areas, and exotic vegetation; an accounting of colonization by native plants; and photographs. The report shall also include the mitigation accounting form (see BIO-11), which outlines accounting information related to species planted or exotics control and mitigation credit remaining. The annual mitigation and monitoring report shall document the current functional capacity of the compensatory mitigation site using the HARC assessment methodology, as well as documenting the baseline functional scores of the impact site in jurisdictional waters of the United States.

BIO-13 The mitigation program shall incorporate applicable principles in the interagency Federal Guidance for the Establishment, Use, and Operation of Mitigation Banks (60 FR 58605–58614) to the extent feasible and appropriate, particularly the guidance on administration and accounting. Nothing in the section 404 or section 2081 Permit or section 1605 agreement shall preclude the applicant from selling mitigation credits to other parties wishing to use those permits or that agreement for a project and/or maintenance activity included in the permits/agreement.

BIO-14 Temporary impacts from construction activities in the riverbed shall be restricted to the following areas of disturbance: (1) an 85-foot-wide zone that extends into the river from the base of the rip-rap or gunite bank protection where it intercepts the river bottom; (2) 100 feet on either side of the outer edge of a new bridge or bridge to be modified; (3) a 60-foot-wide corridor for utility lines; (4) 20-foot-wide temporary access ramps; and (5) 60-foot roadway width temporary construction haul routes. The locations of these temporary construction sites and the routes of all access roads shall be shown on maps submitted with the sub-notification letter submitted to the Corps and CDFG for individual project approval. Any variation from these limits shall be submitted, with a justification for a variation for Corps and CDFG approval. The construction plans should indicate what type of vegetation, if any, would be temporarily disturbed or removed and the post-construction activities to facilitate revegetation of the temporarily impacted areas. The boundaries of the construction site and any temporary access roads within the riverbed shall be marked in the field with stakes and flagging. No construction activities, vehicular access, equipment storage, stockpiling, or significant human intrusion shall occur outside the work area and access roads.

BIO-15 All native riparian trees with a three-inch diameter at breast height (dbh) or greater in temporary construction areas shall be replaced using one- or five-gallon container plants, containered trees, or pole cuttings in the temporary construction areas in the winter following the construction disturbance. The mitigation ratios for temporary impacts to vegetation communities are described in BIO-2. The growth and survival of the replacement trees shall meet the performance standards specified in BIO-6. In addition, the growth and survival of the planted trees shall be monitored until they meet the self sustaining success criteria in accordance with the methods and reporting procedures specified in BIO-6, BIO-7, BIO-11, and BIO-12.

BIO-16 Vegetation communities temporarily impacted by the proposed Project shall be revegetated as described in BIO-2. Large trunks of removed trees may also remain on site to provide habitat for invertebrates, reptiles, and small mammals or may be anchored within the Project site for erosion control. To facilitate restoration, mulch, or native topsoil (the top six- to 12-inch deep layer containing organic material), may be salvaged from the work area prior to construction. Following construction, salvaged topsoil shall be returned to the work area and placed in the restoration site. Within one year, the Project biologist will evaluate the progress of restoration activities in the temporary impact areas to determine if natural recruitment has been sufficient for the site to reach performance goals. In the event that native plant recruitment is determined by the Project biologist to be inadequate for successful habitat establishment, the site shall be revegetated in accordance with the methods designed for permanent impacts (*i.e.*, seeding, container plants, and/or a temporary irrigation system may be recommended). This will help ensure the success of temporary mitigation areas. The applicant shall restore the temporary construction area per the success criteria and ratios described in BIO-1, BIO-2, and BIO-6. Annual monitoring reports on the status of the recovery of temporarily impacted areas shall be submitted to the Corps and CDFG as part of the annual mitigation status report (BIO-11 and BIO-12).

BIO-17 Focused surveys for arroyo toad shall be conducted. Prior to initiating construction for the installation of bridges, storm drain outlets, utility lines, bank protection, trails, and/or other construction activities, all construction sites and access roads within the riverbed as well as all riverbed areas within 1,000 feet of construction sites and access roads shall be surveyed at the appropriate season for arroyo toad. The applicant shall contract with a qualified biologist to conduct focused surveys for arroyo toad. If detected in or adjacent to the Project area, no work will be authorized within 500 feet of occupied habitat until the applicant provides concurrence from the USFWS to CDFG and the Corps. The applicant shall implement measures required by the USFWS Biological Opinion that either supplement or supercede these measures. If present, the

applicant shall develop and implement a monitoring plan that includes the following measures in consultation with the USFWS and CDFG.

1) The applicant shall retain a qualified biologist with demonstrated expertise with arroyo toads to monitor all construction activities in potential arroyo toad habitat and assist the applicant in the implementation of the monitoring program. This person will be approved by the USFWS prior to the onset of ground-disturbing activities. This biologist will be referred to as the authorized biologist hereafter. The authorized biologist will be present during all activities immediately adjacent to or within habitat that supports populations of arroyo toad.

2) Prior to the onset of construction activities, the applicant shall provide all personnel who will be present on work areas within or adjacent to the Project area the following information:

a. A detailed description of the arroyo toad, including color photographs;

b. The protection the arroyo toad receives under the Endangered Species Act and possible legal action that may be incurred for violation of the Act;

c. The protective measures being implemented to conserve the arroyo toad and other species during construction activities associated with the proposed Project; and

d. A point of contact if arroyo toads are observed.

3) All trash that may attract predators of the arroyo toad will be removed from work sites or completely secured at the end of each work day.

4) Prior to the onset of any construction activities, the applicant shall meet on site with staff from the USFWS and the authorized biologist. The applicant shall provide information on the general location of construction activities within habitat of the arroyo toad and the actions taken to reduce impacts to this species. Because arroyo toads may occur in various locations during different seasons of the year, the applicant, USFWS, and authorized biologists will, at this preliminary meeting, determine the seasons when specific construction activities would have the least adverse effect on arroyo toads. The goal of this effort is to reduce the level of mortality of arroyo toads during construction. The parties realize that complete elimination of all mortality is likely not possible because some arroyo toads may occur anywhere within suitable habitat during any given season; the detection of every individual over large areas is impossible because of the small size, fossorial habits, and cryptic coloration of the arroyo toad.

5) Where construction can occur in habitat where arroyo toads are widely distributed, work areas will be fenced in a manner that prevents equipment and vehicles from straying from the designated work area into adjacent habitat. The authorized biologist will assist in determining the boundaries of the area to be fenced in consultation with the USFWS/CDFG. All workers will be advised that equipment and vehicles must remain within the fenced work areas.

6) The authorized biologist will direct the installation of the fence and conduct a minimum of three nocturnal surveys to move any arroyo toads from within the fenced area to suitable habitat outside of the fence. If arroyo toads are observed on the final survey or during subsequent checks, the authorized biologist will conduct additional nocturnal surveys if he or she determines that they are necessary in concurrence with the USFWS/CDFG.

7) Fencing to exclude arroyo toads will be at least 24 inches in height.

8) The type of fencing must be approved by the authorized biologist and the USFWS/CDFG.

9) Construction activities that may occur immediately adjacent to breeding pools or other areas where large numbers of arroyo toads may congregate will be conducted during times of the year (fall/winter) when individuals have dispersed from these areas. The authorized biologist will assist the applicant in scheduling its work activities accordingly.

10) If arroyo toads are found within an area that has been fenced to exclude arroyo toads, activities will cease until the authorized biologist moves the arroyo toads.

11) If arroyo toads are found in a construction area where fencing was deemed unnecessary, work will cease until the authorized biologist moves the arroyo toads. The authorized biologist in consultation with USFWS/CDFG will then determine whether additional surveys or fencing are needed. Work may resume while this determination is being made, if deemed appropriate by the authorized biologist and USFWS.

12) Any arroyo toads found during clearance surveys or otherwise removed from work areas will be placed in nearby suitable, undisturbed habitat. The authorized biologist will determine the best location for their release, based on the condition of the vegetation, soil, and other habitat features and the proximity to human activities. Clearance surveys shall occur on a daily basis in the work area.

13) The authorized biologist will have the authority to stop all activities until appropriate corrective measures have been completed.

14) Staging areas for all construction activities will be located on previously disturbed upland areas designated for this purpose. All staging areas will be fenced within potential toad habitat.

15) To ensure that diseases are not conveyed between work sites by the authorized biologist or his or her assistants, the fieldwork code of practice developed by the Declining Amphibian Populations Task Force (DAPTF 2009) will be followed at all times.

16) Drift fence/pitfall trap surveys will be implemented in toad sensitive areas prior to construction in an effort to reduce potential mortality to this species. Prior to any construction activities in the Project area, silt fence shall be installed completely around the proposed work area and a qualified biologist should conduct a preconstruction/clearance survey of the work area for arroyo toads. Any toads found in the work area should be relocated to suitable habitat. The silt fence shall be maintained for the duration of the work activity.

17) The applicant shall restrict work to daylight hours, except during an emergency, in order to avoid nighttime activities when arroyo toads may be present on the access road. Traffic speed should be maintained at 15 mph or less in the work area.

BIO-18 Conduct focused surveys for California red-legged frogs. Prior to initiating construction for the installation of bridges, storm drain outlets, utility lines, bank protection, trails, and/or other construction activities, all construction sites and access roads within the riverbed as well as all riverbed areas within 1,000 feet of construction sites and access roads shall be surveyed at the appropriate season for California red-legged frogs. The applicant shall contract with a qualified biologist to conduct focused surveys for California red-legged frogs. If detected in or adjacent to the Project area, no work will be authorized within 500 feet of occupied habitat until the applicant provides concurrence from the USFWS to CDFG and Corps. If present, the applicant shall implement measures required by the USFWS Biological Opinion for California red-legged frog that either supplement or supercede these measures. If present, the applicant shall develop and implement a monitoring plan that includes the following measures in consultation with the USFWS and CDFG.

1) The applicant shall retain a qualified biologist with demonstrated expertise with California red-legged frogs to monitor all construction activities in potential red-legged frog habitat and assist the applicant in the implementation of the monitoring program. This person will be approved by the USFWS prior to the onset of ground-disturbing activities. This biologist will be referred to as the authorized biologist hereafter. The authorized biologist will be present during all activities immediately adjacent to or within habitat that supports populations of California red-legged frogs.

2) Prior to the onset of construction activities, the applicant shall provide all personnel who will be present on work areas within or adjacent to the Project area the following information:

a. A detailed description of the California red-legged frogs, including color photographs;

b. The protection the California red-legged frog receives under the Endangered Species Act and possible legal action that may be incurred for violation of the Act;

c. The protective measures being implemented to conserve the California red-legged frogs and other species during construction activities associated with the proposed Project; and

d. A point of contact if California red-legged frogs are observed.

3) All trash that may attract predators of the California red-legged frogs will be removed from work sites or completely secured at the end of each work day.

4) Prior to the onset of any construction activities, the applicant shall meet on site with staff from the USFWS and the authorized biologist. The applicant shall provide information on the general location of construction activities within habitat of the California red-legged frogs and the actions taken to reduce impacts to this species. Because California red-legged frogs may occur in various locations during different seasons of the year, the applicant, USFWS, and authorized biologist will, at this preliminary meeting, determine the seasons when specific construction activities would have the least adverse effect on California red-legged frogs. The goal of this effort is to reduce the level of mortality of California red-legged frogs during construction.

5) Work areas will be fenced in a manner that prevents equipment and vehicles from straying from the designated work area into adjacent habitat. The authorized biologist will assist in determining the boundaries of the area to be fenced in consultation with the USFWS/CDFG. All workers will be advised that equipment and vehicles must remain within the fenced work areas.

6) The authorized biologist will direct the installation of the fence and conduct a minimum of three nocturnal surveys to move any California red-legged frogs from within the fenced area to suitable habitat outside of the fence. If California red-legged frogs are observed on the final survey or during subsequent checks, the authorized biologist will conduct additional nocturnal surveys if he or she determines that they are necessary in concurrence with the USFWS/CDFG.

7) Fencing to exclude California red-legged frogs will be at least 24 inches in height.

8) The type of fencing must be approved by the authorized biologist and the USFWS/CDFG.

9) Construction activities that may occur immediately adjacent to breeding pools or other areas where large numbers of California red-legged frogs may congregate will be conducted during times of the year (fall/winter) when individuals have dispersed from these areas. The authorized biologist will assist the applicant in scheduling its work activities accordingly.

10) If California red-legged frogs are found within an area that has been fenced to exclude California red-legged frogs, activities will cease until the authorized biologist moves the California red-legged frog(s).

11) If California red-legged frogs are found in a construction area where fencing was deemed unnecessary, work will cease until the authorized biologist moves the California red-legged frogs. The authorized biologist in consultation with USFWS/CDFG will then determine whether additional surveys or fencing are needed. Work may resume while this determination is being made, if deemed appropriate by the authorized biologist and USFWS.

12) Any California red-legged frogs found during clearance surveys or otherwise removed from work areas will be placed in nearby suitable, undisturbed habitat. The authorized biologist will determine the best location for their release, based on the condition of the vegetation, access to deep perennial pools, soil, and other habitat features and the proximity to human activities. Clearance surveys shall occur on a daily basis in the work area.

13) The authorized biologist will have the authority to stop all activities until appropriate corrective measures have been completed.

14) Staging areas for all construction activities will be located on previously disturbed upland areas, if possible, designated for this purpose. All staging areas will be fenced.

15) To ensure that diseases are not conveyed between work sites by the authorized biologist or his or her assistants, the fieldwork code of practice developed by the Declining Amphibian Populations Task Force (DAPTF 2009) will be followed at all times.

