Also for the purpose of this analysis, suitable foraging habitat is defined as agriculture, California annual grassland, purple needlegrass, and scrub habitats (alluvial scrub, arrow weed scrub, mulefat scrub, big sagebrush scrub, California sagebrush scrub and associations, California sagebrush–black sage, California sagebrush–California buckwheat scrub, California sagebrush scrub–undifferentiated chaparral, big sagebrush–California buckwheat, and coyote brush scrub) that occur within 0.5 mile of the edge of suitable nesting habitat. The 0.5-mile radius is based on the observation noted above that kites seldom forage farther than a 0.5-mile radius from an active nest site (Hawbecker 1942). A total of 7,702 acres of suitable foraging habitat within 0.5 mile of suitable nesting habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 253 acres of suitable nesting and foraging habitat would be permanently lost through implementation of the RMDP and the SCP, representing 2.6% of these habitats on site (**Figure 4.5-79**, Alternative 2 Impacts to White-Tailed Kite Foraging and Nesting Habitat). Of these impacts, 48 acres are nesting habitat, representing 2.5% of this habitat on site. The remaining 205 acres of impact are foraging habitat, representing 2.7% of this habitat on site. A total of 141 acres of suitable habitat would be temporarily impacted, including 46 acres of nesting habitat and 95 acres of foraging habitat.

Although a relatively small percentage of habitat on site would be permanently lost, nesting habitat for an uncommon special-status species would be lost. Raptors in general are uncommon and receive special protection by CDFG. This impact would have the potential to substantially reduce the habitat of the species on site or rangewide; substantially interfere with the movement of the species or impede the use of a nursery site; cause the species to drop below self-sustaining levels on site or rangewide; threaten

to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7), absent mitigation. Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 3,453 acres of suitable nesting and foraging habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 35.9% of these habitats on site (**Figure 4.5-79**, Alternative 2 Impacts to White-Tailed Kite Foraging and Nesting Habitat). Of these impacts, 93 acres are nesting habitat, representing 4.9% of this habitat on site. The remaining 3,360 acres of impact are foraging habitat, representing 43.6% of this habitat on site.

Both nesting and a relatively large amount and percentage of on-site foraging habitat for the white-tailed kite would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site primarily by eliminating it from foraging in approximately 44.0% of suitable habitat, thus potentially reducing its numbers and restricting its range on site (significance criteria 1 and 7), absent mitigation. Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,706 acres (38.5%). Of these impacts, 141 acres are to nesting habitat, representing 7.4% of this habitat on site. The remaining 3,565 acres of impact are to foraging habitat, representing 46.3% of this habitat on site.

The combined direct and indirect impacts would result in a relatively large amount and percentage of permanent loss of on-site foraging habitat for the white-tailed kite, as well as a substantial amount of loss of nesting habitat, as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from nesting and foraging in 38.5% of suitable habitat, thus potentially reducing its numbers and restricting its range on site (significance criteria 1 and 7), absent mitigation. The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The white-tailed kite nests observed during the various avian surveys conducted within the Project area occurred within the riparian habitats along the Santa Clara River, including nesting in proximity to proposed RMDP facility construction areas. White-tailed kites are expected to forage most frequently in suitable habitat within at least 0.5 mile of active nests. Because white-tailed kites are highly mobile, it is unlikely that RMDP-related construction/grading activities would result in direct injury or mortality of adult birds. However, absent mitigation, construction and/or grading activities associated with the proposed RMDP could adversely affect foraging and nesting kites. Foraging individuals may avoid construction areas, and if construction occurred during the breeding season, active nests could be disturbed or destroyed, and eggs and/or young could be destroyed, injured, or killed. Impacts on foraging behavior by adults during the rearing period could also affect the health of young and survivorship, potentially resulting in reduced reproductive success. In addition, construction activities could cause females to abandon nests, resulting in the loss of the nest due to predators or exposure. These would be significant impacts (significance criteria 1 and 7), absent mitigation. Implementation of the SCP would not directly impact this species.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent and temporary impacts to individuals. Because the species nests and forages on site in habitat that would be directly affected, build-out of the Specific Plan, VCC, and Entrada planning areas could adversely affect nesting kites. This would be a significant impact (significance criteria 1 and 7), absent mitigation.

Secondary Impacts

Short-term, construction-related impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas could potentially affect white-tailed kites nesting or foraging in areas adjacent to construction zones. These impacts include construction-related fugitive dust, nesting and foraging disturbance from increased human activity, noise and ground vibration, and nighttime illumination, which could modify essential behaviors of individuals, increase physiological stress, potentially increase their risk of predation, and potentially cause nest abandonment.

Potential long-term secondary effects resulting from RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas adjacent to nesting and foraging habitat include nighttime lighting; increased human activity; increased noise; harassment and predation by pet,

feral, and stray cats and dogs and other mesopredators (particularly raccoons and opossums); the use of pesticides, which could result in the loss of prey and secondary poisoning; and increased incidence of collisions with vehicles and man-made structures.

Both short-term and long-term secondary impacts would have a substantial adverse effect on this species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7), absent mitigation. Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for white-tailed kite (**Figures 4.5-80** through **4.5-84**, Alternatives 3 through 7 Impacts to White-Tailed Kite Foraging and Nesting Habitat):

- Alternative 3 – 218 acres (2.3%) permanent loss and 177 acres of temporary loss of suitable habitat, including
  - 35 acres (1.8%) of permanent loss and 45 acres of temporary loss of nesting habitat
  - 183 acres (2.4%) of permanent loss and 132 acres of temporary loss of foraging habitat;
- Alternative 4 – 209 acres (2.2%) permanent loss and 180 acres of temporary loss of suitable habitat, including
  - 35 acres (1.8%) of permanent loss and 43 acres of temporary loss of nesting habitat
  - 174 acres (2.3%) of permanent loss and 137 acres of temporary loss of foraging habitat;
- Alternative 5 – 257 acres (2.7%) permanent loss and 172 acres of temporary loss of suitable habitat, including
  - 44 acres (2.3%) of permanent loss and 48 acres of temporary loss of nesting habitat

  - 213 acres (2.8%) of permanent loss and 124 acres of temporary loss of foraging habitat;
- Alternative 6 – 246 acres (2.6%) permanent loss and 177 acres of temporary loss of suitable habitat, including
  - 36 acres (1.9%) of permanent loss and 44 acres of temporary loss of nesting habitat
  - 210 acres (2.7%) of permanent loss and 133 acres of temporary loss of foraging habitat; and
- Alternative 7 – 103 acres (1.1%) permanent loss and 431 acres of temporary loss of suitable habitat, including
  - 14 acres (0.7%) of permanent loss and 37 acres of temporary loss of nesting habitat
  - 89 acres (1.2%) of permanent loss and 394 acres of temporary loss of foraging habitat.

Compared to Alternative 2 for the combined suitable nesting and foraging habitat, which would result in 253 acres (2.6%) of permanent loss and 141 acres of temporary impacts, Alternatives 3 and 4 would have somewhat reduced permanent impacts, Alternative 5 would have marginally increased permanent impacts, Alternative 6 would have marginally reduced permanent impacts, and Alternative 7 would have substantially reduced permanent impacts. For temporary impacts, Alternatives 3 through 6 would have somewhat increased impacts compared to Alternative 2 and Alternative 7 would have substantially increased impacts.

For nesting habitat alone, compared to Alternative 2, which would result in 48 acres (2.5%) of permanent loss and 46 acres of temporary impacts, Alternatives 3 through 6 would have somewhat reduced permanent impacts, and Alternative 7 would have substantially reduced impacts due to the pullback of the Project footprint from the Santa Clara River and its tributaries. For temporary impacts, Alternatives 3 through 6 would not have substantially different impacts and Alternative 7 would have somewhat reduced impacts compared to Alternative 2.

For foraging habitat alone, compared to Alternative 2, which would result in 205 acres (2.7%) of permanent loss and 95 acres of temporary impacts, Alternatives 3 and 4 would have somewhat reduced permanent impacts, Alternatives 5 and 6 would have marginally increased permanent impacts, and Alternative 7 would have substantially reduced permanent impacts. Compared to Alternative 2 for temporary impacts to foraging habitat, Alternatives 3 through 6 would have somewhat increased impacts compared to Alternative 2, and Alternative 7 would have substantially increased impacts.

The overall permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be similar in magnitude compared to Alternative 2. Although a relatively small percentage of habitat would be permanently lost, nesting habitat for an uncommon special-status species would be lost under all of the alternatives. Absent mitigation, this impact would be considered a substantial adverse effect on the habitat of this species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would potentially reduce the number or restrict the range of the species. The direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for white-tailed kite (**Figures 4.5-80** through **4.5-84**, Alternatives 3 through 7 Impacts to White-Tailed Kite Foraging and Nesting Habitat):

- Alternative 3 – 3,280 acres (34.1%) permanent loss of suitable habitat, including
  - 73 acres (3.8%) of permanent loss of nesting habitat
  - 3,207 acres (41.6%) of permanent loss of foraging habitat;
- Alternative 4 – 3,157 acres (32.8%) permanent loss of suitable habitat, including
  - 68 acres (3.5%) of permanent loss of nesting habitat
  - 3,089 acres (40.1%) of permanent loss of foraging habitat;
- Alternative 5 – 3,083 acres (32.1%) permanent loss of suitable habitat, including
  - 69 acres (3.6%) of permanent loss of nesting habitat
  - 3,014 acres (39.1%) of permanent loss of foraging habitat;
- Alternative 6 – 2,734 acres (28.4%) permanent loss of suitable habitat, including
  - 42 acres (2.2%) of permanent loss of nesting habitat
  - 2,692 acres (35.0%) of permanent loss of foraging habitat; and
- Alternative 7 – 2,363 acres (24.6%) permanent loss of suitable habitat, including
  - 45 acres (2.4%) of permanent loss of nesting habitat
  - 2,318 acres (30.1%) of permanent loss of foraging habitat.

Compared to Alternative 2 for combined suitable nesting and foraging habitat, which would result in 3,453 acres (35.9%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. This general pattern is similar for permanent impacts to nesting habitat. Compared to Alternative 2, which would result in 93 acres (4.9%) of permanent loss of nesting habitat, Alternatives 3 through 7 would have reduced impacts. Similarly, compared to Alternative 2 for foraging habitat, which would result in 3,360 acres (43.6%) of permanent loss, Alternatives 3 through 6 would have reduced impacts. Overall for suitable habitat, Alternatives 4 through 7 would have fewer impacts than Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, and each would have successively fewer impacts due to other differences in the Project footprints. Alternative 7 would have the least amount of impact due to pullbacks from the Santa Clara River and its tributaries.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, all would result in impacts to nesting habitat and substantial impacts to foraging habitat. Absent mitigation, these impacts would have a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would potentially reduce the number or restrict the range of the species. Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for white-tailed kite:

- Alternative 3 – 3,498 acres (36.4%) permanent loss of suitable habitat, including
  - 108 acres (5.6%) of permanent loss of nesting habitat
  - 3,390 acres (44.0%) of permanent loss of foraging habitat;
- Alternative 4 – 3,366 acres (35.0%) permanent loss of suitable habitat, including
  - 103 acres (5.3%) of permanent loss of nesting habitat
  - 3,263 acres (42.4%) of permanent loss of foraging habitat;

- Alternative 5 – 3,340 acres (34.7%) permanent loss of suitable habitat, including
  - 113 acres (5.8%) of permanent loss of nesting habitat
  - 3,227 acres (41.9%) of permanent loss of foraging habitat;
- Alternative 6 – 2,980 acres (31.0%) permanent loss of suitable habitat, including
  - 78 acres (4.1%) of permanent loss of nesting habitat
  - 2,902 acres (37.7%) of permanent loss of foraging habitat; and
- Alternative 7 – 2,466 acres (25.6%) permanent loss of suitable habitat, including
  - 59 acres (3.1%) of permanent loss of nesting habitat
  - 2,407 acres (31.3%) of permanent loss of foraging habitat.

Compared to Alternative 2 for suitable nesting and foraging habitat, which would result in 3,706 acres (38.5%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. This general pattern is similar for permanent impacts to nesting habitat. Compared to Alternative 2, which would result in 141 acres (7.4%) of permanent loss of nesting habitat, Alternatives 3 through 7 would have reduced impacts. Compared to Alternative 2 for the combined direct and indirect permanent loss of foraging habitat, which would result in 3,565 acres (46.3%) of permanent loss, Alternatives 3 through 6 would have reduced impacts. Overall for suitable habitat, Alternatives 4 through 7 would have fewer combined impacts than Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, and each would have successively fewer impacts due to other differences in the Project footprints. Alternative 7 would have the least amount of impact due to pullbacks from the Santa Clara River and its tributaries and other differences in the Project footprint.

Although Alternatives 3 through 7 would have reduced combined direct and indirect permanent impacts compared to Alternative 2, all would result in impacts to nesting habitat and substantial impacts to foraging habitat. Absent mitigation, these combined direct and indirect permanent impacts would have a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would potentially reduce the number or restrict the range of the species. Combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to white-tailed kite individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Suitable nesting and foraging habitat is present on site and, absent mitigation, construction/grading activities could result in disruption of foraging activities and destruction of nests and eggs and/or injury or mortality of young where white-tailed kites are nesting. Impacts to white-tailed kite individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative would have similar construction activities and long-term effects.

Short-term effects include construction-related noise, ground vibration, lighting, and disturbance from human activity that could disrupt foraging behavior and natal care and cause nest abandonment. Urban development could result in long-term secondary impacts, such as increased human activity; noise; nighttime lighting; harassment by pet, stray, and feral cats and dogs; secondary poisoning and loss of prey from use of pesticides; and increased incidence of collisions with vehicles and manmade structures.

These short-term and long-term secondary impacts therefore may interfere with the movement of this species on site, impede the use of nursery sites, or substantially reduce the number of this species, absent mitigation. Short-term and long-term secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to the white-tailed kite: (1) impacts to individuals; (2) loss of suitable foraging and nesting habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Nesting and foraging by this species has been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. For example, nest sites have been documented in close proximity to the proposed Potrero Canyon and Long Canyon bridges.

While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, individuals could be displaced from suitable foraging habitat by construction activities. Impacts to individuals also could occur if vegetation clearing and construction/grading activities occur during the breeding season, potentially resulting in the destruction of the nests and loss of eggs and/or young. Construction activities may also alter foraging behavior, reducing the health and survivorship of young, or cause abandonment of nests due to human activity, noise, and ground vibration. Lighting could alter nesting behavior, induce physiological stress, or increase predation risk by nocturnal mesopredators. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 500 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable nesting and foraging habitat for the white-tailed kite resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,466 acres (25.6%) under Alternative 7 to 3,706 acres (38.5%) under Alternative 2. This would be a substantial loss of suitable habitat for this species and will alter its use of the Project area for foraging, and potentially nesting. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a permanent open space system that will provide suitable habitat to support both foraging and breeding by the white-tailed kite in the Project vicinity. In order to provide additional nesting, roosting, and foraging habitat for white-tailed kite, oak woodland restoration will be implemented. This restoration will provide better understory habitat than currently exists for rodent prey in areas that are currently grazed by cattle. Implementation of these mitigation measures will result in protection and management of at least 4,421 acres of the suitable habitat for this species, including 1,546 acres of nesting habitat and 2,875 acres of foraging habitat (*i.e.,* foraging habitat within 0.5 mile of suitable nesting habitat) in the River Corridor SMA, High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With regard to secondary effects, foraging and nesting activities by the white-tailed kite could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may cause adults to vacate foraging areas and abandon nests due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to predators and exposure. These short-term construction-related secondary impacts will be minimized by conducting pre-construction surveys within 500 feet of disturbance zones and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include increased noise; lighting; increased human activity; pesticides, which may cause direct and secondary poisoning and loss of prey; predation and harassment by pet, stray, and feral cats and dogs and other mesopredators; and increased collisions with vehicles and man-made structures. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and

management of 4,421 acres of suitable nesting and foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area will provide white-tailed kites with relatively undisturbed habitat for foraging and nesting. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by predators and reduce behavioral disturbances and physiological stress. Limited recreational usage and access restrictions within the High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect white-tailed kites by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of direct and secondary poisoning, and loss of prey. Provision of a large, relatively undisturbed open space system providing nesting and foraging habitat away from development areas will also help mitigate for increased collisions with vehicles and man-made structures.

The specific mitigation measures for the white-tailed kite are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-15 IMPACTS TO INDIVIDUALS – WHITE-TAILED KITE

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of white-tailed kite individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to white-tailed kite individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading

plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to white-tailed kite individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-16 LOSS OF HABITAT – WHITE-TAILED KITE

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for white-tailed kite through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The River Corridor SMA will preserve and enhance at least 383 acres of suitable habitat for white-tailed kite, including 293 acres of nesting habitat and 90 acres of foraging habitat**.** The High Country SMA will preserve and enhance 2,719 acres of suitable habitat for white-tailed kite, including 871 acres of nesting habitat and 1,848 acres of foraging habitat.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and that oak tree replacement occur as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA, including the following: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for white-tailed kite through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. The Salt Creek area supports 1,319 acres of suitable habitat for the white-tailed kite, including 382 acres of nesting habitat and 937 acres of foraging habitat.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-22 states that the Oak Resources Management Plan shall incorporate the findings of the Draft Newhall Ranch Mitigation Feasibility Report (Dudek 2007A) and areas identified as being suitable for oak woodland enhancement and creation shall be used for mitigation.

BIO-42 requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities (County of Los Angeles 1988). Fencing shall extend to the root protection zone.

BIO-55 requires that maps of suitable riparian habitat be updated for special-status avian species, and the creation or enhancement of habitat shall be similar to the habitat removed.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the white-tailed kite would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-17 SECONDARY IMPACTS – WHITE-TAILED KITE

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on white-tailed kite associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as increased human activity and nighttime lighting. Mitigation measures to minimize inadvertent impacts to habitat outside construction zones will also be implemented.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and which generally refer to habitat

protection, restoration and enhancement, and management, will be implemented to mitigate for the effects of increased human activity. This open space area will also help mitigate for increased incidence of collisions with vehicles and man-made buildings by providing a large undisturbed area to support nesting and foraging.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These mitigation measures require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along the open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to white-tailed kite, including short-term construction-related dust, noise, ground vibration, and increased human activity, as well as long-term effects such as increased human activity; harassment by pet, stray, and feral cats and dogs; secondary poisoning and loss of prey due to the use of pesticides; and increased incidence of collisions with vehicles and man-made structures.

BIO-52 and BIO-56, as described above, will mitigate the effects of construction noise and increased human activity by identifying nest sites and providing for buffers between nests and construction activities.

BIO-1 through BIO-16 and BIO-19 through BIO-22, as described above, will mitigate for increased human activity in the Project area through habitat protection, restoration and enhancement, and management.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to reduce impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to reduce the chance of poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to white-tailed kite would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

INTENTIONALLY LEFT BLANK

LEAST BELL'S VIREO (NESTING) (FE, CE)

Life History

The least Bell's vireo (*Vireo bellii pusillus*) is one of four subspecies of the Bell's vireo; its breeding range includes coastal and inland southern California (including the western edge of southern California's southern deserts), a small area within California's Central Valley, and extreme northern Baja California, Mexico. Although the winter range of full species Bell's vireo is not well known, it generally appears to winter from southern Baja and southern Sonora south along the west coast of Mexico and Central America to Honduras and casually to northern Nicaragua. It is also reported from the eastern coast of Central America from Veracruz south to Honduras (County of Riverside 2008). The subspecies least Bell's vireo does not winter in the Project area.

The least Bell's vireo formerly was a common and widespread summer resident below approximately 600 meters (2,000 feet) AMSL elevation in the western Sierra Nevada, throughout the Sacramento and San Joaquin valleys, and in the coastal valleys and foothills from Santa Clara County south (Zeiner *et al.* 1990A). Least Bell's vireo also was common in coastal southern California from Santa Barbara County south, east of the Sierra Nevada below approximately 1,200 meters (4,000 feet) AMSL, in the Owens and Benton valleys, along the Mojave River and other streams at the western edge of southeastern deserts, and along the entire length of the Colorado River (Grinnell and Miller 1944).

The USFWS (2006) conducted a five-year status review of the least Bell's vireo that compiled comprehensive survey data for five-year increments from 1977 to 2005.[1] As shown in **Table 4.5-55**, the least Bell's vireo breeding population in the United States has increased about tenfold since its federal listing as endangered in 1986, from approximately 291 to approximately 2,968 known territories (51 FR 16474–16482; USFWS 2006). The breeding population has grown during each five-year period since the original federal listing, although the rate of increase has slowed over the last 10 years. Population growth in terms of percentages and numbers has been greatest in San Diego and Riverside counties, with lesser but still significant increases in Orange, Ventura, San Bernardino, and Los Angeles counties (USFWS 2006). Only Santa Barbara County appears to have experienced a significant decline in territories, dropping from a high of 57 territories in 1986–1990 to only 12 in the 1996–2000 and 2001–2005 time periods. The Santa Clara River supports 90% or more of the Ventura County population, which has increased from five to 117 territories during the period of study.

[1] These data represent a minimum estimate of least Bell's vireo territories because they are a composite of multiple surveys covering different reaches and may exclude large stretches of suitable habitat that were not surveyed (USFWS 2006); in other words, these data do not represent a single snapshot of the entire occupied vireo range.

Table 4.5-55
Estimate of Least Bell's Vireo Territories by County[1]

Estimate of Least Bell's Vireo Territories (and Percentage of the Total Population) for a Given Range of Years[2]					
County	**1977–1985[3]**	**1986–1990**	**1991–1995**	**1996–2000**	**2001–2005**

[1] Reproduced from USFWS (2006).
[2] Estimates based on composite of surveys across the specified range of years.
[3] From the original listing (51 FR 16474).
[4] Approximately 50% or greater from Camp Pendleton.
[5] Approximately 90% or greater from the Santa Ana River and its tributaries.
[6] Approximately 90% or greater from the Santa Clara River.
[7] Approximately 90% or greater from the Santa Ynez River.

The USFWS published a Draft Recovery Plan for the least Bell's vireo in 1998 (USFWS 1998B). **Table 4.5-56** shows the distribution of least Bell's vireo territories among the 11 population units identified in the Draft Recovery Plan and the population trend since the original federal listing in 1986 and for the 2001 to 2005 time period versus the 1996 to 2000 time period. The two largest concentrations of least Bell's vireo territories are in the Santa Ana River (including Prado Basin) and on Camp Pendleton/Santa Margarita River. San Diego County, including Camp Pendleton, has the greatest total number of confirmed territories, with the largest concentrations in the Santa Margarita River, San Luis Rey River, Tijuana River, and Anza-Borrego Desert State Park. The Santa Clara River in Los Angeles and Ventura counties also supports a large concentration of territories, with 119 territories in 2001.

Table 4.5-56
Most Recent Comprehensive Estimates of Least Bell's Vireos at 11 Population Units[1,2]

Location	County	Year[3]	Vireo Territories[4]	Population Trend[5]
Tijuana River	San Diego	2004–2005	150	+/–
Dulzura Creek/Jamul Creek/Otay River[6]	San Diego	2001–2005	36	+/I
Sweetwater River	San Diego	2001	103	+/+

[1] Reproduced from USFWS (2006).
[2] As designated in the Draft Recovery Plan (USFWS 1998B).
[3] Year(s) of most recent extensive surveys. Composite of surveys across multiple years were used where within-year surveys were not considered adequately comprehensive.
[4] Minimum estimate; generally a composite of multiple survey efforts covering different reaches; may exclude large stretches of non-surveyed habitat. All estimates are based on survey reports submitted to the USFWS Carlsbad Field Office or values obtained from the U.S. Geological Survey (USGS) database (USGS 2006).
[5] Overall trend since original listing/trend comparing 1996–2000 to 2001–2005. "+" = Increasing, "–" = Declining, "I" = Inadequate data to evaluate.
[6] Primarily derived from Otay River surveys. No comprehensive surveys of Dulzura and Jamul creeks since 1996 were available.
[7] Mainstem only; excludes Pilgrim Creek.
[8] Includes all willow riparian habitat on Marine Corps Base (MCB) Camp Pendleton; excludes portions of Santa Margarita River off of MCB Camp Pendleton.
[9] Mainstem and Prado Basin study area only; excludes San Timoteo Creek, Temescal Wash, and other tributaries.
[10] Excluding Santa Ana River and Santa Clara River mainstems.

Least Bell's vireos primarily occupy riverine riparian habitats along water, including dry portions of intermittent streams that typically provide dense cover within one to two meters (3.3 to 6.6 feet) of the ground, often adjacent to a complex, stratified canopy. Least Bell's vireo nesting habitats in cismontane and coastal areas include southern willow scrub, mulefat scrub, arroyo willow riparian forest edge, wild blackberry thickets, and, more rarely, cottonwood forest, sycamore alluvial woodland, and southern coast live oak riparian forest. Along riparian corridors at desert locations, young willows are favored and, where absent, mesquite (*Prosopsis* spp.) and desert apricot (*Prunus fremontii*) are typically used. In interior regions, least Bell's vireo habitat is usually limited to the immediate vicinity of watercourses below approximately

457 meters (1,500 feet) AMSL (51 FR 16474–16482; Small 1994). In the coastal portions of its southern California range, the least Bell's vireo occurs in lower portions of canyons, typically below 600 meters (2,000 feet) AMSL.

Least Bell's vireos generally begin to arrive from their wintering range in southern Baja California, and possibly mainland Mexico, to establish breeding territories by mid- to late March (Garrett and Dunn 1981; Salata 1983A, 1983B; Hays 1989; Pike and Hays 1992). Nests are typically built within approximately 1 meter (3.3 feet) of the ground in the forks of willows, wild rose, mulefat, or other understory vegetation (Franzreb 1989). Cover surrounding nests is moderately open mid-story with an overstory of willow, cottonwood, sycamore, or oak. Crown cover is usually more than 50% and contains occasional small openings. The most critical structural component to least Bell's vireo breeding habitat is a dense shrub layer at 0.6 to 3 meters (2 to 10 feet) above the ground (Goldwasser 1981; Franzreb 1989). Breeding territories, which are maintained by males and include threats and physical confrontations, range on average from 1 to 3 acres (USFWS 1998B).

Clutch sizes of the least Bell's vireo are between two to five eggs (typically three or four) that are laid shortly after nest construction (Salata 1984; Kus 1994; USFWS 1998B). Incubation is about 14 days, and young fledge about 12 to 14 days after hatching (Zeiner *et al.* 1990A). Fledglings may wander from established breeding territories but remain under parental care for several more weeks (USFWS 1998B). Least Bell's vireos usually produce only one brood per season but attempts of up to four or five additional broods have also been reported (Franzreb 1989; USFWS 1998B).

A large majority of the breeding least Bell's vireos typically depart their breeding grounds by the third week of September, and only a few least Bell's vireos are found wintering in California or the United States as a whole (Barlow 1962; Nolan 1960; Erlich *et al.* 1988; Garrett and Dunn 1981; Salata 1983A, 1983B; Pike and Hays 1992).

During the spring and fall migrations, the Bell's vireo occupies a wider range of habitats, including coastal scrub, riparian, and woodland habitats. The winter range of habitats of the Bell's vireo includes thornscrub vegetation adjacent to watercourses or in riparian gallery forests along the west coast of northern and central Mexico. In southern Mexico and Honduras, tropical deciduous forest and arid tropical scrub along the coast is used as habitat (County of Riverside 2008).

Bell's vireos are known to feed primarily on insects and spiders (Chapin 1925; Bent 1950; Terres 1980). The least Bell's vireo primarily forages in riparian strands of young (*i.e.*, early succession) willows and willow scrub associations of similar structure (*e.g.*, southern willow scrub, mulefat scrub, arrow weed scrub) and may forage in upland vegetation that is adjacent to the riparian vegetation, including chaparral, sage scrub, and oak woodlands later in the breeding season (Gray and Greaves 1984; Salata 1983B; Kus and Miner 1989). Least Bell's vireos forage

in a variety of tree and shrub species and have a preference for black willow, arroyo willow, and mulefat. Individuals are known to travel between three and 61 meters (10 and 200 feet), with a mean travel distance of approximately 15.5 meters (50.8 feet) while foraging, with the majority of these destinations occurring within 30 meters (98 feet) of the edge of riparian vegetation (Kus and Miner 1989). Least Bell's vireo are known to forage in all vertical vegetation layers from ground level to 20 meters (66 feet), but most feeding is concentrated above the ground surface in the lower vegetation layers from ground level to six meters (20 feet) (Kus and Miner 1989; Salata 1983B).

Critical Habitat

The USFWS made a final critical habitat designation for the least Bell's vireo on February 2, 1994 (59 FR 4845). The USFWS vireo critical habitat designation covers approximately 38,000 acres at 10 different locations in six counties in southern California: Santa Barbara, Ventura, Los Angeles, San Bernardino, Riverside, and San Diego.

Newhall Land property includes a portion of the Santa Clara River critical habitat unit located in Ventura and Los Angeles counties (**Figure 4.5-85**, Least Bell's Vireo Critical Habitat in Santa Clara River Critical Habitat Unit). The Santa Clara River unit includes all land within a 3,500-foot-wide zone along the Santa Clara River south of State Route 126 (SR-126) from a point approximately 2.3 miles east of the intersection of Main Street and SR-126 in Piru on the west to the intersection of SR-126 and The Old Road and eastward and southward along The Old Road to its intersection with Rye Canyon Road.

The Santa Clara River critical habitat unit comprises approximately 4,410 acres (approximately 12%) of the total 38,000 acres of least Bell's vireo critical habitat. The Newhall Land portion of the critical habitat unit comprises approximately 4,213 acres: about 95% of the Santa Clara River critical habitat unit and 11% of the total least Bell's vireo critical habitat. Of this, the RMDP Project area within least Bell's vireo critical habitat totals 2,252 acres (**Figure 4.5-85**).

The USFWS described the primary constituent elements for least Bell's vireo critical habitat as follows (59 FR 4846):

> [Biological features that] support feeding, nesting, roosting and sheltering are essential to the conservation of the least Bell's vireo. These habitat features can be described as riparian woodland vegetation that generally contains both canopy and shrub layers, and includes some associated upland habitats. Vireos meet their survival and reproductive needs (food, cover, nest sites, nestling and fledgling protection) within the riparian zone in most areas. In some areas they also forage in adjacent upland habitats.

Because primary constituent elements may be distributed unevenly throughout a given landscape, critical habitat designations often include areas that have no primary constituent elements for the relevant species. As the USFWS acknowledges, critical habitat designations often use "existing, readily recognizable boundaries" to outline critical habitat areas, and this approach may result in the inclusion of lands that do not contain the primary constituent elements (59 FR 4850). In the case of the least Bell's vireo, the designation specifically states (59 FR 4850):

> In cases where areas designated as critical habitat do not contain the primary constituent elements, impacts occurring within this area will not result in a finding of adverse modification by the [USFWS]. Thus, designation of critical habitat will not affect those areas within the legal critical habitat boundaries that do not contain vireo nesting or foraging habitat.

For the purpose of this analysis, primary constituent elements are defined as southern willow scrub, southern cottonwood–willow riparian, arrow weed scrub, mule fat scrub, and Mexican elderberry scrub and woodland that provide the nesting/foraging habitat for the least Bell's vireo, and native shrub habitats (big sagebrush scrub, alluvial scrub, California sagebrush scrub, chaparral, and coyote brush scrub) and woodland habitats (coast live oak, valley oak) within 100 feet of the edge of nesting habitat that also may be used for foraging late in the breeding season. The 100-foot zone is based on the Kus and Miner (1989) study showing that most least Bell's vireo upland foraging occurs within 98 feet of the edge of riparian vegetation, with a mean distance of approximately 51 feet.

Recovery Plan

A Draft Recovery Plan for the Least Bell's Vireo (*Vireo bellii pusillus*) was published by the USFWS in 1998 (USFWS 1998B). The recovery strategy focuses on two major causes of decline of the species: (1) habitat loss and degradation and (2) brown-headed cowbird parasitism. The Draft Recovery Plan identified 14 vireo "population/metapopulation units," including the Santa Clara River population unit. The Draft Recovery Plan does not identify the geographic limits of the Santa Clara population unit, simply stating that "habitat for the [vireo] occurs in patches along much of the river, with location and quality varying from year to year as conditions in the river change following winter storm events" (USFWS 1998B, p. 58).

The Draft Recovery Plan identified the following recovery actions within the population units:

- Protect and manage riparian and adjacent upland habitats within the vireo's historical range.
- Develop management plans for the 14 population/metapopulation units that address major threats and habitat preservation. The Draft Recovery Plan (USFWS 1998B)

identifies the primary threats to native habitats in the Santa Clara River as engineered flood control facilities to protect both urban and agricultural land uses (*e.g.*, bank stabilization), pressures to provide sand and gravel, and the spread of giant reed.

- Conduct annual monitoring according to an established vireo monitoring protocol.
- Continue cowbird removal, control non-native plant species within vireo habitat areas, and establish endowments to fund these activities.
- Develop and evaluate vireo habitat restoration techniques.

Threats

The least Bell's vireo populations have declined in large part due to loss of suitable riparian habitat, degradation of suitable habitat, and nest parasitism by brown-headed cowbirds (USFWS 1998B). Clearing of suitable habitat for urban development, agriculture uses, water projects, fires, off-road vehicles, livestock, flooding from dam releases, and non-native plant species have contributed to the loss and degradation of habitat (CDFG 2000). Noise is also a potential threat to nesting least Bell's vireo. Hein (1997) identified the 60 dBA noise threshold for impacts on the least Bell's vireo based on the theory of masking. At a distance of 100 meters (328 feet), which is the diameter of a 0.8-hectare (1.98-acre) territory, approximately 50% of the least Bell's vireo's song would be masked with a background noise level of 60 dBA equivalent noise level. This level of masking was considered to have potential adverse effects on the behavioral activity, including reproduction, of the least Bell's vireo (Hein 1997). However, it should be noted that the noise threshold established by Hein (1997) for the least Bell's vireo is theoretical and that empirical studies have shown that noise impacts on avian species vary among species and depend on source, duration, and schedule, as well as different kinds of compensatory responses by different species, such as singing more loudly or at different frequencies (*e.g.*, Hirvonen 2001; Reijnen *et al.* 1996; Slabbekoorn and Peet 2003; Wood and Yezerinac 2006). Other potential urban-related threats to least Bell's vireo include dust and ground vibration during construction activities; increased human activity in proximity to nesting areas; lighting, which may induce physiological stress and increase predation risk; predation and harassment by pet, stray, and feral cats and dogs and other mesopredators; pesticides, which may reduce insect prey or cause secondary poisoning; and Argentine ants, which are especially attracted to riparian areas and may prey on nestlings.

Survey Results

Annual survey data have been collected for the least Bell's vireo in the Project vicinity between 1988 and 2007, including the Specific Plan and VCC planning areas and a portion of the Entrada planning area, as well as adjacent areas of Newhall Land property from the Las Brisas Bridge crossing on the west in Ventura County to I-5 on the east. These surveys primarily were conducted by Guthrie from 1988 through 2006, by Labinger *et al.* in various years, and by

Bloom Biological, Inc. in 2007 (Guthrie 1993B, 1995B, 1996B, 1997B, 1998A, 1999B, 2000C, 2001B, 2002C, 2003B, 2004H, 2005B, 2006A; Labinger *et al.* 1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A; Bloom Biological 2007A), in the VCC planning area (Guthrie 1994A, 1995A, 1996A, 2003A, 2006C), and off site in Castaic Junction (Guthrie 1988, 1990, 1991A, 1996A, 1997A, 1998B, 2000E, 2001A, 2002A, 2003A, 2004F, 2004I, 2005A, 2006C; Bloom Biological 2007A).

The least Bell's vireo, including breeding pairs, territorial males, and/or nests, has been observed almost every year along the Santa Clara River within the Specific Plan area, and over multiple years within the VCC planning area and adjacent to the Project site in Castaic Junction in riparian scrub habitat (**Figure 4.5-85**), but with yearly fluctuations in level of occupancy and breeding activity. Despite these yearly fluctuations, there are four definable "local key population" segments within the Santa Clara River that have consistently supported clusters of least Bell's vireo over the several years of riparian bird surveys: (1) a segment extending approximately 2.7 miles west of the RMDP/SCP boundary in Ventura County; (2) a segment extending from about Potrero Mesa to the confluence with Chiquito Canyon; (3) a segment extending from the Indian Dunes area to the confluence with Humble Canyon; and (4) a segment extending from about Airport Mesa to I-5 (**Figure 4.5-85**). There are scattered vireo occurrences interspersed between these local key population areas, but without a consistent clustering of occurrences.

As described above in the critical habitat discussion, this analysis addresses primary constituent elements of vireo habitat. Nesting/foraging habitat that is used throughout the least Bell's vireo breeding season primarily is southern willow scrub and southern cottonwood–willow riparian. Other riparian habitats on site that are potential nesting habitat are arrow weed scrub, mulefat scrub, and Mexican elderberry scrub and woodland. Shrub and woodland habitats within 100 feet of the edge of these nesting/foraging habitats that may be used for foraging late in the breeding season are big sagebrush scrub, alluvial scrub, California sagebrush scrubs, chaparral, coyote brush scrub, coast live oak, and valley oak.

A total of 678 acres of suitable habitat is present in the Project area, including 548 acres of suitable nesting/foraging habitat and 130 acres of shrub and woodland foraging habitat adjacent to nesting habitat (*i.e.*, within 100 feet).

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use

practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 66 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 9.7% of this habitat on site (**Figure 4.5-86**, Alternative 2 Impacts to Least Bell's Vireo Habitat). Of these impacts, 59 acres are nesting/foraging habitat, representing 10.7% of this habitat on site. The remaining 6.9 acres of impact are adjacent foraging habitat only, representing 5.3% of this habitat on site. A total of 56 acres of suitable habitat would be temporarily impacted, including 55 acres of nesting/foraging habitat and 1.4 acres of foraging habitat only.

A breeding population of the least Bell's vireo consistently uses the Project area. As described above, there are four identified local key population areas in the surveyed areas of the River corridor within and adjacent to the Project area. Two of these areas fall within the RMDP and Specific Plan boundaries: the segment extending from about Potrero Mesa to the confluence with Chiquito Canyon; and the segment extending from the Indian Dunes area to the confluence with Humble Canyon. Both permanent loss and temporary impacts to nesting/foraging habitat and adjacent foraging habitat would affect the size and distribution of the least Bell's vireo breeding population both spatially and temporally in the Santa Clara River and potentially in tributaries to the River that contain suitable habitat for this species. Bank stabilization, in particular, adjacent to the two key population areas would have temporary impacts on nesting/foraging habitat for the least Bell's vireo, potentially displacing them from a portion of these areas until habitat recovered to a level suitable for nesting (**Figure 4.5-86**, Alternative 2 Impacts to Least Bell's Vireo Habitat). These permanent and temporary impacts, therefore, would have a substantial adverse effect on the species and its habitat, substantially interfere with its movement and breeding activity, and reduce its range (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 45 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 6.6% of this habitat on site (**Figure 4.5-86**, Alternative 2 Impacts to Least Bell's Vireo Habitat). Of these impacts, 24 acres are nesting/foraging habitat, representing 4.4% of this habitat on site. Of this

nesting/foraging habitat, 17 acres are mulefat scrub, arrow weed scrub, and Mexican elderberry scrub and the remaining 6.8 acres are southern cottonwood–willow riparian forest and southern willow scrub. Because indirect impacts to suitable habitat are generally outside of the River corridor, most of these impacts are within smaller drainages that are less suitable for vireo nesting. The remaining 21 acres of impact are adjacent foraging habitat only, representing 15.9% of this habitat on site.

Although most of this indirect permanent loss of nesting/foraging habitat would occur in smaller drainages and not in the main habitat area for the least Bell's vireo in the River corridor, the loss of this nesting/foraging habitat and adjacent foraging habitat could affect the size and distribution of the least Bell's vireo breeding population in the Project area, particularly as the population continues to expand its breeding distribution in southern California. This permanent impact therefore would have a substantial adverse effect on the species and its habitat, substantially interfere with its movement and breeding activity, and reduce its range (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 111 acres (16.3%). Of these impacts, 83 acres are nesting/foraging habitat, representing 15.1% of this habitat on site. The remaining 28 acres of impact are adjacent foraging habitat only, representing 21.2% of this habitat on site.

This combined permanent loss of nesting/foraging habitat and adjacent foraging habitat would affect the size and distribution of the least Bell's vireo breeding population in the Santa Clara River and potentially in tributaries to the River that contain suitable habitat for this species. This combined permanent impact therefore would have a substantial adverse effect on the species and its habitat, substantially interfere with its movement and breeding activity, and reduce its range (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Least Bell's vireo is a relatively mobile species, so it is unlikely that Project-related construction activities would result in the loss of individual adult least Bell's vireos. However, implementation of the RMDP could result in injury or mortality of least Bell's

vireos due to destruction of nests and loss of young if such construction/grading activities occurred during the nesting season. In addition, construction activities could alter the least Bell's vireo's foraging behavior, potentially affecting provisioning of young and reducing their survivorship, and thus reducing reproductive success. Implementation of the SCP would not directly impact this species. Construction/grading activities such as vegetation clearing occurring during the nesting season could result in destruction of nests and the resulting loss of eggs and/or young or alteration of foraging behavior (significance criteria 1 and 4). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. Because the species has potential to nest on site in habitat that would be directly affected, build-out of the Specific Plan, VCC, and Entrada planning areas could result in loss of young or eggs of this species as a result of destruction of nests (from any construction/grading activities that occur during the nesting season) or alteration of foraging behavior. Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

If construction occurs during the least Bell's vireo nesting season (typically March through August), breeding individuals are likely to be substantially affected by several construction-related secondary effects**,** including noise, ground vibration, increased human activity, and nighttime illumination. These effects could alter essential behaviors such as foraging and breeding, induce physiological stress, and increase predation rates. For example, construction noise may mask singing used for territory advertisement, thus affecting breeding activity. It may also affect the ability of vireo to detect predators. Lighting may both increase stress by disrupting normal rest periods and increase predation by nocturnal predators. An addition, fugitive dust and diminished water quality and altered hydrology (*e.g.*, runoff, erosion, sedimentation) could reduce habitat quality, including insect prey.

Potential long-term secondary impacts include chronic traffic noise (which would have similar effects as construction noise); nest parasitism by cowbirds; nighttime illumination; pesticide use resulting in loss of prey and/or secondary poisoning; increased human activity; harassment and predation by pet, stray, and feral cats and dogs; and increased predation by mesopredators. Habitat quality for the least Bell's vireo could be reduced by diminished water quality and invasion by exotic plant species, such as giant reed and tamarisk, and Argentine ants, which are attracted to riparian areas and may prey on nestlings. All of these impacts could result in lower reproductive success of the least Bell's vireo in the Project area.

Noise is considered to be potential significant threat to least Bell's vireo because of its masking effect (Hein 1997), and other potential effects on behavior such as foraging and prey detection, as described in **Subsection 4.5.5.1.3**, Secondary Impacts. Vehicular traffic will be the major chronic source of noise in the Project area following implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas. There is, however, circumstantial evidence that vireo breed in habitat adjacent to existing two high traffic volume roadways (SR-126 and I-5) in the Project area. A Dudek (2007B) traffic noise study indicated that least Bell's vireos consistently have established breeding territories in close proximity to SR-126 in areas where noise levels somewhat exceed 60 dBA (*i.e.*, 61 to 73 dBA Leq_{hr}), including three of the four key population areas shown in **Figure 4.5-68**: the segment in Ventura County west of the RMDP/SCP boundary; the segment between Potrero Mesa and Chiquito Canyon, and the segment between Airport Mesa and I-5. For example, a monitoring location in the key population area in Ventura County 120 feet from the centerline of SR-126 yielded hourly Leqs (sound energy averages) ranging from 57 dBA at 12:00 and 1:00 a.m. to 66 dBA at 6:00 a.m. The average noise level over a 24-hour period was 61 dBA, slightly above the 60 dBA threshold for adverse effects to the vireo. Sound levels at the key population area between Potrero Mesa and Chiquito Canyon were monitored at three locations that were 430 feet, 630 feet, and 1,650 feet, respectively, from the centerline of SR-126. The average noise levels over 24 hours were 54 dBA at 430 feet (range of 51 to 58 dBA), 55 dBA at 630 feet (range of 52 to 62 dBA), and 51 dBA at 1,650 feet (range of 46 to 58 dBA).

Although these data indicate that vireos occupy habitat where noise levels may exceed 60 dBA, there are no data for actual nest locations, and nests were not monitored to measure reproductive success. For the purpose of this analysis, it is assumed that chronic exposure to noise levels above 60 dBA are a substantially adverse effect on the least Bell's vireo. It is also assumed that potential nesting/foraging habitat within the 60 dBA contour line from a roadway will be degraded and less likely to be used by vireo even though other constituent habitat elements to support breeding and foraging are present.

The main areas of concern for traffic noise are along the three bridge crossings of the Santa Clara River (Potrero Canyon Road Bridge, Long Canyon Road Bridge, and Commerce Center Drive Bridge), increased traffic noise along SR-126 adjacent to the Santa Clara River, and a new road that would extend west from Long Canyon Road and run parallel to the south bank of the Santa Clara River between the River corridor and development (**Figure 4.5-87**, Alternative 2 60 dBA Noise Contours in Relation to Least Bell's Vireo). All three bridges cross the River in proximity to areas that have been occupied by the least Bell's vireo in the past, although the nearest documented vireo occurrence is more 500 feet from the Potrero Canyon Road Bridge. However, because suitable nesting/foraging habitat is present where the three bridges would cross the River, it is assumed for this analysis that vireo could nest in the areas in the future. Traffic volumes would increase on SR-126 adjacent to the River corridor between the western boundary of the Project area and the Long Canyon Bridge. The 60 dBA contour would extend from the

existing 260 feet from centerline of SR-126 to 270 feet west of Potrero Canyon Road and from the existing 270 feet from centerline to 310 feet between Potrero Canyon Road and Long Canyon Road (**Figure 4.5-87**, Alternative 2 60 dBA Noise Contours in Relation to Least Bell's Vireo).

Although the Dudek (2007B) study found that vireo establish breeding territories in areas of the Santa Clara River with noise levels somewhat exceeding 60 dBA, for the purpose of this analysis, it is assumed that suitable nesting/foraging habitat (southern willow scrub, southern cottonwood–willow riparian forest, mulefat scrub, arrow weed scrub, and Mexican elderberry scrub and woodland) within the 60 dBA contour on either side of the bridge crossing (from the bridge deck) would be degraded by noise impacts and that vireos may avoid these areas, thus reducing the amount of available suitable nesting/foraging habitat in the River corridor. A total of 2.6 acres of suitable nesting/foraging habitat, including 1.7 acres of southern cottonwood–willow riparian forest, 0.5 acre of mulefat scrub, and 0.4 acre of arrow weed scrub, occur within the 60 dBA contour, which is not otherwise accounted for in temporary impacts discussed above. Assuming that a typical least Bell's vireo territory is 1 to 3 acres (USFWS 1998B) and that vireos would tend to avoid nesting or foraging in areas subject to noise levels exceeding 60 dBA, the degradation of 2.6 acres of nesting/foraging habitat due to noise impacts would be expected to affect one territory in any given year.

As described in **Subsection 4.5.5.1.3**, Secondary Impacts, typical residential settings do not generate chronic or average noise levels above 60 dBA, although point source noise sources such as emergency vehicle sirens, loud motorcycles, and barking dogs will reach levels of 100 dBA for short periods of time. Also, residential noise, such as a dog barking or gas-powered landscape equipment, attenuates rapidly and generally would not exceed 60 dBA at typical distances between development and the River corridor. In most areas there will be at least 200 feet between the edge of development and the riverbed where vireos may be nesting (*i.e.*, a 100-foot transition area between development and top of river bank and the river bank itself). Because these noises tend to be short in duration and most will attenuate to less than 60 dBA before they reach the riverbed, they are not considered to substantially contribute to adverse noise effects.

Altered hydrology and geomorphology in the Santa Clara River corridor as a result of urban development in the watershed, resulting in impacts to habitat for the least Bell's vireo, are also potential long-term secondary effects of the build-out of the Specific Plan, VCC, and Entrada planning areas. However, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County over the long term. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue.

As a result, the mosaic of habitats in the River that support various special-status species would be maintained, and the population of the species within and immediately adjacent to the River corridor would not be significantly affected.

RMDP facilities include a public trail and viewing platforms adjacent to and along the northern edge of the Santa Clara River corridor, as shown in **Figure 4.5-88**, Special-Status Riparian Bird Observations in Relation to Viewing Platforms. The easternmost trail and viewing platform are adjacent to the key population area segment extending from the Indian Dunes area to the confluence with Humble Canyon. There is a potential for secondary impacts to least Bell's vireo individuals nesting in this location. Secondary impacts primarily would include noise and general increases in human activity that could disrupt behavioral activities such as foraging, territory defense, and nesting, or increase physiological stress. In addition, there is a potential for increased trash along the trail that could enter the River corridor. Due to the very close proximity of viewing platforms and trails to riparian habitats, there is the potential for unauthorized trespass by the public in to sensitive habitat areas. Although there would be no lighting provided for evening use of the trail and viewing platforms, public access during night hours may still occur and could introduce fugitive light and noise. These impacts have the potential to affect the health of young, and potentially reduce survivorship and reproductive success.

Short-term and long-term secondary impacts would substantially adversely affect a special-status species, affect its movement and use of nursery sites (*i.e.*, breeding habitat), and substantially reduce its habitat and range (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

Impacts to USFWS Designated Critical Habitat

The Santa Clara River Critical Habitat Unit comprises approximately 4,410 acres (approximately 12%) of the total 38,000 acres of least Bell's vireo critical habitat. The Newhall Land portion of the critical habitat unit comprises approximately 4,213 acres, or about 95% of the Santa Clara River critical habitat unit and 11% of the total least Bell's vireo critical habitat. Of this, the Project area within least Bell's vireo critical habitat totals 2,252 acres (**Figure 4.5-85**).

A total of 443 acres of the 2,252-acre least Bell's vireo critical habitat designation in the Specific Plan portion within the Project area consists of primary constituent elements of vireo critical habitat. Of the 443 acres, 408 acres are southern willow scrub, southern cottonwood–willow riparian forest, mulefat scrub, arrow weed scrub, and Mexican elderberry scrub and woodland, which are breeding/foraging habitats for the least Bell's vireo. The other 35 acres are riparian/wetland and upland shrub habitats (big sagebrush scrub, sagebrush scrubs, chaparral, and coyote brush scrub) and woodlands (coast live oak, valley oak, and Mexican elderberry woodland) within 100 feet of nesting/foraging habitat that may be used for foraging, especially in the later part of the breeding season. The majority of the critical habitat designation in the

Specific Plan area (approximately 1,408 acres) is made up of upland areas, including areas currently used for agriculture, livestock grazing, and oil production that are outside the existing Santa Clara River corridor. There is no critical habitat within the VCC or Entrada planning areas.

Implementation of the RMDP and build-out of the Specific Plan area would result in a permanent loss of 51 acres of nesting/foraging habitat within critical habitat, representing a permanent loss of 12.5% of the total nesting/foraging habitat. Implementation of the RMDP and build-out of the Specific Plan area would result in the permanent loss of 11 acres of foraging habitat only within critical habitat, representing 31.5% of the total on site (**Figure 4.5-86**, Alternative 2 Impacts to Least Bell's Vireo Habitat. Overall, the permanent loss of 62 acres of habitat containing primary constituent elements represents a loss of 14.0% of the 443 acres of primary constituent elements of critical habitat as a result of construction of RMDP facilities and build-out of the Specific Plan area. An additional 49 acres of suitable habitat, including 48 acres of nesting/foraging habitat and 0.8 acre of foraging habitat only, would be temporarily impacted as a result of implementation of the RMDP. For the purpose of this analysis, any impacts to critical habitat would be significant, absent mitigation.

A determination of "destruction or adverse modification" of designated critical habitat as defined under FESA is made by the USFWS, and is not included in this EIS/EIR.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the least Bell's vireo (**Figures 4.5-89** through **4.5-93**, Alternatives 3 through 7 Impacts to Least Bell's Vireo Habitat):

- Alternative 3 – 46 acres (6.7%) permanent loss and 60 acres of temporary loss of habitat, including
  - 40 acres (7.4%) of permanent loss and 57 acres of temporary loss of nesting/foraging habitat
  - 5.3 acres (4.1%) of permanent loss and 3.2 acres of temporary loss of adjacent foraging only habitat;
- Alternative 4 – 47 acres (7.0%) permanent loss and 55 acres of temporary loss of habitat, including
  - 42 acres (7.6%) of permanent loss and 54 acres of temporary loss of nesting/foraging habitat

  - 5.5 acres (4.2%) of permanent loss and 1.0 acre of temporary loss of adjacent foraging only habitat;
- Alternative 5 – 55 acres (8.1%) permanent loss and 64 acres of temporary loss of habitat, including
  - 48 acres (8.8%) of permanent loss and 59 acres of temporary loss of nesting/foraging habitat
  - 6.7 acres (5.2%) of permanent loss and 4.5 acres of temporary loss of adjacent foraging only habitat;
- Alternative 6 – 39 acres (5.8%) permanent loss and 61 acres of temporary loss of habitat, including
  - 35 acres (6.3%) of permanent loss and 55 acres of temporary loss of nesting/foraging habitat
  - 4.5 acres (3.5%) of permanent loss and 5.3 acres of temporary loss of adjacent foraging only habitat; and
- Alternative 7 – 12 acres (1.7%) permanent loss and 46 acres of temporary loss of habitat, including
  - 9.5 acres (1.7%) of permanent loss and 40 acres of temporary loss of nesting/foraging habitat
  - 2.0 acres (1.5%) of permanent loss and 5.8 acres of temporary loss of adjacent foraging only habitat.

Compared to Alternative 2, which would result in 66 acres (9.7%) of permanent loss and 56 acres of temporary impacts, Alternatives 3 through 7 would have somewhat (Alternative 5) to substantially reduced permanent impacts (Alternative 7). Alternative 7 would have substantially reduced permanent impacts compared to Alternatives 3 through 6 as well because of the pullback of RMDP facilities from the Santa Clara River and its tributaries. Temporary impacts for Alternatives 3 through 6 would not be substantially different from Alternative 2 and Alternative 7 would be substantially reduced compared to the other alternatives.

For nesting/foraging habitat, the general pattern of reduction of permanent impacts compared to Alternative 2, which would result in 59 acres (10.7%) of permanent impacts and 55 acres of temporary impacts for Alternatives 3 through 7 would be similar to that discussed above for overall permanent impacts. For temporary impacts, Alternatives 3 through 6 would not be substantially different from Alternative 2 and Alternative 7 would be substantially reduced compared to the other alternatives.

For foraging habitat only, compared to Alternative 2, which would result in 6.9 acres (5.3%) of permanent impacts and 1.4 acres of temporary impacts, the other alternatives would result in marginally (Alternative 5) to substantially reduced permanent impacts for Alternative 7. For temporary impacts, all of the alternatives would have somewhat higher impacts compared to Alternative 2, except Alternative 4 which would have marginally reduced impacts.

As concluded for Alternative 2, both permanent loss and temporary impacts to nesting/foraging habitat and adjacent foraging habitat under Alternatives 3 through 7 would affect the size and distribution of the least Bell's vireo breeding population both spatially and temporally in the Santa Clara River and potentially in tributaries to the River that contain suitable habitat for this species. These permanent and temporary impacts, therefore, would have a substantial adverse effect on the species and its habitat, substantially interfere with its movement and breeding activity, and reduce its range. Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation under Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the least Bell's vireo (**Figures 4.5-89** through **4.5-93**, Alternatives 3 through 7 Impacts to Least Bell's Vireo Habitat):

- Alternative 3 – 37 acres (5.4%) permanent loss of habitat, including
  - 21 acres (3.9%) of permanent loss of nesting/foraging habitat
  - 15 acres (11.9%) of permanent loss of adjacent foraging only habitat;
- Alternative 4 – 34 acres (5.0%) permanent loss of habitat, including
  - 18 acres (3.3%) of permanent loss of nesting/foraging habitat
  - 16 acres (12.0%) of permanent loss of adjacent foraging only habitat;
- Alternative 5 – 31 acres (4.5%) permanent loss of habitat, including
  - 15 acres (2.8%) of permanent loss of nesting/foraging habitat
  - 16 acres (12.0%) of permanent loss of adjacent foraging only habitat;
- Alternative 6 – 21 acres (3.1%) permanent loss of habitat, including
  - 11 acres (2.0%) of permanent loss of nesting/foraging habitat
  - 10 acres (7.9%) of permanent loss of adjacent foraging only habitat; and

- Alternative 7 – 13 acres (2.0%) permanent loss of habitat, including
  - 6.4 acres (1.2%) of permanent loss of nesting/foraging habitat
  - 6.9 acres (5.3%) of permanent loss of adjacent foraging only habitat.

Compared to Alternative 2, which would result in 45 acres (6.6%) of permanent loss of habitat, Alternatives 3 through 7 would have successively reduced permanent impacts, with Alternatives 6 and 7 having substantially reduced impacts compared to the other alternatives.

For nesting/foraging habitat, compared to Alternative 2, which would result in 24 acres (4.4%) of permanent loss, this general pattern of successive reduction of permanent impacts for Alternatives 3 through 7 would be similar to overall permanent impacts.

For foraging habitat only, compared to Alternative 2, which would result in 21 acres (15.9) of permanent impacts, Alternatives 3, 4, and 5 would be somewhat reduced and Alternatives 6 and 7 would be substantially reduced, primarily due to a pullback of the Project footprint from the Santa Clara River and its tributaries.

As concluded for Alternative 2, this permanent loss of nesting/foraging habitat and adjacent foraging habitat would affect the size and distribution of the least Bell's vireo breeding population in the Santa Clara River and potentially in tributaries to the River that contain suitable habitat for this species. This permanent impact therefore would have a substantial adverse effect on the species and its habitat, substantially interfere with its movement and breeding activity, and reduce its range. Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following combined direct and indirect impacts to suitable habitat for the least Bell's vireo:

- Alternative 3 – 82 acres (12.1%) permanent loss of habitat, including
  - 62 acres (11.2%) of permanent loss of nesting/foraging habitat
  - 21 acres (16.2%) of permanent loss of adjacent foraging only habitat;
- Alternative 4 – 81 acres (12.0%) permanent loss of habitat, including
  - 60 acres (11.0%) of permanent loss of nesting/foraging habitat
  - 21 acres (16.2%) of permanent loss of adjacent foraging only habitat;

- Alternative 5 – 86 acres (12.7%) permanent loss of habitat, including
  - 64 acres (11.6%) of permanent loss of nesting/foraging habitat
  - 22 acres (17.2%) of permanent loss of adjacent foraging only habitat;
- Alternative 6 – 60 acres (8.9%) permanent loss of habitat, including
  - 46 acres (8.3%) of permanent loss of nesting/foraging habitat
  - 15 acres (11.4%) of permanent loss of adjacent foraging only habitat; and
- Alternative 7 – 25 acres (3.7%) permanent loss of habitat, including
  - 16 acres (2.9%) of permanent loss of nesting/foraging habitat
  - 8.9 acres (6.9%) of permanent loss of adjacent foraging only habitat.

Compared to Alternative 2, which would result in 110 acres (16.3%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have somewhat (Alternatives 3, 4, and 5) to substantially (Alternatives 6 and 7) reduced permanent impacts, with Alternative 7 having substantially reduced impacts compared to the other alternatives due to the pullback of the development footprint from the Santa Clara River and its tributaries.

For nesting/foraging habitat, compared to Alternative 2, which would result in 83 acres (15.1%) of combined permanent loss, this general pattern of reduction of permanent impacts for Alternatives 3 through 7 would be similar to overall combined permanent impacts.

For foraging habitat only, compared to Alternative 2, which would result in 28 acres (21.2%) of combined permanent impacts, Alternatives 3, 4, and 5 somewhat reduced impacts, and Alternatives 6 and 7 would have substantially reduced impacts primarily due to pullback of the Project footprint from the Santa Clara River and its tributaries.

As concluded for Alternative 2, this combined permanent loss of nesting/foraging habitat and adjacent foraging habitat would affect the size and distribution of the least Bell's vireo breeding population in the Santa Clara River and potentially in tributaries to the River that contain suitable habitat for this species. This combined permanent impact therefore would have a substantial adverse effect on the species and its habitat, substantially interfere with its movement and breeding activity, and reduce its range. The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation under Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to least Bell's vireo individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would essentially be the same as for Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. The least Bell's vireo is known to nest on site. Construction/grading activities, such as vegetation clearing, conducted during the breeding season could result in destruction of nests and loss of eggs and/or young where the species is nesting, and foraging behavior could be altered such that the health of young and their survivorship would be reduced, thus reducing overall reproductive success. Permanent impacts (Impacts to Individuals) would be significant, absent mitigation under Alternatives 3 through 7.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative would have similar construction activities and long-term effects.

Potential short-term impacts include construction-related dust, noise, ground vibration, nighttime illumination, diminished water quality, and altered hydrology. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas include traffic noise; nighttime illumination; diminished water quality; exotic plant and animal species; litter; cowbird nest parasitism; pesticides; increased human activity; and predation by pet, stray, and feral cats and dogs and mesopredators, as described above for Alternative 2. All of these impacts occurring under Alternatives 3 through 7 could result in lower reproductive success of the least Bell's vireo in the Project area.

As discussed in detail above for Alternative 2, traffic noise exceeding 60 dBA could degrade least Bell's vireo nesting/foraging habitat value in the River corridor where bridges cross the River, along the River corridor adjacent to SR-126 between the western boundary of the Project area and Long Canyon, and along the River corridor between Long Canyon and Potrero Canyon. Chronic traffic noise exceeding 60 dBA could cause vireos to avoid these areas for nesting and foraging. Alternatives 3 through 7 all include at least one bridge crossing of the Santa Clara River: Alternatives 3 and 4 include Long Canyon Road Bridge and Commerce Center Drive Bridge; Alternative 5 includes Potrero Canyon Road Bridge, Long Canyon Road Bridge, and Commerce Center Drive Bridge; Alternative 6 includes Potrero Canyon Road Bridge and Long Canyon Road Bridge; and Alternative 7 includes Long Canyon Road Bridge. Alternatives 3 through 7 would also generally increase noise levels adjacent to SR-126 and Walcott Road, as shown in **Figures 4.5-94** through **4.5-98**, Alternatives 3 through 7 60 dBA Noise Contours in Relation to Least Bell's Vireo. The acreages of suitable least Bell's vireo nesting/foraging habitat

currently present in the 60 dBA noise contour in these areas of the River under Alternatives 3 through 7, after temporary impacts are accounted for (as described above), are as follows:

- Alternative 3 – 2.7 acres, including 1.9 acres of southern cottonwood–willow riparian forest and 0.8 acre of mulefat scrub
- Alternative 4 – 2.7 acres, including 1.9 acres of southern cottonwood–willow riparian forest and 0.8 acre of mulefat scrub
- Alternative 5 – 2.4 acres, including 1.8 acres of southern cottonwood–willow riparian forest and 0.6 acre of mulefat scrub
- Alternative 6 – 24 acres, including 21 acres of southern cottonwood–willow riparian forest, 1.0 acre of mulefat scrub, and 2.0 acres of arrow weed scrub.
- Alternative 7 – 12 acres, including 8.5 acres of southern cottonwood–willow riparian forest, 1.3 acres of mulefat scrub, and 1.8 acres of arrow weed scrub.

The noise impacts to nesting/foraging habitat for Alternatives 2 through 5 are very similar. The noise impacts under Alternatives 6 and 7 are substantially higher because traffic volumes would be increased on sections of SR-126 compared to the other alternatives, resulting in much wider 60 dBA noise contours in these areas. These traffic volumes under Alternative 7 would be higher, for example, because Commerce Center Drive Bridge would not be constructed and, to access the south side of the Santa Clara River from SR-126, traffic would travel further west on SR-126, increasing traffic loads along the northern bank of the Santa Clara River.

As noted above for Alternative 2, noise levels in residential settings typically do not exceed 60 dBA, except for discrete loud noises such as emergency vehicle sirens, barking dogs, loud motorcycles, and gas-powered landscape equipment. Because these noises usually attenuate over relatively short distances (sirens and loud motorcycles being exceptions) and are of short duration and not chronic, they would not have a substantial adverse effect on the least Bell's vireo in the Santa Clara River.

Riparian habitat along the Santa Clara River would not be substantially affected over the long term by altered hydrology or geomorphology under Alternatives 3 through 7 (PACE 2009).

There would be no viewing platforms constructed within the River Corridor SMA under Alternatives 3 through 7.

Short-term and long-term secondary impacts would substantially adversely affect a special-status species, affect its movement and use of nursery sites (*i.e.*, breeding habitat), and substantially reduce its habitat and range. Short-term and long-term secondary impacts would be significant, absent mitigation under Alternatives 3 through 7.

Impacts to USFWS Designated Critical Habitat

Implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following combined direct and indirect impacts to designated critical habitat for the least Bell's vireo:

- Alternative 3 – 42 acres (9.4%) permanent loss and 47 acres of temporary impact to critical habitat, including
    - 34 acres (8.4%) of permanent loss and 46 acres of temporary impact to nesting/foraging habitat
    - 7.2 acres (20.6%) of permanent loss and 0.4 acre of temporary impact to adjacent foraging only habitat;
- Alternative 4 – 42 acres (9.4%) of permanent loss and 47 acres of temporary impact to critical habitat, including
    - 34 acres (8.4%) of permanent loss and 46 acres of temporary impact to nesting/foraging habitat
    - 7.2 acres (20.6%) of permanent loss and 0.4 acre of temporary impact to adjacent foraging only habitat;
- Alternative 5 – 50 acres (11.2%) permanent loss and 51 acres of temporary impacts to habitat, including
    - 41 acres (10.0%) of permanent loss and 50 acres of temporary impacts to nesting/foraging habitat
    - 8.8 acres (25.2%) of permanent loss 1.7 acres of temporary impacts to adjacent foraging only habitat;
- Alternative 6 – 28 acres (6.3%) permanent loss and 49 acres of temporary impacts to habitat, including
    - 25 acres (6.1%) of permanent loss and 47 acres of temporary impacts to nesting/foraging habitat
    - 2.8 acres (8.0%) of permanent loss and 2.0 acres of temporary impacts to adjacent foraging only habitat; and
- Alternative 7 – 12 acres (2.7%) permanent loss and 34 acres of temporary impacts to habitat, including
    - 11 acres (2.6%) of permanent loss and 32 acres of temporary impacts to nesting/foraging habitat
    - 1.4 acres (4.0%) of permanent loss and 2.1 acres of temporary impact to adjacent foraging only habitat.

Compared to Alternative 2, which would result in 62 acres (14.0%) of combined permanent loss of critical habitat and 49 acres of temporary impacts, Alternatives 3 through 7 would have somewhat (Alternatives 3, 4, and 5) to substantially (Alternatives 6 and 7) reduced permanent impacts, with Alternative 7 having substantially reduced impacts compared to the other alternatives due to the pullback of the development footprint from the Santa Clara River and its tributaries.

For nesting/foraging habitat, compared to Alternative 2, which would result in 51 acres (12.5%) of combined permanent loss if critical habitat, this general pattern of reduction of permanent impacts for Alternatives 3 through 7 would be similar to overall combined permanent impacts.

For foraging habitat only, compared to Alternative 2, which would result in 11 acres (31.5%) of combined permanent impacts to critical habitat, Alternatives 3, 4 and 5 would have somewhat reduced impacts, and Alternatives 6 and 7 would have substantially reduced impacts, primarily due to pullback of the Project footprint from the Santa Clara River and its tributaries. For the purpose of this analysis, any impacts to critical habitat would be significant, absent mitigation.

A determination of "destruction or adverse modification" of designated critical habitat as defined under FESA is made by the USFWS, and is not included in this EIS/EIR.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to least Bell's vireo: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Nesting by least Bell's vireos has been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, impacts to individuals could occur if active nests are disturbed during vegetation clearing and construction/grading activities, including destruction of nests and loss of eggs and/or fledglings. Construction activities may also alter foraging behavior and thus potentially reduce the health of young and their survivorship, resulting in lower reproductive success. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and conduct monitoring during construction. If any active nest site is present within 300 feet of the disturbance or noise levels exceed 60 dBA at a nest site, work will be postponed, or otherwise restricted if the biologist determines that the construction activities are disturbing nesting activities. Monitoring will be conducted until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable habitat for the least Bell's vireo resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 25 acres (3.7%) under Alternative 7 to 110 acres (16.3%) under Alternative 2. Impacts to designated critical habitat for least Bell's vireo are included in these impact acreages. Because the habitat impacted by the proposed Project is used for both nesting and foraging, this would be a substantial loss of suitable habitat for this species and could alter its use of the Project area for nesting and foraging. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable nesting and foraging habitat to support the least Bell's vireo in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 359 acres of suitable nesting/foraging habitat for the least Bell's vireo in the River Corridor SMA, including 333 acres of southern cottonwood–willow riparian forest and southern willow scrub and 26 acres of arrow weed scrub and mulefat scrub (**Figure 4.5-12,** River Corridor SMA – Generalized Vegetation Communities and Land Covers), but also including suitable habitat in tributaries in the High Country SMA, and the Salt Creek area. Mitigation will also be provided for permanent and temporary impacts to nesting/foraging habitat in ratios based on vegetation type based on the both the vegetation community type and the score that a portion or the Santa Clara River or tributary achieved using the Hybrid Assessment of Riparian Communities (HARC) method, ranging from 4:1 for southern cottonwood–willow riparian forest in a High Reach value area to 1:1 for arrow weed scrub in a Low Reach value area. The mitigation ratios for temporary impacts for suitable nesting/foraging habitat will be based on the vegetation type and the time period for the temporary impact, ranging from 1:1 for less than two years to 2:1 for over five years. Additional habitat mitigation through replacement or enhancement of nesting/foraging habitat for least Bell's vireo would be provided for certain key habitat zones at higher ratios (identified as "key population areas" in **Figure 4.5-86,** Alternative 2 Impacts to Least Bell's Vireo Habitat). All permanent loss to nesting and foraging habitat in key population area reaches shall be mitigated at a 5:1 ratio unless otherwise authorized by CDFG or USFWS. Temporary habitat loss shall be mitigated at a 2:1 ratio. To replace the lost functions of habitat located adjacent to the Santa Clara River as a result of noise impacts due to site development roadway improvement, all nesting/foraging habitat within the 60 dBA sound contour shall be considered degraded. Habitat within this area shall be mitigated at a ratio of 2:1**.**

With regard to secondary effects, nesting and foraging activities by the least Bell's vireo could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, lighting, and diminished water quality and altered hydrology. These secondary effects may alter foraging and nest defense behavior, cause adults to abandon nests due to stress, and otherwise disrupt normal behavioral patterns and cause nests to be more vulnerable to predators. Short-term effects of dust and diminished water quality and altered hydrology may affect habitat quality and the insect prey base for the least Bell's vireo, thus adversely affecting foraging

behavior and provisioning of young. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 300 feet and by retaining a qualified biologist during all vegetation clearing and grading activities. Several general measures will be implemented to protect wetland habitats that will reduce impacts to the least Bell's vireo. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities, biological monitoring during any stream diversions, restrictions on construction equipment operating in ponds or flowing water, and protection of water quality from mud, silt, and other pollutants. Long-term development-related impacts include habitat fragmentation; increased traffic noise; introduction of secondary effects related to viewing platforms and trails along the River Corridor SMA (under Alternative 2 only); invasive plant species, such as giant reed and tamarisk, and Argentine ants, which may prey on nestlings; cowbird parasitism; diminished water quality, affecting prey and nesting habitat quality; lighting; pesticides, which may cause secondary poisoning and loss of prey; human disturbances of nest sites; and predation by pet, stray, and feral cats and dogs and other mesopredators. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 359 acres of suitable habitat, primarily in the River Corridor SMA, but also the High Country SMA and Salt Creek area, will provide least Bell's vireos with relatively undisturbed habitat for nesting/foraging. Additional mitigation for permanent loss and temporary impacts to nesting/foraging habitat in key population areas at the ratios, as described briefly above and in more detail below, will result in a net increase in suitable nesting/foraging habitat for the vireo, offsetting the degradation of habitat adjacent to roadways due to traffic noise and other adverse edge effects. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by nocturnal predators and limit physiological stress. Limited recreational usage and access restrictions within the River Corridor SMA and High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect least Bell's vireos by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of secondary poisoning and loss of prey. Surveys will be conducted for cowbirds, and trapping will be implemented if necessary. Controls on Argentine ants will help reduce impacts on young in nests.

The specific mitigation measures for the least Bell's vireo are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-18 IMPACTS TO INDIVIDUALS – LEAST BELL'S VIREO (NESTING)

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of least Bell's vireo individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to least Bell's vireo individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity. If construction noise meets or exceeds the 60 dBA threshold, or if the biologist determines that the construction activities are disturbing nesting activities, the biologist shall have the authority to halt the construction and shall devise methods to reduce the noise and/or disturbance in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to least Bell's vireo individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-19 LOSS OF HABITAT – LEAST BELL'S VIREO (NESTING)

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the least Bell's vireo through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, which will preserve and enhance at least 359 acres of suitable nesting/foraging habitat for least Bell's vireo (see **Figure 4.5-12,** River Corridor SMA – Generalized Vegetation Communities and Land Covers).

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the least Bell's vireo through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-

lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-2 sets forth CDFG jurisdictional permanent impact mitigation ratios to be implemented for permanent loss of vireo nesting/foraging habitat, including southern cottonwood–willow riparian forest, southern willow scrub, arrow weed scrub, and mulefat scrub. The mitigation ratios for permanent impacts are based on the both the vegetation community type and the score that a portion or the Santa Clara River or tributary achieved using the Hybrid Assessment of Riparian Communities (HARC) method.

BIO-55, as a supplement to BIO-2 through BIO-16, requires additional habitat mitigation through replacement or enhancement of nesting/foraging habitat for least Bell's vireo for certain key habitat zones at higher ratios (identified as "key population areas" in **Figure 4.5-86,** Alternative 2 Impacts to Least Bell's Vireo Habitat**)**. All permanent loss of nesting/foraging habitat in key population area reaches requires the replacement or enhancement of nesting/ foraging habitat for Least Bell's vireo, defined as southern willow scrub, southern cottonwood–willow riparian, arrow weed scrub, mule fat scrub, and Mexican elderberry scrub and woodland. All permanent loss of nesting/foraging habitat shall be mitigated at a 5:1 ratio unless otherwise authorized by CDFG or USFWS. Temporary habitat loss shall be mitigated at a 2:1 ratio. The requirements for replacing habitat by either creating new habitat or removing exotic species from existing habitat shall follow the procedures outlined in BIO-1 through BIO-16. To replace the lost functions of habitat located adjacent to the Santa Clara River, all nesting/foraging habitat within the 60 dBA sound contour shall be considered degraded. Habitat within this area shall be mitigated at a ratio of 2:1.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the least Bell's vireo would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-20 SECONDARY IMPACTS – LEAST BELL'S VIREO (NESTING)

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on the least Bell's vireo associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as invasion by exotic plant species, abandonment of nests in response to human activity, and greater vulnerability to nocturnal predators as a result of nighttime lighting. These mitigation measures provide for protection, restoration, enhancement, and management of habitat in open space for least Bell's vireo that will offset secondary impacts by providing high-quality habitat away from development areas. Mitigation measures to avoid and minimize impacts to water quality and hydrology and inadvertent impacts to habitat outside disturbance zones during construction will also be implemented.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, and SP-4.6-63, as described above and which generally refer to habitat protection, restoration and enhancement, and management, will be implemented to mitigate for long-term habitat fragmentation effects and increased human activity.

Human and pet activity in the River Corridor SMA will be controlled through implementation of SP-4.6-17, which states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20 states that any grading activities within or adjacent to the River Corridor SMA shall have grading perimeters clearly marked and inspected prior to grading. The Project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. These mitigation measures will address avoidance and minimization of downstream hydrology and water quality effects that could adversely affect least Bell's vireo habitat and/or breeding populations.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to least Bell's vireo, including short-term construction-related dust, noise, ground vibration, and

diminished water quality; and long-term impacts, such as invasive species (including exotic plants, cowbirds, and Argentine ants); increased human activity; greater vulnerability to predation by pet, stray, and feral cats and dogs; and impacts of pesticides, such as indirect poisoning and loss of prey.

Secondary effects of noise and ground vibration during construction will be addressed by BIO-52 and BIO-56, as described above, which will mitigate these effects by identifying nest sites and providing for buffers between nests and construction activities.

Three mitigation measures, BIO-47, BIO-49, and BIO-70, will reduce impacts to the least Bell's vireo during construction activities by protecting water quality.

BIO-47 requires that slow moving water habitats shall be constructed up stream and down stream of any river crossing or bridge construction area that will provide refuge for least Bell's vireo during construction.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction, as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. This will reduce impacts to the least Bell's vireo by protecting habitat quality, including water quality, and by minimizing impacts on its insect prey. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-1 through BIO-16 will improve long-term habitat quality for the least Bell's vireo and include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach

value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios. BIO-2, described above, sets mitigation ratios for the different types of vegetation communities based on their HARC score and whether they are permanent or temporary impacts. This mitigation will result in a net increase in suitable nesting/foraging habitat for the vireo, offsetting traffic noise impacts and other adverse edge effects.

BIO-55 requires replacement or enhancement of nesting/foraging habitat for least Bell's vireo in areas within the 60 dBA sound contour associated with development site roadway improvements. To replace the lost functions of habitat located adjacent to the Santa Clara River, all nesting/foraging habitat within the 60 dBA sound contour shall be considered degraded. Habitat within this area shall be mitigated at a ratio of 2:1.

BIO-63 and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-78 requires implementation of a cowbird trapping program once vegetation clearing begins. The program shall be implemented each day beginning April 1 and concluding on or about November 1, through the construction, maintenance, and monitoring period of the riparian restoration sites. In the event that trapping is terminated after the first few years of development, subsequent phases of the RMDP development shall trigger initiation of trapping surveys.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impacts to least Bell's vireo by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant from riparian areas is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the least Bell's vireo would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

WILLOW FLYCATCHER (NESTING) (CE)/SOUTHWESTERN WILLOW FLYCATCHER (NESTING) (FE, CE)

Life History

The willow flycatcher (*Empidonax traillii*), consisting of four or five subspecies, is the most widely distributed of the *Empidonax* flycatchers. The species breeds from the north to the southern portion of Canada from the Pacific to Atlantic coasts, south within the eastern United States to the middle portion of the Midwest and southern New England states, and south within the western United States to the southern portions of Arizona and New Mexico. It is largely absent from the Great Basin area in the west and southeastern United States. It also has a sporadic breeding distribution throughout California, where three of the subspecies occur, including little willow flycatcher (*E. t. brewsteri*), *E. t. adastus* (which has no common name other than "willow flycatcher"), and southwestern willow flycatcher (*E. t. extimus*) (Craig and Williams 1998; Sedgwick 2000). The different subspecies of willow flycatcher each occupy distinct breeding ranges and have subtle differences in color and morphology (Sogge *et al.* 1997), and possibly vocalizations. The willow flycatcher winters in Mexico, Guatemala, Honduras, Nicaragua, Costa Rica, Colombia, and further in South America.

The southwestern willow flycatcher has a known United States breeding range in six states: Arizona, New Mexico, California, southwestern Colorado, extreme southern portions of Nevada and Utah, and, possibly, western Texas. In California, its breeding range extends from the Mexican border north and inland to the City of Independence in the Owens Valley east of the Sierra Nevada, to the South Fork Kern River in the San Joaquin Valley and coastally to the Santa Ynez River in Santa Barbara County (Craig and Williams 1998). The southwestern willow flycatcher was formerly a common summer resident throughout California, but has been extirpated from most of its historic breeding range in California. In California the smallest regularly occurring breeding populations consist of approximately five pairs (occurrences of one or more pairs at several sites are reported annually; however, these may not persist) and the largest is approximately 50 pairs (Haas n.d.). The number of southwestern willow flycatchers in California has been estimated at approximately 200, recorded at 22 locations within 13 drainages (Finch *et al.* 2000).

Willow flycatchers are late spring migrants and have a breeding season of three months or less (Sedgwick 2000). The earliest spring arrival of the willow flycatcher in southern California is typically between late April and early May. Along and near the California coast, migrations of *E. t. brewsteri* and *E. t. extimus* overlap, with *E. t. brewsteri* by far the more common subspecies. The numbers of *E. t. brewsteri* outweigh those of *E. t. extimus* so far that, unless detected at a known breeding site, it is almost certain that a willow flycatcher observed at a low elevation location in southern California is *E. t. brewsteri*, although positive identification in the field to subspecies level may not be possible. When a willow flycatcher is observed in southern

California after about June 22, or if nesting activity is observed, it can be concluded that the individual is *E. t. extimus* (southwestern willow flycatcher). By this date, most migrant willow flycatchers have passed through southern California; however, migrant willow flycatchers may again be observed—virtually always away from the coast—in late July as they pass through the region heading south to their wintering area (Sogge *et al.* 1997).

The southwestern willow flycatcher is a riparian-obligate species restricted to complex streamside vegetation. Four general habitat types are used by the southwestern willow flycatcher at its breeding sites: monotypic high-elevation willow; exotic monotypes (*e.g.*, dense stands of tamarisk (*Tamarix* spp.) or Russian olive (*Elaeagnus angustifolius*)), especially in the desert southwest; native broadleaf-dominated riparian forest; and mixed native/exotic forests (Sogge *et al.* 1997). Of these, native broadleaf-dominated and mixed native/exotic are the primary habitats used by southwestern willow flycatcher in California. The native broadleaf-dominated habitat is composed of a single species, such as Goodding's or other willow (*Salix* spp.) species,, or a mixture of broadleaf trees and shrubs, including cottonwood (*Populus* spp.), willow, box elder (*Acer negundo*), ash (*Fraxinus* spp.), and alder (*Alnus* spp.). Stands are usually three to 15 meters (10 to 50 feet) in height and are characterized by trees of different size classes, yielding multiple layers of canopy (Sogge *et al.* 1997). In San Diego County, there has been one reported low-elevation site along the San Luis Rey River dominated by coast live oak (*Quercus agrifolia*) (Finch *et al.* 2000).

The vegetation of occupied sites includes dense patches interspersed with frequent small openings, open water, and a well-developed herbaceous layer, creating a mosaic that is not uniformly dense (Sogge *et al.* 1997). Willow flycatcher habitat may vary from small irregular patches to large contiguous areas; however, southwestern willow flycatchers typically do not nest in narrow, linear riparian habitats less than 10 meters (33 feet) wide (Sogge *et al.* 1997). Southwestern willow flycatcher nests typically occur in areas with multilayered vegetation and fairly closed (60% to 65%) tree canopy cover (Craig and Williams 1998). This has been noted in the Kern River population (Whitfield and Enos 1996). Other willow flycatcher subspecies may breed in shrubby habitat away from water; however, the southwestern willow flycatcher breeds only in riparian vegetation near surface water or saturated soil (Sogge *et al.* 1997).

Migrant (*i.e.*, non-*extimus*) willow flycatchers, especially *E. t. brewsteri* moving through southern California, typically occur in non-riparian habitats or may be found in riparian habitat patches that are otherwise unsuitable for breeding. The range of habitats used during these migration stopovers is much wider than that preferred by *E.t. extimus* for breeding and may include narrow, linear riparian strips less than 10 meters (33 feet) wide (Sogge *et al.* 1997). Such migration stopover areas may be critically important resources affecting local and regional flycatcher productivity and survival (Sogge *et al.* 1997).

Breeding territory sizes of the southwestern willow flycatcher vary greatly in relation to population density, habitat quality, and nesting stage (USFWS 2002C). The observed range of territory sizes is 0.1 to 2.30 hectares (0.26 to 5.70 acres), with most in the range of 0.2 to 0.5 hectares (0.5 to 1.2 acres) (USFWS 2002C). Clutches of two to four eggs are laid in the third week in June, with fledglings first appearing in mid-July (Sanders and Flett 1989). Fledglings stay close to the nest and to each other for three to five days after leaving the nest and stay in the area for a minimum of 14 to 15 days (Sogge *et al.* 1997).

Small breeding populations of the willow flycatcher (*e.g.*, one or two pairs) may be ephemeral and persist for only a few years. Breeding populations may also reappear at previously occupied sites after one- to five-year absences (Sedgwick 2000). Consequently, Sogge *et al.* (1997) concluded that it cannot be assumed that a habitat is unsuitable or unoccupied in the long term based on flycatchers' absence during a single year, especially if there is evidence of recent use.

Willow flycatchers are insectivores and forage by aerially gleaning prey (capturing insects, for example, while hovering) from trees, shrubs, and herbaceous vegetation or by hawking (capturing in flight) larger insects (Ettinger and King 1980; Sanders and Flett 1989). In one study in Sequoia and Kings Canyon National Parks (Summer and Dixon 1953), about 96% of their diet was animal matter and 4% vegetable matter, such as elderberries and blackberries. Their insect diet included wasps, bees, beetles, flies, caterpillars, moths, grasshoppers, and, occasionally, berries (Craig and Williams 1998), with wasps and bees being the most common component of their diet, followed by beetles.

Critical Habitat

On October 19, 2005, critical habitat was designated for the southwestern willow flycatcher (70 FR 60886–61009). Critical habitat in California is designated in Kern, Santa Barbara, San Bernardino, and San Diego counties. Because no critical habitat is designated for Ventura and Los Angeles counties, critical habitat for the southwestern willow flycatcher is not further addressed in this EIS/EIR.

Recovery Plan

The Final Recovery Plan for the Southwestern Willow Flycatcher was published by the USFWS on August 30, 2002 (USFWS 2002C). Nine recovery actions for the southwestern willow flycatcher were identified in the Final Recovery Plan: "1. Increase and improve occupied suitable habitat, and potential breeding habitat; 2. Increase metapopulation stability; 3. Improve demographic parameters; 4. Minimize threats to wintering and migration habitat; 5. Survey and monitor; 6. Conduct research; 7. Provide public education and outreach; 8. Assure implementation of laws, policies, and agreements that benefit the flycatcher; 9. Track recovery" (USFWS 2002C, p. v).

The Project area is located within the Coastal California Recovery Unit of the Final Recovery Plan, and establishment of new territories is part of the recovery criteria for the subspecies. Within the Santa Clara River, the reach from Bouquet Canyon Road to the Pacific Ocean, which crosses through the Project area, has been identified as a Management Unit where recovery actions should be focused (USFWS 2002C).

Threats

The decline of southwestern willow flycatchers is primarily due to loss, fragmentation, and degradation of suitable riparian habitat resulting from urbanization, recreation, water diversion and impoundments, channelization, invasive plant species, overgrazing by livestock, and conversion of riparian habitat to agricultural land (USFWS 2002C; Sedgwick 2000). Channelization, bank stabilization, levees, and other flow control structures, surface water diversions, and groundwater pumping for agricultural, industrial, and municipal uses are major factors in the deterioration of suitable southwestern willow flycatcher habitat. Agricultural effects include direct removal of riparian vegetation, floodplains alteration, water diversion and groundwater pumping for irrigation, and application of pesticides (herbicides and insecticides), which may affect habitat quality and insect prey, and result in secondary poisoning. Grazing of willows by domestic livestock changes the willow foliage height and volume, reducing habitat quality for southwestern willow flycatcher (Taylor 1986). Agriculture, cattle operations, and urban development attract brown-headed cowbirds that parasitize nests, especially in riparian edge areas or areas where breeding habitat has been degraded, leading to population reductions. Non-native plant species such as tamarisk and giant reed also reduce habitat quality and affect breeding. For example, tamarisk may alter insect fauna and change thermal protection from foliage (Sedgwick 2000), although southwestern willow flycatcher nests in areas where tamarisk is dominant (Durst *et al.* 2006). Urban-related predators, such as domestic house cat, and natural predators that are attracted to urban settings, such as ravens, may affect the southwestern willow flycatcher by increasing predation (Sogge *et al.* 1997). Diminished water quality and altered hydrology during construction and over the long term resulting from urban runoff could affect riparian habitat quality and insect prey for the willow flycatcher both during migration and for breeding. Other urban-related impacts that may affect southwestern willow flycatcher include nighttime lighting and noise, which may both induce physiological stress and increase predation (*e.g.*, predator presence may be masked by ambient noise). Argentine ants, which are attracted to moist habitats in urban settings, may prey on nestlings. Construction-generated dust could affect water quality and insect prey, thus reducing overall habitat quality.

Survey Results

Surveys for riparian birds have been conducted for multiple years from 1988 to 2007 along the Santa Clara River within suitable habitat for the southwestern willow flycatcher (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A,

1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C); within portions of the Santa Clara River by Labinger *et al.* in 1994, 1996, and 1997 (1995, 1996, 1997A, 1997B); and by Labinger and Greaves in 1998 (1999A); within Castaic Creek, Salt Creek, High Country SMA, and portions of the Santa Clara River adjacent to the Project site by Dudek and Associates (2006B, 2006D, 2006E); and within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line by Bloom Biological, Inc. in 2007 (2007A).