BIO-19 The 1,518-acre Salt Creek area shall be offered for dedication to the public pursuant to Condition 42 of the approved Specific Plan using a "rough step" land dedication approach. Irrevocable offers of dedication will be provided to CDFG for identified impact offsets in accordance with the Plan (BIO-1). The Salt Creek area includes

approximately 629 acres of coastal scrub communities within both Ventura and Los Angeles counties. This land dedication shall be managed in conjunction with the 4,205-acre High Country SMA (containing 1,314 acres of coastal scrub communities).

a. To facilitate wildlife movement between the north side of SR-126 and the Salt Creek area, enhancements will be made to the existing agricultural undercrossing and to the agricultural land at the base of Salt Creek as discussed in BIO-59. A Wildlife Movement Enhancement Plan shall be submitted to the Corps and CDFG for approval prior to implementation. The plan shall include at the minimum the following:

    i. A portion of the agricultural field on the north side of SR-126 will be dedicated to wildlife movement. Trees and/or scrubs will be planted in the agricultural field to guide wildlife into the existing undercrossing.

    ii. On the south side of SR-126 two rows of trees/scrubs will be planted to guide wildlife to the Santa Clara River.

    iii. A wildlife corridor will be created through the agricultural fields at the base of Salt Creek Canyon.

BIO-20 Approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Irrevocable offers of dedication will be provided to CDFG for identified impact offsets in accordance with the Plan (BIO-1) using a "rough step" land dedication approach. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated. In the event that the functional value of this burned habitat has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events, then adaptive management pursuant to BIO-21 will be implemented for coastal scrub restoration.

BIO-21 Supplemental restoration of coastal scrub shall be conducted as an adaptive management measure pursuant to BIO-20. Eight areas were identified in the Draft Newhall Ranch Mitigation Feasibility Report in the High Country SMA, Salt Creek area, and River Corridor SMA (Dudek 2007A) for coastal scrub restoration. In the event that coastal scrub restoration is required pursuant to BIO-20, the applicant shall

develop a Coastal Scrub Restoration Plan, subject to the approval of CDFG. The plan shall specify, at a minimum, the following: (1) the location of mitigation sites to be selected from suitable mitigation land in the High Country and Salt Creek areas identified in the Feasibility Study; (2) a description of "target" vegetation (native shrubland) to include estimated cover and abundance of native shrubs; (3) site preparation measures to include topsoil treatment, soil decompaction, erosion control, temporary irrigation systems, or other measures as appropriate; (4) methods for the removal of non-native plants (*e.g*., mowing, weeding, raking, herbicide application, or burning); (5) the source of all plant propagules (*e.g.*, seed, potted nursery stock, *etc*. collected from within five miles of the restoration site), the quantity and species of seed or potted stock of all plants to be introduced or planted into the restoration/enhancement areas; (6) a schedule and action plan to maintain and monitor the enhancement/restoration areas, to include at minimum, qualitative annual monitoring for revegetation success and site degradation due to erosion, trespass, or animal damage for a period no less than two years; (7) as needed where sites are near trails or other access points, measures such as fencing, signage, or security patrols to exclude unauthorized entry into the restoration/enhancement areas; and (8) contingency measures such as replanting, weed control, or erosion control to be implemented if habitat improvement/restoration efforts are not successful.

Habitat restoration/enhancement will be judged successful when: (1) percent cover and species richness of native species reach 50% of cover and species richness at reference sites; and (2) the replacement vegetation has persisted at least one summer without irrigation.

Annual monitoring reports will be prepared and submitted to CDFG and will be made available to the public to guide future mitigation planning. Monitoring reports will describe all restoration/enhancement measures taken in the preceding year; describe success and completion of those efforts and other pertinent site conditions (erosion, trespass, animal damage) in qualitative terms; and describe vegetation survival or establishment in quantitative terms.

BIO-22 a. Newhall Land shall prepare an Oak Resource Management Plan, to be submitted for approval to CDFG and County of Los Angeles, and implemented upon approval. The Plan shall identify areas suitable for oak woodland enhancement and creation. The Plan shall distinguish between oaks to be planted in compliance with CLAOTO (BIO-22b) and the additional measures required by this EIS/EIR (BIO-2 for woodlands in jurisdictional streambeds; and BIO-22c and BIO-22d for upland areas).

The Oak Resource Management Plan shall include measures to create or enhance woodlands as follows: (1) locations and acreages of mitigation sites where woodland

creation or enhancement will occur; (2) a description of proposed cover and number of native trees, shrubs, and grasses per acre to be established. This description shall be based on comparable intact woodlands in the area of impact or elsewhere within the RMDP planning area, consistent with conditions of the proposed mitigation site; (3) site preparation measures to include (as appropriate) topsoil treatment, soil decompaction, erosion control, weed grow/kill cycle, or as otherwise approved by the agencies; (4) methods for the removal of non-native plants (*e.g.*, mowing, weeding, raking, herbicide application, or burning); (5) a plant palette listing all species, including sizes, planting densities, or seeding rates, to be based on target vegetation; (6) the source of all plant propagules (*e.g.*, seed, potted nursery stock) and the quantity and species of seed or potted stock of all plants to be introduced or planted into the mitigation areas; (7) temporary irrigation, protection from herbivores, fertilizer, weeding, *etc.*; (8) a schedule and action plan to maintain and monitor the enhancement/restoration areas to include, at minimum, qualitative annual monitoring for revegetation success and site degradation due to erosion, trespass, or animal damage for a period no less than five years total and no less than two years after removal of irrigation (if any); (9) where sites are near trails or other access points, measures such as fencing, signage, or security patrols to exclude unauthorized entry into the mitigation areas shall be implemented as needed; (10) tree protection standards to be implemented for individual trees or woodlands adjacent to development activity; (11) success criteria as stated in BIO-22b and BIO-22d; and (12) contingency measures, such as replanting, erosion control, irrigation system repair, or understory re-seeding, to be implemented if habitat improvement/restoration efforts do not meet the success criteria stated in the plan.

b. To meet the minimum mitigation criteria set forth in CLAOTO, Newhall Land will replace impacted oaks (measuring 8 inches in diameter, or greater, or with a combined diameter of 12 inches for multi-stem oaks) at a ratio of 2:1. Additionally, oaks meeting the criteria for classification as a Heritage Tree (defined by CLAOTO as "any oak tree measuring 36 inches or more in diameter") will be replaced at a ratio of 10:1.

Whether they are planted in dedicated open space areas or developed areas, replacement oak trees planted in conformance with CLAOTO shall adhere to the following standards:

1. Replacement oak trees shall be exclusively indigenous species, shall be at least a 15-gallon size specimen, and measure at least one inch in diameter one foot above the base, unless otherwise approved by the County Forester.

2. Replacement trees shall be properly cared for and maintained for a period of two years and replaced by Newhall Land if mortality occurs within that period.

3. Replacement planting shall be conducted in phases as impacts occur. Alternatively, Newhall Land may choose to plant replacement trees in open space areas prior to realization of Project-related impacts (pre-mitigation). Any pre-mitigation shall adhere to the standards outlined herein.

4. Following completion of the two-year maintenance period, the County Forester shall provide final authorization that CLAOTO standards have been met.

c. In addition to the CLAOTO requirements (BIO-22b, above), this EIS/EIR requires replacement of oak trees at the ratios in the table below for trees lost or impacted in uplands. These trees are in addition to the CLAOTO requirement described above. These additional trees may also be incorporated into woodland habitat enhancement or creation, as described above.

Additional replacement ratios are provided in **Table 4.5-70**.

Table 4.5-70
Additional BIO-22c Oak Tree Replacement Ratios

Trunk Diameter*	Mitigation Ratio
8 – 35	0.5:1
36 +	2.5:1

* Trunk diameter measured at 4.5 feet above mean natural grade. Mitigation required for single-stem oaks with a minimum 8-inch diameter and multi-stem oaks with a combined diameter of 12 inches.

d. Newhall will mitigate lost oak woodlands occurring on upland sites (*i.e.*, outside CDFG/Corps jurisdictional stream channels) by creating or enhancing oak woodlands in the Salt Creek area and High Country SMA. At minimum, Newhall Land will mitigate woodland habitat at a 1:1 ratio through creation of new oak woodlands. As an alternative, Newhall Land may choose to enhance, improve, and manage existing degraded woodland areas at a minimum 2:1 ratio for lost woodland acreage.

For woodland enhancement or replacement, dominant species (coast live oak or valley oak) and planting densities will be based on mitigation site suitability. All plant propagules, including acorns or tree cuttings and all seed or potted nursery stock of oaks or other species, shall be collected within a five-mile radius and within 1,000 feet elevation of the restoration site.

The woodland creation or enhancement sites shall be monitored for oak tree survival and vigor and other habitat values, including species diversity and wildlife use. The replacement or enhancement sites will be considered "complete" upon meeting all of the following success criteria, or as otherwise approved by CDFG. Any replacement oak trees planted in woodlands for conformance with CLAOTO will also be subject to CLAOTO performance criteria (BIO-22b).

1. Regardless of the date of initial woodland creation or enhancement, each site must have been without active manipulation by irrigation, planting, or re-seeding for a minimum of three years prior to evaluation for successful completion.

2. The percent cover and species richness of restored or enhanced native vegetation shall be evaluated based on target vegetation described in the woodland creation or enhancement plan.

3. Densities (numbers/acre) of surviving, healthy oak shall be within 5% of the plan target density. Cover and species richness of other native shrubs shall reach 50% of the cover and species richness described for the "target" woodland. Optimal woodland densities and acorn planting quantities, by oak woodland type, are presented in **Table 4.5-71**.

Table 4.5-71
Optimal Woodland Densities and Acorn Planting Quantities, by Oak Woodland Type

Woodland Type	Average Existing Woodland Density (trees per acre)	Target Density for Newhall Land (trees per acre)
Coast live oak woodland	22	50
Mixed oak woodland	19	40
Valley oak woodland	16	25

4. Non-native grass cover shall not exceed the "target" woodland non-native grass cover, and other non-native species shall not exceed 10% cover at any time. Any species listed on the California State Agricultural list (CDFA 2009) or Cal-IPC list of noxious weeds (Cal-IPC 2006, 2007) will not be present on the revegetation site at the time that project success is determined.

BIO-23 A final Spineflower Conservation Plan (SCP) shall be adopted and implemented after approval by CDFG, including the permanent dedication of preserves (see draft in Appendix 1.0). The proposed spineflower preserve areas shall be offered to CDFG as a permanent conservation easement within one year after issuance of the requested 2081 Permit to ensure long-term protection. The conservation easement shall be to CDFG and contain appropriate funding and restrictions to help ensure that the spineflower preserve lands are protected in perpetuity.

BIO-24 The spineflower preserves shall be managed by Newhall Land and their preserve manager(s) and/or natural lands management organization(s) (NLMO). Newhall Land shall submit a statement of qualifications for their proposed preserve manager(s)/NLMO(s) for approval by CDFG. Newhall Land will fund in full all

implementation of spineflower preserve management as decribed in the SCP and all mitigation measures listed in this document.

BIO-25 Disturbed portions (*i.e.*, agricultural lands, disturbed lands, and developed lands) of the spineflower preserves, or buffers will be restored through revegetation with native plant communities. In summary, areas that have greater than 30% relative cover by weeds will be restored to have relative cover comparable to that of existing occupied spineflower habitat. In addition, Cal-IPC List A and B plants that are present within the spineflower preserve will be controlled. Restoration and enhancement efforts within the spineflower preserve areas shall be in conformance with the Spineflower Conservation Plan.

BIO-26 In the event that a spineflower preserve, or buffer, or a portion of a spineflower preserve, or buffer burns in a wildfire or suffers from mass movements (*e.g.*, landslides, slope sloughing, or other geologic events), the spineflower preserve manager and Newhall Land shall promptly review the site and determine what action, if any, should be taken. The primary anticipated post-fire spineflower preserve management activity involves monitoring the site and controlling annual weeds that may invade burned areas following a fire event, especially when such weeds (that were not previously present or not present in similar densities) exceed the 30% maximum threshold (see BIO-25). If fire-control lines or other forms of bulldozer damage occur in the spineflower preserves, these areas will be repaired and revegetated to pre-burn conditions or better. An emergency fire response plan will be prepared (in accordance with Mitigation Measure SP-4.6-72) prior to the establishment of the spineflower preserves and approved by CDFG and Los Angeles County Fire Department.

The same methods will be applied to mass-movement, landslide, or slope-sloughing types of events. This measure shall be implemented in conformance with the Spineflower Conservation Plan.

BIO-27 Spineflower preserve temporary fencing shall be shown on construction plans and installed prior to initiating construction clearing and grubbing activities within 200 feet of spineflower preserves, including the buffers. The spineflower preserve manager or a qualified biologist shall monitor fence installation. Clearing for fence installation shall be minimized to what is necessary to install the fence and, where possible, shall leave the roots of native plants in place to allow regrowth. As necessary, native vegetation will be restored and weed management will be performed following fence installation to ensure temporarily cleared native plant areas do not become weed dominated after installation. General Project clearing and grubbing within 200 feet of the fence may commence upon verification by the

spineflower preserve manager or the qualified biologist that protective fencing is in place and is adequate. Appropriate BMPs shall be installed at the edge of development manufactured slopes when the spineflower preserve is within 200 feet and down-slope of proposed development.

BIO-28 Construction documents shall indicate that the grading contractor is responsible for protecting spineflower during construction work. The construction documents shall indicate that the contractor is responsible for informing all employees and subcontractors of the environmentally sensitive areas and the proper conduct of work when working near (*e.g.*, within 100 feet) of these areas. The construction documents shall require a pre-construction meeting to perform an "environmental education session" with the grading contractor/contractor's employees, subcontractors, and equipment operators prior to commencing construction work within 100 feet of the spineflower preserves. The environmental education session shall be conducted by the spineflower preserve manager or a qualified biologist and focus on informing workers of the location and sensitivity of the spineflower and the requirements for protecting it. The construction documents shall indicate that the grading contractor shall be responsible for mitigating any impacts to spineflower due to the negligence of the grading contractor/contractor's employees, subcontractors, or equipment operators. If accidental take occurs during construction, the loss shall be addressed in accordance with the section 2081 Permit issued by CDFG.