Between 1993 and 1998, surveys were conducted in conjunction with surveys for least Bell's vireo, and although protocol southwestern willow flycatcher surveys were not conducted during these years, willow flycatchers were observed within the Project area in three separate years during this period (Guthrie 1993B, 1997B, 1998A). Southwestern willow flycatcher habitat within the Project area has been surveyed annually from 1999 to 2007 following the USFWS protocol for this species and willow flycatchers were observed during several survey years (Guthrie 1999B, 2000C, 2001B, 2002C, 2004H, 2005B; Bloom Biological 2007A).

Any willow flycatcher (*i.e.*, all subspecies of the willow flycatcher) occurring within the boundaries of California is state-listed as endangered. Willow flycatchers, almost certainly all of which were *E. t. brewsteri*, have been detected almost every year within the River corridor in the Project area during the focused bird surveys since 1997, but nesting by the southwestern willow flycatcher has not been confirmed. All of the individuals of the willow flycatcher documented within the Project area were considered to be migrants (*i.e.*, *E. t. brewsteri*) or transients (possibly *E. t. extimus*) because they were only detected once during the survey period, and nesting was never documented. Rarely, a location may have supported willow flycatchers twice (possibly not the same individuals) within a survey season, but no individuals were observed after June 22. Although nesting by the southwestern willow flycatcher has not been documented in the Project area, recent nesting in the Santa Clara River has been documented near Fillmore, downstream of the Project area. Two breeding pairs were observed in 2006 by J. Gallo, with one nest producing two successful fledglings and the other failing (Root 2008).

Currently, the Project area appears to be a migratory stop for one or more of the subspecies of willow flycatcher. (Note, however, that southwestern willow flycatchers do not appear to use any stopover locales *en route* to California breeding sites.) Evidence of willow flycatcher nesting has not been documented on site. In the unlikely event that southwestern willow flycatcher numbers increase dramatically, and nearby breeding populations also become established, this subspecies could colonize suitable areas of the Santa Clara River within the Project area for nesting. The breeding pairs observed near Fillmore in 2006 indicate the potential for breeding on site in the future. For this reason, this EIS/EIR analyzes impacts both to migration habitat for the willow flycatcher and to suitable nesting and foraging habitat for the southwestern willow flycatcher

subspecies, including potential future impacts to nesting individuals should the southwestern willow flycatcher breeding population expand to the Project area.

Southern cottonwood–willow riparian, southern coast live oak riparian forest, and southern willow scrub are migration habitats for the willow flycatcher. These habitats could also be used for nesting in the future should the southwestern willow flycatcher attempt to breed on site. There is a total of 445 acres of suitable migration and nesting habitat for willow flycatcher in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 39 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 8.7% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). A total of 44 acres would be temporarily impacted.

Because the willow flycatcher is state-listed endangered and the southwestern willow flycatcher subspecies is also a federally listed endangered species, the permanent loss of migration, nesting, and foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities associated with implementation of the RMDP and the SCP would have a substantial adverse effect on the species or its habitat; substantially interfere with the movement and breeding activity of the species; and reduce its range (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 7.8 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 1.8% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat).

Because the willow flycatcher is state-listed endangered and the southwestern willow flycatcher subspecies is also a federally listed endangered species, the permanent loss of migration, nesting, and foraging habitat that would occur as a result of construction and/or grading activities associated with build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on the species or its habitat; substantially interfere with the movement and breeding activity of the species; and reduce its range (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 47 acres (10.4%).

Because the willow flycatcher is state-listed endangered and the southwestern willow flycatcher subspecies is also a federally listed endangered species, the combined direct and indirect permanent loss of migration, nesting, and foraging habitat as a result of construction and/or grading activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on the species or its habitat; substantially interfere with the movement and breeding activity of the species; and reduce its range (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The willow flycatcher is a relatively mobile species and it is unlikely that construction activities associated with implementation of the RMDP would result in the direct loss of individual adult birds. However, if the southwestern willow flycatcher subspecies nests on site in the future, vegetation clearing associated with implementation of the RMDP could result in destruction of eggs and/or injury or mortality of young due to destruction of nests if these activities occurred during the nesting season of this species. In addition, construction activities could alter the southwestern willow flycatcher's foraging behavior, potentially affecting the health of young and their survivorship, potentially reducing reproductive success. Implementation of the SCP would not directly impact this species. Impacts to eggs or young would be a substantial adverse effect on a special-status species (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. Because the species has potential to nest on site in habitat that would be directly affected, build-out of the Specific Plan, VCC, and Entrada planning areas could result in loss of young or eggs of this species as a result of destruction of nests from any construction/grading activities that occur during the nesting season or alteration of foraging behavior. Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, and nighttime illumination. These impacts could alter essential behaviors such as foraging and breeding, induce physiological stress, and increase predation rates. Fugitive dust and diminished water quality and altered hydrology (*e.g.*, runoff, erosion, sedimentation) could reduce habitat quality, including insect prey. Although construction would be of a short-term nature, if these activities occurred during the breeding season they could have a substantial direct adverse effect on the southwestern willow flycatcher due to potential disruption of breeding and nesting activities.

Potential long-term secondary impacts associated with urban development would be the same as those described above for least Bell's vireo. These impacts include traffic noise; nighttime illumination; invasion by exotic species such as giant reed, tamarisk, and Argentine ants; increased litter; diminished water quality and altered hydrology; brown-headed cowbird nest parasitism; pesticide use resulting in loss of prey and/or secondary poisoning; increased human activity; harassment and predation by pet, stray, and feral cats and dogs; and increased mesopredators as a result of increased habitat fragmentation. These secondary impacts may alter essential activities such as foraging and breeding, induce physiological stress, interfere with care of young, and result in abandonment of nests and lower reproductive success along the urban–open space edge over the long term. However, the noise impact analysis for vireo is primarily related to nesting activity. The southwestern willow flycatcher has not been documented to nest in the Project area, and therefore the noise analysis is limited to migrating individuals. Secondary effects from noise are not expected to have the same level of impacts as the nesting least Bell’s vireos, because migrants are not establishing territories on site and are using the area on a transitory basis. Large areas within the River corridor would remain below the 60 dBA noise threshold, and migratory birds would be able to continue using these areas.

Altered hydrology and geomorphology in the Santa Clara River corridor as a result of urban development in the watershed, resulting in impacts to migration habitat for the willow flycatcher and nesting habitat for the southwestern willow flycatcher subspecies, are also potential long-

term secondary effects of the build-out of the Specific Plan, VCC, and Entrada planning areas. However, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County over the long term. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue. As a result, the mosaic of habitats in the River that support various special-status species would be maintained, and the population of the species within and immediately adjacent to the River corridor would not be significantly affected.

RMDP facilities include a public trail and viewing platforms adjacent to and along the northern edge of the Santa Clara River corridor, as shown in **Figure 4.5-88**, Special-Status Riparian Bird Observations in Relation to Viewing Platforms. The easternmost trail and viewing platform is adjacent to the key population area segment extending from the Indian Dunes area to the confluence with Humble Canyon. There is a potential for secondary impacts to willow flycatcher nesting in this location. Secondary impacts primarily would include noise and general increases in human activity that could disrupt behavioral activities such as foraging, territory defense, and nesting, or increase physiological stress. In addition, there is a potential for increased trash along the trail that could enter the River corridor. Due to the very close proximity of viewing platforms and trails to riparian habitats, there is the potential for unauthorized trespass by the public in to sensitive habitat areas. Although there would be no lighting provided for evening use of the trail and viewing platforms, public access during night hours may still occur and could introduce fugitive light and noise. These impacts have the potential to affect the health of young, and potentially reduce survivorship and reproductive success.

Short-term and long-term secondary impacts would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the willow flycatcher and southwestern willow flycatcher subspecies (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 25 acres (5.6%) of permanent loss and 43 acres of temporary loss;
- Alternative 4 – 26 acres (5.8%) of permanent loss and 41 acres of temporary loss;
- Alternative 5 – 31 acres (7.0%) of permanent loss and 47 acres of temporary loss;
- Alternative 6 – 17 acres (3.9%) of permanent loss and 43 acres of temporary loss; and
- Alternative 7 – 7.9 acres (1.8%) of permanent loss and 24 acres of temporary loss.

Compared to Alternative 2, which would result in 39 acres (8.7%) of permanent habitat loss and 44 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 through 7 would be substantially reduced. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3, 4, 5, and 6 be marginally to somewhat different. The temporary loss of habitat under Alternative 7 would be substantially reduced, compared to Alternative 2. The difference for permanent and temporary impacts under Alternative 7 compared to the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Although the overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be substantially reduced compared to Alternative 2, and temporary impacts would be marginally to substantially different, impacts to habitat for a state-listed and federally listed endangered species would still occur. These direct and temporary impacts (Loss of Habitat) therefore would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the willow flycatcher and southwestern willow flycatcher subspecies (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 6.9 acres (1.6%) of permanent loss;
- Alternative 4 – 3.5 acres (0.8%) of permanent loss;
- Alternative 5 – 2.6 acres (0.6%) of permanent loss;
- Alternative 6 – 1.3 acres (0.3%) of permanent loss; and
- Alternative 7 – 0.7 acre (0.1%) of permanent loss.

Compared to Alternative 2, which would result in 7.8 acres (1.8%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 and 5 would have somewhat reduced impacts compared to Alternative 3 and Alternatives 6 and 7 would have additional reductions to impacts to willow flycatcher/southwestern willow flycatcher suitable habitat compared to the other alternatives.

Although the permanent loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, impacts to habitat for a state-listed and federally listed endangered species would still occur. These indirect permanent impacts (Loss of Habitat) therefore would be significant, absent mitigation, under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the willow flycatcher and southwestern willow flycatcher subspecies:

- Alternative 3 – 32 acres (7.2%) of permanent loss;
- Alternative 4 – 29 acres (6.5%) of permanent loss;
- Alternative 5 – 34 acres (7.5%) of permanent loss;
- Alternative 6 – 19 acres (4.2%) of permanent loss; and
- Alternative 7 – 8.5 acres (1.9%) of permanent loss.

Compared to Alternative 2, which would result in 47 acres (10.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. There would generally be successive reductions to impacts to willow flycatcher/southwestern willow flycatcher suitable habitat in the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3, 4, 6, and 7. Alternative 5 would have the next largest impact compared to Alternative 2.

Although the combined direct and indirect permanent loss of habitat from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, impacts to habitat for a state-listed and federally listed endangered species would still occur. The combined direct and indirect permanent impacts (Loss of Habitat) therefore would be significant, absent mitigation, under Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to willow flycatcher/southwestern willow flycatcher individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2. Although adult birds would likely avoid impacts, if nesting by southwestern willow flycatcher occurs in the Project area in the future, destruction of eggs and/or injury or mortality of young due to destruction of nests could occur if vegetation clearing activities occurred during the nesting season of the southwestern willow flycatcher. Foraging behavior by willow flycatcher/southwestern willow flycatcher also may be altered. Direct and indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation, under Alternatives 3 through 7.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Potential short-term impacts include construction-related dust, noise, ground vibration, nighttime illumination, diminished water quality, and altered hydrology. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas include traffic noise; nighttime illumination; diminished water quality; exotic plant and animal species; litter; cowbird nest parasitism; pesticides; increased human activity; and predation by pet, stray, and feral cats and dogs and mesopredators, as described above for Alternative 2. Riparian habitat along the Santa Clara River would not be substantially affected over the long term by altered hydrology or geomorphology under Alternatives 3 through 7 (PACE 2009).

There would be no viewing platforms constructed within the River Corridor SMA under Alternatives 3 through 7.

These potential short-term and long-term secondary effects would have a substantial adverse effect on the species and contribute to the reduction of its range and distribution. These long-term and short-term secondary impacts would be significant, absent mitigation for Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to willow flycatcher and the southwestern willow flycatcher subspecies: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Willow flycatchers have been documented using the Santa Clara River within the Project area during migration, but nesting by the southwestern willow flycatcher subspecies has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. However, this subspecies has been documented to breed downstream in the Fillmore area (Root 2008), and there is some potential that it could nest on site in the future. While adult willow flycatchers are highly mobile and migrants are likely able to escape direct injury or mortality from relatively slow-moving construction equipment, impacts to breeding southwestern willow flycatcher individuals could occur if active nests are disturbed during vegetation clearing and construction/grading activities, including destruction of nests and loss of eggs and/or fledglings. Construction activities may also alter foraging behavior of southwestern willow flycatchers and thus potentially reduce the health of young and their survivorship, resulting in lower reproductive success. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable migrant habitat for the willow flycatcher and potential nesting habitat for the southwestern willow flycatcher subspecies resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 8.5 acres (1.9%) under Alternative 7 to 47 acres (10.4%) under Alternative 2. Because this habitat is used by migrants and potentially by nesting individuals of a listed species, this would be a substantial loss of suitable habitat for this species and could alter its use of the Project area for foraging and potentially for nesting. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable foraging and potential nest habitat to support the willow flycatcher/southwestern willow flycatcher in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 314 acres of

suitable habitat for the willow flycatcher/southwestern willow flycatcher, in the River Corridor SMA (**Figure 4.5-12**, River Corridor SMA – Generalized Vegetation Communities and Land Covers), but also including suitable habitat in tributaries in the High Country SMA and the Salt Creek area (approximately 8 acres).

With regard to secondary effects, foraging activities and potentially nesting by the willow flycatcher/southwestern willow flycatcher could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, lighting, and diminished water quality and altered hydrology. These secondary effects may alter foraging and potentially nest defense behavior by breeding southwestern willow flycatchers, cause adult southwestern willow flycatchers to abandon nests due to stress, and otherwise disrupt normal behavioral patterns and cause nests to be more vulnerable to predators. Short-term effects of dust and diminished water quality and altered hydrology may affect habitat quality and the insect prey base for the willow flycatcher/southwestern willow flycatcher, thus adversely affecting foraging behavior and potentially provisioning of young by southwestern willow flycatcher. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 300 feet and by retaining a qualified biologist during all vegetation clearing and grading activities. Several general measures will be implemented to protect wetland habitats that will reduce impacts to the willow flycatcher/southwestern willow flycatcher. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities, biological monitoring during any stream diversions, restrictions on construction equipment operating in ponds or flowing water, and protection of water quality from mud, silt, and other pollutants. Long-term development-related impacts include habitat fragmentation; increased traffic noise; introduction of secondary effects related to viewing platforms and trails along the River Corridor SMA (under Alternative 2 only); invasive species such as giant reed and tamarisk and Argentine ants, which may prey on nestlings; cowbird parasitism; increased noise; diminished water quality, affecting prey and nesting habitat quality; lighting; pesticides, which may cause secondary poisoning and loss of prey; human disturbances of nest sites; and predation by pet, stray, and feral cats and dogs and other mesopredators. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 314 acres of suitable habitat in the River Corridor SMA, but also a small amount of habitat in the High Country SMA and Salt Creek area, will provide the willow flycatcher/southwestern willow flycatcher with relatively undisturbed habitat for foraging during migration and potentially for nesting by southwestern willow flycatcher. Lighting restrictions along the perimeter of natural areas will help reduce predation of any nest sites by nocturnal predators and reduce physiological stress. Limited recreational usage and access restrictions within the High Country SMA, control of pet, stray, and feral cats and dogs in or near open space areas, trail signage, and homeowner education regarding special-status resources in preserved natural habitat areas will help protect willow flycatcher/southwestern willow flycatcher by allowing them to forage and potentially nest without disturbance. Controls on pesticides will reduce the chance of secondary poisoning

and loss of prey. Surveys will be conducted for cowbirds and trapping will be implemented if necessary. Controls on Argentine ants will help reduce impacts to young in nests.

The specific mitigation measures for the willow flycatcher/southwestern willow flycatcher are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-21 IMPACTS TO INDIVIDUALS – WILLOW FLYCATCHER/SOUTHWESTERN WILLOW FLYCATCHER (NESTING)

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate impacts to willow flycatcher individuals, including nesting southwestern willow flycatcher individuals, through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to willow flycatcher individuals, including nesting southwestern willow flycatcher individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing

and construction in the vicinity. If construction noise meets or exceeds the 60 dBA Leq threshold, or if the biologist determines that the construction activities are disturbing nesting activities, the biologist shall have the authority to halt the construction and shall devise methods to reduce the noise and/or disturbance in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to willow flycatcher individuals, including nesting southwestern willow flycatcher individuals, would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-22 LOSS OF HABITAT – WILLOW FLYCATCHER/SOUTHWESTERN WILLOW FLYCATCHER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the willow flycatcher/southwestern willow flycatcher through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, which will preserve and enhance 314 acres of suitable habitat for willow flycatcher/southwestern willow flycatcher (**Figure 4.5-12**, River Corridor SMA – Generalized Vegetation Communities and Land Covers).

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the willow flycatcher/southwestern willow flycatcher through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the willow flycatcher/southwestern willow flycatcher would be adverse but not significant.

IMPACT 4.5-23 SECONDARY IMPACTS – WILLOW FLYCATCHER/SOUTHWESTERN WILLOW FLYCATCHER (NESTING)

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on the willow flycatcher/southwestern willow flycatcher associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as traffic noise, invasion by exotic plant species, abandonment of nests from human activity, and greater vulnerability to nocturnal predators as a result of nighttime lighting. These mitigation measures provide for protection, restoration, enhancement, and management of habitat in open space for southwestern willow flycatcher that will offset secondary impacts by providing high-quality habitat away from development areas. Mitigation measures to avoid and minimize impacts to water quality and hydrology as well as inadvertent impacts to habitat outside disturbance zones during construction will also be implemented.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, and SP-4.6-63, as described above and which generally refer to habitat protection, restoration and enhancement, and management will be implemented to mitigate for long-term habitat fragmentation effects and increased human activity.

Human and pet activity in the River Corridor SMA will be controlled through implementation of SP-4.6-17, which states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20 states that any grading activities within or adjacent to the River Corridor SMA shall have grading perimeters clearly marked and inspected prior to grading. The Project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. These mitigation measures will address avoidance and minimization of downstream hydrology and water quality effects that could adversely affect willow flycatcher/southwestern willow flycatcher habitat and/or migrant and breeding populations.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to willow flycatcher/southwestern willow flycatcher, including short-term construction-related dust, noise, ground vibration, and diminished water quality, and long-term impacts, such as invasive species (including exotic plants, cowbirds, and Argentine ants); increased human activity; greater vulnerability to predation by pet, stray, and feral cats and dogs; and impacts of pesticides such as indirect poisoning and loss of prey.

Secondary effects of noise and ground vibration during construction will be addressed by BIO-52 and BIO-56, as described above, which will mitigate these effects by identifying nest sites and providing for buffers between nests and construction activities.

Three mitigation measures, BIO-47, BIO-49, and BIO-70, will reduce impacts to the willow flycatcher/southwestern willow flycatcher during construction activities by protecting water quality.

BIO-47 requires that slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area that will provide refuge for willow flycatcher/southwestern willow flycatcher during construction.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. This will reduce impacts to willow flycatcher/southwestern willow flycatcher by protecting habitat quality, including water quality, and by minimizing impacts on its insect prey. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-1 through BIO-16 will improve long-term habitat quality for the willow flycatcher/southwestern willow flycatcher and include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-55 requires replacement or enhancement of nesting and foraging habitat for southwest willow flycatcher. All permanent loss to nesting and foraging habitat shall be mitigated at a 5:1 ratio unless otherwise authorized by CDFG or USFWS. Temporary habitat loss shall be mitigated at a 2:1 ratio. To replace the lost functions of habitat located adjacent to the Santa Clara River, all nesting and breeding habitat within the 60 dBA sound contour shall be considered degraded. Habitat within this area shall be mitigated at a ratio of 2:1.

BIO-63 and BIO-73 will be implemented to mitigate for increased human activity, and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-78 requires implementation of a cowbird trapping program once vegetation clearing begins. The program shall be implemented each day beginning April 1 and concluding on or about November 1, through the construction, maintenance, and monitoring period of the riparian restoration sites. In the event that trapping is terminated after the first few years of development, subsequent phases of the RMDP development shall trigger initiation of trapping surveys.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impact to willow flycatcher/southwestern willow flycatcher by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant from riparian areas is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help

prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the willow flycatcher/southwestern willow flycatcher would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

INTENTIONALLY LEFT BLANK

WESTERN YELLOW-BILLED CUCKOO (NESTING) (FC, BCC, CE)

Life History

The yellow-billed cuckoo (*Coccyzus americanus*) occurs as a breeding bird in temperate North America, south to Mexico, and the Greater Antilles. It possibly breeds in Central America and northwestern South America, although its breeding range may be confused by reports of non-breeding adult vagrants outside of known breeding areas during the breeding season. The northern limit of its distribution extends west from southern Maine through southern New Hampshire, Vermont, northern and central New York, extreme southwestern Quebec, southern Ontario, the Upper Peninsula of Michigan, northern Minnesota, and possibly into southeastern North Dakota and northeastern and western South Dakota (Hughes 1999). Its breeding range extends southward along the Atlantic Coast to southern Florida, and west to the extreme eastern portion of Wyoming, the eastern plains of Colorado, and throughout Texas (Hughes 1999). The yellow-billed cuckoo is extremely rare and local in the northern Rocky Mountain area and the Great Plains, locally breeding in southeastern Montana, southern Idaho, southern Wyoming, and most of Utah (Hughes 1999). The yellow-billed cuckoo is rare and local in the southwestern Unites States. It breeds along the major river valleys in southern and western New Mexico, and central and southern Arizona. It occurs at isolated sites in the Sacramento Valley in northern California, and along the Kern and Colorado river systems in southern California (Gaines and Laymon 1984; Laymon and Halterman 1989).

Two subspecies of the yellow-billed cuckoo are recognized, eastern yellow-billed cuckoo (*C. a. americanus*) and western yellow-billed cuckoo (*C. a. occidentalis*), although the validity of the taxonomic grouping has been debated (Franzreb and Laymon 1993). The two subspecies are separated by their geographic distribution. The western yellow-billed cuckoo's range is considered to be where it formerly bred from southwestern British Columbia, western Washington, northern Utah, central Colorado, and western Texas south and west to southern Baja California, Sinaloa, and Chihuahua in Mexico (Hughes 1999). The eastern yellow-billed cuckoo's range is considered to be the remainder of the species' range in eastern North America, eastern Mexico, and the Greater Antilles. The boundary between the two subspecies is considered to be the Pecos River in Texas (Hughes 1999).

In California, the western yellow-billed cuckoo's breeding distribution is now thought to be restricted to isolated sites in the Sacramento, Amargosa, Kern, Santa Ana, and Colorado river valleys (Laymon and Halterman 1987).

Breeding habitat for the western yellow-billed cuckoo primarily consists of large blocks of riparian habitat, particularly cottonwood–willow riparian woodlands (66 FR 38611–38626). Laymon and Halterman (1989) proposed that the suitable habitat for the western yellow-billed cuckoo for California be defined as habitat classified as willow–cottonwood with a patch size greater than 80 hectares (198 acres) and width greater than 600 meters (1,270 feet). It prefers

dense riparian thickets with dense low-level foliage near slow-moving water sources. Although it is usually found in habitats where willow (*Salix* spp.) is a dominant component, they have been observed in mesquite thickets along the Colorado River and orchards in the Sacramento Valley (Zeiner *et al.* 1990A). Nests are constructed in willows on horizontal branches in trees, shrubs, and vines, but cottonwoods (*Populus* spp.) are used extensively for foraging and humid lowland forests are used during migration (Hughes 1999).

Clutches of two or three eggs are laid in mid-June to mid-July and incubation occurs over nine to 11 days. Development of the young is very rapid, with fledgling occurring in six to nine days; the entire breeding cycle may be only 17 days from egg-laying to fledging of the young (66 FR 38611). Cuckoos are a monogamous species and both sexes incubate and care for the young (Zeiner *et al.* 1990A). The yellow-billed cuckoo has been noted to be both an intraspecific and interspecific brood parasite (Hughes 1999); however, this appears to only occur in the eastern yellow-billed cuckoo. The western yellow-billed cuckoo is rarely parasitized by the brown-headed cowbird; however, it is not considered to be common and it was assumed that the cowbird was not successful due to the short breeding period of the yellow-billed cuckoo (Hughes 1999). The degree to which the western yellow-billed cuckoo shows site fidelity is unknown; however, the absence of pairs on known breeding sites in some years and presence of breeding birds on previously vacant sites suggests that breeding may not occur in the same location every year (Gaines and Laymon 1984).

The western yellow-billed cuckoo is a long-distance migrant, though details of its migration patterns are not well known (Hughes 1999). It is a relatively late spring migrant, arriving on the breeding grounds starting mid- to late May (Franzreb and Laymon 1993). The migratory route of western yellow-billed cuckoos is not well known because few specimens collected on wintering grounds have been ascribed to the western or eastern subspecies. The western yellow-billed cuckoo likely moves down the Pacific Slope of Mexico and Central America to northwestern South America (Hughes 1999).

Yellow-billed cuckoos generally forage for caterpillars and other large insects by gleaning (Hughes 1999). They occasionally prey on small lizards, frogs, eggs, and young birds as well (Zeiner *et al.* 1990A). Foraging occurs extensively in cottonwood riparian habitat (Hughes 1999).

The western yellow-billed cuckoo is sensitive to habitat fragmentation and degradation of riparian woodlands due to agricultural and residential development (Hughes 1999), and major declines among western populations reflect local extinctions and low colonization rates (Laymon and Halterman 1989). Even where habitat is not degraded, they have been extirpated from breeding areas occupied by four or fewer pairs (Laymon and Halterman 1987), possibly due to the inherent instability of small populations (Laymon and Halterman 1989). Extensive surveys (1986 to 1987) indicated that only 30 to 33 pairs and 31 unmated males remain in California,

with the reason for the high number of unmated males being unknown (Laymon and Halterman 1989). Non-native invasive species such as tamarisk may preclude use by western yellow-billed cuckoos; previously occupied willow–cottonwood habitats that type-converted to monotypic stands of tamarisk were no longer inhabited (Laymon and Halterman 1987). Pesticides may affect behavior of western yellow-billed cuckoo by loss of balance or may cause death by direct contact. Sublethal poisoning of young by pesticides has been caused by spraying active nests in walnut orchards, and individuals have been observed falling from trees, and dead or dying with symptoms of poisoning, within days of DDT spraying to control Dutch elm disease (Hughes 1999). Pesticides may contaminate preferred prey items, particularly lepidopteran larva. In addition, some prey species, such as frogs, occur in pesticide-laden runoff adjoining agricultural land (Laymon and Halterman 1987). The western yellow-billed cuckoo also has shown pesticide effects on reproduction due to eggshell thinning (Gaines and Laymon 1984; Laymon and Halterman 1987). Like other riparian bird species, several other potential human- or development-related factors may affect western yellow-billed cuckoos. Construction-related impacts include dust; noise and ground vibration; diminished water quality and altered hydrology; increased human activity in close proximity to foraging areas; and lighting which may alter foraging behavior, induce physiological stress, and increase predation risk. Long-term effects related to development include increased human activity; noise; lighting; diminished water quality and altered hydrology; predation and harassment by pet, stray, and feral cats and dogs and other mesopredators; and brown-headed cowbird nest parasitism.

Survey Results

Surveys for riparian birds have been conducted for multiple years from 1988 to 2007 along the Santa Clara River within suitable habitat for the western yellow-billed cuckoo (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C); within portions of the Santa Clara River by Labinger *et al.* in 1994, 1996, and 1997 (1995, 1996, 1997A, 1997B); and by Labinger and Greaves in 1998 (1999A); within Castaic Creek, Salt Creek, High Country SMA, and portions of the Santa Clara River adjacent to the Project site by Dudek and Associates (2006B, 2006D, 2006E); and within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line by Bloom Biological, Inc. in 2007 (2007A). The western yellow-billed cuckoo has occasionally been documented within the River corridor during these surveys, although the locations of these observations were not mapped. This species has been observed historically in 1979, 1981, and 1992 (Labinger *et al.* 1997A); however, no observations of nesting, paired, or territorial western yellow-billed cuckoos have been documented within the Project area.

Currently, the Project site appears to be a migratory stop for individual western yellow-billed cuckoos but may also be used for post-migratory movements. Some suitable nesting and

foraging habitat is present within the Project area in southern cottonwood–willow riparian, southern coast live oak riparian forest, and southern willow scrub communities. If the population of the western yellow-billed cuckoo becomes more abundant, this species may expand its breeding territory to suitable areas of the Santa Clara River. For this reason, this EIS/EIR analyzes impacts to suitable nesting and foraging habitat for the western yellow-billed cuckoo and potential future impacts to nesting individuals should the breeding population expand to the Project area. This approach thus also accounts for impacts that would occur to suitable migratory stopover habitat. A total of 446 acres of suitable habitat is present within the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 39 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 8.7% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). A total of 44 acres would be temporarily impacted.

Because the western yellow-billed cuckoo is a state-listed endangered species, the permanent loss of nesting and foraging habitat and temporary impacts as a result of construction and/or grading activities associated with implementation of the RMDP and the SCP would have a substantial adverse effect on the species or its habitat; substantially interfere with the movement and breeding activity of the species; and reduce its range (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 7.8 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 1.8% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat).

Because the western yellow-billed cuckoo is a state-listed endangered species, the permanent loss of nesting and foraging habitat as a result of construction and/or grading activities associated with build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on the species or its habitat; substantially interfere with the movement and breeding activity of the species; and reduce its range (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 47 acres (10.4%).

Because the western yellow-billed cuckoo is a state-listed endangered species, the combined direct and indirect permanent loss of nesting and foraging habitat as a result of construction and/or grading activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on the species or its habitat; substantially interfere with the movement and breeding activity of the species; and reduce its range (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The western yellow-billed cuckoo is a relatively mobile species and it is unlikely that construction activities associated with implementation of the RMDP would result in the direct loss of individual adult birds. However, if the species were to nest on site, implementation of the RMDP could result in injury or mortality of western yellow-billed cuckoos due to destruction of nests and loss of young if such construction/grading activities occurred during the nesting season. In addition, construction activities could alter the western yellow-billed cuckoo's foraging behavior, potentially affecting the health of young and their survivorship and potentially reducing reproductive success. Implementation of the SCP would not directly impact this species. Construction/grading

activities, such as vegetation clearing, occurring during the nesting season could result in destruction of nests and resulting in loss of eggs and/or young (significance criteria 1 and 4). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The western yellow-billed cuckoo is a relatively mobile species and it is unlikely that build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of individual adult birds. However, if the western yellow-billed cuckoo nests on site in the future, mortality of young and/or eggs due to destruction of nests could occur if construction/grading activities occurred during the nesting season of this species In addition, alteration of foraging behavior could adversely affect provisioning of young. Destruction of nests or eggs, injury or mortality of young, or disruption of foraging activities would be a substantial adverse effect on a special-status species (significance criterion 1). Indirect, permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, fugitive dust, diminished water quality and altered hydrology, and nighttime illumination. Fugitive dust and diminished water quality and altered hydrology (*e.g.*, runoff, erosion, sedimentation) could reduce habitat quality, including insect prey. Lighting could induce physiological stress and increase risk of predation. Although construction would be short-term nature, if these activities occurred during the breeding season they could have a substantial direct adverse effect on this species due to potential disruption of breeding and nesting activities.

Potential long-term secondary impacts associated with urban development would be the same as those described above for least Bell's vireo. These impacts include traffic noise; nighttime illumination; invasion by exotic species such as giant reed, tamarisk, and Argentine ants (which may prey on nestlings); diminished water quality and altered hydrology; increased litter; cowbird nest parasitism; pesticide use resulting in loss of prey and/or secondary poisoning; increased human activity; harassment and predation by pet, stray, and feral cats and dogs; and increased mesopredators as a result of increased habitat fragmentation. These secondary impacts may result in abandonment of nests and lower reproductive success along the urban–open space edge over the long term. However, the noise impact analysis for vireo is primarily related to nesting activity. The western yellow-billed cuckoo has not been documented to nest in the project area, and therefore the noise analysis is limited to migrating individuals. Secondary effects from noise are not expected to have the same level of impacts as to nesting least Bell’s vireo, because

migrants are not establishing territories on site and are using the area on a transitory basis. Large areas within the River corridor remain below the 60 dBA noise threshold, and migratory birds would be able to continue using these areas.

Altered hydrology and geomorphology in the Santa Clara River corridor as a result of urban development in the watershed, and resulting impacts to nesting habitat for the western yellow-billed cuckoo, are also potential long-term secondary effects of the build-out of the Specific Plan, VCC, and Entrada planning areas. However, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County over the long term. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue. As a result, the mosaic of habitats in the River that support various special-status species would be maintained, and the population of the species within and immediately adjacent to the River corridor would not be significantly affected.

RMDP facilities include a public trail and viewing platforms adjacent to and along the northern edge of the Santa Clara River corridor, as shown in **Figure 4.5-88**, Special-Status Riparian Bird Observations in Relation to Viewing Platforms. The easternmost trail and viewing platform is adjacent to the key population area segment extending from the Indian Dunes area to the confluence with Humble Canyon. There is a potential for secondary impacts to western yellow-billed cuckoo nesting in this location. Secondary impacts primarily would include noise and general increases in human activity that could disrupt behavioral activities such as foraging, territory defense, and nesting, or increase physiological stress. In addition, there is a potential for increased trash along the trail that could enter the River corridor. Due to the very close proximity of viewing platforms and trails to riparian habitats, there is the potential for unauthorized trespass by the public in to sensitive habitat areas. Although there would be no lighting provided for evening use of the trail and viewing platforms, public access during night hours may still occur and could introduce fugitive light and noise. These impacts have the potential to affect the health of young, and potentially reduce survivorship and reproductive success.

Short-term and long-term secondary impacts would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the western yellow-billed cuckoo (**Figures 4.5-55** through **4.5-59,** Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 25 acres (5.6%) of permanent loss and 43 acres of temporary loss;
- Alternative 4 – 26 acres (5.8%) of permanent loss and 41 acres of temporary loss;
- Alternative 5 – 31 acres (7.0%) of permanent loss and 47 acres of temporary loss;
- Alternative 6 – 17 acres (3.9%) of permanent loss and 43 acres of temporary loss; and
- Alternative 7 – 7.9 acres (1.8%) of permanent loss and 24 acres of temporary loss.

Compared to Alternative 2, which would result in 39 acres (8.7%) of permanent habitat loss and 44 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 through 7 would be substantially reduced. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be somewhat different and the loss of habitat under Alternative 7 would be substantially less. The difference for permanent and temporary impacts under Alternative 7 compared to the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Although the overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be substantially reduced compared to Alternative 2, and temporary impacts would be similar to substantially reduced, impacts to habitat for a state-listed endangered species would still occur. These direct permanent and temporary impacts (Loss of Habitat) therefore would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the western yellow-billed cuckoo (**Figures 4.5-55** through **4.5-59,** Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 6.9 acres (1.6%) of permanent loss;
- Alternative 4 – 3.5 acres (0.8%) of permanent loss;
- Alternative 5 – 2.6 acres (0.6%) of permanent loss;
- Alternative 6 – 1.3 acres (0.3%) of permanent loss; and
- Alternative 7 – 0.7 acre (0.1%) of permanent loss.

Compared to Alternative 2, which would result in 7.8 acres (1.8%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternative 4 would have somewhat reduced impacts compared to Alternative 3 (which is marginally different than Alternative 2) and Alternatives 5, 6, and 7 would have additional reductions compared to the other alternatives.

Although the permanent loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, impacts to habitat for a state-listed endangered species would still occur. These indirect permanent impacts (Loss of Habitat) therefore would be significant, absent mitigation under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the western yellow-billed cuckoo:

- Alternative 3 – 32 acres (7.2%) of permanent loss;
- Alternative 4 – 29 acres (6.5%) of permanent loss;
- Alternative 5 – 34 acres (7.5%) of permanent loss;
- Alternative 6 – 19 acres (4.2%) of permanent loss; and
- Alternative 7 – 8.5 acres (1.9%) of permanent loss.

Compared to Alternative 2, which would result in 47 acres (10.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. There would generally be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 3, 4, 6, and 7. Alternative 5 would have the next largest impact compared to Alternative 2.

Although the combined direct and indirect permanent loss of habitat from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC

(Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, impacts to habitat for a state-listed endangered species would still occur. The combined direct and indirect permanent impacts (Loss of Habitat) therefore would be significant, absent mitigation under Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to western yellow-billed cuckoo individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2. If the western yellow-billed cuckoo were to nest on site in the future, construction/grading activities, such as vegetation clearing, conducted during the breeding season could result in destruction of nests and loss of eggs and/or young where the species is nesting, and foraging behavior could be altered such that the health of young and their survivorship and overall reproductive success would be reduced. Permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar impacts as those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Potential short-term impacts include construction-related dust, noise, ground vibration, nighttime illumination, diminished water quality and altered hydrology. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas include traffic noise; nighttime illumination; diminished water quality; exotic plant and animal species; litter; cowbird nest parasitism; pesticides; increased human activity; and predation by pet, stray, and feral cats and dogs and mesopredators, as described above for Alternative 2. All of these impacts occurring under Alternatives 3 through 7 could result in lower reproductive success of the western yellow-billed cuckoo were it to nest in the Project area in the future.

Riparian habitat along the Santa Clara River would not be substantially affected over the long term by altered hydrology or geomorphology under Alternatives 3 through 7 (PACE 2009).

There would be no viewing platforms constructed within the River Corridor SMA under Alternatives 3 through 7.

These potential short-term and long-term secondary effects would have a substantial adverse effect on the species and contribute to the reduction of its range and distribution. These long-term and short-term secondary impacts would be significant, absent mitigation for Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to western yellow-billed cuckoo: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Although individuals have been occasionally observed in the Santa Clara River within the Project area, nesting by western yellow-billed cuckoos has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. Observed individuals were assumed to be migrants. While migrating adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, foraging and resting could be affected by construction activities if birds are flushed from habitat or otherwise avoid construction areas. If the western yellow-billed cuckoo were to nest on site in the future, construction activities such as vegetation clearing could result in impacts to individuals, including injury and mortality, if active nests with eggs or young are disturbed or destroyed. Construction activities may also alter foraging behavior by adults and thus potentially reduce the health of young and their survivorship and result in lower reproductive success. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable habitat for the western yellow-billed cuckoo resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 8.5 acres (1.9%) under Alternative 7 to 47 acres (10.4%) under Alternative 2. This would be substantial loss of suitable foraging and resting habitat, and potentially nesting habitat, for this species and could alter its use of the Project area for foraging and resting, and potentially nesting. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable foraging and resting habitat and potential nesting habitat to support the western yellow-billed cuckoo in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 314 acres of suitable habitat for the western yellow-billed cuckoo in the River Corridor SMA (**Figure 4.5-12,**

River Corridor SMA – Generalized Vegetation Communities and Land Covers), and also a small amount of habitat in the High Country SMA and Salt Creek area (approximately 8 acres).

With regard to secondary effects, foraging and resting, and potentially nesting, activities by the western yellow-billed cuckoo could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, lighting, and diminished water quality and altered hydrology. These secondary effects may alter foraging, resting, and, potentially, nest defense behavior; cause migrating and, potentially, nesting adults to abandon habitat areas due to stress, and otherwise disrupt normal behavioral patterns; and, if the species were to nest on site, cause nests to be more vulnerable to predators. Short-term effects of dust and diminished water quality and altered hydrology may affect habitat quality and the insect prey base for the western yellow-billed cuckoo, thus adversely affecting foraging behavior and potentially provisioning of young. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 300 feet, and by retaining a qualified biologist during all vegetation clearing and grading activities. Several general measures will be implemented to protect wetland habitats that will reduce impacts to the western yellow-billed cuckoo. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities, biological monitoring during any stream diversions, restrictions on construction equipment operating in ponds or flowing water, and protection of water quality from mud, silt, and other pollutants. Long-term development-related impacts include habitat fragmentation; increased traffic noise; introduction of secondary effects related to viewing platforms and trails along the River Corridor SMA (under Alternative 2 only); invasive species such as giant reed and tamarisk and Argentine ants which could prey on nestlings if nesting occurred on site; cowbirds parasitism, if nesting occurred on site; increased noise; diminished water quality, affecting prey and nesting habitat quality; lighting; pesticides that may cause secondary poisoning and loss of prey; human disturbances of nest sites, if nesting occurred on site; and predation by pet, stray, and feral cats and dogs and other mesopredators. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 314 acres of suitable habitat in the River Corridor SMA, and the small amount of habitat in the High Country SMA and Salt Creek area (approximately 8 acres), will provide western yellow-billed cuckoos with relatively undisturbed habitat for foraging and resting, and potentially nesting. Lighting restrictions along the perimeter of natural areas will help reduce predation of any nest sites by nocturnal predators and reduce physiological stress. Limited recreational usage and access restrictions within the River Corridor SMA and High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect western yellow-billed cuckoos by allowing them to forage and rest, and potentially nest, without disturbance. Controls on pesticides will reduce the chance of secondary poisoning and loss of prey. Surveys will be conducted for cowbirds and trapping will be implemented if necessary.

Controls on Argentine ants will help reduce impacts on young in nests, if nesting occurred on site.

The specific mitigation measures for the western yellow-billed cuckoo are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-24 IMPACTS TO INDIVIDUALS – WESTERN YELLOW-BILLED CUCKOO (NESTING)

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of western yellow-billed cuckoo individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to western yellow-billed cuckoo individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing

and construction in the vicinity. If construction noise meets or exceeds the 60 dBA Leq threshold, or if the biologist determines that the construction activities are disturbing nesting activities, the biologist shall have the authority to halt the construction and shall devise methods to reduce the noise and/or disturbance in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to western yellow-billed cuckoo individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-25 LOSS OF HABITAT – WESTERN YELLOW-BILLED CUCKOO

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the western yellow-billed cuckoo through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, which will preserve and enhance at least 314 acres of suitable habitat for western yellow-billed cuckoo (**Figure 4.5-12,** River Corridor SMA – Generalized Vegetation Communities and Land Covers).

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the western yellow-billed cuckoo through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the western yellow-billed cuckoo would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-26 SECONDARY IMPACTS – WESTERN YELLOW-BILLED CUCKOO (NESTING)

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on the western yellow-billed cuckoo associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such traffic noise, invasion by exotic plant species, abandonment of nests from human activity, and greater vulnerability to nocturnal predators as a result of nighttime lighting. These mitigation measures provide for protection, restoration, enhancement, and management of habitat in open space for western yellow-billed cuckoo that will offset secondary impacts by providing high-quality habitat away from development areas. Mitigation measures to avoid and minimize impacts to water quality and hydrology and inadvertent impacts to habitat outside disturbance zones during construction will also be implemented.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, and SP-4.6-63, as described above and which generally refer to habitat protection, restoration and

enhancement, and management, will be implemented to mitigate for long-term habitat fragmentation effects and increased human activity.

Human and pet activity in the River Corridor SMA will be controlled through implementation of SP-4.6-17, which states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20 states that any grading activities within or adjacent to the River Corridor SMA shall have grading perimeters clearly marked and inspected prior to grading. The Project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. These mitigation measures will address avoidance and minimization of downstream hydrology and water quality effects that could adversely affect western yellow-billed cuckoo foraging and resting habitat, and potentially breeding populations.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to western yellow-billed cuckoo, including short-term construction-related dust, noise, ground vibration, and diminished water quality; and long-term impacts such as invasive species (including exotic plants, as well as cowbirds and Argentine ants, in nesting occurs on site); increased human activity; greater vulnerability to predation by pet, stray, and feral cats and dogs; and impacts of pesticides such as indirect poisoning and loss of prey.

Secondary effects of noise and ground vibration during construction will be addressed by BIO-52 and BIO-56, as described above, which will mitigate these effects by identifying nest sites and providing for buffers between nests and construction activities.

Three mitigation measures, BIO-47, BIO-49, and BIO-70, will reduce impacts to the western yellow-billed cuckoo during construction activities by protecting water quality.

BIO-47 requires that slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area that will provide refuge for western yellow-billed cuckoo during construction.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. This will reduce impacts to western yellow-billed cuckoo by protecting habitat quality, including water quality, and by minimizing impacts on its insect prey. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-1 through BIO-16 will improve long-term habitat quality for the western yellow-billed cuckoo and include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-55 requires replacement or enhancement of nesting and foraging habitat for western yellow-billed cuckoo. All permanent loss to nesting and foraging habitat shall be mitigated at a 5:1 ratio unless otherwise authorized by CDFG or USFWS. Temporary habitat loss shall be mitigated at a 2:1 ratio. To replace the lost functions of habitat located adjacent to the Santa Clara River, all nesting and breeding habitat within the 60 dBA sound contour shall be considered degraded. Habitat within this area shall be mitigated at a ratio of 2:1.

BIO-63 and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-78 requires implementation of a cowbird trapping program once vegetation clearing begins. The program shall be implemented each day beginning April 1 and concluding on or about November 1, through the construction, maintenance, and monitoring period of the riparian restoration sites. In the event that trapping is terminated after the first few years of development, subsequent phases of the RMDP development shall trigger initiation of trapping surveys.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impact to western yellow-billed cuckoo by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant from riparian areas is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the western yellow-billed cuckoo would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

COASTAL CALIFORNIA GNATCATCHER (FT, CSC)

Life History

The coastal California gnatcatcher (*Polioptila californica californica*) (California gnatcatcher) occurs in coastal southern California and Baja California year-round, where it depends on a variety of arid scrub habitats. The California gnatcatcher occurs mainly on cismontane slopes (coastal side of the mountains) in southern California, ranging from Ventura and northern Los Angeles counties south through the Palos Verdes Peninsula to Orange, Riverside, San Bernardino, and San Diego counties. The species range continues south to El Rosario, Mexico (Dudek 2007B). Atwood (1990) reported that 99% of all coastal California gnatcatcher locality records occurred at or below an elevation of 984 feet AMSL. Since that time, data collected at higher elevations show that the species may occur as high as 3,000 feet AMSL, but that more than 99% of the known coastal California gnatcatcher locations occurred below 2,500 feet AMSL (65 FR 63680). Because of the natural topography of the southern California hills and mountain ranges, most of the higher-elevation locations are more inland, where population densities tend to be much lower than coastal populations.

The coastal California gnatcatcher typically occurs in or near sage scrub habitat which is composed of relatively low-growing, dry-season deciduous and succulent plants. Characteristic plants of this community include California sagebrush, various species of sage (*Salvia* spp.), California buckwheat, lemonadeberry, California encelia, and cactus. coastal California gnatcatchers also occur in chaparral, grassland, and riparian habitats where sage scrub is adjacent (Bontrager 1991). The use of these habitats appears to be most frequent during late summer, autumn, and winter, with smaller numbers of birds using such areas during the breeding season. The coastal California gnatcatcher tends to occur most frequently within the California sagebrush-dominated stands on mesas, gently sloping areas, and along the lower slopes of the Coast Ranges (Atwood 1990). The species occurs in high frequencies and densities in scrub communities with an open or broken canopy, whereas it is absent from scrub dominated by tall shrubs and occurs in low frequencies and densities in low scrub with a closed canopy (Weaver 1998).

Coastal California gnatcatchers glean insects and spiders from foliage of shrubs, primarily California buckwheat and coastal sage (Atwood 1993). Their diet is primarily composed of spiders but is also composed of wasps, bees, and ants (Burger *et al.* 1999). Coastal California gnatcatcher habitat use has been positively associated with total insect species richness and total individual insect abundance (County of Riverside 2008).

Coastal California gnatcatchers nests usually are located in a small shrub or cactus one to three feet above the ground. Territory size varies and is influenced by season and locale (Preston *et al.* 1998), but is unrelated to vegetation structure (Braden *et al.* 1997B). During the breeding season, territories in coastal areas are often smaller—averaging 5.7 acres (Atwood, Tsai *et al.*

1998)—than those in more inland regions, which average 8.4 acres (Braden *et al.* 1997B). Bailey and Mock (1998) observed juvenile dispersal distances averaging less than 1.9 miles from the nest territory and the longest documented juvenile dispersal is about 9.9 miles (Mock 2004). Based on an exponential dispersal model fitted to Rancho San Diego dispersal data, Bailey and Mock (1998) estimated that the coastal California gnatcatcher is capable of dispersing up to 13.5 miles.

Critical Habitat

On April 24, 2003, the USFWS published the Proposed Rule determining the critical habitat of the coastal California gnatcatcher on approximately 495,795 acres of land in Los Angeles, Orange, Riverside, San Bernardino, San Diego and Ventura counties (68 FR 20228). The Proposed Rule delineated lands as critical habitat into 13 critical habitat units, described each unit, and set forth the reasons for proposing the unit as critical habitat. Unit 13 encompassed approximately 103,290 acres in eastern Ventura and western Los Angeles counties, along the southern and eastern slopes of the Santa Susana Mountains and a portion of the interior foothills of the San Gabriel Mountains.

The Proposed Rule referenced only two areas of occupied gnatcatcher habitat in Unit 13, one area in Ventura County and the other in the foothills of the San Gabriel Mountains in Los Angeles County, approximately 14 miles apart, at opposite ends of Unit 13. The Proposed Rule acknowledged that Unit 13 is largely unoccupied by gnatcatchers and that the Unit's "primary function" is as a "regional source population" for the species and as "the east–west linkage" between the two known gnatcatcher locations in Ventura and Los Angeles counties (68 FR 20244).

On April 8, 2004, the USFWS published the notice of availability of the draft economic analysis for the proposed designation of critical habitat of the gnatcatcher (69 FR 18516). The draft economic analysis, dated February 24, 2004, was prepared for the USFWS by Economic & Planning Systems, Inc.

On December 19, 2007, the USFWS published the Revised Designation of Critical Habitat for the coastal California gnatcatcher (72 FR 72010–72213). The Revised Designation reduced the final critical habitat designation by 298,492 acres from the 2003 Proposed Rule. The Revised Designation included a re-evaluation of Unit 13, and the USFWS determined that the portions of the Santa Clarita Valley, including the Project area, are "not essential to the conservation of the coastal California gnatcatcher." (72 FR 72013). The USFWS determined that the excluded area does not have the spatial configuration and primary constituent elements essential to the conservation of the species.

Based on the Revised Designation, there is no current coastal California gnatcatcher critical habitat designation for the Project area, and, therefore critical habitat is not further addressed in the California gnatcatcher analysis in this EIS/EIR.

Recovery Plan

No recovery plan for the coastal California gnatcatcher has been published.

Threats

The coastal California gnatcatcher has declined due to widespread destruction of its coastal scrub habitat (Atwood 1990). It was estimated as early as the 1970s that up to 90% of coastal scrub has been lost as a result of development and land conversion (Westman 1981; Barbour and Major 1977), and coastal scrub is considered to be one of the most depleted habitat types in the United States (Kirkpatrick and Hutchinson 1977; Axelrod 1978; Klopatek *et al.* 1979, Westman 1987; O'Leary 1990). In addition, agricultural use, such as grazing and field crops, urbanization, air pollution, increases in fire frequency, and the introduction of exotics have all had an adverse impact on extant coastal scrub habitat. In particular, high fire frequencies and the lag period associated with recovery of the vegetation may significantly reduce the viability of affected subpopulations of the coastal California gnatcatcher (56 FR 47053-47060). Increased competition with introduced Mediterranean annual grasses may cause coastal scrub stand-thinning (Minnich and Dezzani 1998). Another significant threat to the coastal California gnatcatcher is the increased risk of predation, which is the most common cause of nest failures for the California gnatcatcher (Grishaver *et al.* 1998). Nest predators are numerous and especially include native snakes, but also urban-adapted birds such ravens and crows, mesopredators such as raccoons and opossums, ground squirrels, and coyotes (Grishaver *et al.* 1998). The coastal California gnatcatcher also may be parasitized by the brown-headed cowbird, although the cowbird's contribution to nest failure varies in different areas (Grishaver *et al.* 1998). Several other potential human- or development-related factors may affectcoastal California gnatcatchers. Construction-related impacts include dust; noise and ground vibration; increased human activity in close proximity to nesting and foraging areas; and lighting, which may alter behavior, induce physiological stress, and increase predation risk. Long-term effects related to development include increased human activity; noise; lighting; pesticides, which may reduce prey and cause secondary poisoning; and predation and harassment by pet, stray, and feral cats and dogs.

Survey Results

Surveys for upland bird species were conducted throughout the Project site and in nearby areas between 1995 and 2008.

Breeding coastal California gnatcatchers have been documented off site to the east and southwest (**Figure 4.5-99**, California Gnatcatcher Observations and Habitat within the Greater Newhall Ranch Region). Two single observations of dispersing coastal California gnatcatchers were observed during 2007 and 2008 construction monitoring in the Project vicinity, as described further below. This species has not been observed within the Specific Plan, VCC or Entrada planning areas during USFWS protocol surveys. Focused surveys for the coastal California gnatcatcher were conducted in various areas of the Project site in 2000 (Guthrie 2000A, 2000B, 2000D) and 2004 (Guthrie 2004A, 2004B, 2004D, 2004E, 2004G). Dudek conducted USFWS protocol surveys within the Mission Village and Landmark Village proposed project sites in 2007 and 2008 (Priest 2007B; Lemons 2008). Compliance Biology conducted USFWS protocol surveys within the VCC planning area in 2008 (Compliance Biology 2008). Focused surveys have also been conducted off site in the Legacy Village area (Guthrie 2004C; Impact Sciences, Inc. 2000; SAIC 2003) and other adjacent off-site areas (Compliance Biology 2003B, 2006A; PCR 1998). Non-protocol avian surveys were conducted by Bloom Biological, Inc. in 2007 and 2008 (Bloom Biological, Inc. 2008).

Although focused surveys have not documented the coastal California gnatcatcher on site, it has been observed twice in the Project area during the course of biological monitoring. The first observation occurred during monitoring conducted in the VCC planning area when an individual coastal California gnatcatcher was observed on October 5, 2007 (**Figure 4.5-100**, California Gnatcatcher Observations and Habitat within the Immediate Newhall Ranch Area), by Dudek biologist Jeff Priest and biologist Ron Francis, a sub-consultant to Dave Crawford, Compliance Biology, Inc. (Priest 2007A). This observation occurred for approximately eight to 10 minutes within the VCC planning area in coastal scrub habitat located on the hills in the north-central portion of the site, on an easterly facing slope. Subsequent USFWS protocol surveys within the VCC planning area were negative in 2008 (Compliance Biology 2008). The second set of observations was made on August 8 and August 15, 2008, by Dudek biologist Traci Caddy (Ortega 2008), during monitoring for improvements of the Del Valle Training Center Road located south of the town of Val Verde off of Chiquito Canyon and east of the Del Valle Training Center (**Figure 4.5-100**). The August 8 observation occurred during the pre-construction nesting bird survey, with an individual observed for approximately five minutes in California sagebrush scrub before it flew west. The August 15 observation occurred during construction monitoring, with the individual observed for approximately five minutes in California sagebrush–California buckwheat scrub before it flew west. The coastal California gnatcatcher was not observed for the remaining three weeks of construction monitoring, which terminated September 15.

Given the relatively late time of year of the observations, the limited time period of the observations (*i.e.*, a single observation in 2007 and the one-week time period in 2008), and the fact that no other coastal California gnatcatchers have ever been observed in the Project area despite extensive focused and general surveys during the breeding season, these two sets of

observations are believed to be of dispersing or transient individuals, perhaps from isolated populations of coastal California gnatcatchers that have been periodically observed to the east of the Project site (**Figure 4.5-99**, California Gnatcatcher Observations and Habitat within the Greater Newhall Ranch Region). The Project area is within the known dispersal distances of this species from two off-site observations of the coastal California gnatcatcher: the Chivas Canyon location, 3.6 miles southwest of the Project area, and the Golden Valley location, 6.3 miles east of the Project area. Although the site appears to provide habitat for dispersal, it is unknown whether the site could support nesting populations of coastal California gnatcatcher. However, for the purpose of this analysis, it is assumed that the coastal California gnatcatcher could colonize and breed on site, although if this occurred, the breeding population probably would be small.

Suitable coastal scrub habitats on site to support dispersal and potential nesting for the coastal California gnatcatcher include California sagebrush scrub, California sagebrush scrub–undifferentiated chaparral, big sagebrush–California buckwheat, California sagebrush–*Artemisia californica*, California sagebrush–black sage, California sagebrush–California buckwheat scrub, and California sagebrush–purple sage (**Figure 4.5-101**, Scrub and Chaparral Wildlife Habitat). A total of 4,327 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 30 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 0.7% of these habitats on site (**Figure 4.5-102**, Alternative 2 Impacts to Scrub and Chaparral Wildlife Habitat). A total of 2.3 acres would be directly temporarily impacted.

The coastal California gnatcatcher has only been documented to use the Project area for dispersal, but it has the potential to colonize and breed on site in small numbers. If the coastal California gnatcatcher were to nest on site in areas subject to permanent or

tem0porary disturbances resulting from implementation of the RMDP, this permanent loss of habitat and temporary impacts would have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 1,487 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 34.4% of suitable habitats on site (**Figure 4.5-102**, Alternative 2 Impacts to Scrub and Chaparral Wildlife Habitat).

A large amount and percentage of suitable habitat for the coastal California gnatcatcher would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. If the coastal California gnatcatcher were to nest on site in areas subject to permanent habitat loss, this loss of habitat would have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 1,517 acres (35.1%).

A large amount and percentage of suitable habitat for the coastal California gnatcatcher would be permanently lost as a result of the combined direct and indirect impacts. If the coastal California gnatcatcher were to nest on site in areas subject to permanent habitat loss, this loss of habitat would have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of

the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Dispersing coastal California gnatcatchers have been documented in the Project vicinity on two separate occasions. Dispersing birds are highly mobile and therefore injury or mortality of these individuals is not expected to occur as a result of implementation of the RMDP and the SCP. Individuals could easily vacate areas subject to vegetation clearing and other construction/grading activities; however, their use of and distribution in the Project area during dispersal could be affected by construction activities. If the coastal California gnatcatcher were to colonize and nest in the Project area, vegetation clearing or grading during the nesting season could result in destruction of nests, eggs, or young, cause nest abandonment, or alter foraging behavior and provisioning of young, which could result in reduced survivorship and reduced reproductive success. Injury or mortality of individual birds, and specifically destruction of nest, eggs, or young; interference with foraging and provisioning of young; or nest abandonment; would have a substantial direct adverse effect on this species; (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct impacts to individuals, but over a much larger area. Construction and/or grading activities may occur during the nesting season and could result in the destruction of nest, eggs, or young, interfere with foraging and provisioning of young, or cause nest abandonment. These impacts would have a substantial adverse impact on this species (significance criterion 1). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

In the short term, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas occurring during the breeding season would have the potential to affect both dispersing and nesting coastal California gnatcatcher adjacent to construction zones. These impacts could include exposure to construction-related dust, noise, ground vibration, and nighttime lighting. Dust could degrade habitat quality, noise and ground vibration could affect nesting and foraging behavior, and nighttime lighting could induce physiological stress and increase predation by nocturnal

predators. Potential long-term development-related secondary impacts include habitat fragmentation; habitat degradation from frequent wildfires; increased human activity; nighttime illumination; potential harassment by humans and pet, stray, and feral cats and dogs and other mesopredators; loss of food sources and secondary poisoning from pesticides; and predation of nestlings by Argentine ants along the open space–development interface.

These short-term and long-term secondary impacts would permanently reduce the number of coastal California gnatcatchers that may occur along the urban–open space edge, interfere with the movement of the species between habitat areas due to fragmentation, and contribute to the reduction of the range and distribution of the coastal California gnatcatcher in the Project area (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the coastal California gnatcatcher (**Figures 4.5-103** through **4.5-107**, Alternatives 3 through 7 Impacts to Scrub and Chaparral Wildlife Habitat):

- Alternative 3 – 28 acres (0.6%) of permanent loss and 4.5 acres of temporary loss;
- Alternative 4 – 28 acres (0.7%) of permanent loss and 2.0 acres of temporary loss;
- Alternative 5 – 32 acres (0.7%) of permanent loss and 6.0 acres of temporary loss;
- Alternative 6 – 28 acres (0.6%) of permanent loss and 7.6 acres of temporary loss; and
- Alternative 7 – 19 acres (0.4%) of permanent loss and 13 acres of temporary loss.

Compared to Alternative 2, which would result in 30 acres (0.7%) of permanent habitat loss and 2.3 acres of temporary impacts, the permanent loss of habitat would not be substantially different under Alternatives 3, 4, 5, and 6 and would be somewhat less under Alternative 7. Compared to Alternative 2, the temporary loss of habitat would not be substantially different under Alternatives 3, 4, 5, and 6 and would be marginally greater under Alternative 7. The difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would result in fewer permanent impacts and more temporary impacts to suitable habitat for the coastal California gnatcatcher compared to the other alternatives.

Although the overall loss of habitat resulting from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be less than or similar in magnitude to the overall habitat loss under Alternative 2, if the coastal California gnatcatcher were to nest on site, these impacts would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the coastal California gnatcatcher (**Figures 4.5-103** through **4.5-107**, Alternatives 3 through 7 Impacts to Scrub and Chaparral Wildlife Habitat):

- Alternative 3 – 1,408 acres (32.5%) of permanent loss;
- Alternative 4 – 1,368 acres (31.6%) of permanent loss;
- Alternative 5 – 1,316 acres (30.4%) of permanent loss;
- Alternative 6 – 1,088 acres (25.1%) of permanent loss; and
- Alternative 7 – 1,007 acres (23.3%) of permanent loss.

Compared to Alternative 2, which would result in 1,487 acres (34.4%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7 and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would reduce impacts to suitable habitat for the coastal California gnatcatcher compared to the other alternatives.

Although the permanent habitat loss under Alternatives 3 through 7 would be less than the habitat loss under Alternative 2, a large amount and percentage of suitable habitat for the coastal California gnatcatcher would still be permanently lost as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under these alternatives. If the coastal California gnatcatcher were to nest on site, this indirect permanent loss of habitat under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and

Entrada planning areas would result in the following combined direct and indirect permanent impacts to suitable habitat for the coastal California gnatcatcher:

- Alternative 3 – 1,436 acres (33.2%) of permanent loss;
- Alternative 4 – 1,396 acres (32.3%) of permanent loss;
- Alternative 5 – 1,349 acres (31.2%) of permanent loss;
- Alternative 6 – 1,116 acres (25.8%) of permanent loss; and
- Alternative 7 – 1,026 acres (23.7%) of permanent loss.

Compared to Alternative 2, which would result in 1,517 acres (35.1%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, there would also be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 that would reduce impacts to suitable habitat for the coastal California gnatcatcher compared to the other alternatives.

Although the combined permanent habitat loss under Alternatives 3 through 7 would be less than the habitat loss under Alternative 2, a large amount and percentage of suitable habitat for the coastal California gnatcatcher would still be permanently lost as a result of implementation of the RMDP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under these alternatives. If the coastal California gnatcatcher were to nest on site, this combined permanent loss of habitat under Alternatives 3 through 7 would be significant, absent mitigation.

Impacts to Individuals

The potential impacts to coastal California gnatcatcher individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than for Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Individuals could be displaced from occupied habitat by construction activities, and construction occurring during the nesting season could result in the destruction of nest, eggs, or young, interfere with foraging and provisioning of young, or cause nest abandonment, if the species were to colonize and nest on site. These impacts to individual coastal California gnatcatchers occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative

3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development. Short-term impacts include construction-related dust, noise, ground vibration, and nighttime illumination, that could cause habitat degradation, disrupt nesting and foraging activities, and abandonment of nests, if the coastal California gnatcatcher were to colonize and nest on site. Potential long-term secondary impacts include habitat fragmentation, habitat degradation due to wildfire, increased human activity, nighttime illumination, increased predation, and secondary poisoning, as described above for Alternative 2. These secondary impacts would permanently reduce coastal California gnatcatcher populations along the urban–open space edge and contribute to the reduction of the range and distribution of this species in the Project area. Short-term and long-term secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to coastal California gnatcatcher: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and habitat outside the Project footprint.

The coastal California gnatcatcher currently is only known to use the Project area during dispersal. However, it has the potential to colonize and nest on site, although breeding population probably would be small. While dispersing adults and juveniles are mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, individuals could be displaced from occupied habitat by construction activities. If the coastal California gnatcatcher were to colonize and nest on site, impacts to individuals also could occur if active nests were disturbed during vegetation clearing and construction/grading activities, resulting in the destruction of the nests and loss of eggs and/or young, or interfere with foraging or provisioning of young. Construction activities may also cause abandonment of nests due to human activity, noise, and ground vibration. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities. This species is highly detectable and territorial, and its presence is easily documented if it occurs as a breeding resident.

The combined permanent loss of suitable habitat for the coastal California gnatcatcher resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 1,026 acres (23.7%) under Alternative 7 to 1,517 acres (35.1%) under Alternative 2. This would be a substantial loss of suitable habitat for this species and will alter its use of the Project area, both during dispersal and potentially for nesting. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a permanent open space system that will provide suitable habitat to support both foraging and breeding by the coastal California gnatcatcher in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 1,936 acres of suitable habitat for the coastal California gnatcatcher in the High Country SMA and the Salt Creek area (**Figure 4.5-3**). If coastal California gnatcatcher is documented as a breeding resident, occupied habitat will be mitigated at a ratio of 3:1.

With regard to secondary effects, foraging and potential nesting activities by the coastal California gnatcatcher could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may cause adults to vacate territories and abandon nests due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to nocturnal predators. These short-term construction-related secondary impacts will be minimized by conducting pre-construction surveys to determine if active nests, are present in the disturbance zone or within 300 feet and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include habitat fragmentation; wildfire; increased human activity; lighting; pesticides, which may cause secondary poisoning and loss of food resources; harassment by pet, stray, and feral cats and dogs and other mesopredators; and Argentine ants that may prey on nestlings. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 1,936 acres of suitable habitat in the High Country SMA and Salt Creek area will provide coastal California gnatcatchers with relatively undisturbed habitat. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by predators and reduce behavioral disturbances and physiological stress. Limited recreational usage and access restrictions within the High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect coastal California gnatcatchers by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of direct and secondary poisoning and loss of food sources.

The specific mitigation measures for the coastal California gnatcatcher are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-27 IMPACTS TO INDIVIDUALS – COASTAL CALIFORNIA GNATCATCHER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate impacts to coastal California gnatcatcher individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to coastal California gnatcatcher individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, clearing and construction in the vicinity shall be postponed at the discretion of the biologist, until the nest is vacated.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to coastal California gnatcatcher individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-28 LOSS OF HABITAT – COASTAL CALIFORNIA GNATCATCHER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for coastal California gnatcatcher through habitat protection, restoration and enhancement, and management.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The High Country SMA will protect and manage at least 1,307 acres of suitable habitat for coastal California gnatcatcher.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measure to mitigate for the loss of habitat for coastal California gnatcatcher through habitat protection, restoration and enhancement, and management.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The Salt Creek area includes 629 acres of suitable habitat for the coastal California gnatcatcher.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-55 will be implemented to mitigate for loss of documented occupied nesting habitat for coastal California gnatcatcher. If the coastal California gnatcatcher is identified nesting on site, the applicant will acquire or preserve nesting coastal California gnatcatcher habitat at a 3:1 ratio for impacts to documented occupied habitat, or by the ratio specified in BIO-2, which ever is greater. Mitigation acquisition shall occur at an agreed-upon location as approved by the USFWS upon consultation.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the California gnatcatcher would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-29 SECONDARY IMPACTS – COASTAL CALIFORNIA GNATCATCHER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as habitat fragmentation, increased human activity, inadvertent impacts to habitat during construction, and nighttime lighting.

SP-4.6-36 through SP-4.6-42, as described above, refer to habitat protection and management in the High Country SMA that will be implemented to mitigate for long-term habitat fragmentation effects and increased human activity.

Several mitigation measures will control human activities in the High Country SMA. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 addresses edge effects along open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only on developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-34 and SP-4.6-35 require that all grading perimeters within the High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to biological resources outside the grading area in the High Country SMA.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to California gnatcatcher, including short-term construction-related dust, noise, ground vibration and increased human activity as well as long-term habitat fragmentation, increased human activity, greater vulnerability to predation by pet, stray, and feral cats and dogs and other mesopredators, as well as Argentine ants, and loss of food sources and secondary poisoning from pesticide use.

BIO-52 and BIO-56, as described above, will mitigate the effects of noise and ground vibration by identifying nest sites and providing for buffers between nests and construction activities.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-19 through BIO-21, as described above, will mitigate for increased human activity in the Project area through habitat protection, restoration and enhancement, and management.

BIO-63 and BIO-69 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-64 will be implemented to prevent poisoning and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used

within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impacts to California gnatcatcher by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the California gnatcatcher would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

INTENTIONALLY LEFT BLANK

RINGTAIL CAT (CFP)

Life History

The ringtail cat (*Bassariscus astutus*) (ringtail) is a California Fully Protected species that occurs throughout the southwestern United States and south into Baja California and the provinces of Guerrero, Oaxaca, and Veracruz of mainland Mexico (Hall 1981). It occurs in all of Arizona and Texas, and virtually all of New Mexico and Oklahoma (Hall 1981). It also occurs in southwestern Oregon, the southern and eastern portions of Nevada, the western and eastern portions of Utah, the southwest corner of Wyoming, the western and central portions of Colorado, south-central Kansas, southwestern Missouri, and northern Louisiana (Hall 1981). The ringtail occurs throughout much of California, absent only in the San Joaquin Valley and the extreme northwestern corner of the state (Hall 1981; Zeiner *et al.* 1990B). There is relatively little information for the current status of the ringtail in California. Belluomini (1980) conducted a review of the ringtail in California based on sighting records, museum specimens, and the current scientific literature, resulting in 446 occurrence records in 49 counties in California, and the species was only absent from Modoc Plateau, Antelope Valley, and portions of the San Joaquin Valley. Abundances were highest along riparian areas in northern California and scarcest in the Mojave and Colorado deserts, the east slope of the Sierra Nevada, the San Joaquin Valley, and northeastern California (Belluomini 1980). There are two clusters of records for ringtail in Los Angeles County: two occurrences in the Santa Monica Mountains and three occurrences on the southern flank of the San Gabriel Mountains (Belluomini 1980).

Suitable habitat for ringtails consists of broken semi-arid country with a mixture of hardwood forest and shrubland in close association with rocky areas or riparian habitats (Poglayen-Neuwall and Toweill 1988; Zeiner *et al.* 1990B). Ringtails typically occur at elevations ranging from sea level to 4,590 feet (1,400 meters) AMSL, but may occur at elevations ranging from 6,560 feet to 9,514 feet (2,000 to 2,900 meters) AMSL (Poglayen-Neuwall and Toweill 1988). Their primary habitat is oak, pinyon pine, and juniper woodlands, but they also occur in conifer forests, chaparral, desert, and dry tropical habitats as long as rocky outcroppings, canyons, boulder piles, or talus slopes are present (Poglayen-Neuwall and Toweill 1988). Ringtails are dependent on open water and usually do not occur more than 0.6 mile (one kilometer) from a permanent water source (Zeiner *et al.* 1990B). Ringtails are generally uncommon and distributed sporadically, and occur in varying population densities where they do occur. In two California locales, densities ranged from 10.5 to 20.5 ringtails per square kilometer in the northern Central Valley, and from 0.08 to 2.3 ringtails per square kilometer in chaparral in a Pacific drainage of the Sierra Nevada (Poglayen-Neuwall and Toweill 1988).

Ringtails are primarily nocturnal but also exhibit crepuscular activity (at dawn and dusk) (Kavanau 1971). They are omnivorous, but primarily eat rodents, rabbits, hares, carrion, and arthropods, but also small birds, snakes, frogs, and fish (Poglayen-Neuwall and Toweill 1988).

The birth of one to four offspring typically occurs in May and June (Poglayen-Neuwall and Toweill 1988). Young develop rapidly and attain adult size by 30 weeks (Poglayen-Neuwall and Toweill 1988).

Ringtail home ranges are widely variable and are related to sex and habitat factors (Poglayen-Neuwall and Toweill 1988). Ringtail home ranges have been estimated to vary from as small as 12 acres (five hectares) in a riparian habitat to as large as 336 acres (136 hectares) (Poglayen-Neuwall and Toweill 1988).

Other than habitat loss and fragmentation, which is probably the greatest threat to the southern California ringtail populations, no other specific threats related to development have been identified for this species. However, a potential threat related to habitat loss and fragmentation is a decline in coyotes in fragmented habitats, resulting in the "mesopredator release" effect (Crooks and Soulé 1999), including raccoons and foxes that are potential predators on ringtails (Zeiner *et al.* 1990B). An increase in raccoons also could increase competition for food. Other development-related potential threats are nighttime lighting, which could make ringtails more vulnerable to nocturnal predators such as owls, raccoons, and foxes, and disturbance due to increased human activity within or in proximity to ringtail habitat (*e.g.*, increased stress, harassment, disturbance of dens, trampling of vegetation, off-road vehicles); pet, stray, and feral cats and dogs; and rodenticides that could reduce the rodent prey of ringtails.

Survey Results

The ringtail has not been observed in the Project area. Impact Sciences (2005) conducted track/scent station monitoring for mammals, with negative results for the ringtail. This species also has never been observed in the numerous wildlife surveys conducted in the Specific Plan area, including recent wildlife surveys conducted by Dudek (Dudek and Associates 2006B, 2006C, 2006D, 2006E). Although their survey results were negative, Impact Sciences concluded that the species has a moderate potential to occur on site in dense woodland or riparian areas. The nearest recent occurrence of ringtail is a 2007 observation in Elderberry Canyon approximately 0.5 mile above Castaic Dam in a narrow rocky canyon (Huntley 2009). The Belluomini (1980) review included two recorded occurrence areas in Los Angeles County: the Santa Monica Mountains and the southern flank of the San Gabriel Mountains. If the ringtail does occur on site, it likely occurs in very low densities. The area with the highest potential to support the species is the Santa Clara River corridor because of the presence of open water and riparian habitats. The potential for the ringtail to occur in the proposed upland development areas is considered to be very low because of a general lack of suitable riparian and open water habitat. Within upland areas on site, it has greater potential to occur in canyons and/or wooded areas of the High Country SMA. Vegetation communities on site considered to be suitable habitat for the ringtail are southern coast live oak riparian forest, southern cottonwood–willow

riparian, southern willow scrub, coast live oak woodland, valley oak woodland, and mixed oak woodland. A total of 1,451 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (NO ACTION/NO PROJECT)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 48 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 3.3% of these habitats on site (**Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat). A total of 46 acres would be temporarily impacted.

This species has not been observed during the numerous surveys along the River corridor or elsewhere in the Project area. If ringtails were present, even a small permanent loss of occupied habitat and temporary impacts as a result of construction and/or grading activities could remove a den area and would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species population to drop below self-sustaining levels on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 73 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 5.0% of these communities on site (**Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat).

This species has not been observed during the numerous surveys along the River corridor and it is considered to have a low potential to occur in the Project area due to a general lack of suitable habitat. If ringtails were present, however, because of its rarity even the relatively small amount and percentage of suitable habitat for the ringtail that would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species population to drop below self-sustaining levels on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 120 acres (8.3%). Although this species has a low probability of occurring in the Project area, if ringtails were present, because of its rarity the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on ringtail on site; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species population to drop below self-sustaining levels on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

If the ringtail were present in the proposed Project construction zone, absent mitigation, construction and/or grading activities related to RMDP facilities could result in injury or mortality of any individuals occupying this habitat. The primary risk would be to young in a den as a result of vegetation clearing, where individuals may be injured or killed by direct contact with construction equipment or be flushed from dens and exposed to increased predation and vehicle collisions. Flushed individuals, including adults and young, may become disoriented and unable to find safe refuge, resulting in an increased risk of mortality. Implementation of the SCP would not directly impact this species. Although a relatively small amount of habitat would be removed and the potential for impacts to individuals is considered to be very low, the loss of any ringtails occupying this habitat as a result of construction and/or grading activities would have a substantial

adverse effect on a special-status species (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is similar to that described above for direct permanent impacts to individuals. The loss of any ringtails occupying this habitat as a result of construction and/or grading activities would have a substantial adverse effect on a special-status species (significance criterion 1). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would have the potential to affect any ringtails in areas adjacent to construction zones. These impacts could include disruptions of essential behavioral activities (*e.g.*, foraging, breeding, and/or rearing of young) due to increased human activity, noise, and nighttime illumination, the latter of which may disrupt the species' nocturnal behavior and make them more vulnerable to predation by nocturnal predators, such as owls, raccoons, and foxes. As noted above, individuals flushed from dens during construction may become disoriented and unable to find safe refuge, thus increasing their risk of mortality. Implementation of the SCP would not affect this species.

Potential long-term development-related secondary impacts associated with use of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas include disruption of nocturnal activities; increased human activities within and in proximity to suitable habitat (*e.g.*, increased stress, harassment, trampling of vegetation, and/or off-road vehicles); greater vulnerability to predation by nocturnal predators as a result of nighttime lighting; greater vulnerability to predation by pet, stray, and feral cats and dogs within about 200 feet of the urban–open space edge (CBI 2000) as well as other nocturnal mesopredators, such as owl, raccoon, and fox (Crooks and Soulé 1999); increased competition for food resources with raccoons; and loss of rodent prey as a result of rodenticides that may be used to control pest rodents (*e.g.*, ground squirrels in landscaped areas or golf courses). These secondary impacts could permanently affect ringtails that may occur in proximity to the urban–open space edge and thus have a substantial adverse effect on a special-status species (significance criterion 1). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the ringtail (**Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 34 acres (2.4%) of permanent loss and 45 acres of temporary loss;
- Alternative 4 – 35 acres (2.4%) of permanent loss and 43 acres of temporary loss;
- Alternative 5 – 44 acres (3.0%) of permanent loss and 48 acres of temporary loss;
- Alternative 6 – 34 acres (2.3%) of permanent loss and 44 acres of temporary loss; and
- Alternative 7 – 13 acres (0.9%) of permanent loss and 37 acres of temporary loss.

Compared to Alternative 2, which would result in 48 acres (3.3%) of permanent loss and 46 acres of temporary impacts, the permanent and temporary loss of habitat under Alternatives 3, 4, and 6 would be somewhat less overall. Compared to Alternative 2, the permanent loss of habitat under Alternative 5 and the temporary loss of habitat under Alternatives 3 through 6 would not be substantially different. The substantial difference between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries and other changes to the Project footprint under Alternative 7 that would result in reduced permanent impacts to suitable habitat for the ringtail compared to the other alternatives.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, and because, if present, any loss of suitable habitat would have an adverse effect on this species, direct impacts (Loss of Habitat) would be significant, absent mitigation under Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the ringtail (**Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 62 acres (4.3%) of permanent loss;
- Alternative 4 – 57 acres (3.9%) of permanent loss;
- Alternative 5 – 57 acres (3.9%) of permanent loss;
- Alternative 6 – 32 acres (2.2%) of permanent loss; and
- Alternative 7 – 34 acres (2.3%) of permanent loss.

Compared to Alternative 2, which would result in 73 acres (5.0%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 and 5 would be somewhat reduced and Alternatives 6 and 7 substantially reduced compared to Alternative 3.

Even though the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than the overall habitat loss under Alternative 2, if present, any loss of suitable habitat would have an adverse effect on this species. Indirect impacts (Loss of Habitat) would be significant, absent mitigation under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the ringtail:

- Alternative 3 – 96 acres (6.6%) of permanent loss;
- Alternative 4 – 92 acres (6.3%) of permanent loss;
- Alternative 5 – 101 acres (7.0%) of permanent loss;
- Alternative 6 – 65 acres (4.5%) of permanent loss; and
- Alternative 7 – 47 acres (3.2%) of permanent loss.

Compared to Alternative 2, which would result in 120 acres (8.3%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. However, if present, any loss of suitable habitat would have an adverse effect on this species. Therefore, the combined direct and indirect permanent loss of suitable habitat for the ringtail occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual ringtails as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Therefore, impacts to individual ringtails occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as increased human activity, habitat fragmentation, increased risk of predation, and nighttime lighting. Therefore, the loss or degradation of suitable habitat and impacts to individual ringtails due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to the ringtail cat: (1) impacts to individuals; (3) loss of habitat; and (2) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur during construction as a result of increased human activity, noise, and lighting. If individuals, including adults and young, are flushed from dens during construction they may become disoriented and unable to find safe refuge, resulting in increased risk of mortality from predation or vehicle collisions. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for ringtail in suitable habitat in and within 300 feet of the construction zone. If the species is observed in the breeding and rearing period, no construction-related activities shall occur within 300 feet until it has been determined that construction activities would not adversely affect the rearing of young. Biological monitoring will also be conducted during initial vegetation clearing and grading activities.

The combined permanent loss of suitable habitat for the ringtail cat resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3

only), and Entrada planning areas would range from 47 acres (3.2%) under Alternative 7 to 120 acres (8.3%) under Alternative 2. Because the species is typically associated with areas of dense vegetative cover, rocky areas, and/or steep canyons with nearby permanent water, most of this suitable habitat probably would not support the entire life cycle of the species, but could be used for movement and dispersal. If the species were present, because of its rarity, this would be substantial loss of suitable habitat for this species and probably would alter its use of the Project area. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide potential habitat to for the ringtail cat in the Project vicinity, although only a small portion may be suitable for permanent occupation and support of breeding, such as more remote canyons in the High Country SMA. Implementation of these mitigation measures will result in protection and management of approximately 1,170 acres of potential habitat for the ringtail cat in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, ringtails occupying habitat in close proximity to construction activities could be adversely affected during construction due to increased human activity, noise, and lighting, which could affect their essential activities such as foraging, breeding, and caring for young. Individuals, including adults and young, could be flushed from dens, resulting in disorientation and increased exposure to predators and vehicle collisions. The pre-construction surveys described above will avoid and minimize these potential short-term impacts. Potential long-term effects of development include habitat fragmentation effects, including increased mesopredators; increased human activity; pet, stray, and feral cats and dogs; and use of rodenticides, which may cause secondary poisoning or affect their rodent prey base. The primary mitigation for these long-term effects is the preservation of a large open space system that will provide foraging habitat to support the ringtail in the Project vicinity, and in particular the High Country SMA, which has the greatest potential to support the ringtail. Implementation of Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in protection and management of approximately 1,170 acres of suitable habitat for the ringtail. This habitat will be conserved within three main interconnected open space areas totaling approximately 6,300 acres: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**). Several specific mitigation measures will also be implemented to control human activities in open space areas, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. Pesticides, including rodenticides, will be controlled through an integrated pest management (IPM) plan. Implementation of these measures will allow this species to persist on site, if present, after development in the large amount of permanent open space that will be protected and managed.

All specific mitigation measures for the ringtail cat are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-30 IMPACTS TO INDIVIDUALS – RINGTAIL CAT

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified two mitigation measures that will help avoid impacts to ringtail individuals through pre-development surveys.

SP-4.6-53 states that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present. Each of these surveys shall be conducted in accordance with consultation requirements set forth in SP-4.6-59, described below, and documented in a separate report. Based on the results of the surveys, additional conditions and mitigation measures may be required.

SP-4.6-59 states that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance and further mitigation activities. Based on the results of the consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to avoid impacts to ringtail individuals through pre-construction coordination and ringtail surveys.

BIO-52 requires that prior to grading and construction activities, a qualified biologist attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractors describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-83 requires a pre-construction survey for ringtail 30 days prior to construction activities. The survey area shall include suitable riparian and woodland habitat within the construction disturbance zone and a 300-foot buffer around the construction site. Should the ringtail be observed in the breeding and rearing period, no construction-related activities shall occur within 300 feet until it has been determined that the ringtail is no longer be present and/or that

construction activities would not adversely affect the rearing of young. Should the ringtail be observed outside the breeding and rearing period, denning ringtail shall be safely evicted by a qualified biologist (as determined by a Memorandum of Understanding with CDFG). All activities that involve the ringtail shall be documented and reported to CDFG.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, through ongoing surveys and avoidance, impacts to ringtail individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7. Because the ringtail is a California Fully Protected species, no injury or mortality of individuals would occur as a direct result of construction activities.

IMPACT 4.5-31 LOSS OF HABITAT – RINGTAIL CAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will help mitigate the loss of habitat for ringtail cat through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The River Corridor SMA will preserve and

enhance at least 330 acres of potential habitat for ringtail cat. The High Country SMA will preserve and enhance 572 acres of potential habitat for ringtail cat.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA are the same as required for the River Corridor SMA and oak tree replacement occurs as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA, including the following: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for ringtail cat through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-42 requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities (County of Los Angeles 1988). Fencing shall extend to the root protection zone.

BIO-55 requires that maps of suitable riparian habitat be updated for special-status avian species, and the creation or enhancement of habitat shall be similar to the habitat removed.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the ringtail cat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-32 SECONDARY IMPACTS – RINGTAIL CAT

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will help reduce potential secondary impacts to the ringtail, including increased human activity, habitat fragmentation, increased incidence of vehicle collisions, and nighttime lighting.

Several of the mitigation measures relate to habitat protection, restoration and enhancement, and management of the large open space system that will provide habitat for the ringtail in perpetuity.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 address habitat restoration in the River Corridor SMA and provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

Several other mitigation measures address increased human activity, including pets, and edge effects, such as nighttime lighting in proximity to suitable ringtail habitat.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where

feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side of bank stabilization and development.

SP-4.6-17 and SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the River Corridor SMA and High Country SMA.

SP-4.6-56 requires that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that will reduce short-term and long-term secondary impacts to ringtail, including construction-related activities, increased human activities, harassment and predation by pet, stray, and feral cats and dogs, and the use of pesticides (including rodenticides).

BIO-52 and BIO-83, as described above, address potential secondary impacts during construction by requiring a qualified biologist to monitor construction activities (BIO-52) and pre-construction surveys for the ringtail and a 300-foot buffer between construction zones and areas supporting ringtail breeding and rearing (BIO-83).

BIO-1 through BIO-16 are related to habitat protection, restoration and enhancement, and management to offset increased human activity. These measures include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. In addition, BIO-19 describes the dedication of 1,518 acres in the Salt Creek area, which includes 269 acres of suitable habitat for the ringtail.

BIO-63 requires as-needed control of stray and feral cats and dogs in open space areas. All pets must be on leash in any areas within or adjacent to open space areas.

BIO-64 describes the preparation of an integrated pest management (IPM) plan that addresses the use of pesticides, including rodenticides and insecticides, in areas in proximity to potential ringtail habitat and thus reduces the potential impact of rodenticides on prey taken by ringtails.

BIO-73 requires permanent fencing to be installed along all trails that pass through the River Corridor SMA. This measure will minimize impacts to protected vegetation communities and special-status wildlife species that may occur due to increased use of open space areas by humans and domestic animals.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to ringtails and their habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

INTENTIONALLY LEFT BLANK

UNDESCRIBED SNAIL SPECIES (NO CURRENT STATUS)

Life History

In 2006, an undescribed species of snail (*Pyrgulopsis* sp. *nova*) was observed on the Project site within portions of the Middle Canyon Spring. A specimen was collected and sent to the Smithsonian Institute in Washington, D.C., for identification and was determined to be an unidentified species of spring snail. The undescribed snail belongs to the genus *Pyrgulopsis* (Hershler 2007), which belongs to the Hydrobiidae (spring snail) family (Liu and Hershler 2007).

Little is known about the snail's life history and it has not been fully described taxonomically. In addition, the snail's habitat requirements are unknown and a comprehensive distribution survey has not yet been attempted. Snails in the family Hydrobiidae are aquatic obligates in each phase of their life history (adults, eggs, larvae), have limited vagility (*i.e.*, free movement), and are presumably incapable of dispersing on their own across terrestrial barriers among hydrographically isolated habitats (Liu and Hershler 2007). Therefore, snails belonging to the family remain very localized in their distribution (Monthey 1998). While not well understood, the dispersal of the undescribed snail may occur from a variety of mechanisms, including flood or mechanical transport by wildlife. Hydrobiids are not currently known to disperse widely and known populations remain very isolated. .

Hydrobiids are prone to differentiation on a fine geographic scale, with most species being restricted to a single spring, spring complex, or local watershed (Liu and Hershler 2007). Typically, these snails are dioecious (*i.e.*, constitute separate genders) and semelparous (*i.e.*, breed once in their lifetime and then die). Individuals have a lifespan of one year, with 90% or more of the population turning over annually. Eggs are laid in the spring and hatch in two to four weeks.

On the Project site, the undescribed snails have been historically observed within the groundwater-fed spring in swiftly flowing, clear to low-turbidity, shallow water (one-half to six centimeters deep), on a sandy to silty substrate embedded with some coarse materials. The spring core area is fed by several springheads and occupies an area approximately 400 feet by 400 feet, and supports southern cottonwood–willow riparian forest. However, vegetation components and strata vary among areas of the spring.