BIO-29 Construction plans shall include necessary design features and construction notes to demonstrate consistency of development in the vicinity of spineflower preserves with the Spineflower Conservation Plan (SCP). In addition to applicable erosion control plans and performance under SCAQMD Rule 403d dust control (SCAQMD 2005), the Project stormwater pollution prevention plan (SWPPP) shall include minimum BMPs. Together, the implementation of these requirements shall ensure that spineflower populations are protected during construction. At a minimum, the following measures/restrictions shall be incorporated into the SWPPP and noted on construction plans, where appropriate, to avoid impacting spineflower during construction:

- Avoid planting or seeding invasive species in development areas within 200 feet of spineflower preserve areas;
- Do not use erosion control devices that may contain weeds, such as hay bales, *etc.*, within 100 feet of spineflower preserves;
- Do not windrow or stockpile soil along spineflower preserve boundaries;
- Do not locate staging areas, maintenance, or concrete washout areas adjacent to or upstream of spineflower preserves;

- Do not store toxic compounds, including fuel, oil, lubricants, paints, release agents, or any other construction materials that could damage spineflower if spilled near spineflower areas, upstream of spineflower preserves, or along spineflower preserve boundaries;
- Provide location and details for any fencing for temporary and permanent access control along preserve boundaries (per BIO-31 for temporary fencing and BIO-36 for permanent fencing);
- Provide location and details for any dust control fencing along preserve boundaries (per BIO-32); and
- Provide location and details for any stormwater run-on controls/BMPs coming from development area to spineflower preserve (per BIO-38 and BIO-39).

BIO-30 The spineflower preserve manager or qualified biologist shall review construction plans and specifications, SWPPP, and, where appropriate, erosion control plans and implementation of SCAQMD Rule 403d dust control measures (SCAQMD 2005) prior to construction within 200 feet of spineflower preserves for compliance with the Spineflower Conservation Plan and associated permits and Project-related environmental documents.

BIO-31 Spineflower preserves shall be protected prior to clearing and during construction with temporary construction fencing as described in BIO-27. Openings shall be included in the fence when located within wildlife corridors and vegetation community connectivity areas to allow for the safe passage of wildlife. The spineflower preserve manager or a qualified biologist shall indicate the location and width of each of these openings. The fencing shall be three-strand non-barbed wire fence or bright orange U.V. stabilized polyethylene construction "snow" fencing, attached to metal t-posts that extend at least four feet above grade or equivalent. Protective fencing shall be maintained in good condition until completion of Project construction. Where construction activities occur within 200 feet of a spineflower preserve, the spineflower preserve manager or qualified biologist shall review fencing weekly during construction monitoring visits and note any fencing that is in need of repair. Repairs shall be completed within three working days of notification by the spineflower preserve manager or qualified biologist.

BIO-32 Development areas shall have dust control measures implemented and maintained to prevent dust from impacting vegetation within the spineflower preserve areas. Dust control shall be implemented during construction in compliance with SCAQMD Rule 403d (SCAQMD 2005). Where construction activities occur within 100 feet of a spineflower location, chemical dust suppression shall not be utilized. Where determined necessary by the spineflower preserve manager or qualified biologist, a

screening fence (*i.e.*, a six-foot high chain link fence with green fabric up to a height of five feet) shall be installed to protect spineflower locations.

BIO-33 The spineflower preserve manager or qualified biologist shall perform weekly construction monitoring for all construction activities within 200 feet of spineflower preserve areas. The spineflower preserve manager's or qualified biologist's construction monitoring tasks shall include reviewing and approving protective fencing, dust control measures, and erosion control devices before construction work begins; conducting a contractor education session at the preconstruction meeting; and reviewing the site weekly (minimum) during construction to ensure the fencing, dust control, and BMP measures are in place and functioning correctly and that work is not directly or indirectly impacting spineflower plants. Each site visit shall be followed up with a summary monitoring report sent electronically to Newhall Land indicating the status of the site. Monitoring reports shall include remedial recommendations and issue resolution discussions when necessary.

BIO-34 Plant palettes proposed for use on landscaped slopes, street medians, park sites, and other public landscaped and FMZ areas within 100 feet of a spineflower preserve shall be reviewed and approved within 30 days by the spineflower preserve manager or qualified biologist and CDFG to ensure that the proposed landscape plants will not naturalize and require maintenance or cause vegetation community degradation in the spineflower preserve and buffer areas. Container plants to be installed within public areas within 200 feet of the spineflower preserves shall be inspected by the spineflower preserve manager or qualified biologist for the presence of disease, weeds, and pests, including Argentine ants. Plants with pests, weeds, or diseases shall be rejected. In addition, for public areas within 200 feet of spineflower preserves, landscape plants shall not be on the Cal-IPC California Invasive Plant Inventory (most recent version) or on the list of Invasive Ornamental Plants listed in Appendix B of the SCP. The current Cal-IPC list can be obtained from the Cal-IPC web site (http://www.cal-ipc.org/ip/inventory/index.php).

BIO-35 All portions of the spineflower preserves shall be closed, with the exception of pre-identified existing dirt roads and utility easements. The pre-identified existing dirt roads and utility easement access roads shall function as access routes for the spineflower preserve manager, spineflower preserve maintenance personnel, utility personnel, and emergency services vehicles only (*e.g.*, police, fire, and medical) No other vehicle or foot traffic, including nature or recreational trails, will be permitted in the preserve, including the buffer. The dirt roads shall be gated and locked at the outside edges of the buffer zone. Signs discouraging unauthorized access shall be posted. The only persons or entities issued gate keys shall be the spineflower

preserve managers and their employees, easement holding utility companies, emergency services, Newhall Land, and CDFG.

BIO-36 Fencing shall be installed along the outside edge of the spineflower preserve and buffer areas adjacent to proposed developments, parks, golf courses, or other "active land uses" to prevent unauthorized access. Specific areas that are adequately protected by steep terrain (1.5:1 or steeper) and/or dense vegetation may not require fencing but would require signage. The determination of the need for fencing in these areas shall be subject to the approval of the spineflower preserve manager or qualified biologist. If monitoring determines that slope and/or vegetation is not effective at deterring unauthorized access, additional fencing may be required by the spineflower preserve manager or qualified biologist. Fencing is not required in areas bordered by large parcels of conserved natural open space areas or the Santa Clara River riparian corridor, as installing fencing in these areas would be unnecessary and damaging to existing vegetation and wildlife corridors.

Fencing must extend a minimum of four feet above grade and include wood-doweled split rail fencing, exterior grade heavy-duty vinyl three-railed fencing, three-strand non-barbed wire, or similar. Fencing installed adjacent to native vegetation communities and natural open space areas will allow for the passage of animals.

BIO-37 Outdoor all-weather signs measuring approximately 12 by 16 inches shall be posted on all spineflower preserve access gates and along spineflower preserve fencing at approximately 800 feet on center, except adjacent to road crossings, where signs will be posted. The placement will take topography into account, emphasizing placement on ridgelines where signs will be visible to emergency fire personnel and others. Signs shall state in English and Spanish that the area is a biological preserve that hosts a state-listed endangered and federal candidate plant species and that trespassing is prohibited (in accordance Mitigation Measure SP-4.6-68). Signs shall indicate that fuel modification and management work is not allowed within the spineflower preserve or buffer areas. Signage at any trailheads near spineflower preserves shall describe the spineflower preserve, its purpose, and the applicable restrictions regarding spineflower conservation. The signage shall state that people who do not abide by these rules or who damage the protected species will be subject to prosecution, including fines and/or imprisonment. All signage shall include emergency contact information and shall be reviewed and approved by the spineflower preserve manager or qualified biologist.

BIO-38 Storm drain outfalls from proposed development areas shall only be installed uphill from spineflower preserve areas where necessary to retain pre-construction hydrological conditions within the spineflower preserves, sustain existing riparian and wetland vegetation communities, and/or allow for the restoration of currently disturbed

areas to native riparian/alluvial vegetation communities. When located in a spineflower preserve area, storm drains must meet the following criteria:

- Storm drains must not impact spineflower either directly or indirectly;
- Storm drains may only daylight at the bottom of slopes within spineflower preserve areas; and
- Under no circumstances shall storm drains daylight onto steeply sloped areas or other areas that would cause erosion.

BIO-39 Any surface water entering a spineflower preserve area from development areas is required to pass through BMP measures, which will be described in the SWPPP. Storm drain outlets must contain adequate energy dissipaters to prevent downstream erosion and stream channel down-cutting. Additionally, storm drain outlets must be designed based on pre- and post-construction hydrological studies (in accordance with Mitigation Measure SP-4.6-69). Storm drains and permanent structural BMPs shall be designed by a licensed civil engineer. Requirements of BIO-29 and BIO-38, where applicable, shall be incorporated into the facility design and shall be subject to approval by the spineflower manager or qualified biologist. Long-term maintenance of storm drain BMPs will be the responsibility of the designated maintenance entity.

BIO-40 The Draft RMDP Slender Mariposa Lily Mitigation and Monitoring Plan (Dudek 2007I) shall be revised and submitted to CDFG for review and approval prior to ground disturbance to occupied habitat. Upon approval, the plan will be implemented by the applicant or its designee. The revised plan will demonstrate the feasibility of enhancing or restoring slender mariposa lily habitat in selected areas to be managed as natural open space (*i.e.*, the Salt Creek area or High Country SMA, spineflower preserves, or River Corridor SMA) without conflicting with other resource management objectives. Habitat replacement/enhancement will be at a 1:1 ratio (acres restored/enhanced to acres impacted).

The revised plan will describe habitat improvement/restoration measures to be completed prior to introducing slender mariposa lily. Habitat improvement/restoration will be based on native occupied slender mariposa lily habitat. The revised plan will specify: (1) the location of mitigation sites (may be selected from among 559 acres of suitable mitigation land in the High Country SMA and Salt Creek area identified in the Draft Newhall Ranch Mitigation Feasibility Study (Dudek 2007A); (2) a description of "target" vegetation (native shrubland or grassland) to include estimated cover and abundance of native shrubs and grasses in occupied slender mariposa lily habitat on Newhall Ranch land (either at sites to be destroyed by construction or at sites to be preserved); (3) site preparation measures to include topsoil treatment, soil decompaction, erosion control, temporary irrigation systems, or other measures as

appropriate; (4) methods for the removal of non-native plants (*e.g.*, mowing, weeding, raking, herbicide application, or burning); (5) the source of all plant propagules (seed, potted nursery stock, *etc.*), the quantity and species of seed or potted stock of all plants to be introduced or planted into the restoration/enhancement areas; (6) a schedule and action plan to maintain and monitor the enhancement/restoration areas, to include at minimum, qualitative annual monitoring for revegetation success and site degradation due to erosion, trespass, or animal damage for a period no less than two years; (7) as needed where sites are near trails or other access points, measures such as fencing, signage, or security patrols to exclude unauthorized entry into the restoration/enhancement areas; and (8) contingency measures such as replanting, weed control, or erosion control to be implemented if habitat improvement/restoration efforts are not successful.

Habitat restoration/enhancement will be judged successful when (1) percent cover and species richness of native species reach 50% of their cover and species richness at undisturbed occupied slender mariposa lily habitat at reference sites; and (2) the replacement vegetation has persisted at least one summer without irrigation. At that point slender mariposa lily propagules (seed or bulbs) will be introduced onto the site.

The revised plan will specify methods to collect propagules and introduce slender mariposa lily into these mitigation sites. Introductions will use source material (seeds or bulbs) from no more than 1.0 mile distant, similar slope exposures, and no more than 500 ft. elevational difference from the mitigation site, unless otherwise approved by CDFG. Bulbs may be salvaged and transplanted from slender mariposa lily occurrences to be lost; alternately, seed may be collected from protected occurrences, following CDFG-approved seed collection guidelines (*i.e.*, MOU for rare plant seed collection). Newhall Land or its designee will monitor the reintroduction sites for no fewer than five additional years to estimate slender mariposa lily survivorship (for bulbs) or seedling establishment (for seeded sites).

Annual monitoring reports will be prepared and submitted to CDFG and will be made available to the public to guide future mitigation planning for slender mariposa lily. Monitoring reports will describe all restoration/enhancement measures taken in the preceding year; describe success and completion of those efforts and other pertinent site conditions (erosion, trespass, animal damage) in qualitative terms; and describe mariposa lily survival or establishment in quantitative terms.

A minimum of 133 acres of slender mariposa lily cumulative occupied area will be conserved and managed in the RMDP and SCP Project boundaries. Of these 133 acres, approximately 103 acres of slender mariposa lily cumulative occupied area will be conserved and managed in the RMDP and SCP Project boundary in the High Country

SMA and Salt Creek area, and two acres occur within the River Corridor SMA and/or proposed spineflower preserves. Additional cumulative occupied area will be conserved and managed in the San Martinez Grande Canyon area at a 1:1 ratio (acres conserved and managed to acres impacted) based on impacts to cumulative occupied area within the Entrada planning area, as a means to ensure regional biodiversity of the species. Up to an additional 28 acres of slender mariposa lily cumulative occupied area can be conserved and managed in the San Martinez Grande Canyon area for this purpose.

BIO-41 Thirty days prior to construction activities in grassland, scrub, chaparral, oak woodland, riverbank, and agriculture habitats, or other suitable habitat a qualified biologist shall conduct a survey within the proposed construction disturbance zone and within 200 feet of the disturbance zone for American badger.

If American badgers are present, occupied habitat shall be flagged and ground-disturbing activities avoided within 50 feet of the occupied den. Maternity dens shall be avoided during the pup-rearing season (February 15 through July 1) and a minimum 200 foot buffer established. This buffer may be reduced based on the location of the den upon consultation with CDFG. Maternity dens shall be flagged for avoidance, identified on construction maps, and a qualified biologist shall be present during construction. If avoidance of a non-maternity den is not feasible, badgers shall be relocated either by trapping or by slowly excavating the burrow (either by hand or mechanized equipment under the direct supervision of the biologist, removing no more that four inches at a time) before or after the rearing season (February 15 through July 1). Any relocation of badgers shall occur only after consultation with CDFG. A written report documenting the badger removal shall be provided to CDFG within 30 days of relocation.