In addition to the direct loss of habitat, these undescribed snails would be vulnerable to changes in hydrologic conditions. The spring is supported by groundwater; therefore, any changes to aquifer hydrology could adversely affect water quantity and quality at the spring. Modifications to water quantity or quality in the spring or flow speed of water through the spring could result in multiple negative secondary effects, including elevated water temperatures, lower dissolved oxygen availability, and the accumulation of fine sediments which could smother preferred

substrates and impair egg-laying or survivorship of eggs or young (Cordeiro 2002). Because 90% of the population turns over annually, any condition that impairs egg-laying or survivorship of eggs or young (*e.g.*, excessive smothering sedimentation) may result in extirpation (Furnish and Monthey 1998). Additionally, disturbances associated with increased human presence could adversely affect the species and its habitat. Specifically, unauthorized entry into the spring could degrade the quality of the habitat and result in the trampling of individual snails. Furthermore, increased predation from non-native animals and the spread of non-native, invasive plant species into the spring would also threaten the snail population. Proposed development could remove native vegetation upslope, increase runoff from roads and other paved surfaces, and result in an increase in ornamental landscaping and lawns, all of which ultimately lead to increased irrigation. Non-native plant species have also been found to invade native riparian vegetation communities and to become established after trampling or following periods of drought. The successful invasion of exotic plant species may alter habitats and displace native species over time, leading to extirpation of native species such as the undescribed snail.

Survey Results

Comprehensive surveys for the undescribed snail species have not been completed on the Project site to date. However, reconnaissance level surveys were conducted in February 2009 in all flowing drainages within the proposed RMDP Project area, except for upper Ayers Canyon, which would not be subject to project disturbance. This species was not detected during the February 2009 surveys and is only known to occur in the Middle Canyon Spring complex (Swift 2009). The species was first observed within Middle Canyon Spring by USFWS biologists in 2006. In 2007, Dudek biologists observed over 100 snails (these snails were not identified to genus or species, and it is not known whether they were the undescribed snail or another freshwater snail) in Middle Canyon Spring and the lower-most reach of the Middle Canyon drainage, and immediately below the river terrace where the spring discharges into the upper river floodplain. At the time the unidentified snails were observed in the mouth of the Middle Canyon drainage (non-spring area), agricultural runoff from irrigated fields in the lower valley of Middle Canyon supported flow in the lower portion of the drainage (Dudek 2007C).

In order to study and establish the natural baseline conditions hydrology of the spring for the purpose of future management, agricultural irrigation activities were terminated in September 2007. Cessation of irrigation resulted in a return to ephemeral hydrologic conditions in the lower drainage but had nearly undetectable affect in water levels and source groundwater to the spring. In 2008, the undescribed snails were abundant within the Middle Canyon Spring and small outlet channels downslope of Middle Canyon Spring (GSI 2008). Currently no snails occur in the lower Middle Canyon drainage due to the absence of irrigation runoff but remain present in the Middle Canyon Spring (Carpenter and Harpole 2008).

Middle Canyon Spring is a natural hydrologic feature that appears to have been present for many years. The adjacent Middle Canyon drainage is ephemeral, but periodically has supported perennial flow in lower portions of the drainage as a result of agricultural runoff. The upstream irrigation may have temporarily augmented the suitable habitat at the Middle Canyon Spring by supplying surface water in the lower-most reach of the Middle Canyon drainage. If the unidentified snails observed in 2007 within the Middle Canyon drainage were the undescribed snails, the undescribed snails may have dispersed from the natural spring area after agricultural runoff began running in the lower-most portion of the Middle Canyon drainage. The Middle Canyon Spring and the Middle Canyon drainage have no direct hydrologic connection, though both have periodic connectivity with the Santa Clara River during very high flows. If the undescribed snails did disperse into the lower-most portion of the Middle Canyon drainage, it is unknown whether the undescribed snails dispersed *via* the Santa Clara River or whether they were transported to the lower-most portion of the Middle Canyon drainage *via* wildlife, livestock, or anthropogenic action. The locations on the Project site where the undescribed snails have been observed are shown on **Figure 4.5-23**, Middle Canyon Spring – Vicinity Map, and **Figure 4.5-24**, Middle Canyon Spring – Existing Conditions.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP would result in direct permanent impacts to the Middle Canyon drainage but not to Middle Canyon Spring, where this species occurs. A span bridge, abutment, and flood control modification within the Middle Canyon drainage would be installed as part of the RMDP, resulting in direct permanent loss of and temporary impacts to formerly occupied area in the lower Middle Canyon drainage. Middle Canyon Spring, currently the only known occurrence of the undescribed snail species, would not be directly impacted by implementation of the proposed RMDP. The spring itself would not be directly disturbed by construction activities during the implementation of the RMDP because it is within a portion of the River Corridor SMA

that would not be directly affected by bank stabilization or bridge construction to the north of the spring. No impacts to this species would occur through implementation of the SCP.

Implementation of the RMDP and SCP would not result in the loss of habitat and would not have a substantial direct adverse effect on the known population of the undescribed snail species; impede the use of native wildlife nursery sites; have the potential to substantially reduce the known occupied habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would not be significant because no impacts would occur.

Indirect Permanent Impacts

The build-out of the Specific Plan, VCC, and Entrada planning areas would not result in habitat impacts within the Middle Canyon Spring complex. Populations of the undescribed snail species and associated habitat are not expected to occur in areas to be disturbed by the build-out of the Specific Plan, VCC, and Entrada planning areas, because the species has only been detected in the Middle Canyon Spring complex, and reconnaissance level surveys of all drainages supporting permanent surface water have not detected this species. Therefore, the loss of habitat associated with build-out of these areas would not have a substantial adverse effect on the species; impede the use of native wildlife nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would not be significant because impacts are not expected to occur.

Combined Direct and Indirect Permanent Impacts

Implementation of the RMDP and the SCP would not affect this species. The build-out of the Specific Plan, VCC, and Entrada planning areas would not result in indirect permanent impacts to the Middle Canyon Spring complex; therefore, the combined direct and indirect permanent impacts (Loss of Habitat) would not be significant, because impacts are not expected to occur.

Impacts to Individuals

Because the undescribed snail species is only known to occur within Middle Canyon Spring, which is being preserved, implementation of the RMDP would not result in the direct loss of individuals of the species, nor would it have a substantial direct adverse effect on the known population of the species; impede the use of native wildlife nursery sites; have the potential to substantially reduce the known occupied habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would not be significant because no impacts are not expected to occur.

Build-out of the Specific Plan area would not impact individual undescribed snails within the Specific Plan area. This species has only been detected in the Middle Canyon Spring complex, and reconnaissance level surveys of all drainages supporting permanent surface water have not detected this species; therefore, build-out of the VCC and Entrada planning areas is not anticipated to impact any individual snails. Because no impacts to individuals would occur, the build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on the species; impede the use of native wildlife nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would not be significant because impacts are not expected to occur.

Secondary Impacts

Construction activities associated with the RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect the undescribed snail in areas adjacent to construction zones. RMDP facilities (road with bridge abutments and flood control features) would be constructed within the Middle Canyon drainage. Secondary impacts associated with this construction include impacts to hydrology and water quality. Implementation of the SCP would not result in secondary impacts to this species.

Construction activities associated with the Specific Plan and the future occupancy of the Specific Plan area also could result in short-term secondary impacts, such as exposure to fugitive dust, contact with chemical pollutants, human intrusion into Middle Canyon Spring, and alterations to the hydrologic or biogeochemical properties of the spring. Potential long-term secondary impacts associated with build-out of the Specific Plan area include the introduction of non-native, invasive plant and animal species, intrusion into the spring by humans and domestic animals, light from Commerce Center Drive Bridge, light and vibration from vehicles, and hydrologic and/or biogeochemical changes. GSI (2008) concluded that, based on an evaluation

of current hydrogeologic conditions and modeled post-development conditions, the future spring hydrology and water quality would not be substantially altered; however, for purposes of this analysis minor hydrologic changes (increase or decrease in groundwater supply to the spring) were considered as a potential impact. The potential loss of the undescribed snail species as a result of these short-term and long-term secondary impacts would constitute a substantial adverse effect on the species; would impede the use of native wildlife nursery sites; and could substantially reduce the number and restrict the range of the species (significance criteria 1, 4, and 7). Both short-term and long-term secondary impacts (Impacts to Individuals) would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

No direct permanent loss of or temporary impacts to the Middle Canyon Spring complex would occur under Alternatives 3 through 7. Because the implementation of the RMDP under Alternatives 3 through 7 would avoid impacts to the Middle Canyon Spring complex and is generally similar to the overall habitat loss under Alternative 2, the direct permanent and temporary impacts (Loss of Habitat) under Alternatives 3 through 7 would not be significant, because no impacts are expected to occur.

No direct permanent or temporary impacts would occur to the Middle Canyon Spring complex as a result of implementation of the SCP under Alternatives 3 through 7.

Indirect Permanent Impacts

As with Alternative 2, build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not result in permanent impact to the Middle Canyon Spring complex. The indirect permanent impacts (Loss of Habitat) associated with Alternatives 3 through 7 would not be significant because impacts are not expected to occur.

Combined Direct and Indirect Permanent Impacts

Similar to Alternative 2, no impacts to habitat for the undescribed snail would occur through implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through and 7.

Impacts to Individuals

Under Alternatives 3 through 7, no loss of individual undescribed snails in Middle Canyon Spring would occur as a result of implementation of the RMDP and the SCP or build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas. The loss of individuals resulting from implementation of Alternatives 3 through 7 would not be significant because impacts are not expected to occur.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and build-out of the Specific Plan area under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar effects from short-term construction activities and long-term occupancy of the Specific Plan area, such as exposure to fugitive dust, contact with chemical pollutants, human intrusion, hydrologic or biogeochemical alterations, non-native, invasive species, domestic animals, light from Commerce Center Drive Bridge, and light and noise from vehicles. The implementation of the SCP and the build-out of the VCC (Alternative 3 only) and Entrada planning areas would not result in secondary impacts to this species. The loss or degradation of habitat and the loss of individual undescribed snails due to secondary impacts resulting from implementation of the RMDP and build-out of the Specific Plan area under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

This species would not be subject to direct or indirect impacts by the proposed Project. Construction activities would not occur in the Middle Canyon Spring complex, and this species is not expected to occur outside of this area. Nonetheless, Mitigation Measure BIO-86 is being proposed to require surveys for this species in all perennial water sources prior to construction. BIO-86 requires focused surveys by a qualified biologist for the undescribed snail species prior to the commencement of grading/construction activities in any drainage area supporting perennial flow. Any individuals of the undescribed snail species found within the Middle Canyon drainage shall be relocated to appropriate habitat within Middle Canyon Spring. If undescribed snails are discovered during aquatic and semi-aquatic pre-construction surveys in any other perennial flowing water, the applicant shall consult with CDFG prior to initiating disturbance of the area.

The Project would result in significant secondary impacts to individuals and habitat occupied by this species, absent mitigation. The applicant will implement several mitigation measures to avoid, minimize, and mitigate secondary impacts to individuals and associated habitat. The primary measure to protect the Middle Canyon Spring complex is to avoid construction activities within the complex. Potential short-term secondary impacts include accidental clearing,

trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; and hydrologic alterations and water quality. These impacts would be minimized by providing guidelines for grading and construction activities; by retaining a qualified biologist during all grading and construction activities, by providing erosion control plans, dust control, and an overall Project SWPPP; by providing guidelines for stream diversion; by preventing pollutants from entering flowing streams and storm flows; by requiring that the Specific Plan conform to all provisions of required NPDES permits and water quality permits required by the RWQCB, and by requiring temporary fencing and signage around the Middle Canyon Spring during all phases of construction adjacent to the spring.

Potential long-term secondary impacts to the undescribed snail include the introduction of non-native, invasive plant and animal species, increased human activity, trampling, and soil compaction. These impacts would be minimized to a level that is adverse but not significant by: providing revegetation plans for the River Corridor SMA; placing restrictions on plant palettes proposed for use on landscaped slopes; restricting access to, grazing within, and recreational usage of the River Corridor SMA; and providing for transition areas along the River Corridor SMA.

As described above, a number of factors may affect the long-term viability of the undescribed snail. In order to address both short-term and long-term secondary impacts to this species, the applicant will prepare a plan that identifies measures to maintain the undescribed snail species. The plan (outlined in BIO-77 below) will provide guidelines for collecting additional data on existing site conditions, developing a construction monitoring program and a post-development monitoring program, developing threshold parameters that activate consultation with CDFG and adaptive management measures for water quality and water quantity issues, excluding unauthorized entry into the spring, and contingency measures. BIO-77 identifies interim thresholds to trigger immediate consultation with CDFG, and any actions, if needed, to offset potential effect, should data indicate a deviation of more than 10% from the existing condition. The plan shall be subject to the approval of CDFG prior to disturbance within 100 feet of flowing water in the Middle Canyon drainage and/or 200 feet of Middle Canyon Spring.

Additionally, both short-term and long-term secondary impacts will be minimized through revegetation, restoration, and enhancement plans designed to provide for the long-term maintenance of the River Corridor SMA in a natural state and through the implementation of the plan.

All specific mitigation measures for the undescribed snail are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-33 SECONDARY IMPACTS – UNDESCRIBED SNAIL SPECIES

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR included measures that will mitigate for short-term secondary impacts to the undescribed snail, such as altered hydrology and water quality.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-20, which states that any grading activities within or adjacent to the River Corridor SMA shall have grading perimeters clearly marked and inspected prior to grading. The Project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources**.**

In order to avoid and minimize impacts due to hydrologic alterations and water quality impacts, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-58, which requires conformance with all provisions of required National Pollutant Discharge Elimination System (NPDES) permits and water quality permits required by the RWQCB.

In order to avoid and minimize impacts due to the introduction of non-native, invasive plant species, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-7 and SP-4.6-19:

SP-4.6-7 requires that revegetation plans for the River Corridor SMA include guidelines for the maintenance of the mitigation site during the establishment of plantings, control of non-native plants, maintenance of the irrigation system, and replacement of plants, if necessary.

SP-4.6-19 requires that transition areas be in areas where there is no steep grade separation, that native riparian plants be incorporated into landscaping where feasible, that roads and bridges be designed to discourage access to River Corridor SMA, that bank stabilization be composed of ungrouted rock, and that a minimum 100-foot-wide buffer be provided between top river-side of bank stabilization and development.

In order to avoid and minimize impacts due to increased human activity, trampling, and the compaction of soils, the Newhall Ranch Specific Plan Program EIR identified Mitigation Measures SP-4.6-17, SP-4.6-18 and SP-4.6-19, and SP-4.6-24:

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes,

other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-24 states that the River Corridor SMA conservation and public access easement shall prohibit grazing and agriculture and shall restrict recreational use to the established trail system.

Each potential secondary impact would be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA in a natural state. These measures include SP-4.6-1 through SP-4.6-16 and SP-4.6-63, SP-4.6-17, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-47a, and SP-4.6-55 and SP-4.6-58:

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

SP-4.6-47a permits mitigation banking within the River Corridor SMA, High Country SMA, and Open Area, subject to requirements for riparian habitats, oak resources, and Mexican elderberry scrub.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends additional mitigation measures to mitigate for secondary impacts to the undescribed snail.

In order to avoid and minimize impacts from accidental clearing, trampling, and grading; runoff, sedimentation, erosion, and chemical and toxic compound pollution; and exposure to fugitive dust, as well as from hydrologic alterations and water quality impacts, this EIS/EIR identifies Mitigation Measures BIO-45, BIO-52, and BIO-74:

BIO-45 defines the timing and design of stream diversion bypass channels and dewatering activities and related restrictions to ensure that proper construction, operation, and abandonment diversion or dewatering will occur.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements, conduct meetings with contractor describing the importance of restricting work to the restricted areas, discuss procedures for minimizing harm to or harassment of wildlife, review the construction area in the field with the contractor in accordance with the final grading plan, conduct a final field review of staking, be present during initial vegetation clearing and grading, and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-74 requires installation of temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to construction within 200 feet of the spring and, if applicable, within 100 feet of flowing water in the Middle Canyon drainage. Permanent fencing and signage shall be erected along the bordering subdivision tract following construction. A qualified biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. Any upslope runoff from construction areas will be directed away from the Middle Canyon Spring. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

In order to further avoid and minimize impacts from dust, runoff, sedimentation, erosion, and chemical and toxic compound pollution, this EIS/EIR identifies Mitigation Measures BIO-70 and BIO-71:

BIO-70 will be implemented to mitigate for a variety of potential short-term secondary impacts, including hydrology, water quality, and exposure to fugitive dust, and specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 requires dust control measures for development areas to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control plans shall comply with SCAQMD Rule 403 (SCAQMD 2005) and chemical dust suppression shall not be utilized within 100 feet of known special-status plant communities.

Short-term secondary impacts associated with runoff, sedimentation, erosion, and chemical and toxic compound pollution and with hydrologic alterations and water quality impacts would also be mitigated by implementation of Mitigation Measure BIO-49, which prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

In order to avoid and minimize impacts from the introduction of non-native, invasive plant species, this EIS/EIR identifies Mitigation Measure BIO-72:

BIO-72 specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

In order to avoid and minimize long-term secondary impacts from increased human activity and trampling, this EIS/EIR identifies Mitigation Measures BIO-73 and BIO-74:

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-74 requires installation of temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to construction within 200 feet of the spring and, if applicable,

within 100 feet of flowing water in the Middle Canyon drainage. Permanent fencing and signage shall be erected along the bordering subdivision tract following construction. A qualified biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. Any upslope runoff from construction areas will be directed away from the Middle Canyon Spring. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

Several additional measures (BIO-51 and BIO-77) will be implemented to mitigate for long-term secondary impacts related to water quality and quantity, light from Commerce Center Drive Bridge, and light and noise from vehicles.

BIO-51 will minimize impacts to natural areas and riparian resources, including the Middle Canyon Spring, from associated lighting and stormwater runoff associated with bridges (*i.e.*, Commerce Center Drive Bridge) over the Santa Clara River. All lighting will be designed to be directed away from natural areas (pursuant to SP-4.6-56) using shielded lights, low sodium-vapor lights, bollard lights, or other available light and glare minimization methods. Bridges will be designed to minimize normal vehicular lighting from trespassing into natural areas using side walls a minimum of 24 inches high. All stormwater from the bridges will be directed to water treatment facilities for water quality treatment.

BIO-77 describes preparation of a plan and measures to be implemented by the applicant to maintain the populations of the undescribed snail and sunflower species. The plan will provide guidelines for collecting data on existing site conditions, developing a construction monitoring program and a post-development monitoring program, developing threshold parameters that activate adaptive management measures for water quality and water quantity issues, excluding unauthorized entry into the spring, and contingency measures. The plan shall be subject to the approval of CDFG prior to disturbance within 100 feet of flowing water in the Middle Canyon drainage and/or 200 feet of Middle Canyon Spring.

Secondary impacts would also be addressed through the implementation of a series of mitigation measures designed to provide for the long-term maintenance of the River Corridor SMA in a natural state. These measures include Mitigation Measures BIO-1 through BIO-16 and BIO-73:

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of

success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.BIO-86 requires focused surveys for the undescribed snail species by a qualified biologist prior to the commencement of grading/construction activities in any area supporting perennial flow. Any individuals of the undescribed snail species found within the Middle Canyon drainage shall be relocated to appropriate habitat within Middle Canyon Spring. If undescribed snails are discovered during aquatic and semi-aquatic pre-construction surveys in any other perennial flowing water, the applicant shall consult with CDFG prior to initiating disturbance of the area. A report documenting the number of snails located, the conditions of the area, and where the species has been relocated to, if applicable, shall be submitted to CDFG within 60 days following the relocation.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to previously undescribed snail species would be adverse but not significant.

COAST HORNED LIZARD (CSC)

Life History

The coast horned lizard (*Phrynosoma coronatum*) occurs throughout most of California in locations west of the desert and Cascade-Sierran highlands, in elevations from sea level to around 2,438 meters (8,000 feet) AMSL (Stebbins 2003). Prior to 1997, two subspecies (*P.c. blainvillei, P.c. frontale*) were recognized, but recent work has demonstrated that the two are synonymous (Brattstrom 1997).

Despite a wide-ranging distribution, the coast horned lizard seems to be restricted to localized populations because of its association with loose soils that have a high sand content (Jennings and Hayes 1994). The species is found in a wide variety of vegetation types with the requisite loose sandy soils, including California sagebrush scrub, annual grassland, chaparral, oak woodland, riparian woodland, and coniferous forest (Klauber 1939; Stebbins 1954). Other identified habitat characteristics include open areas with limited overstory for basking and low but relatively dense shrubs for refuge (Jennings and Hayes 1994). In inland areas, the species is restricted to areas with pockets of open microhabitat, created by disturbance (*e.g.*, floods, fire, roads, grazed areas, fire breaks) (Jennings and Hayes 1994).

Up to 90% of the diet of the coast horned lizard consists of native harvester ants (*Pogonomyrmex* spp.) (Pianka and Parker 1975), and coast horned lizards do not appear to eat non-native Argentine ants (*Linepithema humile*) (Jennings and Hayes 1994). Other slow moving insects, such as beetles, flies, and caterpillars, are consumed opportunistically when encountered (Presch 1969; Pianka and Parker 1975).

Coast horned lizards emerge from hibernation in March, and they become surface active in April through July, after which most adults aestivate (enter summer hibernation) (Hagar 1992). The adults reappear again briefly in late summer and return to overwintering sites between August and early October depending upon elevation (Klauber 1939; Howard 1974; Hagar 1992). In southern California, the male coast horned lizard reproductive cycle begins during mid- to late March and ends in June (Goldberg 1983). Coast horned lizards lay one clutch of six to 17 eggs (average of 11 to 12 eggs) each year from May through early July (Stebbins 1954; Howard 1974; Goldberg 1983). Incubation requires approximately two months and hatchlings first appear in late July and early August (Shaw 1952; Howard 1974; Hagar 1992). There are no movement and dispersal data specifically for the coast horned lizard, but horned lizards as a group show limited home ranges, usually less than five acres (*e.g.*, Munger 1984).

The two main threats to the coast horned lizard from urban development are habitat loss and fragmentation and the spread of Argentine ants. Habitat fragmentation is a threat because coast horned lizards probably have limited mobility and relatively small home ranges. They are considered to be relatively sedentary animals and thus unsuitable habitat and physical obstacles,

such as roads separating suitable habitat patches, likely are a significant barrier to dispersal. Argentine ants, as a highly invasive species, colonize disturbed soils associated with building foundations, roads, and landfills, and they expand into adjacent areas, eliminating native ant colonies (Ward 1987). Argentine ants are also associated with moist microhabitats, which may be artificially created by over-irrigation and/or surface runoff from urban areas. Because coast horned lizards do not appear to eat non-native Argentine ants (Jennings and Hayes 1994), this species can eliminate the coast horned lizard's primary food source. In southern California, Argentine ants are considered to have greatly reduced the numbers of the coast horned lizard (Suarez and Case 2002). Other threat factors associated with urban development include an increase in the abundance of urban-related predators; such as pet, stray, and feral cats and dogs; increased human activity resulting in collection or habitat degradation (*e.g.*, trampling of vegetation and introduction of exotic species); pesticides, which may reduce prey or cause secondary poisoning; off-road vehicles; cattle grazing; and frequent fires that may cause long-term habitat transitions from shrublands (scrubs and chaparrals) to annual grassland.

Survey Results

A habitat assessment and surveys for reptiles using pitfall traps were conducted on portions of the Specific Plan area in 2004 and 2006 (Impact Sciences 2006A). One coast horned lizard was captured during the 2006 pitfall trap surveys, and five additional coast horned lizards were incidentally observed during the 2004 reptile surveys (Impact Sciences 2006A). The coast horned lizard observed during the 2006 surveys was captured in the eastern portion of the Specific Plan area (in the vicinity of the Potrero Village development area) in an area described as containing sandy soils and riparian and non-native grassland vegetation (Impact Sciences 2006A). No location or habitat association information was provided for the coast horned lizards incidentally observed during the 2004 surveys. Coast horned lizard was also observed along the Santa Clara River floodplain, approximately 500 feet south of The Old Road Bridge in 2006 (Huntley 2006). Given that coast horned lizards have been observed in the Project area, they are assumed to be present within the following on-site plant communities that provide suitable habitat: alluvial scrub, arrow weed scrub, big sagebrush scrub, coastal scrub alliances and associations, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, California annual grassland, California walnut woodland, Mexican elderberry, *Eriodictyon* scrub, mixed oak woodland and forest, purple needlegrass, river wash, valley oak woodland, and valley oak/grass. A total of 10,734 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use

practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 140 acres of suitable habitat would be permanently lost through implementation of the RMDP, representing 1.3% of suitable habitat on site (**Figure 4.5-72,** Alternative 2 Impacts to General Wildlife Habitats). A total of 61 acres would be temporarily impacted. Activities associated with implementation of the SCP (*e.g.*, fence construction) could also result in a small loss of potential habitat for the species, although this impact has not been quantified.

The coast horned lizard is still a wide-ranging species, however, it is becoming increasingly uncommon as a result of loss of habitat and impacts from the Argentine ant. Although construction of the proposed Project would be phased over time, the loss of habitat that would occur as a result of construction and/or grading activities would have a substantial adverse effect on this species (significance criterion 1). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 3,144 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 29.3% of suitable habitat on site (**Figure 4.5-72,** Alternative 2 Impacts to General Wildlife Habitats).

Although the coast horned lizard is still a wide-ranging species, a relatively large amount and percentage of on-site habitat for the coast horned lizard would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from 29.3% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,283 acres (30.6%). Because of the large amount and percentage of habitat loss, the combined direct and indirect impacts to suitable

habitat would have a substantial adverse effect on the distribution of the coast horned lizard on site, thus substantially reducing its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Coast horned lizards are relatively sedentary, and those large-scale construction and/or grading activities associated with the RMDP causing permanent and temporary impacts likely would result in injury or mortality of individuals as a result of direct contact with or crushing by construction equipment used for vegetation clearing and grading. In addition, hibernating individuals could be injured or killed during construction and/or grading activities conducted during colder months by entombment or direct contact with grading equipment. Activities associated with implementation of the SCP (*e.g.*, fence construction) could also result in impacts to coast horned lizard individuals if fence construction occurred during colder months when horned lizards are hibernating. This species probably is capable of escaping potential impacts from fence construction when it is active on the ground surface in the warmer months because ground disturbances would be much more localized.

Because this species is becoming increasingly less common, impacts to coast horned lizards that would occur as a result of construction and/or grading activities would have a substantial adverse effect on this species (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals, but over a much larger area. There is a potential for substantial injury and mortality of coast horned lizards during vegetation clearing, grading, and other construction-related activities. This potential loss of individuals would have a substantial adverse effect on this species on site by eliminating it from approximately 29.3% of potentially occupied habitat, thus substantially reducing its number and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

In the short-term, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would have the

potential to affect coast horned lizards in areas adjacent to construction zones. These impacts include the inadvertent disturbance of habitat and loss of individual lizards in areas outside the development footprint; construction-related dust, which may affect its prey; and other disruptions associated with increased human activity. Although construction activities associated with RMDP facilities will be short term, will be phased over a relatively long period of time, and will affect a relatively small proportion of potential coast horned lizard suitable habitat in the Project area, this species is becoming increasingly uncommon; therefore, the construction activities would have a substantial adverse effect on this species (significance criterion 1). Short-term secondary impacts would be significant, absent mitigation.

Long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas could also include habitat fragmentation and isolation of some local populations of coast horned lizard, making the species more vulnerable to extirpation from smaller habitat patches. In addition, over the long term, the close proximity of urban development to suitable coast horned lizard habitat could result in disruption of essential behavioral activities (*e.g.*, foraging, reproduction) and greater vulnerability to several potential secondary impacts, including human-caused habitat degradation (*e.g.*, trampling of vegetation and introduction of invasive species, such as Argentine ants, or off-road vehicles); harassment and collection; predation by pet, stray, and feral cats and dogs; increased roadkill; and use of pesticides, which may reduce its prey or cause secondary poisoning. These secondary impacts would permanently reduce coast horned lizard populations along the urban–open space edge and would contribute to the reduction of the range and distribution of the coast horned lizard in the Project area (significance criteria 1 and 7). Long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the coast horned lizard (**Figures 4.5-73** through **4.5-77,** Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 138 acres (1.3%) of permanent loss and 74 acres of temporary loss;
- Alternative 4 – 133 acres (1.2%) of permanent loss and 61 acres of temporary loss;
- Alternative 5 – 157 acres (1.5%) of permanent loss and 79 acres of temporary loss;

- Alternative 6 – 169 acres (1.6%) of permanent loss and 79 acres of temporary loss; and
- Alternative 7 – 73 acres (0.7%) of permanent loss and 151 acres of temporary loss.

Compared to Alternative 2, which would result in 140 acres (1.3%) of permanent loss and 61 acres of temporary impacts, the combined direct permanent and temporary loss of habitat under Alternatives 3, 5, 6, and 7 would be somewhat greater, and the combined direct permanent and temporary loss of habitat would be somewhat less under Alternative 4. The difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and greater temporary impacts under that alternative.

The overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be similar in magnitude compared to Alternative 2, and would be substantially less under Alternative 7. Because the coast horned lizard is becoming increasingly uncommon, direct impacts for Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the coast horned lizard (**Figures 4.5-73** through **4.5-77,** Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 2,937 acres (27.4%) of permanent loss;
- Alternative 4 – 2,815 acres (26.2%) of permanent loss;
- Alternative 5 – 2,736 acres (25.5%) of permanent loss;
- Alternative 6 – 2,420 acres (22.5%) of permanent loss; and
- Alternative 7 – 2,127 acres (19.8%) of permanent loss.

Compared to Alternative 2, which would result in 3,144 acres (29.3%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that reduce impacts to

coast horned lizard suitable habitat under Alternative 7 compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the coast horned lizard occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the coast horned lizard:

- Alternative 3 – 3,075 acres (28.6%) of permanent loss;
- Alternative 4 – 2,948 acres (27.5%) of permanent loss;
- Alternative 5 – 2,893 acres (27.0%) of permanent loss;
- Alternative 6 – 2,589 acres (24.1%) of permanent loss; and
- Alternative 7 – 2,199 acres (20.5%) of permanent loss.

Compared to Alternative 2, which would result in 3,283 acres (30.6%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the coast horned lizard occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual coast horned lizards that would occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to

Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual coast horned lizards occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as construction-related dust; human-caused habitat degradation; harassment and collection; predation by pet, stray, and feral cats and dogs; invasive species such as Argentine ants; use of pesticides; and increased roadkill. Short-term and long-term secondary impacts to coast horned lizard resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to coast horned lizard: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment, entombment of hibernating individuals, and increased exposure of individuals left without protective cover. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys within the proposed disturbance area will be conducted by a qualified biologist in possession of a scientific collecting permit to capture and relocate coast horned lizards. General procedures to avoid and minimize impacts to coast horned lizards during construction will be implemented, and a qualified biologist will be present during construction in order to relocate any identified remaining individuals, further reducing impacts to the species.

The combined permanent loss of suitable habitat for the coast horned lizard resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,199 acres (20.5%) under Alternative 7 to 3,283 acres (30.6%) under Alternative 2. This would be a substantial loss of suitable habitat and would reduce the size and distribution of the coast horned lizard population in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional

mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable habitat to support the coast horned lizard in the Project vicinity. Implementation of these mitigation measures will result in protection, restoration and enhancement, and management of approximately 5,687 acres of suitable habitat for this species. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**). Restoration and enhancement of habitat used by the coast horned lizard in these areas will improve habitat quality for the species.

With respect to secondary effects, coast horned lizards occupying habitat in close proximity to construction zones may be disturbed by construction activities, including increased human activity, noise, ground vibration, and dust. Biological monitoring during vegetation clearing and grading, as well as dust suppression measures, will help reduce these construction-related impacts. Potential long-term effects of development include habitat fragmentation; increased human activity, including habitat degradation and collection; invasive species such as Argentine ant; pet, stray, and cats and feral dogs; vehicle collisions; and use of pesticides. The large open space system will provide adequate protected open space that will in part offset these impacts, especially habitat fragmentation and vehicle collisions. Several specific mitigation measures will also be implemented to control human activities in open space areas, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. Pesticides will be controlled through an integrated pest management (IPM) plan. Argentine ant invasions of upland habitats in the open space system will be monitored and controlled to the extent feasible. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

All specific mitigation measures for coast horned lizard are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-34 IMPACTS TO INDIVIDUALS – COAST HORNED LIZARD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified two mitigation measures that would avoid, minimize, or mitigate the loss of coast horned lizard individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during

development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to reduce impacts to coast horned lizard individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-54 requires surveys to capture and relocate coast horned lizard, silvery legless lizard, coastal western whiptail, rosy boa, San Bernardino ringneck snake, and coast patch-nosed snake individuals 30 days prior to construction activities in suitable habitats.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to coast horned lizard individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-35 LOSS OF HABITAT – COAST HORNED LIZARD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the coast horned lizard through protection, restoration and enhancement, and management of habitat. Although this species primarily uses scrub and chaparral habitats, protection, restoration and enhancement, and management of habitat in the River Corridor SMA will reduce impacts to this species.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. The River Corridor SMA includes terrestrial habitats that are used by coast horned lizard,

and these areas would benefit from restoration activities. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the coast horned lizard through protection, restoration and enhancement, and management of habitat.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios. As noted above, terrestrial habitats used by coast horned lizard occur in association with riparian and wetland habitats and will benefit from restoration activities.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the coast horned lizard would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-36 SECONDARY IMPACTS – COAST HORNED LIZARD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to the coast horned lizard, including short-term construction activities and long-term effects due to factors such as human-caused habitat degradation**,** harassment and collection, and increased roadkill.

SP-4.6-53 and SP-4.6-59, as described above, will be implemented to mitigate impacts from increased short-term human activity associated with construction.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will be implemented to mitigate impacts from increased long-term human activity through protection, restoration and enhancement, and management of habitat.

SP-4.6-17, SP-4.6-20, SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-39 will be implemented to protect against both potential short-term construction-related secondary impacts and long-term

secondary impacts to habitat and/or coast horned lizard individuals associated with increased human activity and grazing.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-27 and SP-4.6-39 require removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-1 through SP-4.6-16, SP-4.6-17, SP-4.6-18, SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will be implemented to mitigate for impacts due to habitat fragmentation and potential isolation of populations.

In addition, SP-4.6-29 through SP-4.6-32 will be implemented to mitigate for impacts related to increased human activity in the High Country SMA through limiting access to daytime use of the designated trail system; prohibiting pets (with the exception of horses on established trails); prohibiting hunting, fishing, and motor or off-trail bike riding; and providing trail design guidelines to minimize impacts to native habitats.

SP-4.6-33 will be implemented to mitigate potential adverse edge effects by permitting construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures that address secondary effects such as construction-related dust, increased human activity, predation by pet, stray, and feral cats and dogs, and invasion by Argentine ants, which are known to displace native ant prey for the coast horned lizard; and pesticides, which may reduce prey or cause secondary poisoning.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, will be implemented to mitigate for impacts from increased human activity through habitat protection, restoration and enhancement, and management.

BIO-63, BIO-64, BIO-69, and BIO-73 will also be implemented to mitigate impacts related to increases in human activity:

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-64 will be implemented to prevent loss of prey and secondary poisoning and requires preparation of an IPM plan controlling the use of pesticides on site prior to the issuance of building permits.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-72, BIO-85, and BIO-87 will be implemented to reduce and control Argentine ants in open space areas.

BIO-72 specifies that container plants for use within 100 feet of the open space areas shall be inspected for pests, including Argentine ants. Plant palettes also will include non-invasive species that do not require high irrigation rates, which will help keep moisture levels low at the open space-urban interface. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the

preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to coast horned lizard and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

COAST PATCH-NOSED SNAKE (CSC)

Life History

The coast patch-nosed snake (*Salvadora hexalepis virgultea*) ranges from west-central Nevada south to the tip of Baja California and northwestern Sonora, and from coastal southern California to southwestern Utah and central Arizona. The coast patch-nosed snake is found at elevations from below sea level to around 2,130 meters (6,988 feet) AMSL (Goldberg 1995).

The coast patch-nosed snake is diurnal (Stebbins 2003) and can be found throughout the day during the milder months of spring. Activity is restricted to the mornings and late afternoons during the summer months. As an active, diurnal snake, it will occasionally take refuge in rock crevices, in small mammal burrows, and under vegetation. May and June are the typical months of peak activity; however, in the southern part of its range, activity may extend all year during mild to warm weather. This subspecies is a broad generalist in its diet and an opportunistic feeder that probably preys on anything it can overpower including small mammals (*Dipodomys*), lizards (*Aspidoscelis, Coleonyx*), and the eggs of lizards and snakes (Stebbins 2003).

Goldberg (1995) found that breeding generally occurs from July through October, but possibly as early as late spring. Clutch size typically ranges from four to seven eggs (Wright and Wright 1957). Goldberg (1995) also found four females lacking yolk deposition in ovarian tissues in the month of April, suggesting that not all females breed each year. Under laboratory conditions, the incubation period of eggs is about 85 days (Stebbins 2003). Friable or sandy soil or the presence of rodent burrows are required conditions for the reproductive cycle of patch-nosed snakes (Zeiner *et al.* 1988).

The main threats to the coast patch-nosed snake from urban development are likely habitat fragmentation and isolation of populations. The coast patch-nosed snake has not been studied adequately to specifically identify secondary threats, but it probably is also vulnerable to several effects related to urbanization. An increase in the abundance of urban-related predators; such as pet, stray, and feral cats and dogs; could result in mortality of coast patch-nosed snakes. Increased human activity could result in habitat degradation (*e.g.*, trampling of vegetation and introduction of exotic species) and in harassment and collection. Increased traffic could result in increased roadkill. The use of rodenticides near open space could result in a reduced prey base, potential secondary poisoning, and fewer mammal burrows that provide shelter and protection.

Survey Results

A habitat assessment and surveys for reptiles were conducted on portions of the Specific Plan area in 2004 and 2006 (Impact Sciences 2006A). Coast patch-nosed snakes were not trapped or otherwise observed during the surveys. The Project area is located toward the northern extent of the subspecies' range (Stebbins 2003) and, based on the CNDDB (CDFG 2007A), the coast

patch-nosed snake has only been documented south of the Project area. However, because this subspecies is uncommon and based on the presence of suitable habitat, because the Project area is within the range of the subspecies as described by Stebbins (2003), and because the Project area was not surveyed in its entirety or at a level of detail necessary to determine presence or absence of a particular reptile species, the coast patch-nosed snake was identified as having potential to occur in the Project area (Impact Sciences 2006A). Therefore, the coast patch-nosed snake is considered potentially present within the following on-site plant communities: alluvial scrub, big sagebrush scrub, coastal scrub alliances and associations, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, *Eriodictyon* scrub, and river wash. A total of 6,908 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/ No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 102 acres of suitable habitat would be permanently lost through implementation of the RMDP, representing 1.5% of suitable habitat on site (**Figure 4.5-72,** Alternative 2 Impacts to General Wildlife Habitats). A total of 47 acres would be temporarily impacted. Activities associated with implementation of the SCP (*e.g.*, fence construction) could also result in a small loss of potential habitat for the coast patch-nosed snake, although this impact has not been quantified.

Although the coast patch-nosed snake is still a wide-ranging species, it has suffered habitat loss and fragmentation due to urban development and, therefore, the loss of habitat that would occur as a result of construction and/or grading activities would have a substantial adverse effect on coast patch-nosed snake (significance criterion 1). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 2,006 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 29.0% of suitable habitat on site (**Figure 4.5-72,** Alternative 2 Impacts to General Wildlife Habitats).

Although the coast patch-nosed snake is still a wide-ranging species, a relatively large amount and percentage of on-site habitat for the coast patch-nosed snake would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of coast patch-nosed snake on site by eliminating it from 29.0% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,107 acres (30.5%). Because of the large amount and percentage of habitat loss, the combined direct and indirect impacts to suitable habitat would have a substantial adverse effect on the distribution of the coast patch-nosed snake on site, thus substantially reducing its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Coast patch-nosed snakes are not very mobile, and those large-scale construction and/or grading activities associated with the RMDP causing permanent and temporary impacts likely would result in injury or mortality of individuals as a result of direct contact with or crushing by construction equipment used for vegetation clearing and grading. In addition, hibernating individuals could be injured or killed during construction and/or grading activities conducted during colder months by entombment or direct contact with grading equipment. Activities associated with implementation of the SCP (*e.g.*, fence construction) could also result in impacts to coast patch-nosed snake individuals if fence construction occurred during colder months when individuals are hibernating. The coast patch-nosed snake probably is capable of escaping potential impacts from fence construction when it is active on the ground surface in the warmer months because ground disturbances would be much more localized.

Although the coast patch-nosed snake is still widely distributed throughout its range, it is uncommonly observed and assumed to be declining as a result of habitat loss and fragmentation. Impacts to coast patch-nosed snakes that would occur as a result of construction and/or grading activities would have a substantial adverse effect on coast patch-nosed snake (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals, but over a much larger area. There is a potential for substantial mortality of coast patch-nosed snakes during vegetation clearing, grading, and other construction-related activities. This potential loss of individuals would have a substantial adverse effect on coast patch-nosed snake on site by eliminating it from 29.0% of potentially occupied habitat, thus substantially reducing its number and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas could include disruptions associated with increased human activity, noise, and ground vibration, and nighttime illumination, the latter of which may disrupt the natural activity cycle of this diurnal species, making it more vulnerable to predation by nocturnal predators, such as owls and coyotes. Although the secondary impacts of the construction activities would be short term and would be phased over time, this species appears to be declining within its range. Therefore, short-term secondary effects would have a substantial adverse effect on coast patch-nosed snake (significance criterion 1). Short-term secondary impacts would be significant, absent mitigation.

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in habitat fragmentation and isolation of some local populations of the coast patch-nosed snake, making the species more vulnerable to extirpation from smaller habitat patches. In addition, over the long term, the close proximity of urban development to suitable coast patch-nosed snake habitat could result in disruption of essential behavioral activities (*e.g.*, foraging and reproduction) and greater vulnerability to several potential secondary impacts, including human-caused habitat degradation (*e.g.*, trampling of vegetation and introduction of invasive species, such as Argentine ant) and harassment and collection; predation by pet, stray, and feral cats and dogs as well as other mesopredators; increased predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; increased incidence of roadkill; and introduction of rodenticides that may be used to control prey species (*e.g.*, small rodents), resulting in both the loss of burrows used by coast patch-nosed snake for refuge and a reduction in the prey base for this species. These

secondary impacts would permanently reduce coast patch-nosed snake populations along the urban–open space edge and would contribute to the reduction of the range and distribution of the coast patch-nosed snake in the Project area (significance criteria 1 and 7). Long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the coast patch-nosed snake (**Figures 4.5-73** through **4.5-77,** Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 95 acres (1.4%) of permanent loss and 54 acres of temporary loss;
- Alternative 4 – 97 acres (1.4%) of permanent loss and 45 acres of temporary loss;
- Alternative 5 – 100 acres (1.4%) of permanent loss and 59 acres of temporary loss;
- Alternative 6 – 84 acres (1.2%) of permanent loss and 56 acres of temporary loss; and
- Alternative 7 – 47 acres (0.7%) of permanent loss and 76 acres of temporary loss.

Compared to Alternative 2, which would result in 102 acres (1.5%) of permanent loss and 47 acres of temporary impacts, the combined direct permanent and temporary loss of habitat under Alternative 3 would be the same, it would be marginally lower under Alternative 6, not substantially different under Alternatives 4 and 5, and somewhat lower under Alternative 7. The larger difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and greater temporary impacts under this alternative.

The overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be similar in magnitude compared to Alternative 2, and would be somewhat less under Alternative 7. Because the coast patch-nosed snake appears to be declining in its range, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the coast patch-nosed snake (**Figures 4.5-73** through **4.5-77,** Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 1,895 acres (27.4%) of permanent loss;
- Alternative 4 – 1,830 acres (26.5%) of permanent loss;
- Alternative 5 – 1,780 acres (25.8%) of permanent loss;
- Alternative 6 – 1,525 acres (22.1%) of permanent loss; and
- Alternative 7 – 1,355 acres (19.6%) of permanent loss.

Compared to Alternative 2, which would result in 2,006 acres (29.0%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and/or Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that reduce impacts to coast patch-nosed snake suitable habitat under Alternative 7 compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the coast patch-nosed snake occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the coast patch-nosed snake:

- Alternative 3 – 1,989 acres (28.8%) of permanent loss;
- Alternative 4 – 1,927 acres (27.9%) of permanent loss;
- Alternative 5 – 1,879 acres (27.2%) of permanent loss;

- Alternative 6 – 1,609 acres (23.3%) of permanent loss; and
- Alternative 7 – 1,402 acres (20.3%) of permanent loss.