Collection and relocation of animals shall only occur with the proper scientific collection and handling permits.

BIO-42 All oaks that will not be removed that are regulated under CLAOTO with driplines within 50 feet of land clearing (including brush clearing) or areas to be graded shall be enclosed in a temporary fenced zone for the duration of the clearing or grading activities. Fencing shall extend to the root protection zone (*i.e.*, the area at least 15 feet from the trunk or five feet beyond the drip line, whichever distance is greater). No parking or storage of equipment, solvents, or chemicals that could adversely affect the trees shall be allowed within 25 feet of the trunk at any time. Removal of the fence shall occur only after the Project arborist or qualified biologist confirms the health of preserved trees.

BIO-43 Prior to initiating construction for the installation of bridges, storm drain outlets, utility lines, bank protection, trails, and/or other construction activities that result in any

disturbance to the banks or wetted channel, aquatic habitats within construction sites and access roads, as well as all aquatic habitats within 300 feet of construction sites and access roads, shall be surveyed by a qualified biologist for the presence of the unarmored threespine stickleback, arroyo chub, and Santa Ana sucker. The Corps and CDFG shall be notified at least 14 days prior to the survey and shall have the option of attending. The biologist shall file a written report of the survey with both agencies within 14 days of the survey and no later than 10 days prior to any construction work in the riverbed. If there is evidence that fish spawn has occurred in the survey area, then surveys shall cease unless otherwise authorized by USFWS. If surveys determine that gravid fish are present, that spawning has recently occurred, or that juvenile fish are present in the proposed construction areas, all activities within aquatic habitat will be suspended. Construction within aquatic habitats shall only occur when it is determined that juvenile fish are not present within the Project area.

BIO-44 Temporary bridges, culvert crossings, or other feasible methods of providing access across the river shall be constructed outside of the winter season and not during periods when spawning is occurring. Prior to the construction of any temporary or permanent crossing of the Santa Clara River, the applicant shall develop a Stream Crossing and Diversion Plan. The plan shall include the following elements: the timing and methods for pre-construction aquatic species surveys; a detailed description of the diversion methods (*e.g.*, berms shall be constructed of on-site alluvium materials of low silt content, inflatable dams, sand bags, or other approved materials); special-status species relocation; fish exclusion techniques, including the use of block netting and fish relocation; methods to maintain fish passage during construction; channel habitat enhancement, including the placement of vegetation, rocks, and boulders to produce riffle habitat; fish stranding surveys; and the techniques for the removal of crossings prior to winter storm flows. The Plan shall be submitted to the USFWS and CDFG for approval at least 30 days prior to implementation.

If adult special-status fishes are present and spawning has not occurred, they shall be relocated prior to the diversion or crossing. Block nets of 1/8-inch woven mesh will be set upstream and downstream. On days with possible high temperature or low humidity (temperatures in excess of 80° F), work will be done in the early morning hours, as soon as sufficient light is available, to avoid exposing fishes to high temperatures and/or low humidity. If high temperatures are present, the fishes will be herded to downstream areas past the block net. Once the fishes have been excluded by herding, a USFWS staff member or his or her agents shall inspect the site for remaining or stranded fish. A USFWS staff member or his or her agents shall relocate the fish to suitable habitat outside the Project area (including those areas potentially subject to high turbidity). During the diversion/relocation of fishes, the USFWS or his or her agents shall be present at all times.

BIO-45 a. **Stream diversion bypass channels**:

Stream diversion bypass channels will be constructed when the active wetted channel is within the work zone. Diversion bypass channels will be built in accordance with BIO-44 and in consultation with CDFG/USFWS. Equipment shall not be operated in areas of ponded or flowing water unless authorized by CDFG/USFWS.

The diversion channel shall be of a width and depth comparable to the natural river channel. In all cases where flowing water is diverted from a segment of the stream channel, the bypass channel will be constructed prior to the diversion of the active stream. The bypass channel will be constructed prior to diverting the stream, beginning in the downstream area and continuing in an upstream direction. Where feasible and in consultation with CDFG/USFWS, the configuration of the diversion channel will be curved (sinuous) with multiple sets of obstructions (*i.e.*, boulders, large logs, or other CDFG/USFWS-approved materials) placed in the channel at the point of each curve (*i.e.*, on alternating sides of the channel). If emergent aquatic vegetation is present in the original channel, the applicant will transplant suitable vegetation into the diversion channel and on the banks prior to or at the time of the water diversion. A qualified restoration ecologist will supervise the construction of the diversion channels on site. The integrity of the channel and diversion shall be maintained throughout the intended diversion period. Channel bank or barrier construction shall be adequate to prevent seepage into or from the work area.

Construction of diversion channels shall not occur if surveys determine that gravid fish are present, spawning has recently occurred, or juvenile fish are present in the proposed construction areas.

At the conclusion of the diversion, either at the commencement of the winter season, or the completion of construction, the applicant will coordinate with CDFG/USFWS to determine if the diversion should be left in place or the stream returned to the original channel. If CDFG/USFWS determine the stream should be diverted to the original channel, the original channel will be modified prior to re-diversion (*i.e.*, while dry) to construct curves (sinuosity) into that channel, including the placement of obstructions (*i.e.*, boulders, large logs, or other CDFG/USFWS-approved materials). The original channel will be replanted with emergent vegetation as the diversion channel was planted. If the diversion channel is abandoned, the boulders will remain in place.

b. **Dewatering:**

Construction dewatering in close proximity to stream flow shall implement the following:

- Assess local stream and groundwater conditions, including flow depths, groundwater elevations, and anticipated dewatering cone of influence (radius of draw down).

- Assess surface water elevations upstream, adjacent to, and downstream of the extraction points, to assess any critical flow regimes susceptible to excessive draw down and therefore fish stranding issues.

- Assess surface water elevations downstream of the discharge locations (if discharge is proposed to the flowing stream) to assess any flow regimes and overbank areas that may be susceptible to flooding and therefore fish stranding at the cessation of discharge. Discharge locations shall also be assessed for potential channel bed erosion from dewatering discharge, and appropriate BMPs must be implemented to prevent excessive erosion or turbidity in the discharge.

- The information above shall be summarized and provided in a plan approved by CDFG and Corps.

- Fish shall be excluded from any artificial flowing channels from dewatering discharge. Methods to ensure separation may include, but are not limited to: block netting at the confluence; creation of a physical drop greater than four inches at the confluence; or maintaining a velocity range unsuitable for fish passage, such as a berm at the confluence with small diameter pipes for discharge.

BIO-46 During any stream diversion or culvert installation activity, a qualified biologist(s) shall be present and shall patrol the areas within, upstream, and downstream of the work area. The biologists shall inspect the diversion and inspect for stranded fish or other aquatic organisms. Under no circumstances shall the unarmored threespine stickleback be collected or relocated, unless USFWS personnel or their agents implement this measure. Any event involving stranded fish shall be recorded and reported to CDFG and USFWS within 24 hours.

BIO-47 Slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area to provide refuge for special-status fishes during construction. Where feasible and in consultation with CDFG and USFWS, the applicant shall enhance slow-moving water habitats for each linear foot disturbed by hand-excavating shallow side channels and placing multiple sets of obstructions (*e.g.*, boulders, large logs, or other CDFG- and USFWS-approved materials) in the channel.

BIO-48 Installation of bridges, culverts, or other structures shall not impair the movement of fish and aquatic life. Bottoms of temporary culverts shall be placed at or below channel grade. Bottoms of permanent culverts shall be placed below channel grade. Culvert

crossings shall include provisions for a low flow channel where velocities are less than two feet per second to allow fish passage.

BIO-49 Water containing mud, silt, or other pollutants from construction activities shall not be allowed to enter a flowing stream or be placed in locations that may be subject to normal storm flows during periods when storm flows can reasonably be expected to occur.

BIO-50 Prior to initiating construction for the installation of bridges, storm drain outlets, utility lines, bank protection, trails, and/or other construction activities, all construction sites and access roads within the riverbed as well as all riverbed areas within 500 feet of construction sites and access roads shall be surveyed at the appropriate season for southwestern pond turtle. Focused surveys shall consist of a minimum of four daytime surveys, to be completed between April 1 and June 1. The survey schedule may be adjusted in consultation with CDFG to reflect the existing weather or stream conditions. The applicant shall develop a Plan to address the relocation of southwestern pond turtle. The Plan shall include but not be limited to the timing and location of the surveys that would be conducted for this species; identify the locations where more intensive efforts should be conducted; identify the habitat and conditions in the proposed relocation site(s); the methods that would be utilized for trapping and relocating individuals; and provide for the documentation/recordation of the numbers of animals relocated. The Plan shall be submitted to CDFG for approval 60 days prior to any ground-disturbing activities within potentially occupied habitat.

If southwestern pond turtles are detected in or adjacent to the Project, nesting surveys shall be conducted. Focused surveys for evidence of southwestern pond turtle nesting shall be conducted in, or adjacent to, the Project when suitable nesting habitat exists within 1,300 feet of occupied habitat in an area where Project-related ground disturbance will occur (*e.g.*, development, ground disturbance). If both of those conditions are met, a qualified biologist shall conduct focused, systematic surveys for southwestern pond turtle nesting sites. The survey area shall include all suitable nesting habitat within 1,300 feet of occupied habitat in which Project-related ground disturbance will occur. This area may be adjusted based on the existing topographical features on a case-by-case basis with the approval of CDFG. Surveys will entail searching for evidence of pond turtle nesting, including remnant eggshell fragments, which may be found on the ground following nest depredation.

If a southwestern pond turtle nesting area would be adversely impacted by construction activities, the applicant shall avoid the nesting area. If avoidance of the nesting area is determined to be infeasible, the authorized biologist shall coordinate with CDFG to

identify if it is possible to relocate the pond turtles. Eggs or hatchlings shall not be moved without written authorization from CDFG.

The qualified biologist shall be present during all activities immediately adjacent to or within habitat that supports populations of southwestern pond turtle. Clearance surveys for pond turtles shall be conducted within 500 feet of potential habitat by the authorized biologist prior to the initiation of construction each day. The resume of the proposed biologist will be provided to CDFG for approval prior to conducting the surveys.

BIO-51 Bridges over the Santa Clara River shall be designed to minimize impacts to natural areas and riparian resources from associated lighting and stormwater runoff. All lighting will be designed to be directed away from natural areas (pursuant to SP-4.6-56) using shielded lights, low sodium-vapor lights, bollard lights, or other available light and glare minimization methods. Bridges will be designed to minimize normal vehicular lighting from trespassing into natural areas using side walls a minimum of 24 inches high. All stormwater from the bridges will be directed to water treatment facilities for water quality treatment.

BIO-52 Prior to grading and construction activities, a qualified biologist shall be retained to conduct a Worker Environmental Awareness Program (WEAP) for all construction/contractor personnel. A list of construction personnel who have completed training prior to the start of construction shall be maintained on site and this list shall be updated as required when new personnel start work. No construction worker may work in the field for more than five days without participating in the WEAP. The qualified biologist shall provide ongoing guidance to construction personnel and contractors to ensure compliance with environmental/permit regulations and mitigation measures. The qualified biologist shall perform the following:

- Provide training materials and briefings to all personnel working on site. The material shall include but not be limited to the identification and status of plant and wildlife species, significant natural plant community habitats (*e.g.*, riparian), fire protection measures, and review of mitigation requirements.
- A discussion of the federal and state Endangered Species Acts, Bald and Golden Eagle Protection Act, Migratory Bird Treaty Act, other state or federal permit requirements and the legal consequences of non-compliance with these acts;
- Attend the pre-construction meeting to ensure that timing/location of construction activities do not conflict with other mitigation requirements (*e.g.*, seasonal surveys for nesting birds, pre-construction surveys, or relocation efforts);
- Conduct meetings with the contractor and other key construction personnel describing the importance of restricting work to designated areas. Maps showing

the location of special-status wildlife or populations of rare plants, exclusion areas, or other construction limitations (*e.g.*, limitations on nighttime work) will be provided to the environmental monitors and construction crews prior to ground disturbance;

- Discuss procedures for minimizing harm to or harassment of wildlife encountered during construction and provide a contact person in the event of the discovery of dead or injured wildlife;
- Review/designate the construction area in the field with the contractor in accordance with the final grading plan;
- Ensure that haul roads, access roads, and on-site staging and storage areas are sited within grading areas to minimize degradation of vegetation communities adjacent to these areas (if activities outside these limits are necessary, they shall be evaluated by the biologist to ensure that no special-status species habitats will be affected);
- Conduct a field review of the staking (to be set by the surveyor) designating the limits of all construction activity;
- Flag or temporarily fence any construction activity areas immediately adjacent to riparian areas;
- Ensure and document that required pre-construction surveys and/or relocation efforts have been implemented;
- Be present during initial vegetation clearing and grading; and
- Submit to CDFG an immediate report (within 72 hours) of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-53 Prior to the issuance of a grading permit for ground disturbance, construction, or site preparation activities, the applicant shall retain the services of a qualified biologist to conduct pre-construction surveys for western spadefoot toad within all portions of the Project site containing suitable breeding habitat. Surveys shall be conducted during a time of year when the species could be detected (*e.g.*, the presence of rain pools). If western spadefoot toad is identified on the Project site, the following measures will be implemented.

(1) Under the direct supervision of the qualified biologist, western spadefoot toad habitat shall be created within suitable natural sites on the Specific Plan site outside the proposed development envelope. The amount of occupied breeding habitat to be impacted by the Project shall be replaced at a 2:1 ratio. The actual relocation site design and location shall be approved by CDFG. The location shall be in suitable habitat as far away as feasible from any of the homes and

roads to be built. The relocation ponds shall be designed such that they only support standing water for several weeks following seasonal rains in order that aquatic predators (*e.g.*, fish, bullfrogs, and crayfish) cannot become established. Terrestrial habitat surrounding the proposed relocation site shall be as similar in type, aspect, and density to the location of the existing ponds as feasible. No site preparation or construction activities shall be permitted in the vicinity of the currently occupied ponds until the design and construction of the pool habitat in preserved areas of the site has been completed and all western spadefoot toad adults, tadpoles, and egg masses detected are moved to the created pool habitat.