Compared to Alternative 2, which would result in 2,107 acres (30.5%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and/or Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the coast patch-nosed snake occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual coast patch-nosed snakes that would occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual coast patch-nosed snakes occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as human-caused habitat degradation and harassment and collection; invasive species such as Argentine ant; predation by pet, stray, and feral cats and dogs as well as other mesopredators; increased predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; increased incidence of roadkill; and introduction of rodenticides that may be used to control prey species (*e.g.*, small rodents), resulting in both the loss of burrows used by coast patch-nosed snake for refuge and a reduction in the prey base for this species. Short-term and long-term secondary impacts to coast patch-nosed snake resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC

(Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to coast patch-nosed snake: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment, entombment of individuals in burrows, and increased exposure of individuals left without protective cover. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys within the proposed disturbance area will be conducted by a qualified biologist in possession of a Scientific Collecting Permit to capture and relocate coast patch-nosed snakes. General procedures to avoid and minimize impacts to coast patch-nosed snakes during construction will be implemented, and a qualified biologist will be present during construction in order to relocate any identified remaining individuals, further reducing impacts to the species.

The combined permanent loss of suitable habitat for the coast patch-nosed snake resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 1,402 acres (20.3%) under Alternative 7 to 1,989 acres (30.5%) under Alternative 2. This would be a substantial loss of suitable habitat and would reduce the size and distribution of the coast patch-nosed snake population, if present, in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable habitat to support the coast patch-nosed snake in the Project vicinity. Implementation of these mitigation measures will result in protection, restoration and enhancement, and management of approximately 3,724 acres of suitable habitat for this species. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**). Restoration and enhancement of habitat used by the coast patch-nosed snake in these areas will improve habitat quality for the species by providing additional cover and habitat for prey species.

With respect to secondary effects, coast patch-nosed snakes occupying habitat in close proximity to construction zones may be disturbed by construction activities, including increased human activity, noise, ground vibration, and lighting. Biological monitoring during vegetation clearing and grading, as well as dust suppression measures, will help reduce these construction-related impacts. Potential long-term effects of development include habitat fragmentation; increased human activity, including habitat degradation and collection; invasive species, such as Argentine ant; pet, stray, and cats and feral dogs; vehicle collisions; and use of rodenticides. The large

open space system will provide adequate protected open space that will in part offset these impacts, especially habitat fragmentation and vehicle collisions. Several specific mitigation measures will also be implemented to control human activities in open space areas, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. Rodenticides will be controlled through an integrated pest management (IPM) plan. Argentine ant invasions of upland habitats in the open space system will be monitored and controlled to the extent feasible. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

All specific mitigation measures for coast patch-nosed snake are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-37 IMPACTS TO INDIVIDUALS – COAST PATCH-NOSED SNAKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified two mitigation measures that will avoid, minimize, or mitigate impacts to coast patch-nosed snake individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to reduce impacts to coast patch-nosed snake individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-54 requires surveys to capture and relocate coast horned lizard, silvery legless lizard, coastal western whiptail, rosy boa, San Bernardino ringneck snake, and coast patch-nosed snake individuals 30 days prior to construction activities in suitable habitats.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to coast patch-nosed snake individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-38 LOSS OF HABITAT – COAST PATCH-NOSED SNAKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the coast patch-nosed snake through protection, restoration and enhancement, and management of habitat. Although coast patch-nosed snake primarily uses scrub, chaparral habitat, and river wash habitats, protection, restoration and enhancement, and management of habitat in the River Corridor SMA will reduce impacts to this species.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. The River Corridor SMA includes terrestrial habitats that are used by coast patch-nosed snake, and these areas would benefit from restoration activities. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the coast patch-nosed snake through protection, restoration and enhancement, and management of habitat.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios. As noted above, terrestrial habitats used by coast patch-nosed snake occur in association with riparian and wetland habitats and will benefit from restoration activities.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the coast patch-nosed snake would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-39 SECONDARY IMPACTS – COAST PATCH-NOSED SNAKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to the coast patch-nosed snake, including short-term construction activities and long-term effects due to factors such as human-caused habitat degradation, habitat fragmentation, lighting, and harassment and collection.

SP-4.6-53 and SP-4.6-59, as described above, will be implemented to mitigate impacts from increased short-term human activity associated with construction.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will be implemented to mitigate impacts from increased long-term human activity through protection, restoration and enhancement, and management of habitat.

SP-4.6-17, SP-4.6-20, SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-39 will be implemented to protect against both potential short-term construction-related secondary impacts and long-term secondary impacts to habitat and/or coast patch-nosed snake individuals associated with increased human activity and grazing.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-27 and SP-4.6-39 require removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All

enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-1 through SP-4.6-16, SP-4.6-17, SP-4.6-18, SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will be implemented to mitigate for impacts due to habitat fragmentation and potential isolation of populations.

In addition, SP-4.6-29 through SP-4.6-32 will be implemented to mitigate for impacts related to increased human activity in the High Country SMA through limiting access to daytime use of the designated trail system; prohibiting pets (with the exception of horses on established trails); prohibiting hunting, fishing, and motor or off-trail bike riding; and providing trail design guidelines to minimize impacts to native habitats.

SP-4.6-33 will be implemented to mitigate potential adverse edge effects by permitting construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 will be implemented to mitigate for potential lighting impacts by requiring that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures that address specific potential edge effects, including harassment by humans; predation by pet, stray, and feral cats and dogs; invasion by Argentine ants; and use of rodenticides.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, will be implemented to mitigate for impacts from increased human activity through habitat protection and restoration and enhancement.

In addition, BIO-63, BIO-64, BIO-69, and BIO-73 will be implemented to mitigate impacts related to increases in human activity:

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-72, BIO-85, and BIO-87 will be implemented to reduce and control Argentine ants in open space areas.

BIO-72 specifies that container plants for use within 100 feet of the open space areas shall be inspected for pests, including Argentine ants. Plant palettes also will include non-invasive species that do not require high irrigation rates, which will help keep moisture levels low at the open space-urban interface. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to the coast patch-nosed snake and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

SILVERY LEGLESS LIZARD (CSC)

Life History

The silvery legless lizard (*Anniella pulchra pulchra*) occurs from Antioch, California; south through the Coast, Transverse, and Peninsular ranges and the western slopes of the Sierra Nevada southward into northwestern Baja California, Mexico (Stebbins 2003). The species also occurs in the Antelope Valley and as isolated populations in disjunct mountain ranges along the western edge of the Mojave Desert. Silvery legless lizards have been found at elevations ranging from sea level to 1,554 meters (5,100 feet) AMSL (Stebbins 2003).

The silvery legless lizard is a fossorial (*i.e.*, burrowing) animal and is found primarily in areas with sandy or loose soils where they typically are found beneath leaf litter (Holland and Goodman 1998; Zeiner *et al*. 1988). This species may be found in sparsely vegetated areas in a variety of habitats, including beach dunes; chaparral; California sagebrush scrub; oak woodlands; pine forests; pine–oak woodland; sandy washes; and stream terraces with sycamores, cottonwoods, or oaks (Zeiner *et al*. 1988; Stebbins 2003; Holland and Goodman 1998). The species may forage in leaf litter by day for insects, insect larvae, and spiders and emerge on the surface at dusk or at night (NatureServe 2007; Stebbins 2003). The species is also found under or in the close vicinity of logs, rocks, old boards, and the compacted debris of woodrat nests (Jennings and Hayes 1994). Rocky soils or areas disturbed by agriculture, sand mining, or other human uses are not suitable for legless lizards (Miller 1944; Bury 1972; Hunt 1983; Stebbins 2003). Soil moisture is considered essential for legless lizards to conserve energy at high temperatures and to also allow shedding to occur (Jennings and Hayes 1994). Legless lizards burrow deeper in the soil in the summer in order to avoid high soil temperature at the surface (Hunt 1997). Ovulation occurs in May through July and live births occur in July through October, with typical litter sizes of one or two, but up to four can occur. Females do not produce young every year in southern California (NatureServe 2007).

The silvery legless lizard's dependence on substrates with a high sand content, which are naturally spatially variable, as well as their limited dispersal ability, results in highly fragmented populations (Hunt 1997). The species is vulnerable to habitat disturbance and cannot survive in urbanized, agricultural, or other areas where a loose substrate in which to burrow has been removed or altered (*e.g.*, disturbed by plowing or bulldozing) (Jennings and Hayes 1994). Other factors that may alter the substrate such that the species cannot survive include livestock grazing, off-road vehicle activities, excessive trampling by humans, and the introduction of exotic plant species. These factors decrease soil moisture or alter the conformation of the substrate, which may act to limit the food base or make the substrate physically unsuitable for silvery legless lizards (Jennings and Hayes 1994). Pesticides may also affect silvery legless lizards through reduction of prey or secondary poisoning because of its insect diet (Honegger 1975). Despite

their fossorial behavior, legless lizards are preyed upon by a variety of predators, including domestic and feral cats, which prey heavily on this species (Hunt and Zander 1997).

Survey Results

The reptile assessment and associated surveys conducted by Impact Sciences (2006A) identified silvery legless lizard in the Project area. Of the habitats surveyed, silvery legless lizard was only observed within the leaf litter of coast live oak woodlands in Chiquito Canyon. Overall, 23 individual silvery legless lizards were captured and released (Impact Sciences 2006A). Silvery legless lizard was also observed at two locations in Long Canyon in 2005 (Huntley 2006). In addition to being present on site within coast live oak woodlands, the silvery legless lizard is considered potentially present within the following on-site plant communities: other upland woodlands (*i.e.*, valley oak woodland, California walnut woodland), river wash, riparian scrub (*i.e.*, arrow weed scrub, big sagebrush scrub, mulefat scrub, southern willow scrub, alluvial scrub, big sagebrush–California buckwheat, Mexican elderberry, and shrub tamarisk), riparian woodland (*i.e.*, southern cottonwood–willow riparian forest, southern coast live oak riparian forest), chaparral (*i.e.*, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral), and California sagebrush scrub habitats (*i.e.*, California sagebrush scrub and associations, California sagebrush–black sage, California sagebrush–California buckwheat scrub, California sagebrush scrub–undifferentiated chaparral). A total of 11,254 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 194 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.7% of suitable habitat on site (**Figure 4.5-114,** Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat). A total of 113 acres would be temporarily impacted. However, because soil compaction can make habitats unsuitable

for the silvery legless lizard, areas to be temporarily impacted are considered to be a permanent loss of habitat for silvery legless lizard, thus resulting in a permanent loss of 307 acres of habitat, representing 2.7% of suitable habitat on site.

Although the silvery legless lizard is still a wide-ranging species, its habitat has been lost to urban development and substantially degraded by other impacts such as agriculture, grazing, off-road vehicles, and invasive species. Therefore, the direct loss of habitat that would occur as a result of construction and/or grading activities would have a substantial adverse effect on silvery legless lizard (significance criterion 1). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 3,158 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 28.1% of suitable habitat on site (**Figure 4.5-114,** Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat).

Although the silvery legless lizard is still a wide-ranging species, a relatively large amount and percentage of on-site habitat for the silvery legless lizard would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of silvery legless lizard on site by eliminating it from 28.1% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct (including permanent and temporary impacts) and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,465 acres (30.7%). Because of the large amount and percentage of habitat loss, the combined direct and indirect impacts to suitable habitat would have a substantial adverse effect on the distribution of the silvery legless lizard on site, thus substantially reducing its range on site (significance criteria 1 and 7). The combined direct and indirect permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Silvery legless lizards are not very mobile and, therefore, large-scale construction and/or grading activities causing permanent and temporary impacts likely would result in injury or mortality of individuals as a result of direct contact with or crushing by construction equipment used for vegetation clearing and grading. In addition, aestivating and hibernating individuals could be injured or killed during construction and/or grading activities conducted during both hotter and colder months by direct contact with grading equipment or entombment. The risk of impacts to individuals associated with fence construction for the SCP is probably relatively low because disturbances would be much more localized.

Because of general habitat loss and degradation throughout its range, impacts to silvery legless lizards that would occur as a result of construction and/or grading activities would have a substantial adverse effect on silvery legless lizard (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals, but over a much larger area. There is a potential for substantial injury and mortality of silvery legless lizards during vegetation clearing, grading, and other construction-related activities. This potential loss of individuals would have a substantial adverse effect on silvery legless lizard on site by eliminating it from 28.1% of potentially occupied habitat, thus substantially reducing its number and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP and SCP facilities would have the potential to affect silvery legless lizard in areas adjacent to construction zones. These impacts could include soil compaction associated with construction staging and equipment storage areas. Even though the silvery legless lizard is subterranean, it may forage on the surface at night and construction-related dust could affect its prey. Because of general habitat loss and degradation throughout its range, secondary impacts associated with construction activities would have a substantial adverse effect on silvery legless lizard; cause it to drop below self-sustaining levels on site or rangewide; threaten to eliminate it on site or rangewide; or substantially reduce its number or restrict its

range (significance criterion 1). Short-term secondary impacts would be significant, absent mitigation.

Secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include short-term construction-related secondary impacts, such as the inadvertent disturbance of habitat and loss of individual lizards and disruptions associated with increased human activity, and soil compaction associated with construction staging and equipment storage areas. Potential long-term, development-related secondary impacts include compaction of soils from excessive recreational use; the introduction of exotic plant and animal species, such as Argentine ants; habitat fragmentation and isolation of populations; potential disruption of essential behavioral activities and greater vulnerability to human activities (*e.g.*, habitat degradation and harassment); predation by pet, stray, and feral cats and dogs within about 200 feet of the urban–open space edge (CBI 2000); and use of pesticides which may reduce its prey or cause secondary poisoning. These secondary impacts could permanently reduce populations of silvery legless lizard and contribute to the reduction of its range and its distribution in the Project area (significance criteria 1 and 7). Long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the silvery legless lizard (**Figures 4.5-115** through **4.5-119,** Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat) (note that, because of soil compaction, temporary impacts are considered to be a permanent loss of suitable habitat for silvery legless lizard):

- Alternative 3 – 177 acres (1.6%) of permanent loss and 127 acres of temporary loss, for a total loss of 304 acres (2.7%);
- Alternative 4 – 173 acres (1.5%) of permanent loss and 111 acres of temporary loss, for a total loss of 284 acres (2.5%);
- Alternative 5 – 203 acres (1.8%) of permanent loss and 136 acres of temporary loss, for a total loss of 339 acres (3.0%);

- Alternative 6 – 202 acres (1.8%) of permanent loss and 131 acres of temporary loss, for a total loss of 335 acres (3.0%); and
- Alternative 7 – 82 acres (0.7%) of permanent loss and 185 acres of temporary loss, for a total loss of 267 acres (2.4%).

Compared to Alternative 2, which would result in 194 acres (1.7%) of direct permanent loss and 113 acres of temporary impacts (307 acres (2.7%) total loss), the combined permanent and temporary loss of habitat under Alternative 3 would not be substantially different, and the combined permanent and temporary loss of habitat would be marginally reduced under Alternative 4, substantially reduced under Alternative 7, and somewhat increased under Alternatives 5 and 6. However, the percentage of total impacts would be small under all of the alternatives, ranging from 2.4% for Alternative 7 to 3.0% for Alternatives 5 and 6. The difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and greater temporary impacts under that alternative.

The overall permanent loss of habitat for the silvery legless lizard from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be similar in magnitude compared to overall habitat loss under Alternative 2, and is substantially less under Alternative 7. Because of habitat loss and degradation throughout its range, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the silvery legless lizard (**Figures 4.5-115** through **4.5-119,** Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass, and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 2,949 acres (26.2%) of permanent loss;
- Alternative 4 – 2,824 acres (25.1%) of permanent loss;
- Alternative 5 – 2,742 acres (24.4%) of permanent loss;
- Alternative 6 – 2,423 acres (21.5%) of permanent loss; and
- Alternative 7 – 2,128 acres (18.9%) of permanent loss.

Compared to Alternative 2, which would result in 3,158 acres (28.1%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be

constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that would reduce impacts to silvery legless lizard suitable habitat under Alternative 7 compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the silvery legless lizard occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct (including permanent and temporary impacts) and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the silvery legless lizard:

- Alternative 3 – 3,523 acres (31,3%) of permanent loss;
- Alternative 4 – 3,108 acres (27.6%) of permanent loss;
- Alternative 5 – 3,081 acres (27.4%) of permanent loss;
- Alternative 6 – 2,839 acres (25.2%) of permanent loss; and
- Alternative 7 – 2,395 acres (21.3%) of permanent loss.

Compared to Alternative 2, which would result in 3,465 acres (30.7%) of combined direct (including permanent and temporary impacts) and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the silvery legless lizard occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual silvery legless lizards as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual silvery legless lizards occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as construction-related dust; human-caused habitat degradation; harassment and collection; invasion by exotic plant and animal species, such as Argentine ants; predation by pet, stray, and feral cats and dogs; and use of pesticides. Short-term and long-term secondary impacts to silvery legless lizard resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to silvery legless lizard: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment, entombment of aestivating and hibernating individuals, and increased exposure of individuals left without protective cover. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys within the proposed disturbance area will be conducted by a qualified biologist in possession of a scientific collecting permit to capture and relocate silvery legless lizards. General procedures to avoid and minimize impacts to silvery legless lizards during construction will be implemented, and a qualified biologist will be present during construction in order to relocate any identified remaining individuals, further reducing impacts to the species.

The combined permanent loss of suitable habitat for the silvery legless lizard resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,395 acres (21.3%) under Alternative 7 to 3,465 acres (30.7%) under Alternative 2. This would be substantial loss of suitable habitat and will reduce the size and distribution of the silvery legless lizard population in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable habitat to support the silvery legless lizard in the Project vicinity. Implementation of these mitigation measures will result in protection, restoration and enhancement, and management of approximately 6,060 acres of suitable habitat for this species. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**). Restoration and enhancement of habitat used by the silvery legless lizard in these areas will improve habitat quality for the species.

With respect to secondary effects, silvery legless lizards occupying habitat in close proximity to construction zones may be disturbed by construction activities, including increased human activity, noise, ground vibration, and dust. Biological monitoring during vegetation clearing and grading, as well as dust suppression measures, will help reduce these construction-related impacts. Potential long-term effects of development include habitat fragmentation; increased human activity, including habitat degradation and collection; invasive species such as Argentine ant; pet, stray, and cats and feral dogs; and use of pesticides. The large open space system will provide adequate protected open space that will in part offset these impacts, especially habitat fragmentation. Several specific mitigation measures will also be implemented to control human activities in open space areas, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in, or adjacent to, open space areas. Pesticides will be controlled through an integrated pest management (IPM) plan. Argentine ant invasions of upland habitats in the open space system will be monitored and controlled to extent feasible. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

All specific mitigation measures for silvery legless lizard are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-40 IMPACTS TO INDIVIDUALS – SILVERY LEGLESS LIZARD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified two mitigation measures that will avoid, minimize, or mitigate the loss of silvery legless lizard individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to reduce the impacts to silvery legless lizard individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-54 requires surveys to capture and relocate silvery legless lizard, coast horned lizard, coastal western whiptail, rosy boa, San Bernardino ringneck snake, and coast patch-nosed snake individuals 30 days prior to construction activities in suitable habitats.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to silvery legless lizard individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-41 LOSS OF HABITAT – SILVERY LEGLESS LIZARD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the silvery legless lizard through protection, restoration and enhancement, and management of habitat.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the silvery legless lizard through protection, restoration and enhancement, and management of habitat.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation,

restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the silvery legless lizard would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-42 SECONDARY IMPACTS – SILVERY LEGLESS LIZARD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to the silvery legless lizard, including short-term construction activities and long-term effects due to factors such as human-caused habitat degradation and harassment.

SP-4.6-53 and SP-4.6-59, as described above, will be implemented to mitigate impacts from increased short-term human activity associated with construction.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will be implemented to mitigate impacts from increased long-term human activity through protection, restoration and enhancement, and management of habitat.

SP-4.6-17, SP-4.6-20, SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-39 will be implemented to protect against both potential short-term construction-related secondary impacts and long-term secondary impacts to habitat and/or silvery legless lizard individuals associated with increased human activity and grazing.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-27 and SP-4.6-39 require removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-1 through SP-4.6-16, SP-4.6-17, SP-4.6-18, SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will be implemented to mitigate for impacts due to habitat fragmentation and potential isolation of populations.

In addition, SP-4.6-29 through SP-4.6-32 will be implemented to mitigate for impacts related to increased human activity in the High Country SMA through limiting access to daytime use of the designated trail system; prohibiting pets (with the exception of horses on established trails); prohibiting hunting, fishing, and motor or off-trail bike riding; and providing trail design guidelines to minimize impacts to native habitats.

SP-4.6-33 will be implemented to mitigate potential adverse edge effects by permitting construction of buildings and other structures only upon developed pads within certain Planning

Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures that address secondary effects such as construction-related dust, increased human activity, invasion by Argentine ants, and predation by pet, stray, and feral cats and dogs, and use of pesticides.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, will be implemented to mitigate for impacts from increased human activity through habitat protection, restoration and enhancement, and management.

In addition, BIO-63, BIO-69, and BIO-73 will be implemented to mitigate impacts related to increases in human activity:

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-64 will be implemented to prevent loss of prey and secondary poisoning and requires preparation of an integrated pest management (IPM) plan controlling the use of pesticides on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-72, BIO-85, and BIO-87 will be implemented to reduce and control Argentine ants in open space areas.

BIO-72 specifies that container plants for use within 100 feet of the open space areas shall be inspected for pests, including Argentine ants. Plant palettes also will include non-invasive species that do not require high irrigation rates, which will help keep moisture levels low at the open space-urban interface. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to silvery legless lizard and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

SOUTH COAST GARTER SNAKE (CSC)

Life History

The common garter snake (*Thamnophis sirtalis*) has the northernmost range of any reptile in North America, and is wide ranging and locally abundant. The genus *Thamnophis* and the species *T. sirtalis* represent taxonomic clades, and are closely related genetic groups sharing common ancestry. South coast garter snake (*Thamnophis sirtalis* ssp.) may represent a distinct taxon but has not yet been described (Jennings and Hayes 1994). Natural history records for the south coast garter snake in California include sightings from Santa Clara River Valley (Ventura County) south to San Pasqual (San Diego County) (NatureServe 2007). South coast garter snakes are endemic to southern California's coastal plain and found primarily between sea level and 800 meters (2,625 feet) AMSL (NatureServe 2007). The south coast garter snake has a small range along the coast of southern California. The snake had been displaced from 75% of its historical localities as of 1994 (Jennings and Hayes 1994). Individuals can be numerous along permanent and semi-permanent sources of water (Zeiner *et al.* 1988). The diurnal snakes are most active in the early morning and late afternoon in the summer and in midday in cooler times (Zeiner *et al.* 1988). Common garter snakes forage on land and in quiet pools of water. They prey on slugs, earthworms, leeches, small fish, tadpoles, insects, small mammals and birds, and lizards (Jennings and Hayes 1994; Zeiner *et al.* 1988).

Common garter snakes generally retreat to communal hibernation burrows in October (Jennings and Hayes 1994). Occasionally, on warmer winter days, the snakes will emerge from hibernation and bask in the sun. Common garter snakes of southern California in higher elevations, inland, and in colder areas hardly emerge from their hibernation (Zeiner *et al.* 1988). Hibernation lasts until March. Males emerge first and prepare for mating.

During the spring emergence, males will court and mate with females. The polygynandrous south coast garter snake may breed with several partners, but not all may mate. Sexually mature females (two years old) are able to store sperm and may still give birth without mating that season (Zimmerman 2002). When males and females have mated, they disperse and head for summer feeding and birthing habitat. Common garter snakes are viviparous, or live-bearing, reptiles. Gravid females will bear two to 20 live young between the late summer and early fall (Jennings and Hayes 1994). Female common garter snakes give birth in and under loose bark, rotting logs, and dense vegetation near ponds and stream margins (Zeiner *et al.* 1988).

As of the 1990s, the south coast garter snake was extinct from 18 historical localities and endangered in 24 more (Jennings and Hayes 1994). In addition to the direct loss of habitat, south coast garter snakes are vulnerable to several effects related to urbanization. Development not only directly removes habitat, but urban development also may impede natural movement between habitats (Jennings and Hayes 1994) and habitat quality may be reduced by alteration of channel morphology (NatureServe 2007). Additionally, predation by introduced aquatic species

(*e.g.*, bullfrogs, bass, and snapping turtles), collection for pets, extermination because of fear, urban-related predation pressures (*e.g.*, dogs, raccoons, skunks), competition with non-native turtles, contaminant spills, grazing, off-road vehicle use, and vehicle strikes on roads (Zeiner *et al.* 1988) have all contributed to the sharp decline of this species in recent decades.

Survey Results

South coast garter snakes are distributed throughout marshes, meadows, sloughs, ponds, slow-moving water courses, and riparian vegetation communities and adjacent upland environments. There is a low potential for this species to occur on site based on habitats present within the Project area. The species has not been found within the Project area along the Santa Clara River during field surveys. No focused surveys have been conducted for this species, but no observations have been noted in several wildlife surveys for other riparian and aquatic species (SMEA 1995A; Aquatic Consulting Services 2002A, 2002B, 2002C, 2002D; Impact Sciences 2002; Compliance Biology 2004D; Impact Sciences 2001; Ecological Sciences 2004A). There are known populations of south coast garter snake within the Santa Clara River downstream of the Project area, but no known populations in the upper Santa Clara River watershed. Surveys within the Project area have not resulted in any observations or indications that the common garter snake is present. Based on these negative survey results, the south coast garter snake probably does not occur in the Project area, but, if present, likely has a limited distribution. Because there is some, albeit low, potential for this species to occur on site, the potential impacts of the proposed Project are evaluated in this EIS/EIR. Alluvial scrub, arrow weed scrub, big sagebrush scrub, bulrush–cattail wetland, cismontane alkali marsh, coastal and valley freshwater marsh, herbaceous wetland, Mexican elderberry, mulefat scrub, river wash, southern coast live oak riparian forest, southern cottonwood–willow riparian, and southern willow scrub vegetation communities are suitable habitat for the south coast garter snake. A total of 1,180 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 116 acres of suitable habitat would be permanently lost through implementation of the RMP and the SCP, representing 9.8% of suitable habitat on site (**Figure 4.5-54,** Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). A total of 103 acres would be directly temporarily impacted.

No south coast garter snakes have been documented in the Project area in several wildlife surveys, but this analysis assumes at least a low potential for occurrence. Although a limited amount of habitat would be permanently lost, because this species has a small range and had been displaced from 75% of its historical locations as of 1994, habitat loss associated with implementation of the RMDP and the SCP would have a substantial direct adverse effect on this species if it occurs on site; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 109 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 9.2% of the suitable habitat on site (**Figure 4.5-54,** Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat).

No south coast garter snakes have been documented on the Project area in several wildlife surveys, but this analysis assumes at least a low potential for occurrence. Although a limited amount of habitat would be permanently lost, because this species has a small range and had been displaced from 75% of its historical locations as of 1994, habitat loss due to build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial direct adverse effect on this species if it occurs on site; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 224 acres (19.0%).

Although a limited amount of habitat would be permanently lost as a result of the combined direct and indirect permanent impacts, because this species has a small range and had been displaced from 75% of its historical locations as of 1994, habitat loss due to implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial direct adverse effect on this species if it occurs on site; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The species has not been found in the Santa Clara River during numerous surveys of the River corridor in the Project area and is considered to have a low probability of occurring on site. Some suitable habitat is present in the Salt Creek (although water quality is impaired) and Potrero Canyon tributaries on the south side of the River, but wildlife surveys in these areas have not detected this species. Implementation of the proposed RMDP would require the construction of bridges and bank stabilization within the River corridor and in Potrero Canyon, but it is not expected that construction and grading activities would result in injury or mortality of south coast garter snake. However, for the purpose of this analysis, at least a low probably of the occurrence of the species on site is assumed. If present, construction activities could result in injury or mortality of south coast garter snakes in the disturbance zone as a result of direct contact of adults and juveniles with construction equipment or by entombment as a result of grading activities. In addition, construction and/or grading activities that result in degradation of aquatic habitats, such as by introduction of mud, silt, or chemical pollutants, may cause south coast garter snakes to abandon the site and make them more vulnerable to impacts such as vehicle collisions and exposure to predators and harsh environmental conditions. Implementation of the SCP would not directly impact this species.

Because this species is very uncommon, has a small range, and had been displaced from 75% of its historical locations as of 1994, if impacts to individuals occurred as a result of construction activities, the impact would have a substantial direct adverse effect on this

species; could cause the species to drop below self-sustaining levels on site or rangewide; could threaten to eliminate the species on site or rangewide; or could substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

Although suitable habitat for south coast garter snake is present, no individuals have been observed in the Project area during wildlife surveys and the probability of the species occurring on site is low. However, because a low probability of occurrence on site is assumed for this analysis, impacts to individuals resulting from the build-out of the Specific Plan, VCC, and Entrada planning areas could occur, including injury or mortality of individuals in the disturbance zone as a result of direct contact with construction equipment or by entombment as a result of grading activities. In addition, construction and/or grading activities that result in degradation of aquatic habitats, such as by introduction of mud, silt, or chemical pollutants, may cause south coast garter snakes to abandon the site and make them more vulnerable to impacts such as vehicle collisions and exposure to predators and harsh environmental conditions. These impacts, if they occurred, would have a substantial adverse effect on this species; could cause the species to drop below self-sustaining levels on site or rangewide; could threaten to eliminate the species on site or rangewide; or could substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas could result in construction-related ground vibration which may flush individuals, if present, from refuge areas and expose them to predators and potentially harsh environmental conditions (*e.g.* hot, dry weather). Short-term construction activities could generate dust and disperse sediments and pollutants from construction sites into the Santa Clara River and affect on-site and downstream south coast garter snake populations. Hydrologic and water quality-related impacts could include chemical pollution, increased turbidity, excessive sedimentation, flow interruptions, and changes in water temperature due to short-term changes to the active channel morphology. Construction-related dust could impair water quality and reduce available prey. These factors could result in substantial impacts to south coast garter snakes and/or the degradation of habitat quality. Other construction-related secondary impacts associated with implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas could include disruptions to behavioral activities associated with

increased human activity. Implementation of the SCP would not result in secondary impact to this species.

Build-out of the Specific Plan, VCC, and Entrada planning areas could result in habitat fragmentation that could inhibit the movement of the south coast garter snake, if present, in the Project area, especially in areas used by individuals to move into terrestrial habitats. Furthermore, implementation of the RMDP and the long-term occupancy of the Specific Plan, VCC, and Entrada planning areas could result in adverse secondary effects to south coast garter snakes. The proximity of urban development to suitable south coast garter snake habitat could result in disruption of essential behavioral activities, including foraging, breeding, and hibernation. Other potential impacts include predation by introduced invasive species (*e.g.*, Argentine ants, bullfrogs, and exotic fish); collection as pets; urban-related predation pressures (*e.g.*, by cats, dogs, raccoons, skunks, ravens, and crows); off-road vehicle use; cattle grazing; increased incidence of vehicle collisions on roads (Holland 1994); use of pesticides, which may cause secondary poisoning and loss of prey; and invasion of exotic plant species, such as tamarisk, giant reed, and pampas grass that may cause altered hydrology and channel morphology, thus degrading south coast garter snake habitat.

Because this species is very uncommon, has a small range, and had been displaced from 75% of its historical locations as of 1994, these short-term and long-term secondary impacts could have a substantial adverse effect on the south coast garter snake if present on site; could substantially reduce the habitat of the species on site or rangewide; could cause the species to drop below self-sustaining levels on site or rangewide; could threaten to eliminate the species on site or rangewide; or could substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the south coast garter snake (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 89 acres (7.6%) of permanent loss and 110 acres of temporary loss;
- Alternative 4 – 91 acres (7.7%) of permanent loss and 100 acres of temporary loss;

- Alternative 5 – 97 acres (8.2%) of permanent loss and 116 acres of temporary loss;
- Alternative 6 – 74 acres (6.3%) of permanent loss and 107 acres of temporary loss; and
- Alternative 7 – 18 acres (1.5%) of permanent loss and 100 acres of temporary loss.

Compared to Alternative 2, which would result in 116 acres (9.8%) of permanent loss and 103 acres of temporary impacts, the combined permanent and temporary loss of habitat would be somewhat lower under Alternative 5 and substantially lower under Alternatives 3, 4, 6, and 7. The relatively large difference in permanent impacts between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries as well as other reductions to the Project footprint under Alternative 7 that would result in substantially fewer permanent impacts to suitable habitat for the south coast garter snake compared to the other alternatives.

The overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 ranges from marginally reduced to substantially reduced compared to the overall habitat loss under Alternative 2. Because this species is very uncommon, has a small range, and had been displaced from 75% of its historical locations as of 1994, the direct impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the south coast garter snake (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 85 acres (7.2%) of permanent loss;
- Alternative 4 – 67 acres (5.7%) of permanent loss;
- Alternative 5 – 64 acres (5.4%) of permanent loss;
- Alternative 6 – 36 acres (3.0%) of permanent loss; and
- Alternative 7 – 22 acres (1.8%) of permanent loss.

Compared to Alternative 2, which would result in 109 acres (9.2%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the

development footprints for the Specific Plan and/or Entrada planning areas under Alternatives 4 through 7 and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes to the Project footprint under Alternative 7 that would result in reduced impacts to suitable habitat for south coast garter snake compared to the other alternatives.

Because this species is very uncommon, has a small range, and had been displaced from 75% of its historical locations as of 1994, the overall permanent loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the south coast garter snake:

- Alternative 3 – 175 acres (14.8%) of permanent loss;
- Alternative 4 – 158 acres (13.4%) of permanent loss;
- Alternative 5 – 161 acres (13.6%) of permanent loss;
- Alternative 6 – 110 acres (9.3%) of permanent loss; and
- Alternative 7 – 39 acres (3.3%) of permanent loss.

Compared to Alternative 2, which would result in 224 acres (19.0%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have substantially reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. Alternative 3 impacts are somewhat higher than impacts under Alternatives 4 through 7 because VCC would not be constructed under Alternatives 4 through 7. There would generally be successive reductions in the Specific Plan and/or Entrada planning areas under Alternatives 4 through 7 (Alternative 5 impacts are marginally higher than Alternative 4 impacts) and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 that would reduce impacts to suitable habitat for the south coast garter snake compared to the other alternatives.

Because this species is very uncommon, has a small range, and had been displaced from 75% of its historical locations as of 1994, the combined direct and indirect permanent loss of habitat from implementation of the RMD and the SCP and build-out of the

Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual south coast garter snakes as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than the potential under Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. The potential for impacts to individuals is very low. However, because this species is very uncommon, has a small range, and had been displaced from 75% of its historical locations as of 1994, if impacts to individuals occurred as a result of construction activities, the impact would have a substantial direct adverse effect on this species; could cause the species to drop below self-sustaining levels on site or rangewide; could threaten to eliminate the species on site or rangewide; or could substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Therefore, impacts to individual south coast garter snakes occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only) and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2. Each alternative has similar short-term effects from construction activities, such as ground vibration and potential impacts to hydrology and water quality, construction-related dust, and increased human activity. Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in long-term secondary effects such as human-caused habitat degradation, harassment, and collection; predation by pet, stray, and feral cats and dogs; invasive wildlife species; increased incidence of roadkill; and use of pesticides.

Because this species is very uncommon, has a small range, and had been displaced from 75% of its historical locations as of 1994, these short-term and long-term secondary impacts could have a substantial adverse effect on the south coast garter snake if present on site; could substantially reduce the habitat of the species on site or rangewide; could cause the species to drop below self-sustaining levels on site or rangewide; could threaten to eliminate the species on site or rangewide; or could substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to south coast garter snake: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals, if present, could occur during construction as a result of vegetation clearing and grading and construction activities in ponds and flowing water, including injury and mortality due to direct contact with construction equipment, entombment of hibernating individuals, and increased exposure of individuals flushed from habitat or left without protective cover. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys will be conducted in the riverbed and all riverbed areas within 500 feet of the construction zone and access roads at the appropriate season for south coast garter snake (April 1 to September 1). Any detected individuals will be relocated to suitable pre-approved locations identified in a Relocation Plan prepared by the applicant and approved by CDFG. General procedures to avoid and minimize impacts to south coast garter snake during construction will be implemented, and a qualified biologist will be present during construction in order to relocate any additional encountered individuals. Clearance surveys will be conducted each day prior to construction. Several general measures will be implemented to protect wetland habitats that will reduce impacts to the south coast garter snake. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities, biological monitoring during any stream diversions, restrictions on construction equipment operating in ponds or flowing water, design of bridges, culverts, and other structure so as not to impair the movement of aquatic species, and protection of water quality from mud, silt, and other pollutants.

The combined permanent loss of suitable habitat for the south coast garter snake resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 39 acres (3.3%) under Alternative 7 to 224 acres (19.2%) under Alternative 2. Because this species is extremely uncommon and has a small range, if present, this would be a substantial loss of suitable habitat and will reduce the size and distribution of the south coast garter snake population in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in the protection of approximately 818 acres of suitable habitat for this species, primarily in the River Corridor SMA, but also within the High Country SMA and Salt Creek area (**Figure 4.5-3**). In addition, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts in water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area over the long term as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County. The technical

analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue. Following build-out, the River corridor floodplain would remain 1,000 to 2,000 feet wide and retain the mosaic of habitats, including the relatively narrow wetted channel, benches, and dry terraces that would support the life history of the south coast garter snake.

With respect to secondary effects, any south coast garter snakes occupying habitat in close proximity to construction zones may be disturbed by construction activities, including ground vibration and dust. Ground vibration could cause individuals to emerge from burrows and other refuge areas and expose them to predators, adverse environmental conditions, and increase their chance of injury or mortality from construction equipment and vehicles. Dust may adversely affect water quality and their insect prey. Aquatic habitat, including downstream areas, could be disturbed during construction by hydrological alterations and pollutants that impair water quality, thus adversely affecting habitat quality and prey for this species. Pre-construction surveys to relocate individuals found within 500 of construction areas and access roads, daily clearance surveys, biological monitoring during vegetation clearing and grading in and adjacent to occupied habitat, as well as dust suppression measures, will help reduce the potential effects of ground vibration and dust. Any south coast snakes detected prior to or during construction will be relocated to identified suitable habitat by a qualified biologist holding a Scientific Collecting Permit according to a CDFG-approved Relocation Plan. Several general mitigation measures, as described above, will be implemented to protect on-site and downstream wetland and aquatic habitat quality, and in particular, protection of downstream water quality from mud, silt, and other pollutants. Potential long-term effects of development include increased human activity, including habitat degradation and collection; invasive species, including Argentine ant and invasive plants such as giant reed; pet, stray, and cats and feral dogs; vehicle collisions; and use of pesticides. The River Corridor SMA will provide adequate protected open space that will in large part offset these long-term impacts. Several specific mitigation measures will also be implemented to control human activities in the River Corridor SMA, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. Pesticides will be controlled through an integrated pest management (IPM) plan. Argentine ant invasions of upland habitats in the open space system will be monitored and controlled to extent feasible. Implementation of these measures would allow this species to persist on site after development in the River Corridor SMA.

All specific mitigation measures for south coast garter snake are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-43 IMPACTS TO INDIVIDUALS – SOUTH COAST GARTER SNAKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified four mitigation measures that would avoid, minimize, or mitigate the loss of south coast garter snake individuals through pre-development surveys and conformance with state and federal permits related to wetlands and water quality.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that will reduce potential impacts to south coast garter snake individuals. Most of these mitigation measures address potential impacts to wetland/riparian habitats, such as hydrologic alterations and water quality impacts that could adversely affect south coast garter snakes. In addition, pre-construction coordination and biological monitoring will be conducted to reduce impacts.

BIO-89 requires preconstruction surveys at the appropriate season (April 1 to September 1) for south coast garter snake prior to initiating construction for installation of bridges, storm drain outlets, utility lines, bank protection, trails, and/or other construction activities, all construction sites and access roads within the Santa Clara River riverbed and all riverbed areas within 300 feet of construction sites and access roads. Any detected individuals will be relocated to suitable pre-approved locations identified in a Relocation Plan prepared by the applicant and approved by CDFG. The Relocation Plan will include several key elements: (1) timing and location of surveys, including areas where more intensive surveys should be done; (2) trapping/capture and relocation methods; and (3) procedures for recordkeeping of the number of individuals relocated. A qualified biologist will be present during all construction activities within or adjacent to occupied habitat and clearance surveys will be conducted daily in this habitat before onset of construction activities.

The following three mitigation measures, BIO-46, BIO-48, and BIO-49, focus primarily on special-status fish, but they generally will also reduce impacts to the south coast garter snake and other semi-aquatic species.

BIO-46 states that during any stream diversion or culvert installation activity, a qualified biologist(s) shall be present, and shall patrol the areas within, upstream, and downstream of the work area. The biologists shall inspect the diversion and inspect for stranded south coast garter snakes.

BIO-48 states that bridges, culverts, and other structures may not impair movement of fish and aquatic life and specifies relative depth requirements for temporary and permanent culverts.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to south coast garter snake individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7

IMPACT 4.5-44 LOSS OF HABITAT – SOUTH COAST GARTER SNAKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for south coast garter snake through habitat protection, restoration and enhancement, and management. SP-4.6-55 and SP-4.6-58, as described above, will also mitigate for loss of habitat as a result of compliance with state and federal permits related to wetlands and water quality.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. In addition to providing a buffer between the development edge and wetland/riparian habitat in the River Corridor SMA, these transition areas will provide potential winter habitat for the south coast garter snake. They may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system totaling approximately 6,100 acres that will reduce habitat fragmentation effects (**Figure 4.5-3**).

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the south coast garter snake. These measures refer to habitat protection, restoration and enhancement, and management

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the south coast garter snake would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-45 SECONDARY IMPACTS – SOUTH COAST GARTER SNAKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures to mitigate for construction-related short-term secondary impacts to the south coast garter snake, such as altered hydrology and water quality and inadvertent impacts to suitable habitat adjacent to construction zones as well as increased human activity. Mitigation measures to offset long-term secondary impacts, such as habitat fragmentation; invasive plant species; increased human activity; increased predation by pet, stray, and feral cats and dogs and other mesopredators; and other sources of habitat degradation (*e.g.*, grazing), were also identified**.**

In order to mitigate impacts from contact with chemical pollutants, increased sedimentation, increased turbidity, changes in flow, and changes in water temperature during construction, the Newhall Ranch Specific Plan Program EIR identified SP-4.6-55 and SP-4.6-58, as described above.

In order to avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These measures require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA. These measures, in combination with SP-4.6-53 and SP-4.6-59, which require pre-development surveys as described above, will also help reduce the effects of increased human activity. However, these mitigation measures are primarily designed to minimize impacts to off-site resources and alone will not completely mitigate human activity impacts. Because of the infeasibility of locating hibernating individuals prior to construction, long-term mitigation measures relating to habitat preservation and management will contribute to the persistence of the species on site and offset these short-term impacts.

The following mitigation measures address the long-term secondary effects listed above. The Newhall Ranch Specific Plan Program EIR identified the several mitigation measures that primarily address habitat fragmentation, increased predation by mesopredators, increased human populations and recreation in close proximity to open space and wetland/riparian and terrestrial winter habitat for the south coast garter snake, and other activities that could result in degradation of habitat, such as cattle grazing.

SP-4.6-1 through SP-4.6-16, SP-4.6-18, SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and which relate to the protection, restoration and enhancement, and management of the River Corridor SMA and High Country SMA, will prevent habitat fragmentation and increased predation by mesopredators (by ensuring the continued presence of top predators, such as coyotes) and will offset the impacts of grazing and increased human activity in the Project area.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19, as described above, address the transition area between development and the River Corridor SMA that will both buffer the River Corridor SMA from adverse edge effects and provide potential winter habitat for the south coast garter snake.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

In order to mitigate impacts from grazing, SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

Measures Recommended by EIS/EIR

This EIS/EIR recommends additional mitigation measures to mitigate for secondary impacts to south coast garter snake, including construction-related dust, ground vibration, short-term impacts to hydrology and water quality and long-term impacts, such as increased human activity; habitat degradation from exotic plants; predation by pet, stray, and feral cats and dogs and mesopredators; and increased predation by invasive exotic species, such as Argentine ants and bullfrogs.

BIO-89, as described above, requires preconstruction surveys for south coast garter snake prior to initiating construction activities within 500 feet of construction sites and access roads, as well as daily clearance surveys prior to construction. Detected individuals will be relocated to suitable pre-approved locations identified in a CDFG-approved Relocation Plan. These measures will minimize adverse secondary effects such as ground vibration and dust on the south coast garter snake because individuals would be removed from the general construction area.