(2) Based on appropriate rainfall and temperatures, generally between the months of February and April, the biologist shall conduct pre-construction surveys in all appropriate vegetation communities within the development envelope. Surveys will include evaluation of all previously documented occupied areas and a reconnaissance-level survey of the remaining natural areas of the site. All western spadefoot adults, tadpoles, and egg masses encountered shall be collected and released in the identified/created relocation ponds described above.

(3) The qualified biologist shall monitor the relocation site for five years, involving annual monitoring during and immediately following peak breeding season such that surveys can be conducted for adults as well as for egg masses and larval and post-larval toads. Further, survey data will be provided to CDFG by the monitoring biologist following each monitoring period and a written report summarizing the monitoring results will be provided to CDFG at the end of the monitoring effort. Success criteria for the monitoring program shall include verifiable evidence of toad reproduction at the relocation site.

BIO-54 Prior to construction the applicant shall develop a relocation plan for coast horned lizard, silvery legless lizard, coastal western whiptail, rosy boa, San Bernardino ringneck snake, and coast patch-nosed snake. The Plan shall include but not be limited to the timing and location of the surveys that would be conducted for each species; identify the locations where more intensive efforts should be conducted; identify the habitat and conditions in the proposed relocation site(s); the methods that would be utilized for trapping and relocating the individual species; and provide for the documentation/recordation of the species and number of the animals relocated. The Plan shall be submitted to CDFG for approval 60 days prior to any ground disturbing activities within potentially occupied habitat.

The Plan shall include the specific survey and relocation efforts that would occur for construction activities that occur both during the activity period of the special status species (generally March to November) and for periods when the species may be present in the work area but difficult to detect due to weather conditions (generally

December through February). Thirty days prior to construction activities in coastal scrub, chaparral, oak woodland, riparian habitats, or other areas supporting these species qualified biologists shall conduct surveys to capture and relocate individual coast horned lizard, silvery legless lizard, coastal western whiptail, rosy boa, San Bernardino ringneck snake, and coast patch-nosed snake in order to avoid or minimize take of these special-status species. The plan shall require a minimum of three (3) surveys conducted during the time of year/day when each species is most likely to be observed. Individuals shall be relocated to nearby undisturbed areas with suitable habitat. If construction is scheduled to occur during the low activity period (generally December through February) the surveys shall be conducted prior to this period if possible and exclusion fencing shall be placed to limit the potential for re-colonization of the site prior to construction. The qualified biologist will be present during ground-disturbing activities immediately adjacent to or within habitat that supports populations of these species. Clearance surveys for special-status reptiles shall be conducted by a qualified biologist prior to the initiation of construction each day.

Results of the surveys and relocation efforts shall be provided to CDFG in the annual mitigation status report. Collection and relocation of animals shall only occur with the proper scientific collection and handling permits.

BIO-55 a. As a supplement to BIO-1 through BIO-16, additional habitat mitigation through replacement or enhancement of nesting/foraging habitat for least Bell's vireo will be provided for certain key habitat zones at higher ratios (identified as "key population areas" in **Figure 4.5-86**, Alternative 2 Impacts to Least Bell's Vireo Habitat). Southern willow scrub, southern cottonwood–willow riparian, arrow weed scrub, mulefat scrub, and Mexican elderberry scrub and woodland that provide nesting/foraging habitat for least Bell's vireo in "key population areas" shall be replaced or enhanced. All permanent loss to nesting/foraging habitat in key population areas shall be mitigated at a 5:1 ratio unless otherwise authorized by CDFG or USFWS. Temporary habitat loss of foraging/nesting habitat in key population areas shall be mitigated at a 2:1 ratio. The requirements for replacing habitat by either creating new habitat or removing exotic species from existing habitat shall follow the procedures outlined in BIO-1 through BIO-16. To replace the lost functions of habitat located adjacent to the Santa Clara River due to noise impacts, all nesting/foraging habitat within the 60 dBA sound contour (associated with development site roadway improvements) shall be considered degraded. Nesting/foraging habitat within this area shall be mitigated at a ratio of 2:1.

b. The loss of documented occupied nesting habitat for coastal California gnatcatcher shall be mitigated. If the coastal California gnatcatcher is identified nesting on site, the applicant will acquire or preserve nesting coastal California gnatcatcher habitat at a 3:1 ratio for impacts to documented occupied habitat, or by the ratio specified in BIO-2,

whichever is greater. Mitigation acquisition shall occur at an agreed-upon location as approved by the USFWS upon consultation. The applicant shall enter into a binding legal agreement regarding the preservation of occupied habitat describing the terms of the acquisition, enhancement, and management of those lands.

BIO-56 Within 30 days of ground-disturbing activities associated with construction or grading that would occur during the nesting/breeding season of native bird species potentially nesting on the site (typically March through August in the Project region, or as determined by a qualified biologist), the applicant shall have weekly surveys conducted by a qualified biologist to determine if active nests of bird species protected by the Migratory Bird Treaty Act and/or the California Fish and Game Code are present in the disturbance zone or within 300 feet (500 feet for raptors) of the disturbance zone. Pre-construction surveys shall include nighttime surveys to identify active rookery sites. The surveys shall continue on a weekly basis, with the last survey being conducted no more than seven days prior to initiation of disturbance work. If ground-disturbing activities are delayed, then additional pre-disturbance surveys shall be conducted such that no more than seven days will have elapsed between the survey and ground-disturbing activities.

If active nests are found, clearing and construction within 300 feet of the nest (500 feet for raptors) shall be postponed or halted, at the discretion of the biologist in consultation with CDFG, until the nest is vacated and juveniles have fledged, as determined by the biologist, and there is no evidence of a second attempt at nesting. In the event that golden eagles establish an active nest in the River Corridor SMA, the buffers will be established in consultation with CDFG. Potential golden eagle nesting will be reported to CDFG within 24 hours. Limits of construction to avoid an active nest shall be established in the field with flagging, fencing, or other appropriate barriers and construction personnel shall be instructed on the sensitivity of nest areas. The biologist shall serve as a construction monitor during those periods when construction activities will occur near active nest areas to ensure that no inadvertent impacts to these nests occur. Results of the surveys shall be provided to CDFG in the annual mitigation status report.

For listed riparian songbirds (least Bell's vireo, southwestern willow flycatcher, yellow-billed cuckoo) USFWS protocol surveys shall be conducted. If active nests are found, clearing and construction within 300 feet of the nest shall be postponed or halted, at the discretion of the biologist in consultation with CDFG and USFWS, until the nest is vacated and juveniles have fledged, as determined by the biologist, and there is no evidence of a second attempt at nesting. If no active nests are observed, construction may proceed. If active nests are found, work may proceed provided that construction activity is located at least 300 feet from active nests (or as authorized through the

context of the Biological Opinion and 2081b Incidental Take Permit). This buffer may be adjusted provided noise levels do not exceed 60 dBA hourly Leq at the edge of the nest site as determined by a qualified biologist in coordination with a qualified acoustician.

If the noise meets or exceeds the 60 dBA Leq threshold, or if the biologist determines that the construction activities are disturbing nesting activities, the biologist shall have the authority to halt the construction and shall devise methods to reduce the noise and/or disturbance in the vicinity. This may include methods such as, but not limited to, turning off vehicle engines and other equipment whenever possible to reduce noise, installing a protective noise barrier between the nest site and the construction activities, and working in other areas until the young have fledged. If noise levels still exceed 60 dBA Leq hourly at the edge of nesting territories and/or a no-construction buffer cannot be maintained, construction shall be deferred in that area until the nestlings have fledged. All active nests shall be monitored on a weekly basis until the nestlings fledge. The qualified biologist shall be responsible for documenting the results of the surveys and the ongoing monitoring and for reporting these results to CDFG and USFWS.

For coastal California gnatcatcher, the applicant shall conduct USFWS protocol surveys in suitable habitat within the Project area and all areas within 500 feet of access or construction-related disturbance areas. Suitable habitats, according to the protocol, include "coastal sage scrub, alluvial fan, chaparral, or intermixed or adjacent areas of grassland and riparian habitats." A permitted biologist shall perform these surveys according to the USFWS' (1997a) Coastal California Gnatcatcher Presence/Absence Survey Guidelines. If a territory or nest is confirmed, the USFWS and CDFG shall be notified immediately. If present, a 500-foot disturbance-free buffer shall be established and demarcated by fencing or flagging. No Project activities may occur in these areas unless otherwise authorized by USFWS and CDFG. Construction activities in suitable gnatcatcher habitat will be monitored by a full-time qualified biologist. The monitoring shall be of a sufficient intensity to ensure that the biologist could detect the presence of a bird in the construction area.

BIO-57 Thirty days prior to construction activities, a qualified biologist shall conduct CDFG protocol surveys to determine whether the burrowing owl is present at the site. The surveys shall consist of three site visits and shall be conducted in areas dominated by field crops, disturbed habitat, grasslands, and along levee locations, or if such habitats occur within 500 feet of a construction zone. If located, occupied burrows shall not be disturbed during the nesting season (February 1 through August 31) unless a qualified biologist approved by CDFG verifies through non-invasive methods that either the birds have not begun egg-laying and incubation or that juveniles from the occupied burrows are foraging independently and are capable of independent survival. If the

burrowing owl is detected but nesting is not occurring, construction work can proceed after any owls have been evacuated from the site using CDFG-approved burrow closure procedures and after alternative nest sites have been provided in accordance with the CDFG Staff Report on Burrowing Owl Mitigation (10-17-95).

Unless otherwise authorized by CDFG, a 500-foot buffer, within which no activity will be permissible, will be maintained between Project activities and nesting burrowing owls during the nesting season. This protected area will remain in effect until August 31 or at CDFG's discretion and based upon monitoring evidence, until the young owls are foraging independently.

Results of the surveys and relocation efforts shall be provided to CDFG in the annual mitigation status report.

BIO-58 Thirty days prior to construction activities in grassland, scrub, chaparral, oak woodland, riverbank, and agriculture habitats, or other suitable habitat a qualified biologist shall conduct a survey within the proposed construction disturbance zone and within 200 feet of the disturbance zone for San Diego black-tailed jackrabbit and San Diego desert woodrat.

If San Diego black-tailed jackrabbits are present, non-breeding rabbits shall be flushed from areas to be disturbed. Dens, depressions, nests, or burrows occupied by pups shall be flagged and ground-disturbing activities avoided within a minimum of 200 feet during the pup-rearing season (February 15 through July 1). This buffer may be reduced based on the location of the den upon consultation with CDFG. Occupied maternity dens, depressions, nests, or burrows shall be flagged for avoidance, and a biological monitor shall be present during construction. If unattended young are discovered, they shall be relocated to suitable habitat by a qualified biologist. The applicant shall document all San Diego black-tailed jackrabbit identified, avoided, or moved and provide a written report to CDFG within 72 hours. Collection and relocation of animals shall only occur with the proper scientific collection and handling permits.

If active San Diego desert woodrat nests (stick houses) are identified within the disturbance zone or within 100 feet of the disturbance zone, a fence shall be erected around the nest site adequate to provide the woodrat sufficient foraging habitat at the discretion of the qualified biologist in consultation with CDFG. Clearing and construction within the fenced area will be postponed or halted until young have left the nest. The biologist shall serve as a construction monitor during those periods when disturbance activities will occur near active nest areas to ensure that no inadvertent impacts to these nests will occur. If avoidance is not possible, the applicant will take the following sequential steps: (1) all understory vegetation will be cleared in the area immediately surrounding active nests followed by a period of one night without further

disturbance to allow woodrats to vacate the nest, (2) each occupied nest will then be disturbed by a qualified wildlife biologist until all woodrats leave the nest and seek refuge off site, and (3) the nest sticks shall be removed from the Project site and piled at the base of a nearby hardwood tree (preferably a coast live oak or California walnut). Relocated nests shall not be spaced closer than 100 feet apart, unless a qualified wildlife biologist has determined that a specific habitat can support a higher density of nests. The applicant shall document all woodrat nests moved and provide a written report to CDFG.

All woodrat relocation shall be conducted by a qualified biologist in possession of a scientific collecting permit.

BIO-59 Road undercrossings will be built in accordance with accepted design criteria to allow the passage of mountain lions and mule deer. The applicant shall prepare a Wildlife Movement Corridor Plan that specifically addresses wildlife movement corridors at San Martinez Grande, Chiquito Canyon, and Castaic Creek, which shall be monitored for one year prior to construction of the SR-126 widenings. The Plan shall address current movement that is occurring, the methods that will be implemented to provide for passage, including lighting, fencing, vegetation planting, the installation of bubblers to encourage wildlife usage, and the size of the passage. The applicant shall install motion cameras at these locations in consultation with CDFG and monitor these passages for a period of two years subsequent to constructing improvements. A report of the wildlife documented to utilize these crossings shall be provided to CDFG annually. In addition, the Salt Creek crossing west of the Project area will be enhanced prior to initiation of construction in Long Canyon (southern portion of the Homestead Village). This crossing will be monitored for one year at the initiation of RMDP development, for two years at the time the crossing is enhanced, and then for three years after Project build-out. Prior to the construction of adjacent developments, signs will be placed along the roads indicating potential wildlife crossings where mountain lions and mule deer are likely to cross.

BIO-60 Thirty days prior to construction activities, a qualified biologist shall conduct a pre-construction survey for mountain lion natal dens. The survey area shall include the construction footprint and the area within 2,000 feet of the Project disturbance boundaries. Should an active natal den be located, the applicant shall cease work within 2000 feet and inform CDFG with 24 hours. No construction activities shall occur in the 2000 foot buffer until a qualified biologist in consultation with CDFG establishes an appropriate setback from the den that would not adversely affect the successful rearing of the cubs. No construction activities or human intrusion shall occur within the established setback until the cubs have been successfully reared or the cats have left the area.

BIO-61 No earlier than 30 days prior to the commencement of construction activities, a pre-construction survey shall be conducted by a qualified biologist to determine if active roosts of special-status bats are present on or within 300 feet of the Project disturbance boundaries. Should an active maternity roost be identified (in California, the breeding season of native bat species is generally from April 1 through August 31), the roost shall not be disturbed and construction within 300 feet shall be postponed or halted, until the roost is vacated and juveniles have fledged. Surveys shall include rocky outcrops, caves, structures, and large trees (particularly trees 12 inches in diameter or greater at 4.5 feet above grade with loose bark or other cavities). Trees and rocky outcrops shall be surveyed by a qualified bat biologist (*i.e.*, a biologist holding a CDFG collection permit and a Memorandum of Understanding with CDFG allowing the biologist to handle bats). If active maternity roosts or hibernacula are found, the rock outcrop or tree occupied by the roost shall be avoided (*i.e.*, not removed) by the Project. If avoidance of the maternity roost must occur, the bat biologist shall survey (through the use of radio telemetry or other CDFG approved methods) for nearby alternative maternity colony sites. If the bat biologist determines in consultation with and with the approval of CDFG that there are alternative roost sites used by the maternity colony and young are not present then no further action is required.

If a maternity roost will be impacted by the Project, and no alternative maternity roosts are in use near the site, substitute roosting habitat for the maternity colony shall be provided on, or in close proximity to, the Project site no less than three months prior to the eviction of the colony. Large concrete walls (*e.g.*, on bridges) on south or southwestern slopes that are retrofitted with slots and cavities are an example of structures that may provide alternative potential roosting habitat appropriate for maternity colonies. Alternative roost sites must be of comparable size and proximal in location to the impacted colony. CDFG shall also be notified of any hibernacula or active nurseries within the construction zone.

If non-breeding bat hibernacula are found in trees scheduled to be removed or in crevices in rock outcrops within the grading footprint, the individuals shall be safely evicted, under the direction of a qualified bat biologist, by opening the roosting area to allow airflow through the cavity or other means determined appropriate by the bat biologist (*e.g.*, installation of one-way doors). In situations requiring one-way doors, a minimum of one week shall pass after doors are installed and temperatures should be sufficiently warm for bats to exit the roost because bats do not typically leave their roost daily during winter months in southern coastal California. This action should allow all bats to leave during the course of one week. Roosts that need to be removed in situations where the use of one-way doors is not necessary in the judgment of the qualified bat biologist in consultation with CDFG shall first be disturbed by various means at the direction of the bat biologist at dusk to allow bats to escape during the

darker hours, and the roost tree shall be removed or the grading shall occur the next day (*i.e.*, there shall be no less or more than one night between initial disturbance and the grading or tree removal). These actions should allow bats to leave during nighttime hours, thus increasing their chance of finding new roosts with a minimum of potential predation during daylight.

If an active maternity roost is located on the Project site, and alternative roosting habitat is available, the demolition of the roost site must commence before maternity colonies form (*i.e.*, prior to March 1) or after young are flying (*i.e.*, after July 31) using the exclusion techniques described above.

BIO-62 At least 1,900 acres of Open Area within the Specific Plan area shall be offered for dedication to an NLMO in fee and/or by conservation easement. These 1,900 acres of the Open Area will be left as natural vegetation. Dedication of open areas lands shall be reported annually to CDFG.

BIO-63 Each tract map Home Owners' Association shall supply educational information to future residents regarding pets, wildlife, and open space areas. The material shall discuss the presence of native animals (*e.g.*, coyote, bobcat, and mountain lion), indicate that those native animals could prey on pets, indicate that no actions shall be taken against native animals should they prey on pets allowed outdoors, and indicate that pets must be leashed while using the designated trail system and/or in any areas within or adjacent to open space. Control of stray and feral cats and dogs will be conducted in open space areas on an as-needed basis by the NLMO(s) or the Newhall Ranch JPA managing the River Corridor SMA, High Country SMA, or Salt Creek area or by the HOAs managing the Open Areas. Feral cats and dogs may be trapped and deposited with the local Society for the Prevention of Cruelty to Animals or the Los Angeles County Department of Animal Control.

BIO-64 An integrated pest management (IPM) plan that addresses the use of pesticides (including rodenticides and insecticides) on site will be prepared prior to the issuance of building permits for the initial tract map. Preparation of the CC&Rs for each tract map shall include language that prohibits the use of anticoagulant rodenticides in the Project site.

BIO-65 Pre-construction surveys for San Emigdio blue butterfly shall occur in all areas containing host plants in sufficient density to support this species. A qualified Lepidoptera biologist shall conduct focused surveys at a time of year and during weather conditions when the detection of eggs, larvae, or adults is possible. All occupied habitat shall be mapped and the locations provided to CDFG. Should the removal of quail brush or other documented host plants from occupied San Emigdio blue butterfly habitat in Potrero Canyon or other areas be required, the plants shall be

removed when eggs and larvae are not present (*i.e.*, mid-September to March). Removal of quail brush plants from the documented habitat in Potrero Canyon may only be conducted from April through early September if it is determined by a qualified biologist that eggs and/or larvae are not present on the plants to be removed.

BIO-66 The removal of quail brush or other documented host plants from any occupied San Emigdio blue butterfly habitat in Potrero Canyon or other areas shall be replaced at a minimum of a 1.5:1 ratio. The replacement plants shall be planted contiguous to the existing quail brush plants associated with the San Emigdio blue butterfly habitat. The success of the replanting shall be monitored for survival and vigor consistent with survivorship requirements of Mitigation Measure BIO-6 and BIO-7.

BIO-67 Prior to any construction activities occurring within 200 feet of any occupied San Emigdio blue butterfly habitat in Potrero Canyon or other areas, the boundaries of preserved areas of the habitat shall be clearly marked with flagging. The flagging would serve to identify the boundaries of the habitat to construction personnel and to prevent the inadvertent construction-related loss of quail brush or other host plants associated with the habitat. Construction personnel working in the area shall be informed that the removal of or damage to any flagged quail brush or other host plants located outside the disturbance footprint is prohibited.

BIO-68 Any special-status species bat day roost sites found by a qualified biologist during pre-construction surveys conducted per BIO-61, to be directly (within project disturbance footprint) or indirectly (within 300 feet of project disturbance footprint) impacted are to be mitigated with creation of artificial roost sites. The Project applicant shall establish (an) alternative roost site(s) within suitable preserved open space located at an adequate distance from sources of human disturbance.

BIO-69 The Project applicant and/or NLMO shall develop and implement a conservation education and citizen awareness program for the High Country SMA informing the public of the special-status resources present within the High Country SMA and providing information on common threats posed by the presence of people and pets to those resources. The NLMO shall install trailhead and trail signage indicating the High Country SMA is a biological conservation area and requesting that people and their animals stay on existing trails at all times. The NLMO shall provide quarterly maintenance patrols to remove litter and monitor trail expansion and fire hazards within the High Country SMA, funded by the JPA.

BIO-70 Construction plans shall include necessary design features and construction notes to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction. In addition to applicable erosion control plans and performance under SCAQMD Rule 403d dust control (SCAQMD 2005), the

Project stormwater pollution prevention plan (SWPPP) shall include the following minimum BMPs. Together, the implementation of these requirements shall ensure protection of adjacent habitats and wildlife species during construction. At a minimum, the following measures/restrictions shall be incorporated into the SWPPP, and noted on construction plans where appropriate, to avoid impacting special-status species during construction:

- Avoid planting or seeding invasive species in development areas within 200 feet of native vegetation communities.
- Provide location and details for any dust control fencing along Project boundaries (BIO-71).
- Vehicles shall not be driven or equipment operated in areas of ponded or flowing water, or where wetland vegetation, riparian vegetation, or aquatic organisms may be destroyed, except as otherwise provided for in the 404 Permit or 1603 Agreement.
- Silt settling basins installed during the construction process shall be located away from areas of ponded or flowing water to prevent discolored, silt-bearing water from reaching areas of ponded or flowing water during normal flow regimes.
- If a stream channel has been altered during the construction and/or maintenance operations, its low flow channel shall be returned as nearly as practical to pre-Project topographic conditions without creating a possible future bank erosion problem or a flat, wide channel or sluice-like area. The gradient of the streambed shall be returned to pre-Project grade, to the extent practical, unless it represents a wetland restoration area.
- Temporary structures and associated materials not designed to withstand high seasonal flows shall be removed to areas above the high water mark before such flows occur.
- Staging/storage areas for construction equipment and materials shall be located outside of the ordinary high water mark.
- Any equipment or vehicles driven and/or operated within or adjacent to the stream shall be checked and maintained daily, to prevent leaks of materials that could be deleterious to aquatic life if introduced to water.
- Stationary equipment such as motors, pumps, generators, and welders which may be located within the riverbed construction zone shall be positioned over drip pans. No fuel storage tanks shall be allowed in the riverbed.
- No debris, bark, slash sawdust, rubbish, cement or concrete or washing thereof, oil, petroleum products, or other organic material from any construction, or

associated activity of whatever nature, shall be allowed to enter into, or be placed where it may be washed by rainfall or runoff into, watercourses included in the permit. When construction operations are completed, any excess materials or debris shall be removed from the work area.

- No equipment maintenance shall be done within or near any stream where petroleum products or other pollutants from the equipment may enter these areas with stream flow.
- The operator shall install and use fully covered trash receptacles to contain all food, food scraps, food wrappers, beverage containers, and other miscellaneous trash.
- The operator shall not permit pets on or adjacent to the construction site.
- No guns or other weapons are allowed on the construction site during construction, with the exception of the security personnel and only for security functions. No hunting shall be authorized/permitted during construction.

BIO-71 Development areas shall have dust control measures implemented and maintained to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where construction activities occur within 100 feet of known special-status plant species locations, chemical dust suppression shall not be utilized. Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations. See BIO-32 for dust control requirements related to spineflower preserves.

BIO-72 Plant palettes proposed for use on landscaped slopes, street medians, park sites, and other public landscaped and FMZ areas within 100 feet of native vegetation communities shall be reviewed by a qualified restoration specialist to ensure that the proposed landscape plants will not naturalize and require maintenance or cause vegetation community degradation in the open space areas (River Corridor SMA, High Country SMA, Salt Creek area, and natural portions of the Open Area). Container plants to be installed within public areas within 100 feet of the open space areas shall be inspected by a qualified restoration specialist for the presence of disease, weeds, and pests, including Argentine ants. Plants with pests, weeds, or diseases shall be rejected. In addition, landscape plants within 100 feet of native vegetation communities shall not be on the Cal-IPC California Invasive Plant Inventory (most recent version) or on the list of Invasive Ornamental Plants listed in Appendix B of the SCP. The current Cal-IPC list can be obtained from the Cal-IPC web site (http://www.cal-ipc.org/ip/inventory/index.php). Landscape plans will include a plant

palette composed of native or non-native, non-invasive species that do not require high irrigation rates. Except as required for fuel modification, irrigation of perimeter landscaping shall be limited to temporary irrigation (*i.e.*, until plants become established).

BIO-73 Permanent fencing shall be installed along all River Corridor SMA trails adjacent to the Santa Clara River, or other sensitive resources, in order to minimize impacts associated with increased human presence on protected vegetation communities and special-status plant and wildlife species. The fencing will be split rail to avoid inhibiting wildlife movement. Viewing platforms will be located in land covers currently mapped as agriculture, disturbed land, or developed land.

BIO-74 To protect Middle Canyon Spring and to reduce potential direct impacts to any special-status species that may be located within the spring complex due to unrestricted access, the Project applicant or its designee shall avoid all construction-related activities within the Middle Canyon Spring complex and erect and maintain temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to and during all phases of construction within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. A qualified biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. The areas behind the temporary fencing shall not be used for the storage of any equipment, materials, construction debris, or anything associated with construction activities. Any upslope runoff from construction areas will be directed away from the Middle Canyon Spring.

Following the final phase of construction of any Newhall Ranch subdivision tract adjacent to Middle Canyon Spring, the Project applicant or its designee shall install and maintain permanent fencing along the subdivision tract bordering the spring. Permanent signage shall be installed on the fencing along the spring boundary to indicate that the fenced area is a biological preserve that contains protected species and habitat. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

a. As described in BIO-51, the Commerce Center Drive Bridge will be designed to minimize secondary impacts associated with lighting and water quality impacts through the installation of indirect and downcast lighting, and routing of stormwater to water quality treatment facilities.

BIO-75 Focused surveys for the undescribed species of everlasting (a special-status plant species) shall be conducted by a qualified botanist prior to the commencement of grading/construction activities wherever suitable habitat (primarily river terraces) could

be affected by direct, indirect, or secondary construction impacts. The surveys shall be conducted no more than one year prior to commencement of construction activities within suitable habitat, and the surveys shall be conducted at a time of year when the plants can be located and identified. Should the species be documented within the Project boundary, avoidance measures shall be implemented to minimize impacts to individual plants wherever feasible. These measures shall include minor adjustments to the boundaries/location of haul routes and other Project features. If, due to Project design constraints, avoidance of all plants is not possible, then further measures, described in BIO-76, shall be implemented to salvage seeds and/or transplant individual plants. All seed collection and/or transplantation methods, as well as the location of the receptor site for seeds/plants (assumed to be within preserved open space areas of Newhall Ranch along the Santa Clara River), shall be coordinated with CDFG prior to impacting known occurrences of the undescribed everlasting.

BIO-76 For any individual project, or any phase of an individual project, to be located where undescribed everlasting plants may occur (*i.e.*, the sites identified in this EIS/EIR and any new sites discovered by preconstruction surveys, per BIO-75, or other future field surveys), Newhall Land shall prepare and implement an Undescribed Everlasting Mitigation and Monitoring Plan prior to the issuance of grading permits.