In order to mitigate impacts from chemical pollution, increased sedimentation, increased turbidity, changes in flow, and changes in water temperature, BIO-46, BIO-48, BIO-49, and BIO-70, as summarized above, will be implemented. In addition, BIO-44, BIO-45, BIO-74, and BIO-77 will be implemented.

BIO-44 requires temporary bridges, culverts, or other feasible methods of providing access across the Santa Clara River. A Stream Crossing and Diversion Plan will be prepared that includes a description of diversion measures, such as berms, inflatable dams, sand bags, or other approved materials.

BIO-45 requires construction of bypass channels when the active wetted channel is within the work zone, in accordance with BIO-44. Equipment shall not be operated in areas of ponded or flowing water unless authorized by CDFG and USFWS.

BIO-47 requires that slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area that will provide refuge for south coast garter snake during construction.

BIO-74 requires installation of temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to construction within 200 feet of the spring and, if applicable, within 100 feet of flowing water in the Middle Canyon drainage. Permanent fencing and signage shall be erected along the bordering subdivision tract following construction. A qualified biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. Any upslope runoff from construction areas will be directed away from the Middle Canyon Spring. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

BIO-77 describes preparation of a plan and mitigation measures be implemented by the applicant specifically to maintain the populations of the undescribed snail and sunflower species, but these measures are also applicable to the south coast garter snake. The plan will provide guidelines for collecting data on existing site conditions; developing a construction monitoring program and a post-development monitoring program; developing threshold parameters that activate adaptive management measures for water quality and water quantity issues; excluding unauthorized entry into the spring; and contingency measures. The plan shall be subject to the approval of CDFG

prior to disturbance within 100 feet of flowing water in Middle Canyon Creek and/or 200 feet of Middle Canyon Spring.

Several mitigation measures will mitigate impacts from habitat fragmentation, increased predation by mesopredators, invasive plant species, and long-term increases in human activity and its associated effects.

BIO-1 through BIO-16 and BIO-19, as described above and which refer to habitat protection, restoration and enhancement, and management in the High Country SMA and Salt Creek area, will mitigate for habitat fragmentation effects, including increased predation by mesopredators, by providing for a large, interconnected open space system.

BIO-63 will be implemented to mitigate impacts from predation by pet, stray, and feral cats and dogs. This measure requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent the pollution of aquatic habitat and potential secondary poisoning and loss of prey by pesticides and requires preparation of an IPM plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA regarding wildlife species and install signage to keep people and their animals on existing trails.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-80 states that the Project applicant shall retain a qualified biologist to develop and implement an Eradication Plan for bullfrog, African clawed frog, and crayfish. Following construction, monitoring shall be conducted at sentinel locations along the River Corridor SMA (and other potential habitat areas) annually for five years. After five years, monitoring shall be conducted bi-annually for 50 years.

BIO-72, BIO-85, and BIO-87 will be implemented to reduce and control Argentine ants in open space areas.

BIO-72 specifies that container plants for use within 100 feet of the open space areas shall be inspected for pests, including Argentine ants. Plant palettes also will include non-invasive species that do not require high irrigation rates, which will help keep moisture levels low at the open space-urban interface. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the south coast garter snake and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

SOUTHWESTERN POND TURTLE (CSC)

Life History

The range of the full species western pond turtle (*Actinemys marmorata*)[1] extends along most of the west coast of North America, primarily west of the Cascade–Sierra crest, from western British Columbia, Canada, to northern Baja California, Mexico (Ernst *et al.* 1994). The subspecies southwestern pond turtle (*A. m. pallida*) ranges south of the San Francisco Bay to northern Baja California, Mexico, and intergrades with the subspecies northwestern pond turtle (*A. m. marmorata*) over a large area in central California (Bury 1970; Stebbins 2003). Isolated populations of the southwestern pond turtle are known to exist as far east as the Mojave Desert in Afton Canyon and the Amargosa River (Lovich 1999). The elevation range for the western pond turtle is from brackish estuarine waters at sea level to over 2,000 meters (6,562 feet) AMSL, but it is uncommon over 1,530 meters (5,020 feet) AMSL (Stebbins 1954; Bury 1963; Holland 1994).

The pond turtle life history described in this subsection applies to both the full species western pond turtle and the subspecies southwestern pond turtle. Where specific information is available for the subspecies southwestern pond turtle, it is described as such. Otherwise, the information is based on studies of the full species western pond turtle.

Western pond turtles are primarily active during the day, but they exhibit some crepuscular activity (around dusk and dawn) and nocturnal activity (Zeiner *et al.* 1988). Although streamed-based behavior is highly variable, western pond turtles typically forage in late afternoon and early evening (Jennings and Hayes 1994). They move a few meters from the local watercourse and into deep pools to feed on slow-moving prey and vegetation (Jennings and Hayes 1994). The young spend most of their time feeding and basking at water's edge. Western pond turtles typically forage on land and in quiet pools of water and, as omnivores with a broad feeding niche, they eat almost anything they can capture (Bury 1986). Western pond turtles are food generalists and highly opportunistic, but they prefer live prey (Ashton *et al.* 1997). Plants are a part of the western pond turtle's diet that provide nutrients when live prey are unavailable, and females are more herbivorous than males (Lovich 1999). Size of prey taken is directly related to the size of the western pond turtle. Western pond turtles consume insects, fish, worms, amphibians and their eggs and larvae, crayfish, cladocera (branchiopod crustaceans such as water fleas), carrion, scat (fecal pellets), filamentous algae, tule (*Schoenoplectus* spp.), cattails (*Typha* spp.), pond lily (*Nuphar polysepalum*), willows (*Salix* spp.), alders (*Alnus* sp.), and ditch grass (*Ruppia* spp.) (Ashton *et al.* 1997; Buskirk 2002; NatureServe 2007).

[1] The scientific name *Actinemys marmorata* is used here following CDFG's Special Animals List (CDFG 2007B) and The Center for North American Herpetology (CNAH 2008). Stebbins (2003) uses the scientific name *Clemmys marmorata*.

Reproductive activity by western pond turtles has been observed from February through November (Holland 1988; Buskirk 2002; Goodman 1997A). Depending on latitude, peak nesting season is from late May through early July but extends from late April through August (Holland 1994). Incubation is typically 80 to 126 days and varies with latitude and temperature (Goodman1997A; Holland 1994; Lardie 1975; Feldman 1982). In the northern portions of their range, hatchlings remain in the nest through the winter, although in southern California, most emerge in the early fall (Holland 1994).

Western pond turtle home range sizes not specifically related to short-term nesting forays and foraging bouts vary between age and sex classes. Bury (1972) studied a population of the western pond turtle in a northern California stream and found that adult males had the largest home range, averaging a mean linear length (*i.e.*, point to point) of 976 meters (3,202 feet). Adult female home ranges averaged 248 meters (814 feet), while juveniles had home ranges with a mean length of 363 meters (1,190 feet). While moving between pools within the stream system, average distances were 354 meters (1,161 feet) for males, 169 meters (554 feet) for females, and 142 meters (466 feet) for juveniles. In an Aliso Creek population, the minimum linear range for nine females averaged 1,273 meters (4,176 feet) (range: 708 to 4,263 meters (2,323 to 13,986 feet)) and two males had ranges of 319 and 709 meters (1,046 and 2,326 feet), respectively (Goodman 1997A). In contrast, the minimum linear ranges for southwestern pond turtles on the San Gabriel River were significantly shorter for females, with an average of 335 meters (1,099 feet) (range: 48 to 966 meters (157 to 3,169 feet)) for 11 females and a range of 1,610 meters (5,282 feet) for a single male. Goodman (1997A) suggested that the relative lack of water in the Aliso Creek study area compared to the San Gabriel River may account for the longer movements of the Aliso Creek population because individuals may have had to move farther to obtain the resources necessary for survival.

For the most part, overwintering sites in the Goodman (1997A) study were relatively close to water. At the Aliso Creek site, the mean distance of overwintering sites from water for seven southwestern pond turtles was 7.3 meters (23.9 feet) (range: 1.5 to 10.7 meters (4.9 to 35.1 feet)). At the San Gabriel River site, the mean distance of overwintering sites for 20 southwestern pond turtles was 32.7 meters (107.3 feet) (range: 12.8 to 60.2 meters (42.0 to 197.5 feet)). However, overwintering sites up to 500 meters (1,640 feet) from watercourses have been observed in southern California for southwestern pond turtles (Holland 1994) and in northern California for western pond turtles (Reese and Welsh 1998). Using radiotelemetry, Reese and Welsh (1997) documented overwintering sites for six males and six females on the Trinity River in Northern California that ranged from 65 meters (213 feet) to 500 meters (1,640 feet), with a mean distance of 203 meters (666 feet). All overwintering sites in the Reese and Welsh (1997) study were outside the riparian zone and located in the adjacent conifer and hardwood forests. Holland (1994) reported that western pond turtles have been found up to one kilometer (3,280 feet) from watercourses and are capable of moving up to five kilometers (3.1 miles) between drainages. Although western pond turtles are capable of moving long distances, they generally are

characterized as relatively sedentary animals. Holland and Goodman (1996) state that "most animals appear to remain within a given watercourse for extended periods of up to several years." In a general review of the terrestrial habitat requirements of semi-aquatic reptiles and amphibians, Semlitsch and Bodie (2003) found that "core terrestrial" habitat (defined as including habitat necessary for feeding, over-wintering, and nesting) ranged from 127 to 289 meters (417 to 950 feet) for reptiles, depending on the species. Semlitsch and Bodie (2003) cited Reese's 1996 Ph.D. dissertation estimate of an average movement of 168 meters (551 feet) and a range of 39 to 423 meters (128 to 1,388 feet) for the western pond turtle as part of their review.

Overwintering sites used by southwestern pond turtles appear to have more vegetation cover than nesting sites. Dominant vegetation at seven overwintering sites at the Aliso Creek site studied by Goodman (1997A) included mulefat, willows, black mustard and tree tobacco, with vegetation cover averaging 65% (range: 25% to 90%). At 20 overwintering sites at the San Gabriel River site, dominant vegetation consisted of scrub oak, yucca, chamise, ceanothus, laurel sumac, bay tree, canyon oak, white sage, black sage, poison-oak, Douglas-fir, monkeyflower, giant rye grass, ash, and non-native grasses. Percent vegetation cover at the 20 sites averaged 64% (range: 20% to 100%).

Loss, alteration, and degradation of aquatic habitat are the greatest threats to the western pond turtle. Over 90% of wetland habitat within its historical California range has been eliminated by agricultural development, flood control, water diversion projects (dams and channelization that alter stream morphology and flow rates), and urbanization (Brattstrom and Messer 1988; NatureServe 2007; Reese and Welsh 1997). Loss of terrestrial habitat in proximity to aquatic habitat is necessary to support the full life cycle of the western pond turtle (Spinks *et al.* 2003). Poor or inadequate terrestrial nesting habitat affects reproduction and recruitment and may preclude establishment of a self-sustaining population. Development may also remove habitat necessary for movement between suitable aquatic habitats, including instream and overland movement.

In addition to direct loss and alteration of habitat, western pond turtles are vulnerable to several adverse effects related to urbanization. Predation on hatchlings by introduced aquatic species (*e.g.*, bullfrogs, bass, and catfish), collection as pets, urban-related predation pressures (*e.g.*, dogs, raccoons, skunks, ravens, and crows), competition with non-native turtles (Holland 1991), contaminant spills, grazing, off-road vehicle use, and vehicle strikes on roads (Holland 1994) have all contributed to the sharp decline this species has experienced in recent decades. Invasion of exotic vegetation species, such as tamarisk, alters hydrology and channel morphology, which degrades pond turtle habitat. Increased moisture along habitat edges due to urban runoff, irrigation, or wet fuel modification zones may also affect nesting success because hard-shelled turtle eggs cannot expand in response to increased internal pressure in moist incubation substrates (Spinks *et al.* (2003).

Survey Results

The southwestern pond turtle has been documented in the Project area at several locations along the Santa Clara River and in the Salt Creek tributary during various field surveys conducted between 1996 and 2006 (**Figure 4.5-6**, Special-Status Wildlife Species Occurrences**)**. The San Marino Environmental Associates (SMEA 1995A) trapping results documented a substantial southwestern pond turtle population in this reach of the Santa Clara River. Aquatic Consulting Services, Inc. (2002A, 2002C, 2002D), observed the southwestern pond turtle during daytime walkover surveys conducted from May to September 2000 along the Santa Clara River near the Commerce Center Drive Bridge, Castaic Junction area, and west of the Project area just upstream of the Salt Creek confluence with the River and upstream of the Las Brisas Bridge. Additional incidental observations of southwestern pond turtle in the RMDP area have been made by Impact Sciences (2002) and Compliance Biology (2004D); within the Santa Clara River in the Entrada planning area by Impact Sciences, Inc. (2001), Ecological Sciences (2004A), and Dudek (Dudek and Associates 2006E); in lower Potrero Canyon (Carpenter 2009); and in Salt Creek by Dudek (Dudek and Associates 2006B). Dudek conducted general wildlife surveys, including specific habitat assessments for the southwestern pond turtle, between early November and late December of 2005 in the Salt Creek area (Dudek and Associates 2006B) and between May and August of 2006 in the Entrada planning area (Dudek and Associates 2006E). In both Dudek reports, the southwestern pond turtle was reported as present but population estimates were not provided. The lower Potrero Canyon observation, which was an adult basking on a bedrock ledge along the bank of a deeply incised plunge pool in the spring of 2004 (Carpenter 2009), and the several occurrences of the southwestern pond turtle just upstream of existing crossing of the River corridor at Potrero Canyon are significant. The existing crossing causes water to pond upstream, resulting in suitable deep water habitat for the pond turtle. In addition, lower Potrero Canyon is outside the 100-year floodplain of the River, contains perennial water flows, and supports substantial adjacent uplands that are suitable for nesting. Lower Potrero Canyon therefore appears to have suitable habitat to meet the life history needs of the species and may be important for nesting and as a refuge for hatchling and juvenile pond turtles. In addition, because it is outside the 100-year floodplain of the Santa Clara River, lower Potrero Canyon may provide an important refuge area for pond turtles in the River during severe flood conditions.

Based on a search of the CNDDB (CDFG 2007A) for the nine USGS 7.5-minute quadrangles including and bordering the Project area, there are seven other documented occurrences of the southwestern pond turtle in the Project region. Suitable wetland/riparian habitat for the southwestern pond turtle in the Project area includes bulrush–cattail wetland, cismontane alkali marsh, southern cottonwood–willow riparian, coastal and valley freshwater marsh, herbaceous wetland, mulefat scrub, southern coast live oak riparian forest, river wash, southern willow scrub, and shrub tamarisk, totaling 1,059 acres. The surveys indicate that the southwestern pond turtle is generally common in the Project area in the Santa Clara River and potentially could occur anywhere in the River corridor and its tributaries where there is sufficient permanent or

semi-permanent water with nearby suitable terrestrial nesting and overwintering sites. In addition to the River corridor, Potrero Canyon may be particularly important for this species, as described above. The surveys generally focused on aquatic habitats used by the southwestern pond turtle within the Project Area. However, focused nesting and overwintering surveys and studies in adjacent terrestrial habitats have not been conducted in the Project area; thus, inferences regarding the southwestern pond turtle's use of terrestrial habitats for nesting and overwintering in the Project area must be based on studies conducted elsewhere in southern California (*e.g.*, Rathbun *et al.* 1992; Holland 1994; Goodman 1997A).

Because use of terrestrial habitats outside the River corridor is not known and is likely linked to specific soil conditions and vegetative cover, the amount of suitable terrestrial habitat was not quantified for the purpose of the impact analysis. However, in order to analyze potential impacts to southwestern pond turtle refugia during severe flooding in the Santa Clara River, the portions of the River corridor within the Project area, as well as the reaches just upstream and downstream of the Project area, that would provide potential wet and dry refugia during 100-year storm events were delineated for Alternatives 2 through 7 do determine whether refugia would be available during extreme flood conditions. Wet refugia is defined as areas within the 100-year floodplain that would provide slow moving flow areas (< 2 fps) for pond turtles that would allow them to avoid the high flow areas that could wash them downstream. Dry refugia is defined as upland areas adjacent to the 100-year floodplain that would be available for pond turtles to escape severe flood events. Dry refugia includes natural habitat such as annual grassland, shrublands, and woodlands that may provide long-term refuge and agricultural lands that would provide temporary refuge. Dry refugia include areas immediately adjacent to the River corridor and the main tributaries south of the River corridor. The northern boundary for the dry refugia area is SR-126. It should be noted that these dry refugia areas were delineated based on immediate adjacency to and accessibility from the River corridor and gentle topography and are not intended to depict documented southwestern pond turtle use areas. For this reason, the refuge analysis is qualitative and not quantitative.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 88 acres of suitable wetland/riparian habitat would be permanently lost through implementation of the RMDP and the SCP, representing 8.3% of suitable habitat on site (**Figures 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). A total of 95 acres would be directly temporarily impacted. Implementation of the SCP would not affect this species.

Although almost 92% of suitable wetland/riparian habitat for the southwestern pond turtle would remain after construction of the RMDP facilities, and substantial wet and dry refugia habitat would remain (**Figure 4.5-120,** Potential Refugia for Southwestern Pond Turtle; Alternative 2 – 100 Year Flood Event), this species is declining throughout its range and even small losses of habitat are considered substantially adverse. Therefore, wetland/riparian and refugia habitat loss due to implementation of the RMDP would have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; and substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). In addition, under this alternative the Potrero Canyon Road Bridge across the Santa Clara River would be constructed and would permanently alter habitat upstream of the existing at-grade agricultural crossing (which creates suitable habitat in the River corridor). Bridge and road construction at the mouth of Potrero Canyon could also preclude pond turtles from using the lower portion of Potrero Canyon, where pond turtles have been observed and which may be important for nesting and use by hatchling and juvenile southwestern pond turtles, as well as provide dry refuge habitat during severe flooding in the River, such as a 100-year flood event. Direct permanent and temporary impacts (Loss of Habitat) would be significant and unavoidable, due to the construction of the Potrero Canyon Road Bridge.

Indirect Permanent Impacts

A total of 52 acres of suitable wetland/riparian habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 4.9% of suitable wetland/riparian habitat on site (**Figure 4.554**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). In addition to impacts to wetland/riparian habitat, build-out of the Specific Plan, VCC, and Entrada planning areas would result in substantial impacts to terrestrial habitats, including agriculture, bordering the Santa Clara River and Potrero Canyon. In addition to providing potential nesting and aestivation and

overwintering sites, these areas provide dry refugia habitat during severe flooding. **Figure 4.5-120**, Potential Refugia for Southwestern Pond Turtle; Alternative 2 – 100 Year Flood Event, illustrates the areas of both wet and dry refugia following build-out. Holland (1994) observed overwintering sites up to 1,640 feet from water and also reports that western pond turtles have been found up to 3,280 feet from watercourses and that they are capable of moving up to 3.1 miles between drainages. These longer movement distances indicate the potential use of terrestrial habitats outside the River corridor that would be affected by build-out of the Specific Plan, VCC, and Entrada planning areas. In particular, development of Homestead Village, Landmark Village, and Mission Village immediately adjacent to the River corridor would result in the loss of potential terrestrial and dry refugia habitat for the southwestern pond turtle.

In addition to loss of wetland and riparian habitat, impacts to terrestrial habitat resulting from build-out of the Specific Plan, VCC, and Entrada planning areas, the Project could substantially reduce suitable nesting, hibernation, and dispersal habitat for the species on site; interfere substantially with the movement of the species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined and indirect permanent loss of suitable wetland/riparian habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 140 acres (13.2%). As described above for direct impacts, construction of the Potrero Canyon Road Bridge may result in the loss of suitable habitat for the pond turtle in the River corridor because the existing at-grade crossing that creates ponded areas would be removed. In addition, suitable refuge and nesting habitat and habitat for hatchlings and juveniles in lower Potrero Canyon would be affected, potentially precluding use of this important area. As described above for indirect impacts, build-out of the Specific Plan, VCC, and Entrada planning areas would also result in substantial impacts to terrestrial habitats (including agriculture) that could be used for nesting, aestivation, overwintering, and refuge bordering the Santa Clara River and Potrero Canyon (**Figure 4.5-54**). Because of the loss of suitable habitat at the Potrero Canyon crossing of the River and loss of refuge and potential nesting habitat in lower Potrero Canyon, as well as the large amount and percentage of terrestrial habitat loss, the combined direct and indirect permanent impacts could substantially reduce suitable habitat for the species on site; interfere substantially with the movement of the species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number

or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant and unavoidable.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The southwestern pond turtle is a documented resident in the Santa Clara River, Salt Creek, and Potrero Canyon portions of the Project area and may occur within portions of the other tributary drainages. Implementation of the RMDP would require the construction of various facilities within the River corridor and adjacent upland areas and in Potrero Canyon in areas that support suitable habitat for the southwestern pond turtle. It is foreseeable that construction and/or grading activities associated with these facilities in both aquatic and terrestrial habitats could result in injury or mortality of southwestern pond turtles in the disturbance zone as a result of direct contact with construction equipment by adults, subadults, juveniles, hatchlings, and eggs in nests or by entombment as a result of grading activities. In addition, construction and/or grading activities that result in degradation of aquatic habitats, such as the introduction of mud, silt, or chemical pollutants, may cause southwestern pond turtles to abandon the site and make them more vulnerable to impacts such as vehicle collisions and predation. Hatchlings, in particular, are extremely vulnerable to ravens and crows that are attracted to construction areas. Implementation of the SCP would not directly affect this species.

Because the southwestern pond turtle is a special-status species and declining throughout its range, the loss of any southwestern pond turtle individuals could have a substantial direct adverse effect on this species; cause the species to drop below self-sustaining levels on site; threaten to eliminate the species on site; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals, but over a much larger area, including substantial terrestrial areas that could be used for aestivation and overwintering. The build-out of the Specific Plan, VCC, and Entrada planning areas would include construction and/or grading activities in areas supporting suitable aquatic and terrestrial habitat for the southwestern pond turtle that could result in injury or mortality of individuals in the disturbance zone as a result of contact with construction equipment by adults, subadults, juveniles, hatchlings, and eggs in nests or by entombment as a result of grading activities. In addition, construction and/or grading activities that result in degradation of aquatic habitats, such as the introduction of mud, silt, or chemical

pollutants, may cause southwestern pond turtles to abandon the site and make them more vulnerable to impacts such as vehicle collisions and predation. As a special-status species, the loss of any southwestern pond turtles could have a substantial adverse effect on this species; cause the species to drop below self-sustaining levels on site; threaten to eliminate the species on site; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term construction-related secondary impacts resulting from implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas, include noise, ground vibration, dust, changes in hydrology, and adverse edge effects, such as increased human activity and nighttime illumination. Each of these potential impacts could result in habitat degradation or increased vulnerability of southwestern pond turtle individuals. Noise and ground vibration could flush individuals from refuge areas and increase their risk of vehicle collisions and predation. Dust may impair habitat quality and reduce insect and aquatic prey. Construction activities could disperse sediments and pollutants from construction sites into the Santa Clara River and affect on-site and downstream aquatic habitats used by southwestern pond turtles. Hydrologic and water quality-related impacts could include chemical pollution, increased turbidity, excessive sedimentation, flow interruptions, and changes in water temperature due to short-term changes to the active channel morphology. These factors could degrade habitat quality or otherwise alter habitat use and cause pond turtles to abandon these areas, potentially resulting in injury or mortality due to predation, vehicle collisions, and harassment. Nighttime illumination could expose southwestern pond turtle to nocturnal predators and general increases in human activity may alter behavioral activities such as foraging, basking, breeding, and nesting, thus impairing the general health of the turtles and potentially reducing their reproductive fitness. Implementation of the SCP would not affect this species.

Build-out of the Specific Plan, VCC, and Entrada planning areas could result in habitat fragmentation that may inhibit the movement of the southwestern pond turtle in the Project area, especially areas used by individuals to move into terrestrial habitats. Furthermore, implementation of the RMDP and the long-term occupancy of the Specific Plan, VCC, and Entrada planning areas could result in adverse secondary effects to southwestern pond turtles. The proximity of urban development to suitable southwestern pond turtle habitat could result in disruption of essential behavioral activities, including foraging, basking, nesting, and overwintering. Lighting associated with RMDP facilities (*e.g.*, bridges) could affect behavioral activities and increase the risk of predation by nocturnal predators. Other potential impacts include predation on hatchlings by introduced aquatic species (*e.g.*, bullfrogs, largemouth bass, and catfish); collection as pets; urban-related predation pressures (*e.g.*, cats, dogs, raccoons, skunks, ravens, and crows); competition with non-native turtles (Holland 1991); off-road vehicle

use; cattle grazing; increased incidence of vehicle collisions on roads (Holland 1994); use of pesticides, which could cause secondary poisoning and loss of prey; and invasion of exotic plant species, such as tamarisk, giant reed, and pampas grass. Establishment of exotic plant species may result in altered hydrology and channel morphology, which degrades southwestern pond turtle habitat. Increased moisture along habitat edges due to urban runoff, irrigation, or wet fuel modification zones may also affect nesting success. Although pond turtle eggs need some moisture to avoid desiccation, high subsurface moisture may be adverse because hard-shelled turtle eggs cannot expand in response to increased internal pressure (Spinks *et al.* 2003).

These short-term and long-term secondary impacts could have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable wetland/riparian habitat for the southwestern pond turtle (**Figures 4.5-55** through **4.5-59,** Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 65 acres (6.2%) of permanent loss and 100 acres of temporary loss;
- Alternative 4 – 68 acres (6.4%) of permanent loss and 91 acres of temporary loss;
- Alternative 5 – 72 acres (6.8%) of permanent loss and 107 acres of temporary loss;
- Alternative 6 – 57 acres (5.4%) of permanent loss and 96 acres of temporary loss; and
- Alternative 7 – 14 acres (1.3%) of permanent loss and 72 acres of temporary loss.

Compared to Alternative 2, which would result in 88 acres (8.3%) of permanent loss and 95 acres of temporary impacts, the permanent loss of suitable wetland/riparian habitat would be substantially reduced under Alternatives 3 through 7. Temporary impacts would not be substantially different under Alternative 6 and would be somewhat reduced under Alternatives 3 and 4, substantially increased under Alternative 5, and substantially

reduced under Alternative 7. The large difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries and other reductions to the Project footprint under Alternative 7 that would result in substantially reduced permanent and temporary impacts to suitable habitat for southwestern pond turtle compared to the other alternatives.

The overall direct permanent loss and temporary impacts to suitable wetland/riparian habitat from implementation of the RMDP and the SCP under Alternative 5 would be somewhat reduced compared to the overall habitat loss under Alternative 2, and substantially reduced under Alternatives 3, 4, 6, and 7. In addition, compared to Alternative 2 where Potrero Canyon Road Bridge would block access to lower Potrero Canyon, access and use of this area would be less affected under Alternatives 3 through 7. However, because the southwestern pond turtle is uncommon and declining in its range, these impacts would still be significant under Alternatives 3 through 7, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable wetland/riparian habitat for the southwestern pond turtle (**Figures 4.5-55** through **4.5-59,** Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 42 acres (3.9%) of permanent loss;
- Alternative 4 – 25 acres (2.4%) of permanent loss;
- Alternative 5 – 19 acres (1.8%) of permanent loss;
- Alternative 6 – 11 acres (1.0%) of permanent loss; and
- Alternative 7 – 7.2 acres (0.7%) of permanent loss.

Compared to Alternative 2, which would result in 52 acres (4.9%) of permanent loss of suitable wetland/riparian habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7 and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would result in reduced impacts to suitable habitat for southwestern pond turtle compared to the other alternatives.

Alternatives 3 through 7 would also result in substantial loss of dry refugia habitat compared to existing conditions (**Figures 4.5-121** through **4.5-124**, Potential Refugia for Southwestern Pond Turtle; Alternatives 3 through 7 – 100 Year Flood Event (note that Alternatives 3 and 4 are combined in **Figure 4.5-121** because available wet and dry refuge would be the same)), although both wet and dry refugia habitat would remain under all of the alternatives. Alternatives 3, 4, 5, and 6 would have similar amounts of dry refugia habitat following build-out and somewhat more than Alternative 2 due to reduced impacts north and south of the River corridor at Potrero Canyon. Alternative 7 would have substantially more dry refuge habitat compared to Alternatives 2 through 6 due to the smaller Landmark Village and Homestead Village project footprints.

Although Alternatives 3 through 7 would have reduced impacts to suitable wetland/ riparian and terrestrial/dry refuge habitat compared to Alternative 2, overall impacts would still be substantially adverse because of the relatively large amount of terrestrial/dry refuge habitat that would be lost adjacent to suitable wetland/riparian habitat along the Santa Clara River corridor and Potrero Canyon. Therefore, the indirect permanent loss of suitable habitat for the southwestern pond turtle occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable wetland/riparian habitat for the southwestern pond turtle:

- Alternative 3 – 107 acres (10.1%) of permanent loss;
- Alternative 4 – 93 acres (8.8%) of permanent loss;
- Alternative 5 – 91 acres (8.6%) of permanent loss;
- Alternative 6 – 68 acres (6.4%) of permanent loss; and
- Alternative 7 – 21 acres (2.0%) of permanent loss.

Compared to Alternative 2, which would result in 140 acres (13.2%) of combined direct and indirect permanent loss of suitable wetland/riparian habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other

Project footprint reductions under Alternative 7 that would result in reduced impacts to suitable habitat for the southwestern pond turtle compared to the other alternatives.

Alternatives 3 through 7 would affect substantial amounts of terrestrial/dry refuge habitat adjacent to the Santa Clara River corridor and Potrero Canyon, primarily due to build-out of the Project area. Therefore, the combined direct and indirect permanent loss of suitable habitat for the southwestern pond turtle occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3, 4, and 7 would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual southwestern pond turtles as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only) and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2, although the potential for such impacts would be successively reduced according to the successive reductions in impacts to terrestrial habitat under each alternative. The potential for impacts to terrestrial habitat occupied by the southwestern pond turtle would be substantially reduced under Alternative 7 because portions of the agricultural lands in the Landmark Village and Homestead East would not be developed. Nonetheless, impacts to southwestern pond turtle individuals occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2. Each alternative has similar short-term effects due to construction activities, such as potential impacts to hydrology and water quality, noise, ground vibration, dust, lighting, and increased human activity. Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in long-term secondary effects, such as nighttime lighting; human-caused habitat degradation, harassment, and collection; predation by pet, stray, and feral cats and dogs; invasive species; use of pesticides; and increased incidence of roadkill. Therefore, short-term and long-term secondary impacts to southwestern pond turtle resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to southwestern pond turtle: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint. Loss of suitable habitat under Alternative 2 would be significant and unavoidable, due to the loss of habitat which would result from the construction of Potrero Canyon Road Bridge, construction of lower Potrero Canyon Road, and realignment of Potrero Creek. This area provides important habitat for refuge during severe flood conditions in the River corridor, nesting habitat, and habitat for hatchlings and juveniles. Although Potrero Canyon Road Bridge would be constructed under Alternatives 5 and 6, the footprint of the bridge and associated road and reconstruction of Potrero Creek would such as to not preclude use of Potrero Canyon by southwestern pond turtles.

Impacts to individuals could occur during construction as a result of vegetation clearing and grading and construction activities in floodplains, ponds and flowing water, and adjacent uplands, including injury and mortality due to direct contact with construction equipment, entombment of hibernating individuals or nests with eggs, and increased exposure of individuals flushed from habitat or left without protective cover. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys within all riverbeds in proposed disturbance areas and within 500 feet of construction zones and access roads will be conducted by a qualified biologist at the appropriate season for the southwestern pond turtle. If detected, additional nesting surveys will be conducted in suitable nesting habitat typically within 1,300 feet of occupied riverbed habitat where ground-disturbing activities would occur. If occupied habitat, including nesting habitat, is documented, a monitoring plan will prepared and implemented to protect the southwestern pond turtle present during construction and submitted to CDFG for approval. The plan will include measures to avoid and minimize impacts to pond turtles. General procedures to avoid and minimize impacts to southwestern pond turtle during construction will be implemented and a qualified biologist will be present during construction in order to relocate any identified remaining individuals, further reducing impacts to the species. General procedures to avoid and minimize impacts to southwestern pond turtle during construction will be implemented, and a qualified biologist will be present during construction in order to relocate any additional encountered individuals. Several general measures will be implemented to protect wetland habitats that will reduce impacts to the southwestern pond turtle. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities; biological monitoring during any stream diversions; restrictions on construction equipment operating in ponds or flowing water; design of bridges, culverts, and other structures so as not to impair the movement of aquatic species; and protection of water quality from mud, silt, and other pollutants.

The combined permanent loss of suitable habitat for the southwestern pond turtle resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3

only), and Entrada planning areas would range from 21 acres (2.0%) under Alternative 7 to 140 acres (13.2%) under Alternative 2. Because this species is uncommon and declining in its range, this would be a substantial loss of suitable habitat and will reduce the size and distribution of the southwestern pond turtle population in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result the protection of approximately 794 acres of suitable habitat for this species, primarily in the River Corridor SMA, but also within the High Country SMA and Salt Creek area (**Figure 4.5-3**). In addition, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts in water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area over the long term as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue. Following build-out, the River Corridor floodplain would remain 1,000 to 2,000 feet wide and retain the mosaic of habitats, including the relatively narrow wetted channel, benches, and dry terraces that would support the life history of the southwestern pond turtle. Under all alternatives there would also be substantial upland habitat adjacent to the 100-year floodplain of the River Corridor SMA available for the southwestern pond turtle during severe flood conditions. **Figures 4.5-120** through **4.5-124,** Potential Refugia for Southwestern Pond Turtle; Alternatives 2 through 7 – 100 Year Flood Event, show that under each of the alternatives there would be both natural habitat areas that provide upland habitat and agricultural areas that could provide refuge for southwestern pond turtle along both sides of the River Corridor SMA during severe flood conditions. These refuge areas include undisturbed habitat, restored habitat areas, the 100-foot wide vegetated transition area between the top of the river side of bank stabilization and adjacent development, and man-made Open Area at the mouths of various tributaries to the River Corridor SMA such as Ayers, Dead-End, Exxon, Humble, and Long canyons. As described above, however, due to construction of the Potrero Canyon Road Bridge, associated lower Potrero Canyon Road, and realignment of Potrero Creek under Alternatives 2, the refuge area and potential nursery site for pond turtle in lower Potrero Canyon would be removed. A large area of upland refuge within the protected Salt Creek Canyon would be available. These mitigation measures for loss of habitat will reduce significant impacts to a level that is adverse but not significant for Alternatives 3, 4, 5, 6, and 7. Due to construction of the Potrero Canyon Road Bridge, associated lower Potrero Canyon Road, and realignment of Potrero Creek and consequent loss of habitat in the River corridor and lower Potrero Canyon, these mitigation measures would not be sufficient to reduce the loss of habitat to a level less than significant for Alternative 2; therefore, loss of habitat under Alternative 2 would remain significant.

With respect to secondary effects, any southwestern pond turtles occupying habitat in close proximity to construction zones may be disturbed by construction activities, including noise, ground vibration, dust, and lighting. Noise and ground vibration could cause individuals to

abandon refuge areas and expose them to predators (especially hatchlings to crows and ravens), adverse environmental conditions, and increase their chance of injury or mortality from construction equipment and vehicles. Dust may adversely affect water quality and their insect and aquatic prey. Nighttime lighting could expose pond turtles to nocturnal predators. Aquatic habitat, including downstream areas, could be disturbed during construction by hydrologic alterations and pollutants that impair water quality, thus adversely affecting habitat quality and prey for this species. The pre-construction surveys and monitoring plan, will help avoid and minimize secondary impacts during construction. Biological monitoring during vegetation clearing and grading, as well as dust suppression measures, will help reduce the potential effects of ground vibration and dust. Any southwestern pond turtles detected during construction will be relocated by a qualified biologist holding a Scientific Collecting Permit per the requirements of the monitoring plan. Several general mitigation measures, as described above, will be implemented to protect on-site and downstream wetland and aquatic habitat quality, and in particular, protection of downstream water quality from mud, silt, and other pollutants. Potential long-term effects of development include increased human activity, including habitat degradation and collection; invasive species such as giant reed; pet, stray, and cats and feral dogs; vehicle collisions; and use of pesticides. The River Corridor SMA will provide adequate protected open space that will in large part offset these long-term impacts. Several specific mitigation measures will also be implemented to control human activities in the River Corridor SMA, including homeowner education and restrictions on recreational activities. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in, or adjacent to, open space areas. Pesticides will be controlled through an integrated pest management (IPM) plan. Argentine ant invasions of upland habitats in the open space system will be monitored and controlled to extent feasible. Implementation of these measures would allow this species to persist on site after development in the River Corridor SMA.

All specific mitigation measures for southwestern pond turtle are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-46 IMPACTS TO INDIVIDUALS – SOUTHWESTERN POND TURTLE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified four mitigation measures that will avoid, minimize, or mitigate the loss of southwestern pond turtle individuals through pre-development surveys and conformance with state and federal permits related to wetlands and water quality.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that will reduce impacts to southwestern pond turtle individuals. Foremost, pre-construction coordination, focused surveys for southwestern pond turtle, and biological monitoring will be conducted to avoid and reduce impacts. Several other general mitigation measures address potential impacts to wetland/riparian habitats, such as hydrologic alterations and water quality impacts that could adversely affect southwestern pond turtles.

BIO-50 requires preconstruction surveys at the appropriate season for southwestern pond turtle prior to initiating construction for installation of bridges, storm drain outlets, utility lines, bank protection, trails, and/or other construction activities, all construction sites and access roads within the Santa Clara River riverbed and all riverbed areas within 500 feet of construction sites and access roads. If detected in or adjacent to the Project area, nesting surveys will be conducted in or adjacent to the Project area where ground-disturbing activities will occur when suitable nesting habitat is present within 1,300 feet of occupied habitat. If the southwestern pond turtle is present, the applicant will prepare and implement a monitoring plan submitted to CDFG that includes the following key elements: (1) measures to relocate pond turtles; (2) habitat and conditions at the proposed relocation sites; (3) methods used to trap and relocate individuals; (4) record keeping for number of individuals relocated; (5) measures to avoid nesting areas, or to minimize impacts to nesting areas if complete avoidance is not feasible; (6) restrictions on moving eggs or hatchlings without CDFG written authorization; (7) biological monitoring during all periods where construction activities occur adjacent to or within occupied habitat; and (8) daily clearance surveys prior to construction.

Additional general measures, as follows, will be implemented to help avoid and minimize impacts to southwestern pond turtle individuals.

The following three mitigation measures, BIO-46, BIO-48, and BIO-49, focus primarily on special-status fish, but they generally will also reduce impacts to the southwestern pond turtle and other semi-aquatic species.

BIO-46 states that, during any stream diversion or culvert installation activity, a qualified biologist(s) shall be present, and shall patrol the areas within, upstream, and downstream of the work area. The biologists shall inspect the diversion and inspect for stranded southwestern pond turtle.

BIO-48 states that bridges, culverts, and other structures may not impair movement of fish and aquatic life and specifies relative depth requirements for temporary and permanent culverts.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to southwestern pond turtle individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-47 LOSS OF HABITAT – SOUTHWESTERN POND TURTLE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for southwestern pond turtle through habitat protection, restoration and enhancement, and management.

SP-4.6-55 and SP-4.6-58, as described above, will also mitigate for loss of habitat as a result of compliance with state and federal permits related to wetlands and water quality.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. In addition to providing a buffer between the development edge and wetland/riparian habitat in the River Corridor SMA, these transition areas will provide potential aestivation and overwintering habitat for the southwestern pond turtle. They may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system totaling approximately 6,100 acres that will reduce habitat fragmentation effects (**Figure 4.5-3**).

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the southwestern pond turtle. These measures refer to habitat protection, restoration and enhancement, and management

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, loss of habitat for the southwestern pond turtle would remain significant. Therefore, implementation of Alternative 2 creates significant and unavoidable impacts.

After mitigation, the loss of habitat for the southwestern pond turtle would be adverse but not significant for Alternatives 3, 4, 5, 6, and 7 because these alternatives would minimize loss of habitat in the River corridor and lower Potrero Canyon.

IMPACT 4.5-48 SECONDARY IMPACTS – SOUTHWESTERN POND TURTLE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures to mitigate for short-term secondary impacts to the southwestern pond turtle, such as altered hydrology and water quality, inadvertent impacts to suitable habitat adjacent to construction zones, and noise and increased human activity. Mitigation measures to offset long-term secondary impacts, such as habitat fragmentation; nighttime lighting; invasive plant species; increased human activity; increased predation by pet, stray, and feral cats and dogs and other mesopredators; and other sources of habitat degradation (*e.g.*, grazing) were also identified**.**

In order to mitigate impacts from contact with chemical pollutants, increased sedimentation, increased turbidity, changes in flow, and changes in water temperature during construction, the

Newhall Ranch Specific Plan Program EIR identified SP-4.6-55 and SP-4.6-58, as described above.

In order to avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These measures require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA. These measures, in combination with SP-4.6-53 and SP-4.6-59, which require pre-development surveys as described above, will also help reduce the effects of noise and increased human activity. However, these mitigation measures primarily are designed to minimize impacts to off-site resources and alone will not completely mitigate noise and human activity impacts. Because of the infeasibility of locating aestivating and overwintering individuals prior to construction, long-term mitigation measures relating to habitat preservation and management will contribute to the persistence of the species on site and offset these short-term impacts from noise.

The following mitigation measures address the long-term secondary effects listed above. The Newhall Ranch Specific Plan Program EIR identified several mitigation measures that primarily address habitat fragmentation, increased predation by mesopredators, increased human populations and recreation in close proximity to open space and wetland/riparian and terrestrial aestivation/overwintering habitat for the southwestern pond turtle, nighttime lighting, and other activities that could result in degradation of habitat, such as cattle grazing.

SP-4.6-1 through SP-4.6-16, SP-4.6-18, SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and which relate to the protection, restoration and enhancement, and management of the River Corridor SMA and High Country SMA, will prevent habitat fragmentation and increased predation by mesopredators (by ensuring the continued presence of top predators such as coyotes) and will offset the impacts of increased human activity and grazing in the Project area.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19, described above, address the transition area between development and the River Corridor SMA that will both buffer the River Corridor SMA from adverse edge effects and provide potential aestivation/overwintering habitat for the southwestern pond turtle.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or

off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

In order to mitigate impacts from grazing, SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends additional measures to mitigate for secondary impacts to southwestern pond turtle, including short-term impacts to hydrology and water quality, dust, and noise and ground vibration, and long-term impacts, such increased human activity; habitat degradation from exotic plants; predation by pet, stray, and feral cats and dogs and mesopredators; and increased predation by invasive exotic species, such as bullfrogs.

BIO-50, described in detail above, in conjunction with BIO-52 described above, will help reduce secondary impacts related to construction by ensuring that occupied habitat areas, including nesting areas, are documented prior to construction and monitored during construction such that inadvertent impacts to individuals and occupied habitat do not occur. This would include monitoring construction activities adjacent to occupied habitat so that potential impacts resulting from increased human activity, noise and ground vibration, dust, and lighting do not occur or are minimized to the extent feasible.

In order to mitigate impacts from chemical pollution, increased sedimentation, increased turbidity, changes in flow, and changes in water temperature, BIO-46, BIO-48, BIO-49, and BIO-70, as summarized above, will be implemented. In addition, BIO-44, BIO-45, BIO-47, BIO-74, and BIO-77 will be implemented.

BIO-44 requires temporary bridges, culverts, or other feasible methods of providing access across the Santa Clara River. A Stream Crossing and Diversion Plan will be prepared that includes a description of diversion measures, such as berms, inflatable dams, sand bags, or other approved materials.

BIO-45 requires construction of bypass channels when the active wetted channel is within the work zone, in accordance with BIO-44. Equipment shall not be operated in areas of ponded or flowing water unless authorized by CDFG/USFWS.

BIO-47 requires that slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area that will provide refuge for southwestern pond turtle during construction.

BIO-74 requires installation of temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to construction within 200 feet of the spring and, if applicable, within 100 feet of flowing water in the Middle Canyon drainage. Permanent fencing and signage shall be erected along the bordering subdivision tract following construction. A qualified biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. Any upslope runoff from construction areas will be directed away from the Middle Canyon Spring. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

BIO-77 describes preparation of a plan and mitigation measures be implemented by the applicant specifically to maintain the populations of the undescribed snail and sunflower species, but these measures are also applicable to the southwestern pond turtle. The plan will provide guidelines for collecting data on existing site conditions; developing a construction monitoring program and a post-development monitoring program; developing threshold parameters that activate adaptive management measures for water quality and water quantity issues; excluding unauthorized entry into the spring; and contingency measures. The plan shall be subject to the approval of CDFG prior to disturbance within 100 feet of flowing water in the Middle Canyon drainage and/or 200 feet of Middle Canyon Spring.