The Plan shall provide for replacement of individual plants to be removed at a minimum 1:1 ratio, within suitable habitat at a site where no future construction-related disturbance will occur. The plan shall specify the following: (1) the location of the mitigation site in protected/preserved areas within the Specific Plan site; (2) methods for harvesting seeds or salvaging and transplantation of individual plants to be impacted; (3) measures for propagating plants (from seed or cuttings) or transferring living specimens from the salvage site to the introduction site; (4) site preparation procedures for the mitigation site; (5) a schedule and action plan to maintain and monitor the mitigation area; (6) the list of criteria and performance standards by which to measure the success of the mitigation site (below); (7) measures to exclude unauthorized entry into the mitigation areas; and (8) contingency measures such as erosion control, replanting, or weeding to implement in the event that mitigation efforts are not successful. The performance standards for the Undescribed Everlasting Mitigation and Monitoring Plan shall be the following:

a. Within four years after reintroducing the undescribed everlasting to the mitigation site, the extent of occupied acreage and the number of established, reproductive plants will be no smaller than at the site lost for project construction.

b. Non-native species cover will be no more than 5% absolute cover through the term of the restoration.

c. Giant reed (*Arundo donax*), tamarisk (*Tamarix ramosissima*), perennial pepperweed (*Lepidium latifolium*), tree of heaven (*Ailanthus altissimus*), pampas grass (*Cortaderia selloana*), and any species listed on the California State Agricultural list (CDFA 2009) or Cal-IPC list of noxious weeds (Cal-IPC 2006, 2007) will not be present on the revegetation site as of the date of completion approval.

BIO-77 A Middle Canyon Spring Habitat Management Plan will be developed that details the measures to be implemented to maintain the populations of the undescribed snail and sunflower species. The plan shall be subject to the approval of CDFG and implemented by Newhall Land prior to disturbance within 100 feet of flowing water in Middle Canyon Creek and/or 200 feet of Middle Canyon Spring. The plan shall include the following elements: (1) collection of data on existing site conditions; (2) construction monitoring program and a post-development monitoring program; (3) threshold parameters that activate adaptive management measures across a series of potential future scenarios, including water quality and water quantity scenarios, including the potential use of infiltration wells, if these should become necessary to ensure water quantity; (4) measures to exclude unauthorized entry into the spring; and (5) contingency measures in the event that management efforts are not successful. Plan elements are further described below:

Pre-development data collection:

Upon approval of the proposed Project, data collection for Middle Canyon Spring and its biotic community will be initiated. Site assessments will be completed by biologists and, as needed, with surveyors, engineers, geologists, and hydrogeologists to collect the following data, subject to limitations on disturbances: (1) inventory of plant species within and adjacent to the spring; (2) percent native and non-native plant cover and percent bare ground within and adjacent to the spring using the relevé method, a visual estimation technique to classify and map large vegetation areas in a limited amount of time (see below); (3) structural description of vegetation communities within each relevé plot; (4) GPS mapping of all trees within core spring area and adjacent 100 feet; (5) GPS mapping of special-status sunflower; (6) census special-status sunflower stem numbers; (7) description of any disturbances to the spring area; (8) establishment of permanent photo points; (9) photo documentation of seasonal changes in the spring; (10) survey and mapping of hydrologic and topographic features in the area adjacent to the spring; (11) population data on the undescribed snail,

including distribution, abundance, density, size classes and seasonal activity, and microhabitat descriptions; (12) invertebrates survey; (13) amphibian survey; (14) characterization of algal and microbial components; (15) survey of spring inlet and outlets for comparison to piezometer water elevations from monitoring points P-1MS, P-2MS, and P-8B; (16) flow rates of spring outlets at a frequency to record diurnal fluctuations; (17) approximate evapotranspiration rates of the vegetation community; (18) piezometer water elevation data from P-1MS, P-2MS, and P-8B collected at a frequency suitable to determine seasonal variations in groundwater elevations; (19) continuously recorded surface water temperature and depth profile at a spring monitoring location and piezometers P-1MS and P-2MS; (20) water quality/chemistry data in the spring and the three nearby piezometers (P-1MS, P-2MS, and P-8B) (dissolved oxygen [DO, spring only], salinity, pH and alkalinity, nitrates, sulfates, relevant cations and anions [bicarbonate, calcium, chloride, magnesium, nitrate as NO_3, potassium, sodium], total dissolved solids [TDS], turbidity [spring only], and suspended solids [spring only]); (21) soil samples along the margin of the spring to determine soil classification types; and (22) as available, compilation of a record of historical photographs and aerial photographs of the spring and adjacent areas.

Vegetation data will be collected using a non-invasive monitoring method and analyzed in accordance with the California Native Plant Society (CNPS) *Relevé Protocol* (2004), which provides for a visual assessment of vegetation communities instead of the more intrusive point-intercept transect methods. This will ensure that collection of vegetation data will limit damage to the spring vegetation and limit the establishment of trails during monitoring visits.

Additionally, for two years following approval of the proposed Project, the applicant, in consultation with CDFG, shall provide for the collection of seed from the undescribed sunflower species by a qualified research institution for long-term seed bank preservation or other conservation purposes. Further, to facilitate additional research of the species, applicant shall allow CDFG access to the spring complex for future conservation purposes.

Prior to establishing the post-development long-term thresholds discussed below, hydrologic and biologic data will be evaluated, and any increase or decrease greater than 10% in monitoring parameters 2, 11 through 16, and 18 through 20, described above, will serve as an interim threshold and will trigger adaptive management measures, such as those described below. Should these thresholds be triggered, CDFG will be notified within 24 hours to determine what actions, if necessary, will be implemented. Biological data collection will contribute to the establishment of habitat criteria necessary for sustaining the undescribed snail and the undescribed sunflower.

Construction monitoring program and data collection

Data collection described above will continue during construction near the spring complex (Commerce Center Drive Bridge and development of Middle Canyon (Mission Village planning area)). Monitors will be on site daily when work is conducted within 100 feet of flowing water in Middle Canyon Creek and/or 200 feet of the spring complex, and weekly during mass grading of Middle Canyon, to observe and report on construction activities. Monitors will ensure that appropriate avoidance and minimization measures are implemented, such as the installation and maintenance of perimeter construction fencing and storm water controls, silt fences, and sand bags. During any period where dewatering occurs within 100 feet of flowing water in Middle Canyon Creek and/or 200 feet of the spring complex, biological and hydrologic parameters will be monitored daily. No dewatering activities shall occur in the spring complex. Discharge of any dewatering waters, nuisance irrigation flows, water quality basin, subdrain, backdrain, or toe drain flows shall be directed away from the spring.

Post-development data collection

Biological and hydrologic monitoring will continue post-development. For the first two years after build-out of Middle Canyon (Mission Village), post-construction monitoring will be as frequent as during the pre-construction period. After the two-year period, data collected and the frequency of monitoring may be adjusted, in consultation with CDFG. The post-development monitoring program will continue to collect data on trends and changes in the populations of the undescribed snail and sunflower and document any shift in spring habitat composition or any changes in conditions that would potentially impact the spring system, as detailed above. Analysis and comparison of collected data will establish long-term thresholds. These thresholds will serve to trigger adaptive management measures during the post-development period.

Adaptive management

As dictated by the thresholds discussed above, the following measures may be implemented after consultation with CDFG in the event a threshold is exceeded. These actions may include, but are not limited to: (1) the addition of supplemental water via an existing deep Saugus well in Middle Canyon; (2) removal of infiltration water by diverting flow from upstream water quality features; (3) implementing invasive species control; and (4) implementing additional controls to prevent unauthorized access to the spring complex.

Monitoring report

Annual monitoring reports will be prepared to summarize the status of the undescribed snail and sunflower and hydrology within Middle Canyon Spring. These reports will be used to evaluate the significance of impacts and the efficacy of mitigation measures. Reports will include results of biological surveys, flow data, groundwater modeling results, water quality data, mapping of the spring features and biota, photo-documentation from permanent photo points, analysis of field and lab data, conclusions based on ongoing monitoring efforts, and recommendations for future management actions. Annual monitoring reports will be submitted to CDFG and Corps.

BIO-78 A cowbird trapping program shall be implemented once vegetation clearing begins and maintained throughout the construction, maintenance, and monitoring period of the riparian restoration sites. A minimum of five traps shall be utilized, with at least one trap adjacent to the project site and one or two traps located at feeding areas or other CDFG-approved location. The trapping contractor may consult with CDFG to request modification of the trap location(s). CDFG must approve any relocation of the traps. Traps will be maintained beginning each year on April 1 and concluding on/or about November 1 (may conclude earlier, depending upon weather conditions and results of capture). The trapping contractor may also consult CDFG on a modified, CDFG-approved trapping schedule modification. The applicant shall follow CDFG and USFWS protocol. In the event that trapping is terminated after the first few years, subsequent phases of the RMDP development will require initiation of trapping surveys to determine whether re-establishment of the trapping program is necessary.

BIO-79 The status of the Potrero Canyon San Emigdio blue butterfly colony shall be monitored by a qualified biologist for a period of five years after Potrero Canyon Road construction completion/operation commencement to evaluate whether the operation of the road may be contributing to a population decline in the colony. Should it be determined that a population decline is occurring, habitat creation for the San Emigdio blue butterfly shall be implemented in suitable locations contiguous to the habitat but away from the road. A habitat creation plan will be prepared that details the location and methods for creating habitat, that specifies success criteria, and that describes measures that will be implemented in the event that the habitat creation does not stabilize the San Emigdio blue butterfly population.

BIO-80 The Project applicant will retain a qualified biologist to develop an Exotic Wildlife Species Control Plan and implement a control program for bullfrog, African clawed frog, and crayfish. The program will require the control of these species during construction within the River corridor and modified tributaries (bridges, diversions, bank stabilization, drop structures). The Plan shall include a description of the species

targeted for eradication, the methods of harvest that will be employed, the disposal methods, and the measures that would be employed to avoid impacts to sensitive wildlife (*e.g.*, stickleback, arroyo toad, nesting birds) during removal activities (*i.e.*, timing, avoidance of specific areas). Annual monitoring shall occur for the first five years after construction of Project facilities. After five years, bi-annual monitoring shall occur for up to 50 years to determine if additional control is necessary. Monitoring will be conducted within sentinel locations along the River Corridor SMA and where the Project provides potential habitat for these species (*e.g.*, future ponds and water features). Control shall be conducted within Project facilities where monitoring results indicate that exotic species have colonized an area.

BIO-81 The installation of new, or relocation of existing, utility poles and phone and cell towers shall be coordinated with CDFG where located in the High Country SMA and Salt Creek area. The applicant or SCE shall install utility poles, phone, and cell towers in conformance with APLIC standards for collision-reducing techniques as outlined in Suggested Practices for Avian Protection on Power Lines: The State of the Art in 2006 (APLIC 2006).

BIO-82 All surfaces on new antennae and phone/utility towers shall be designed and operated with anti-perching devices in conformance with APLIC standards to deter California condors and other raptors from perching. During construction the area shall be kept clean of debris, such as cable, trash, and construction materials. The applicant shall collect all microtrash and litter (anything shiny, such as broken glass), vehicle fluids, and food waste from the Project area on a daily basis. Workers will be trained on the issue of microtrash: what constitutes microtrash, its potential effects on California condors, and how to avoid the deposition of microtrash.

The applicant shall retain a qualified biologist with knowledge of California condors to monitor construction activities within the Project area. The resumes of the proposed biologist(s) will be provided to CDFG for concurrence. This biologist(s) will be referred to as the authorized biologist hereafter. During clearing and grubbing of construction areas, the qualified biologist shall be present at all times. During mass grading, construction sites shall be monitored on a daily basis. The authorized biologist will have the authority to stop all activities until appropriate corrective measures have been completed. If condors are observed landing in the Project area, the applicant shall avoid further construction within 500 feet of the sighting until the animals have left the area, or as otherwise authorized by CDFG and USFWS. All condor sightings in the Project area will be reported to CDFG and USFWS within 24 hours of the sighting. Should condors be found roosting within 0.5 mile of the construction area, no construction activity shall occur between one hour before sunset to one hour after sunrise, or until the condors leave the area, or as otherwise directed by USFWS.

Should condors be found nesting within 1.5 miles of the construction area, no construction activity will occur until further authorization occurs from CDFG and USFWS.

BIO-83 Thirty days prior to construction activities, a qualified biologist shall conduct a preconstruction survey for ringtail. The survey area shall include suitable riparian and woodland habitat (southern coast live oak riparian forest, southern cottonwood–willow riparian forest, southern willow scrub, coast live oak woodland, valley oak woodland, and mixed oak woodland) within the construction disturbance zone and a 300-foot buffer around the construction site. Should the ringtail be observed in the breeding and rearing period of February 1 through August 31, no construction-related activities shall occur within 300 feet of the occupied area for the period of February 1 through August 31 or until the ringtail has been determined by a qualified biologist (in consultation with CDFG) to no longer occupy areas within 300 feet of the construction zone and/or that construction activities would not adversely affect the successful rearing of young. If the ringtail is observed within the construction disturbance zone or in the 300-foot buffer around the construction site in the nonbreeding/rearing period of September 1 through January 31, and avoidance is not possible, denning ringtail shall be safely evicted under the direction of a qualified biologist (as determined by a Memorandum of Understanding with CDFG). All activities that involve the ringtail shall be documented and reported to CDFG.

BIO-84 Bridge and culvert designs, where practicable, shall provide roosting habitat for bats. A qualified biologist shall work with the Project engineer in identifying and incorporating structures into the design that provide suitable roosting habitat for bat species occurring in the Project area. The final design of the roosting structures would be chosen in consultation with CDFG.

BIO-85 To preclude the invasion of Argentine ants into the spineflower preserves and their associated buffers, controls will be implemented using an integrated pest management (IPM) approach in accordance with the approved SCP. The controls include (1) providing "dry zones" between urban development and spineflower preserves, including the buffers; (2) ensuring that landscape container plants installed within 200 feet of spineflower preserves are ant free prior to installation; (3) maintaining natural hydrological conditions in the spineflower preserves, including the buffers, through project design features; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

BIO-86 Requires focused surveys for the undescribed snail species by a qualified biologist prior to the commencement of grading/construction activities in any drainage area supporting perennial flow. Any individuals of the undescribed snail species found within the

Middle Canyon drainage shall be relocated to appropriate habitat within Middle Canyon Spring. If undescribed snails are discovered during aquatic and semi-aquatic pre-construction surveys in any other perennial flowing water, the applicant shall consult with CDFG prior to initiating disturbance of the area. A report documenting the number of snails located, the conditions of the area, and where the species has been relocated to, if applicable, shall be submitted to CDFG within 60 days following the relocation.

BIO-87 Following the completion and occupancy of a development area, quarterly monitoring shall be initiated for Argentine ants along the urban–open space interface at sentinel locations where invasions could occur (*e.g.*, where moist microhabitats that attract Argentine ants may be created). A qualified biologist shall determine the monitoring locations. Ant pitfall traps will be placed in these sentinel locations and operated on a quarterly basis to detect invasion by Argentine ants. If Argentine ants are detected during monitoring, direct control measures will be implemented immediately to help prevent the invasion from worsening. These direct controls may include but are not limited to nest/mound insecticide treatment, or available natural control methods being developed. A general reconnaissance of the infested area would also be conducted to identify and correct the possible source of the invasion, such as uncontrolled urban runoff, leaking pipes, or collected water. Monitoring and control of Argentine ants would occur for a 50-year period.

BIO-88 Any southern California black walnut and mainland cherry trees or shrubs outside riparian areas greater than one inch dbh shall be replaced in the ratio of at least 2:1. Multi-trunk trees/shrub dbh shall be calculated based on combined trunk dbh. Mitigation shall be deemed complete when each replacement tree attains at least one inch in diameter one foot above the base.

BIO-89 Prior to initiating construction for the installation of bridges, storm drain outlets, utility lines, bank protection, trails, and/or other construction activities, all construction sites and access roads within the riverbed as well as all riverbed areas within 300 feet of construction sites and access roads shall be surveyed at the appropriate season for two-striped garter snake and south coast garter snake. Focused surveys shall consist of a minimum of four daytime surveys, to be completed between April 1 and September 1. The survey schedule may be adjusted in consultation with CDFG to reflect the existing weather or stream conditions. If located, the species will be relocated to suitable pre-approved locations identified in the two-striped garter snake and/or south coast garter snake Relocation Plan.

The applicant shall develop a Plan to address the relocation of two-striped garter snake and south coast garter snake. The Plan shall include but not be limited to the timing and

location of the surveys that would be conducted for each species, identify the locations where more intensive efforts should be conducted, identify the habitat and conditions in the proposed relocation site(s), identify the methods that would be utilized for trapping and relocating the individual species, and provide for the documentation/recordation of the species and number of animals relocated. The Plan shall be submitted to CDFG for approval 60 days prior to any ground-disturbing activities, within potentially occupied habitat.

The qualified biologist shall be present during all activities immediately adjacent to or within habitat that supports populations of two-striped garter snake and/or south coast garter snake. Clearance surveys for garter snakes shall be conducted within 200 feet of potential habitat by the authorized biologist prior to the initiation of construction each day. The resume of the proposed biologists will be provided to CDFG for approval prior to conducting the surveys.

INTENTIONALLY LEFT BLANK

4.5.7 SUMMARY OF SIGNIFICANCE FINDINGS

Table 4.5-72 summarizes the significance findings for Alternatives 2 through 7 for direct, indirect, and secondary impacts to vegetation communities and unique landscape features, and lists the associated mitigation measures. **Table 4.5-73** summarizes the significance findings for impacts to common wildlife. It should be noted that, with the exception of the bird guilds, the mitigation measures listed for impacts to common wildlife are not required because all impacts would be less than significant prior to mitigation. These mitigation measures were identified for other biological resources for which impacts would be significant, absent mitigation, but are included for common wildlife because they would also further reduce impacts to these common species. For the bird guilds, impacts to individuals would be significant, absent mitigation, due to potential impacts to nests, eggs, and young, which are prohibited by the Migratory Bird Treaty Act (MBTA) and California Fish and Game Code sections 3503 and 3503.4 (birds of prey), which provides protection for nests, eggs, and nestlings during the breeding season, for species for which hunting or depredation permits are required. BIO-52 and BIO-56, which require preconstruction surveys for nesting birds and biological monitoring during vegetation clearing, are the only mitigation measures required for the bird guild species. **Table 4.5-74** summarizes the significance findings for impacts to wildlife habitat linkages, wildlife corridors, and wildlife crossings, and lists the appropriate mitigation measures. **Table 4.5-75** summarizes the significance findings for special-status species, and lists the appropriate mitigation measures.

INTENTIONALLY LEFT BLANK

Table 4.5-72
Summary of Significance Findings for Impacts to Vegetation Communities and Unique Landscape Features

Vegetation Communities and Land Covers	Direct Impacts (Removal of Vegetation) for Alternatives 2-7	Indirect Impacts (Removal of Vegetation) for Alternatives 2-7	Short-Term Secondary Impacts for Alternatives 2-7	Long-Term Secondary Impacts for Alternatives 2-7	Mitigation for Removal of Vegetation	Mitigation for Secondary Impacts
Riparian Communities	Significant absent mitigation	Significant absent mitigation	Significant absent mitigation	Significant absent mitigation	SP-4.6 (1-26, 26a, 27, 28, 34-43, 47a, 63); BIO (1-16, 19, 52, 62, 69, 73)	SP-4.6 (7, 17-20, 26a, 29-35, 39, 43-45, 49-52, 58, 64); BIO (45-47, 49, 52, 69-73)
California Annual Grassland, Agriculture, Disturbed Land, and Developed Land	Significant absent mitigation	Significant absent mitigation	Significant absent mitigation	Significant absent mitigation	SP-4.6 (17-26, 27, 34-42); BIO (19, 52, 62, 69, 73)	SP-4.6 (17-20, 29-35, 39, 44, 45, 49-52, 58); BIO (45-47, 49, 52, 69-73)
Coastal Scrub Communities	Significant absent mitigation	Significant absent mitigation	Significant absent mitigation	Significant absent mitigation	SP-4.6 (17-26, 27, 34-42); BIO (19, 20, 21, 52, 62, 69, 73)	SP-4.6 (17-20, 29-35, 39, 44, 45, 49-52, 58); BIO (45-47, 49, 52, 69-73)
Chaparral Communities	Significant absent mitigation	Significant absent mitigation	Significant absent mitigation	Significant absent mitigation	SP-4.6 (17-26, 27, 34-42); BIO (19, 52, 62, 69, 73)	SP-4.6 (17-20, 29-35, 39, 44, 45, 49-52, 58); BIO (45-47, 49, 52, 69-73)
Oak Woodland Communities (Coast Live Oak Woodland, Mixed Oak Woodland, Valley Oak/Grass, Valley Oak Woodland)	Significant absent mitigation	Significant absent mitigation	Significant absent mitigation	Significant absent mitigation	SP-4.6 (1-26, 26a, 27, 28, 34-43, 47a, 48, 63); BIO (1-16, 19, 22, 42, 52, 62, 69, 73)	SP-4.6 (7, 17-20, 26a, 29-35, 39, 43-45, 49-52, 58, 64); BIO (45-47, 49, 52, 69-73)
Purple Needlegrass	No impact is expected to occur	No impact is expected to occur	Significant absent mitigation	Significant absent mitigation	n/a	SP-4.6 (17, 31, 32, 33, 49-52); BIO (69, 72)
California Walnut Woodland	No impact is expected to occur	No impact is expected to occur	Significant absent mitigation	Significant absent mitigation	n/a	SP-4.6 (17, 31, 32, 33, 49-52); BIO (69, 72)
Unique Landscape Features	n/a	n/a	n/a	n/a	n/a	n/a

Table 4.5-73
Summary of Significance Findings for Impacts to Common Wildlife

Wildlife Species Guild	Direct Impacts for Alternatives 2-7	Indirect Impacts for Alternatives 2-7	Short-Term Secondary Impacts for Alternatives 2-7	Long-Term Secondary Impacts for Alternatives 2-7	Mitigation for Impacts to the Guild	Mitigation for Direct and Indirect Impacts	Mitigation for Secondary Impacts
Insect	Adverse but not significant	Adverse but not significant	Adverse but not significant	Adverse but not significant	SP-4.6 (1-16, 18, 19, 21-26, 27, 36-42, 58, 63); BIO (1-16, 19, 22, 49, 64, 70-72)	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Mollusk	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3	n/a	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Reptile – Low Mobility	Adverse but not significant	Adverse but not significant	Adverse but not significant	Adverse but not significant	SP-4.6 (1-19, 21-26, 27, 30-32, 36-42, 56, 63); BIO (1-16, 19, 22, 52, 63, 64, 69, 72, 85, 87	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Reptile and Amphibian – Semi-Aquatic	Adverse but not significant	Adverse but not significant	Adverse but not significant	Adverse but not significant	SP-4.6 (1-19, 21-26, 27, 30-32, 36-42, 55, 56, 58, 63; BIO (1-16, 19, 22, 45, 49, 52, 63, 69, 72, 80, 85, 87)	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Fish	Adverse but not significant	No impact is expected to occur	Adverse but not significant	Adverse but not significant	SP-4.6 (1-19, 21-26, 30-32, 55, 58, 63); BIO (1 -16, 45-49, 63, 64)	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Bird – Raptor	Significant absent mitigation	Significant absent mitigation	Adverse but not significant	Adverse but not significant	SP-4.6 (1-19, 21-26, 27, 30-32, 36-42, 56, 63); BIO (1-16, 19, 22, 52, 56, 63, 64, 69, 72, 81, 82)	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Bird – Riparian	Significant absent mitigation	Significant absent mitigation	Adverse but not significant	Adverse but not significant	SP-4.6 (1-19, 21-26, 27, 30-32, 36-42, 56, 63); BIO (1-16, 19, 22, 52, 56, 63, 64, 69, 72, 78)	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Bird – Upland Grassland	Significant absent mitigation	Significant absent mitigation	Adverse but not significant	Adverse but not significant	SP-4.6 (27, 30-32, 36-42, 56); BIO (19, 52, 56, 63, 64, 69)	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Bird – Upland Scrub and Chaparral	Significant absent mitigation	Significant absent mitigation	Adverse but not significant	Adverse but not significant	SP-4.6 (27, 30-32, 36-42, 56); BIO (19-21, 52, 56, 63, 64, 69, 72, 78)	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Bird – Upland Woodland	Significant absent mitigation	Significant absent mitigation	Adverse but not significant	Adverse but not significant	SP-4.6 (1-19, 21-26, 27, 30-32, 36-42, 56, 63); BIO (1-16, 19, 22, 52, 56, 63, 64, 69, 72, 78)	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Bat	Adverse but not significant	Adverse but not significant	Adverse but not significant	Adverse but not significant	SP-4.6 (1-17, 63, 21-26, 27, 30-32, 36-42, 48, 56); BIO (1-16, 19, 22, 63, 69)	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Mammal – Low Mobility	Adverse but not significant	Adverse but not significant	Adverse but not significant	Adverse but not significant	SP-4.6 (1-19, 21-26, 27, 30-32, 36-42, 56, 63); BIO (19-21, 52, 63, 64, 69)	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Mammal – Moderate Mobility	Adverse but not significant	Adverse but not significant	Adverse but not significant	Adverse but not significant	SP-4.6 (1-19, 21-26, 27, 30-32, 36-42, 56, 63); BIO (1-16, 19-22, 52, 63, 64, 69)	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3
Mammal – High Mobility	Adverse but not significant	Adverse but not significant	Adverse but not significant	Adverse but not significant	SP-4.6 (1-19, 21-26, 27, 30-32, 36-42, 56, 63); BIO (1-16, 19-22, 52, 59, 63, 64, 69)	Addressed at species level in Subsection 4.5.5.3	Addressed at species level in Subsection 4.5.5.3

Table 4.5-74
Summary of Significance Findings for Impacts to Wildlife Habitat Linkages, Wildlife Corridors, and Wildlife Crossings

Category	Significant Impacts?	Impacts to Wildlife for Alternatives 2-7	Mitigation for General Significant Impacts	Mitigation for Removal of Vegetation	Mitigation for Secondary Impacts
Wildlife Landscape Habitat Linkages	No	Adverse but not significant	n/a	Mitigation addressed at species level in Subsection 4.5.5.3	Mitigation addressed at species level in Subsection 4.5.5.3
Wildlife Corridors	Yes	Significant absent mitigation	SP-4.6 (1-17, 21-26, 29-32, 36-42, 56, 63); BIO (1-16, 19-21, 59, 63, 69, 72, 73, 85, 87)	Mitigation addressed at species level in Subsection 4.5.5.3	Mitigation addressed at species level in Subsection 4.5.5.3
Wildlife Crossings	No	Adverse but not significant	n/a	Mitigation addressed at species level in Subsection 4.5.5.3	Mitigation addressed at species level in Subsection 4.5.5.3

Adverse but not significant

[1] For those plant species for which several years of mapped occurrence data are available, impacts to those species were evaluated by impacts to individuals rather than by loss of habitat. For those plant species for which occurrences were not mapped (List 4 and Locally Regulated), impacts to those species were evaluated by loss of habitat instead of impacts to individuals

4.5.8 SIGNIFICANT UNAVOIDABLE IMPACTS

The proposed Project would result in significant and unavoidable impacts to San Fernando Valley spineflower, southwestern pond turtle, and San Emigdio blue butterfly resulting from loss of habitat and impacts to individuals.

Significant and unavoidable direct impacts would occur to San Fernando Valley spineflower due to impacts to individuals resulting from implementation of the RMDP and the SCP under Alternative 2.

Significant and unavoidable direct impacts would occur to southwestern pond turtle due to loss of habitat resulting from implementation of the RMDP and the SCP under Alternative 2.

Significant and unavoidable direct, indirect, and secondary impacts to San Emigdio blue butterfly due to loss of habitat and impacts to individuals resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would occur under Alternative 2.