Several mitigation measures will mitigate impacts from habitat fragmentation, predation by mesopredators, invasive plant species, and long-term increases in human activity and its associated effects.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above and which refer to habitat protection, restoration and enhancement, and management in the High Country SMA and Salt Creek area, will mitigate for habitat fragmentation effects, including predation by mesopredators, by providing for a large, interconnected open space system.

BIO-63 will be implemented to mitigate impacts from predation by pet, stray, and feral cats and dogs. This measure requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent the pollution of aquatic habitat and potential secondary poisoning and loss of prey by pesticides, and requires preparation of an IPM plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA regarding wildlife species and install signage to keep people and their animals on existing trails.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-72 will mitigate for invasive plant species. This measure specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-74 requires installation of temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to construction within 200 feet of the spring and, if applicable, within 100 feet of flowing water in the Middle Canyon drainage. Permanent fencing and signage shall be erected along the bordering subdivision tract following construction. A qualified biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. Any upslope runoff from construction areas will be directed away from the Middle Canyon Spring. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

BIO-80 states that the Project applicant shall retain a qualified biologist to develop and implement an Eradication Plan for bullfrog, African clawed frog, and crayfish. Following construction, monitoring shall be conducted at sentinel locations along the River Corridor SMA (and other potential habitat areas) annually for five years. After five years, monitoring shall be conducted bi-annually for 50 years.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the southwestern pond turtle and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

TWO-STRIPED GARTER SNAKE (CSC)

Life History

The two-striped garter snake (*Thamnophis hammondii*) is found in coastal California in the vicinity of the southeast slope of the Diablo Range and the Salinas Valley south along the Coastal and Transverse ranges to Rio Rosario in Baja California, Mexico (NatureServe 2007). Although the two-striped garter snake was historically common throughout this range and is the most common garter snake in southern California's cismontane region (Schwenkmeyer 2007), it is now abundant only in eastern San Diego County. The two-striped garter snake has been displaced from about 40% of its historical range (NatureServe 2007). Populations have been affected by the elimination of natural sloughs and wetlands, loss of riparian habitat due to agriculture and urbanization, predation by non-native bullfrogs, fish, and feral pigs, and loss of amphibian prey.

Two-striped garter snakes are found in a variety of perennial and intermittent freshwater streams within oak woodlands, shrublands, and sparse coniferous forests from sea level to 2,400 meters (7,874 feet) AMSL (Stebbins 2003; Zeiner *et al.* 1988). They are restricted to streams, vernal pools, lakes, and stock and artificial ponds with good adjoining riparian vegetation (Jennings and Hayes 1994; Schwenkmeyer 2007) and are commonly found within wetlands and streams having rocky or sandy beds with willows (*Salix* sp.) or dense vegetation (Zeiner *et al.* 1988). Two-striped garter snakes tend to stay near water, entering it often and retreating to it when alarmed (Stebbins 2003). They use dense vegetation, flat rocks, rocky outcrops, and rotting logs as cover (Zeiner *et al.* 1988). The species tends to avoid open expanses because of increased risk of predation.

Two-striped garter snakes stay close to water in the warmer months but may occur farther from water during cooler months. They are generally active aquatic hunters during the day, but retreat into crevices, mammal burrows, or other upland shelters at night (SMEA 1995A). Their summer and winter ranges can be quite variable, with a summer streamside range of about 50 to 5,000 square meters (0.01 to 1.2 acres) and a median range of 1,500 square meters (0.4 acre). Their winter range in coastal scrub and grasslands in upland areas adjacent to riparian areas is about 50 to 9,000 square meters (0.01 to 2.2 acres), with a median range of 3,400 square meters (0.8 acre) (Jennings and Hayes 1994). Their median summer range of 1,500 square meters can support approximately seven individuals, while their winter range of 3,400 square meters can support approximately three individuals (Zeiner *et al.* 1988).

This typically diurnal snake is most active in mornings and nights of warm days and warm afternoons of cooler days (Zeiner *et al.* 1988). The two-striped garter snake generally retreats to communal hibernation burrows as the days shorten, generally in October but depending on latitude and elevation (Jennings and Hayes 1994). Occasionally, individuals will emerge from hibernation on warmer days to bask in the sun. Two-striped garter snakes in higher elevations,

inland, and in colder areas of southern California hardly emerge from their hibernation dens (Zeiner *et al.* 1988). Hibernation lasts until March, when the males emerge first and prepare for mating.

Two-striped garter snakes forage in and along streams and near quiet pools of water (Zeiner *et al.* 1988). They prey on small fish, fry, and eggs (*Cottus* sp., *Eucyclogobius* sp., *Gasterosteus* sp., *Oncorhynchus* sp.), frogs and toads (*Buto* sp., *Rana* sp., *Pseudacris* sp.), newts (*Taricha* sp.), leeches and earthworms (*Annelida*), and insect larvae (*Anthropoda*) (Jennings and Hayes 1994).

Both male and female two-striped garter snakes may breed with several partners, but not all females mate. Sexually mature females may store sperm for up to 53 months and give birth without having mated that season (Jennings and Hayes 1994). After mating occurs in upland sites, two-striped garter snakes disperse to summer feeding areas. After a nine-week gestation period, gravid females bear one to 36 live young during the late summer in or under loose bark, rotting logs, and dense vegetation (Stebbins 2003; Jennings and Hayes 1994; Schwenkmeyer 2007; Zeiner *et al.* 1988).

In addition to direct loss of habitat, two-striped garter snakes are vulnerable to several effects related to urban development. Large reservoirs, cement-lined stream channels, flood control projects, and barriers to dispersion such as highways, highway obstructions, densely urbanized areas, and areas dominated by buildings and pavement, all impede the life cycle and natural movements of the garter snake (Jennings and Hayes 1994; NatureServe 2007). Predation by non-native bullfrogs and fish, and possibly by African clawed frogs, may contribute to the decline of two-striped garter snake. Two-striped garter snake may also have to compete with introduced species, such as mosquitofish, that prey on the eggs and young of prey taken by two-striped garter snake (*e.g.*, newts, frogs, and toads) (Goodsell and Kats 1999).

Survey Results

The two-striped garter snake has been observed during various surveys in the reach of the Santa Clara River within and adjacent to the Specific Plan area (Aquatic Consulting Services 2002C; Impact Sciences 2002; Compliance Biology 2004; ENTRIX 2006B), within the Entrada planning area (Impact Sciences 2001), and within the VCC planning area (Ecological Sciences 2003A). Other focused surveys completed for this species in the Project vicinity include the following:

- SMEA (1995A) found no two-striped garter snake samples over 127 trap days during special-status aquatic species surveys in the Santa Clara River and San Francisquito Creek.
- SMEA (1995A) found appropriate habitat on the Santa Clara River from Bouquet Canyon Bridge downstream to the west boundary of the study area and noted a healthy downstream population between McBean Parkway and I-5.

- RECON (1999B) determined there was potential habitat for the two-striped garter snake throughout the Project area along the Santa Clara River during a Santa Clara River Corridor Habitat Assessment.
- Aquatic Consulting Services, Inc. (2000A, 2000B, 2000D), found no samples of the two-striped garter snake in the Castaic Junction and Commerce Center Bridge project areas.
- Dudek (Dudek and Associates 2006B) found there was a high potential for the species to occur based on the presence of stream, creek, pool, stream with rocky beds, pond, lake, and vernal pool habitat during surveys in the High Country SMA and Salt Creek areas.

Based on these survey results, a breeding population of two-striped garter snake is likely present in the Project area. Additionally, two-striped garter snake is likely to be found in portions of the Santa Clara River downstream of the Project area. Because two-striped garter snake has been documented to occur in the Santa Clara River and Castaic Creek in the Project area, it is assumed to be present on site within riparian habitat.

Bulrush–cattail wetland, cismontane alkali marsh, southern cottonwood–willow riparian, coastal and valley freshwater marsh, herbaceous wetland, mulefat scrub, southern coast live oak riparian forest, river wash, southern willow scrub, and shrub tamarisk vegetation communities are suitable habitat for the two-striped garter snake. There is a total of 1,059 acres of suitable wetland/riparian habitat in the Project area. This species is also expected to occur sporadically in terrestrial (upland) vegetation communities in the winter adjacent to wetland/riparian habitats, but this potential habitat was not quantified. Locations of two-striped garter snake hibernation dens on site are not known.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 88 acres of suitable wetland/riparian habitat would be permanently lost through implementation of the RMDP and the SCP, representing 8.3% of the suitable habitat on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). A total of 95 acres would be temporarily impacted.

Almost 92% of suitable wetland/riparian habitat for the two-striped garter snake would remain after construction of the RMDP facilities. However, during construction, this species could be displaced from suitable habitat and adverse effects on movement of the species along the River corridor or into adjacent terrestrial habitats due to loss of habitat could occur. In particular, under Alternatives 2, 5 and 6, which include construction of the Potrero Canyon Road Bridge across the Santa Clara River, construction at the mouth of Potrero Creek could affect movement by two-striped garter snake between the River corridor and suitable habitat in lower Potrero Creek. Implementation of the SCP would not directly affect this species. Due to loss of suitable wetland/riparian habitat, implementation of the RMDP would have a substantial direct adverse effect on this species (significance criterion 1). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 52 acres of suitable wetland/riparian habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 4.9% of the suitable wetland/riparian habitat on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). In addition to impacts to wetland/riparian habitat, build-out of the Specific Plan, VCC, and Entrada planning areas would result in substantial impacts to terrestrial habitats bordering the Santa Clara River and Potrero Canyon.

Primarily due to build-out of the Specific Plan, VCC, and Entrada planning areas, the Project could substantially reduce suitable terrestrial habitat for the species on site; interfere substantially with the movement of the species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable wetland/riparian habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 140 acres (13.2%). As described above for indirect impacts, build-out of the Specific Plan, VCC, and Entrada planning areas would result in substantial impacts to terrestrial habitats bordering the Santa Clara River and Potrero Canyon that could be used for winter hibernation (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). Because of the large amount of terrestrial habitat loss, the combined direct and indirect permanent impacts could substantially reduce suitable habitat for the species on site; interfere substantially with the movement of the species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The two-striped garter snake is a documented resident in the Santa Clara River corridor and suitable habitat for this species also occurs in Salt Creek and Potrero canyons on the south side of the River. Implementation of the RMDP would require the construction of various facilities within the River corridor and adjacent upland areas and in Potrero Canyon in areas that support suitable habitat for the two-striped garter snake. It is foreseeable that construction and/or grading activities associated with these facilities in both aquatic and terrestrial habitats could result in injury or mortality of two-striped garter snakes in the disturbance zone as a result of direct contact of adults and juveniles with construction equipment or by entombment as a result of grading activities. In addition, construction and/or grading activities that result in degradation of aquatic habitats, such as by introduction of mud, silt, or chemical pollutants, may cause two-striped garter snakes to abandon the site and make them more vulnerable to impacts such as vehicle collisions and exposure to predators and harsh environmental conditions. Implementation of the SCP would not directly impact this species.

Because they are a special-status species and declining in their range, the loss of any two-striped garter snakes could have a substantial direct adverse effect on this species; cause the species to drop below self-sustaining levels on site; threaten to eliminate the species on site; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for permanent impacts to individuals is the same as described above for direct permanent impacts to individuals, but over a much larger area, including substantial terrestrial areas that could be used for winter hibernation. The build-out of the Specific Plan, VCC, and Entrada planning areas would include construction and/or grading activities in areas supporting suitable aquatic and terrestrial habitat for the two-striped garter snake, which could result in injury or mortality of individuals in the disturbance zone as a result of contact of adults and juveniles with construction equipment or by entombment as a result of grading activities. In addition, construction and/or grading activities that result in degradation of aquatic habitats, such as by introduction of mud, silt, or chemical pollutants, may cause two-striped garter snakes to abandon the site and make them more vulnerable to impacts such as vehicle collisions and exposure to predators and harsh environmental conditions. Therefore, there is a potential for impacts to two-striped garter snake adults and juveniles during construction and/or grading activities associated with the build-out of the Specific Plan, VCC, and Entrada planning areas. Because they are a special-status species and declining in their range, the loss of any two-striped garter snakes could have a substantial adverse effect on this species; cause the species to drop below self-sustaining levels on site; threaten to eliminate the species on site; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas could result in construction-related ground vibration that may flush individuals, if present, from refuge areas and expose them to predators and potentially harsh environmental conditions (*e.g.* hot, dry weather). Short-term construction activities also could generate dust and disperse sediments and pollutants from construction sites into the Santa Clara River and affect on-site and downstream two-striped garter snake populations. Hydrologic and water quality-related impacts could include chemical pollution, increased turbidity, excessive sedimentation, flow interruptions, and changes in water temperature due to short-term changes to the active channel morphology. Construction-related dust could impair water quality and reduce available prey. These factors could result in substantial impacts to two-striped garter snakes and/or the degradation of habitat quality. Other construction-related secondary impacts associated with implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas could include disruptions to behavioral activities associated with increased human activity. Implementation of the SCP would not result in secondary impact to this species.

Build-out of the Specific Plan, VCC, and Entrada planning areas could result in habitat fragmentation that could inhibit the movement of the two-striped garter snake in the Project area, especially in areas used by individuals to move into terrestrial habitats. Furthermore, implementation of the RMDP and the long-term occupancy of the Specific Plan, VCC, and Entrada planning areas could result in adverse secondary effects to two-striped garter snakes. The proximity of urban development to suitable two-striped garter snake habitat could result in disruption of essential behavioral activities, including foraging, breeding, and hibernation. Other potential impacts include predation by introduced invasive species (*e.g.*, Argentine ants, bullfrogs, and exotic fish); collection as pets; urban-related predation pressures (*e.g.*, by cats, dogs, raccoons, skunks, ravens, and crows); off-road vehicle use; cattle grazing; increased incidence of vehicle collisions on roads (Holland 1994); use of pesticides, which may cause secondary poisoning and loss of prey; and invasion of exotic plant species, such as tamarisk, giant reed, and pampas grass, which may cause altered hydrology and channel morphology, thus degrading two-striped garter snake habitat.

These short-term and long-term secondary impacts could have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable wetland/riparian habitat for the two-striped garter snake (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 65 acres (6.2%) of permanent loss and 100 acres of temporary loss;
- Alternative 4 – 68 acres (6.4%) of permanent loss and 91 acres of temporary loss;
- Alternative 5 – 72 acres (6.8%) of permanent loss and 107 acres of temporary loss;

- Alternative 6 – 57 acres (5.4%) of permanent loss and 96 acres of temporary loss; and
- Alternative 7 – 14 acres (1.3%) of permanent loss and 72 acres of temporary loss.

Compared to Alternative 2, which would result in 88 acres (8.3%) of permanent loss and 95 acres of temporary impacts, the permanent loss of suitable wetland/riparian habitat would be substantially reduced under Alternatives 3 through 7. Temporary impacts would be not be substantially different under Alternative 6, somewhat reduced under Alternative 4, somewhat to substantially increased under Alternatives 3 and 5, and substantially reduced under Alternative 7. The large difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries and other reductions to the Project footprint under Alternative 7 that would result in substantially reduced permanent impacts to suitable wetland/riparian habitat for the two-striped garter snake compared to the other alternatives.

Habitat loss due to implementation of the RMDP under Alternatives 3 through 6 would be similar in magnitude compared to the habitat loss under Alternative 2, but would be substantially less under Alternative 7. Although under all alternatives permanent habitat loss would be low, ranging from 14 acres under Alternative 7 to 88 acres under Alternative 2, the impacts could still result in displacement of the two-striped garter snake from suitable habitat and affect its movement within the Project area. The direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation, for Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable wetland/riparian habitat for the two-striped garter snake (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 42 acres (3.9%) of permanent loss;
- Alternative 4 – 25 acres (2.4%) of permanent loss;
- Alternative 5 – 19 acres (1.8%) of permanent loss;
- Alternative 6 – 11 acres (1.0%) of permanent loss; and
- Alternative 7 – 7.2 acres (0.7%) of permanent loss.

Compared to Alternative 2, which would result in 52 acres (4.9%) of permanent loss of suitable wetland/riparian habitat, Alternatives 3 through 7 would have reduced impacts.

Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would result in reduced impacts to suitable wetland/riparian habitat for the two-striped garter snake compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts to suitable wetland/ riparian habitat compared to Alternative 2, overall impacts would still be substantially adverse because of the relatively large amount of terrestrial habitat that would be lost adjacent to suitable wetland/riparian habitat along the Santa Clara River corridor and Potrero Canyon. Therefore, the indirect permanent loss of suitable habitat for the two-striped garter snake occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable wetland/riparian habitat for the two-striped garter snake:

- Alternative 3 – 107 acres (10.1%) of permanent loss;
- Alternative 4 – 93 acres (8.8%) of permanent loss;
- Alternative 5 – 91 acres (8.6%) of permanent loss;
- Alternative 6 – 68 acres (6.4%) of permanent loss; and
- Alternative 7 – 21 acres (2.0%) of permanent loss.

Compared to Alternative 2, which would result in 140 acres (13.2%) of combined direct and indirect permanent loss of suitable wetland/riparian habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 that would reduce impacts to suitable habitat for the two-striped garter snake compared to the other alternatives. Because each of the alternatives would also affect substantial amounts of terrestrial habitat adjacent to

the Santa Clara River corridor and Potrero Canyon, the combined direct and indirect permanent loss of suitable habitat for the two-striped garter snake occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual two-striped garter snakes as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2, although the potential for such impacts would be successively reduced due to the successive reductions in impacts to terrestrial habitat under each alternative. The potential for impacts to terrestrial habitat occupied by the two-striped garter snake would be substantially reduced under Alternative 7 because portions of the agricultural lands in Landmark Village and Homestead East would not be developed. Nonetheless, impacts to individual two-striped garter snakes occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2. Each alternative has similar short-term effects from construction activities, such as ground vibration and potential impacts to hydrology and water quality, construction-related dust, and increased human activity. Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in long-term secondary effects, such as human-caused habitat degradation, harassment, and collection; predation by pet, stray, and feral cats and dogs; invasive wildlife species; increased incidence of roadkill; and use of pesticides.

Because this species is declining in its range, these short-term and long-term secondary impacts could have a substantial adverse effect on the two-striped garter snake; could substantially reduce the habitat of the species on site or rangewide; could cause the species to drop below self-sustaining levels on site or rangewide; could threaten to eliminate the species on site or rangewide; or could substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to two-striped garter snake: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur during construction as a result of vegetation clearing and grading and construction activities in ponds and flowing water, including injury and mortality due to direct contact with construction equipment, entombment of hibernating individuals, and increased exposure of individuals flushed from habitat or left without protective cover. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys will be conducted in the riverbed and all riverbed areas within 500 feet of the construction zone and access roads at the appropriate season for two-striped garter snake (April 1 to September 1). Any detected individuals will be relocated to suitable pre-approved locations identified in a Relocation Plan prepared by the applicant and approved by CDFG. General procedures to avoid and minimize impacts to two-striped garter snake during construction will be implemented, and a qualified biologist will be present during construction in order to relocate any additional encountered individuals. Clearance surveys will be conducted each day prior to construction. Several general measures will be implemented to protect wetland habitats, which will reduce impacts to the two-striped garter snake. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities; biological monitoring during any stream diversions; restrictions on construction equipment operating in ponds or flowing water; design of bridges, culverts, and other structures so as not to impair the movement of aquatic species; and protection of water quality from mud, silt, and other pollutants.

The combined permanent loss of suitable habitat for the two-striped garter snake resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 21 acres (2.0%) under Alternative 7 to 140 acres (13.2%) under Alternative 2. Because this species is uncommon and declining in its range, this would be a substantial loss of suitable habitat and will reduce the size and distribution of the two-striped garter snake population in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result the protection of approximately 794 acres of suitable habitat for this species, primarily in the River Corridor SMA, but also within the High Country SMA and Salt Creek area (**Figure 4.5-3**). In addition, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts in water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area over the long term as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County. The technical analysis further determined

that the River would still retain sufficient width to allow natural fluvial processes to continue. Following build-out, the River Corridor floodplain would remain 1,000 to 2,000 feet wide and retain the mosaic of habitats, including the relatively narrow wetted channel, benches, and dry terraces that would support the life history of the two-striped garter snake. Under all alternatives there would also be substantial upland habitat adjacent to the 100-year floodplain of the River Corridor SMA available for the two-striped garter snake during severe flood conditions. An analysis of dry and wet refugia prepared for the southwestern pond turtle, and depicted in **Figures 4.5-120** through **4.5-124,** Alternatives 2 through 7 Potential Refugia for Southwestern Pond Turtle, show that for each of the alternatives there would be both natural habitat areas that provide upland habitat and agricultural areas that could provide refuge for two-striped garter snake along both sides of the River Corridor SMA area during severe flood conditions. These refuge areas include undisturbed habitat, bank stabilization habitat areas, the 100-foot wide transition area between the top of the river side of bank stabilization and adjacent development, and man-made Open Area at the mouths of various tributaries to the River Corridor SMA such as Ayers, Dead-End, Exxon, Humble, Long, and Potrero canyons. A large area of upland refuge within the protected Salt Creek Canyon would also be available.

With respect to secondary effects, any two-striped garter snakes occupying habitat in close proximity to construction zones may be disturbed by construction activities, including ground vibration and dust. Ground vibration could cause individuals to emerge from burrows and other refuge areas and expose them to predators, adverse environmental conditions, and increase their chance of injury or mortality from construction equipment and vehicles. Dust may adversely affect water quality and their insect prey. Aquatic habitat, including downstream areas, could be disturbed during construction by hydrologic alterations and pollutants that impair water quality, thus adversely affecting habitat quality and prey for this species. Pre-construction surveys to relocate individuals found within 500 of construction areas and access roads, daily clearance surveys, biological monitoring during vegetation clearing and grading in and adjacent to occupied habitat, as well as dust suppression measures, will help reduce the potential effects of ground vibration and dust. Any two-striped garter snakes detected prior to or during construction will be relocated to identified suitable habitat by a qualified biologist holding a Scientific Collecting Permit according to a CDFG-approved Relocation Plan. Several general mitigation measures, as described above, will be implemented to protect on-site and downstream wetland and aquatic habitat quality, and in particular, protection of downstream water quality from mud, silt, and other pollutants. Potential long-term effects of development include increased human activity, including habitat degradation and collection; invasive species, including Argentine ant and invasive plants such as giant reed; pet, stray, and cats and feral dogs; vehicle collisions; and use of pesticides. The River Corridor SMA will provide adequate protected open space that will in large part offset these long-term impacts. Several specific mitigation measures will also be implemented to control human activities in the River Corridor SMA, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas.

Pesticides will be controlled through an integrated pest management (IPM) plan. Argentine ant invasions of upland habitats in the open space system will be monitored and controlled to extent feasible. Implementation of these measures would allow this species to persist on site after development in the River Corridor SMA.

All specific mitigation measures for two-striped garter snake are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-49 IMPACTS TO INDIVIDUALS – TWO-STRIPED GARTER SNAKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified four mitigation measures that would avoid, minimize, or mitigate the loss of two-striped garter snake individuals through pre-development surveys and conformance with state and federal permits related to wetlands and water quality.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that will reduce impacts to two-striped garter snake individuals. Most of these mitigation measures address potential impacts to wetland/riparian habitats, such as hydrologic alterations and water quality impacts that could adversely affect two-striped garter snakes. In addition, pre-construction coordination, focused surveys for two-striped garter snake, and biological monitoring will be conducted to reduce impacts.

BIO-89 requires preconstruction surveys at the appropriate season (April 1 to September 1) for two-striped garter snake prior to initiating construction for installation of bridges, storm drain outlets, utility lines, bank protection, trails, and/or other construction activities, all construction sites and access roads within the Santa Clara River riverbed and all riverbed areas within 300

feet of construction sites and access roads. Any detected individuals will be relocated to suitable pre-approved locations identified in a Relocation Plan prepared by the applicant and approved by CDFG. The Relocation Plan will include several key elements: (1) timing and location of surveys, including areas where more intensive surveys should be done; (2) trapping/capture and relocation methods; and (3) procedures for recordkeeping of the number of individuals relocated. A qualified biologist will be present during all construction activities within or adjacent to occupied habitat and clearance surveys will be conducted daily in this habitat before onset of construction activities.

The following mitigation measures, BIO-46, BIO-48, and BIO-49, focus primarily on special-status fish, but they generally will also reduce impacts to the two-striped garter snake and other semi-aquatic species.

BIO-46 states that during any stream diversion or culvert installation activity, a qualified biologist(s) shall be present, and shall patrol the areas within, upstream, and downstream of the work area. The biologists shall inspect the diversion and inspect for stranded two-striped garter snakes.

BIO-48 states that bridges, culverts, and other structures may not impair movement of fish and aquatic life and specifies relative depth requirements for temporary and permanent culverts.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to two-striped garter snake individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-50 LOSS OF HABITAT – TWO-STRIPED GARTER SNAKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for two-striped garter snake through habitat protection, restoration and enhancement, and management. SP-4.6-55 and SP-4.6-58, as described above, will also mitigate for loss of habitat as a result of compliance with state and federal permits related to wetlands and water quality.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. In addition to providing a buffer between the development edge and wetland/riparian habitat in the River Corridor SMA, these transition areas will provide potential winter habitat for the two-striped garter snake. They may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system totaling approximately 6,100 acres that will reduce habitat fragmentation effects (**Figure 4.5-3**).

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the two-striped garter snake. These measures refer to habitat protection, restoration and enhancement, and management

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the two-striped garter snake would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-51 SECONDARY IMPACTS – TWO-STRIPED GARTER SNAKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures to mitigate for short-term construction-related secondary impacts to the two-striped garter snake, such as altered hydrology and water quality; and inadvertent impacts to suitable habitat adjacent to construction zones as well as increased human activity. Mitigation measures to offset long-term secondary impacts, such as habitat fragmentation; invasive plant species; increased human activity; increased predation by pet, stray, and feral cats and dogs and other mesopredators; and other sources of habitat degradation (*e.g.*, grazing), were also identified**.**

In order to mitigate impacts from contact with chemical pollutants, increased sedimentation, increased turbidity, changes in flow, and changes in water temperature during construction, the Newhall Ranch Specific Plan Program EIR identified SP-4.6-55 and SP-4.6-58, as described above. In order to avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These measures require that all grading perimeters

within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA. These measures, in combination with SP-4.6-53 and SP-4.6-59, which require pre-development surveys as described above, will also help reduce the effects of increased human activity. However, these mitigation measures are primarily designed to minimize impacts to off-site resources and alone will not completely mitigate human activity impacts. Because of the infeasibility of locating hibernating individuals prior to construction, long-term mitigation measures relating to habitat preservation and management will contribute to the persistence of the species on site and offset these short-term impacts.

The following mitigation measures address the long-term secondary effects listed above. The Newhall Ranch Specific Plan Program EIR identified the several mitigation measures that primarily address habitat fragmentation, increased predation by mesopredators, increased human populations and recreation in close proximity to open space and wetland/riparian and terrestrial winter habitat for the two-striped garter snake, and other activities that could result in degradation of habitat, such as cattle grazing.

SP-4.6-1 through SP-4.6-16, SP-4.6-18, SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and which relate to the protection, restoration and enhancement, and management of the River Corridor SMA and High Country SMA, will prevent habitat fragmentation and increased predation by mesopredators (by ensuring the continued presence of top predators, such as coyotes) and will offset the impacts of grazing and increased human activity in the Project area.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19, as described above, address the transition area between development and the River Corridor SMA that will both buffer the River Corridor SMA from adverse edge effects and provide potential winter habitat for the two-striped garter snake.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

In order to mitigate impacts from grazing, SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country

SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

Measures Recommended by EIS/EIR

This EIS/EIR recommends additional mitigation measures to mitigate for secondary impacts to two-striped garter snake, including construction-related dust, ground vibration, short-term impacts to hydrology and water quality and long-term impacts, such as increased human activity; habitat degradation from exotic plants; predation by pet, stray, and feral cats and dogs and mesopredators; and increased predation by invasive exotic species, such as Argentine ants and bullfrogs.

BIO-89, as described above, requires preconstruction surveys for two-striped garter snake prior to initiating construction activities within 500 feet of construction sites and access roads, as well as daily clearance surveys prior to construction. Detected individuals will be relocated to suitable pre-approved locations identified in a CDFG-approved Relocation Plan. These measures will minimize adverse secondary effects such as ground vibration and dust on the two-striped garter snake because individuals would be removed from the general construction area.

In order to mitigate impacts from chemical pollution, increased sedimentation, increased turbidity, changes in flow, and changes in water temperature, BIO-46, BIO-48, BIO-49, and BIO-70, as summarized above, will be implemented. In addition, BIO-44, BIO-45, BIO-47, BIO-74, and BIO-77 will be implemented.

BIO-44 requires temporary bridges, culverts, or other feasible methods of providing access across the Santa Clara River. A Stream Crossing and Diversion Plan will be prepared that includes a description of diversion measures, such as berms, inflatable dams, sand bags, or other approved materials.

BIO-45 requires construction of bypass channels when the active wetted channel is within the work zone, in accordance with BIO-44. Equipment shall not be operated in areas of ponded or flowing water unless authorized by CDFG/USFWS.

BIO-47 requires that slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area that will provide refuge for two-striped garter snake during construction.

BIO-74 requires installation of temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to construction within 200 feet of the spring and, if applicable, within 100 feet of flowing water in the Middle Canyon drainage. Permanent fencing and signage shall be erected along the bordering subdivision tract following construction. A qualified biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. Any upslope

runoff from construction areas will be directed away from the Middle Canyon Spring. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

BIO-77 describes preparation of a plan and mitigation measures be implemented by the applicant specifically to maintain the populations of the undescribed snail and sunflower species, but these measures are also applicable to the two-striped garter snake. The plan will provide guidelines for collecting data on existing site conditions; developing a construction monitoring program and a post-development monitoring program; developing threshold parameters that activate adaptive management measures for water quality and water quantity issues; excluding unauthorized entry into the spring; and contingency measures. The plan shall be subject to the approval of CDFG prior to disturbance within 100 feet of flowing water in the Middle Canyon drainage and/or 200 feet of Middle Canyon Spring.

Several mitigation measures will mitigate impacts from habitat fragmentation, increased predation by mesopredators, invasive plant species, and long-term increases in human activity and its associated effects.

BIO-1 through BIO-16 and BIO-19, as described above and which refer to habitat protection, restoration and enhancement, and management in the High Country SMA and Salt Creek area, will mitigate for habitat fragmentation effects, including increased predation by mesopredators, by providing for a large, interconnected open space system.

BIO-63 will be implemented to mitigate impacts from predation by pet, stray, and feral cats and dogs. This measure requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent the pollution of aquatic habitat and potential secondary poisoning and loss of prey by pesticides and requires preparation of an IPM plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA regarding wildlife species and install signage to keep people and their animals on existing trails.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife BIO-74 requires installation of temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to construction within 200 feet of the spring and, if applicable, within 100 feet of flowing water in the Middle Canyon drainage. Permanent fencing and signage shall be erected along the bordering subdivision tract following construction. A qualified biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. Any upslope runoff from construction areas will be directed away from the Middle Canyon Spring. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

BIO-80 will mitigate for exotic predators. This measure states that the Project applicant shall retain a qualified biologist to develop and implement an Eradication Plan for bullfrog, African clawed frog, and crayfish. Following construction, monitoring shall be conducted at sentinel locations along the River Corridor SMA (and other potential habitat areas) annually for five years. After five years, monitoring shall be conducted bi-annually for 50 years.

BIO-72, BIO-85, and BIO-87 will be implemented to reduce and control Argentine ants in open space areas.

BIO-72 specifies that container plants for use within 100 feet of the open space areas shall be inspected for pests, including Argentine ants. Plant palettes also will include non-invasive species that do not require high irrigation rates, which will help keep moisture levels low at the open space-urban interface. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the two-striped garter snake and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

WESTERN SPADEFOOT TOAD (CSC)

Life History

The western spadefoot toad (*Spea hammondii*) is endemic to California and northern Baja California. The species ranges from the north end of California's great Central Valley near Redding, south, east of the Sierras and the deserts, into northwest Baja California (Jennings and Hayes 1994; Stebbins 2003). Although the species primarily occurs in lowlands, it also occupies foothill and mountain habitats. Within its range, the western spadefoot toad occurs from sea level to 1,219 meters (4,000 feet) AMSL, but mostly at elevations below 910 meters (3,000 feet) AMSL (Stebbins 2003). The species prefers open expanses with sandy or gravelly soils in a variety of habitats, including mixed woodlands, grasslands, coastal sage scrub, chaparral, sandy washes, river floodplains, alluvial fans, playas, and alkali flats (Stebbins 2003; Holland and Goodman 1998). Additionally, Holland and Goodman (1998) report that riparian habitats with suitable water resources may also be used. In southern Orange County, western spadefoot toads occur in the San Juan Creek floodplain in association with riparian habitats (County of Orange and USFWS 2006). However, the species is most common in grasslands with vernal pools or mixed grassland/coastal sage scrub areas (Holland and Goodman 1998). Rain pools must lack fish, bullfrogs, and crayfish in order for successful reproduction and metamorphosis to occur (Jennings and Hayes 1994).

The western spadefoot toad is almost completely terrestrial, remaining underground eight to 10 months of the year and entering water only to breed (Jennings and Hayes 1994; Holland and Goodman 1998; Storey *et al*. 1999). The species aestivates in upland habitats near potential breeding sites in burrows approximately one meter in depth (Stebbins 1972) and adults emerge from underground burrows during relatively warm rainfall events to breed. While adults typically emerge from burrows from January through March, they may also emerge in any month between October and April if rain thresholds are met (Stebbins 1972; Morey and Guinn 1992; Jennings and Hayes 1994; Holland and Goodman 1998).

Eggs are deposited in irregular small clusters attached to vegetation or debris (Storer 1925) in shallow temporary pools or sometimes ephemeral stream courses (Stebbins 1985; Jennings and Hayes 1994) and are usually hatched within six days. Complete metamorphosis can occur rapidly, within as little as three weeks (Holland and Goodman 1998), but may last up to 11 weeks (Burgess 1950; Feaver 1971; Jennings and Hayes 1994).

Western spadefoot toads likely do not move far from their breeding pool during the year (Zeiner *et al*. 1988), and it is likely that their entire post-metamorphic home range is situated around a few pools. However, opportunistic field observations indicate that they readily move up to at least several hundred meters from breeding sites (NatureServe 2007).

Western spadefoot tadpoles consume planktonic organisms and algae, but are also carnivorous and will forage on dead vertebrates and invertebrates (Bragg 1964). Adult western spadefoot toads are known to consume butterfly and moth larvae, beetles, termites, ants, crickets, flies, earthworms, and other invertebrates (Dimmitt and Ruibal 1980A; Morey and Guinn 1992; Stebbins 1972; Whitaker *et al*. 1977).

Loss of aquatic and adjacent upland habitats supporting the life cycle of the western spadefoot toad is a primary threat to this species, but other factors related to urban development probably are contributing to this species' decline. During construction, noise could result in the premature emergence of the western spadefoot toad from burrows because, normally, emergence from dormancy depends on low frequency sound caused by rainfall. Dimmitt and Ruibal (1980B) demonstrated that vibration from an electric motor consistently induced 100% emergence from dormancy under very arid conditions. Over the long term, non-native predators, such as bullfrog, crayfish, and mosquito fish, are a threat to western spadefoot toads, especially during breeding and metamorphosis. In addition, artificial lighting likely increases the species' vulnerability to predation by nocturnal predators, such as raccoon, skunk, opossum, fox, and coyotes, during these periods. An increase in pet, stray, and feral cats and dogs would also make the species more vulnerable to predation during these periods. Other factors that may affect the western spadefoot toad include grazing and off-road vehicles, which both may result in crushing or entombment of individuals and degradation of breeding pools; the spread of exotic plant species (*e.g.*, tamarisk, giant reed, iceplant, and pampas grass), which may degrade western spadefoot toad habitat by altered hydrology, eliminating breeding pools, and restricting access to and quality of upland habitats; and human-related degradation of habitat (*e.g.*, trampling of vegetation).

Survey Results

Focused surveys for the western spadefoot toad have been conducted in the Landmark Village and Mission Village portions of the Project area during the breeding season (Compliance Biology 2006C, 2004E). In the Landmark Village portion of the Project area, no indications of the presence of western spadefoot toad were observed, even at any of five road depressions where there was standing or recently standing water. Within the Mission Village development area, a few tadpoles in a drying pool were hydrated enough to make a positive identification. Another drying pool with desiccated tadpoles was identified just outside the western boundary of the Mission Village development area. Both of these pools appear to be the result of human activity, including road construction and other earth movement. The locations of these breeding pools are shown in **Figure 4.5-6**, RMDP/SCP – Special-Status Wildlife Species Occurrences. A western spadefoot toad was also observed in the Project area during amphibian and fish surveys conducted in the Santa Clara River by Aquatic Consulting Services (2002A). The western spadefoot toad was observed within the Santa Clara River upstream of the Commerce Center Bridge, within an isolated pool (**Figure 4.5-6**).

Western spadefoot toads have also been incidentally observed at other locations in the Project area (**Figure 4.5-6**). According to Compliance Biology (Crawford 2007), western spadefoot toads were observed in the Potrero Village development area within a rain pool in winter 2005; this location is believed to be extant. Dudek (2008E) also detected western spadefoot toad eggs in a basin located on an oil field well pad and storage area in the Potrero Village development area during focused surveys for fairly shrimp in close proximity to the Crawford (2007) observation. Western spadefoot toads were also observed in the VCC planning area in a location that has since been developed; eggs and tadpoles were relocated to created pools near Hasley Creek (Crawford 2007; Compliance Biology 2004G). In total, there have been five separate documented occurrences of the western spadefoot toad in the Project area based on the focused surveys and incidental observations described above.

Suitable breeding habitat for the western spadefoot toad on site includes riparian areas and seasonal drainages containing seasonal pools and suitable aestivation habitat includes surrounding uplands within at least several hundred meters of breeding sites. Because western spadefoot toads are associated with specific microhabitats, however, their total suitable habitat on site was not quantified.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Five occurrences of the western spadefoot toad have been identified in the Project area during focused surveys and by incidental observations; none of these occurrences is within the disturbance footprint of the RMDP. However, there is a high potential for this species to occur in other locations with suitable breeding habitat and areas within at least several hundred meters for suitable breeding sites. The implementation of the RMDP would include the construction of bridges and bank stabilization in and adjacent to riparian areas potentially used by western spadefoot toads as breeding or upland aestivation habitat. Additionally, activities associated with implementation of the SCP

(*e.g.*, fence construction) could also result in a small loss of potential upland habitat for the species. Therefore, the implementation of the RMDP and the SCP could result in the loss of occupied western spadefoot toad habitat. However, this impact has not been quantified because of the apparent sporadic distribution of this species on site and because potential habitat within the Project area only includes suitable breeding sites and adjacent uplands.

Given the high potential for suitable breeding and upland habitat in the Project area, the implementation of the RMDP and the SCP could have a substantial direct adverse effect on this species; interfere substantially with the movement of the species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

Five occurrences of the western spadefoot toad have been identified in the Project area during focused surveys and by incidental observations. The build-out of the Specific Plan area would result in the loss of the known occurrences from the two breeding pools in the Mission Village development area and the one breeding pool in the Potrero Village development area; the other documented occurrences are either outside the development footprint and/or no longer support western spadefoot toads. There is also high potential for this species to occur elsewhere in the Project area within suitable habitat areas. Therefore, the build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of western spadefoot toad breeding and aestivation habitat. Given the high potential for occupied breeding and adjacent upland aestivation habitat in the Project area, the build-out of the Specific Plan, VCC, and Entrada planning areas could have a substantial adverse effect on this species; interfere substantially with the movement of the species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

As described above for direct and indirect impacts, implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent loss of western spadefoot toad breeding and aestivation habitat and likely would also result in the loss of individuals, including adults, juveniles, tadpoles, or egg

masses. Therefore, the combined effect of the implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas could have a substantial adverse effect on this species; interfere substantially with the movement of the species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Combined direct and indirect permanent impacts would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

It is assumed that the western spadefoot toad has a high potential to occur in RMDP construction zones on site. Should western spadefoot toads be present within the disturbance footprint, construction and/or grading activities would result in the direct injury or mortality of western spadefoot toad adults, juveniles, tadpoles, or egg masses as a result of contact with construction equipment, crushing, entombment, or disturbances of breeding pools. Activities associated with implementation of the SCP (*e.g.*, fence construction) could also result in impacts such as injury, mortality or entombment of western spadefoot toads if fence construction occurred when aestivating western spadefoot toads were present, although the potential for this impact is considered to be low. Given the potential for large aggregations of western spadefoot toads at a breeding location (including surrounding upland habitat) (Jennings and Hayes 1994), the implementation of the RMDP could result in the loss of a large number of western spadefoot toads. Therefore, the implementation of the RMDP and the SCP could have a substantial direct adverse effect on this species; interfere substantially with the movement of the species or impede the use of a native nursery site; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential impacts of construction and/or grading activities to known locations of western spadefoot toad observations or areas of suitable habitat are the same as described above for indirect permanent impacts to loss of habitat. The build-out of the Specific Plan, VCC, and Entrada planning areas would likely result in injury or mortality of western spadefoot toad adults, juveniles, tadpoles, or egg masses as a result of contact with construction equipment, crushing, entombment, or disturbances of breeding pools. Therefore, the build-out of the Specific Plan, VCC, and Entrada planning areas could have a substantial adverse effect on this species; interfere substantially with the

movement of the species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect western spadefoot toad in areas adjacent to construction zones in the short term and residential and commercial areas in the long term. There have been few observations of this species on site, but short-term and long-term secondary impacts could occur. Short-term secondary effects include construction-related impacts, such as noise and ground vibration, which may cause premature emergence from burrows, thus exposing toads to predation, risk of crushing by equipment and vehicles, and exposure to harsh environmental conditions (*e.g.*, hot, dry weather); hydrologic or water quality alterations that could affect breeding success, including pollutants, sediments, and construction-generated dust that could affect breeding pools in the Santa Clara River or its tributaries and decrease insect prey for the species; and lighting, which could increase predation by nocturnal predators. Implementation of the SCP, such as fence construction, could result in secondary impacts to this species if activities caused premature emergence, thus exposing individuals to predators and potentially harsh environmental conditions.

Long-term development-related impacts resulting from implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas could increase impervious surfaces in the surrounding watershed, which in the absence of water detention basins and other facilities would increase surface runoff into the Santa Clara River. The proximity of urban development to suitable western spadefoot toad breeding habitat could result in disruption of nocturnal activities and greater vulnerability to predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; greater vulnerability to predation by pet, stray, and feral cats and dogs as well as other mesopredators (raccoons, skunks, opossums, and foxes); collecting by children; degradation of habitat from increased human use (*e.g.*, trampling, trash, and off-road vehicles); invasion by exotic plants (*e.g.*, giant reed, tamarisk, and pampas grass); the spread of non-native predatory species (*e.g.*, bullfrogs, African clawed frogs, exotic fish, and crayfish); increased risk of roadkill on roads adjacent to occupied areas; and reduced water quality from pollutants in runoff and use of pesticides, both of which could have toxic effects (*e.g.*, acute lethal affects or chronic effects on development and reproduction) or reduce prey. Additionally, habitat fragmentation and isolation of some local populations of western spadefoot toads would occur, making them more vulnerable to extirpation.

These short-term and long-term secondary impacts could have a substantial adverse effect on this species; interfere substantially with the movement of the species; have the potential to

substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Therefore, both short-term secondary impacts associated with construction activities and long-term secondary impacts associated with the RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Overall, implementation of the RMDP and the SCP under Alternatives 3 through 7 would have similar impacts to western spadefoot toad breeding and aestivation habitat to the impacts described above for Alternative 2, including permanent loss of habitat and temporary impacts to habitat. Because of various differences in the Project footprints for Alternatives 3 through 7, especially in relation to drainages and immediately adjacent uplands, there would be some differences in the amount of habitat permanently lost and temporarily impacted. For example, within lower Potrero Canyon, there would be fewer permanent impacts related to Potrero Canyon Road and the bridge crossing of the Santa Clara River under Alternatives 3, 4, and 7 because the bridge would not be constructed and Potrero Canyon Road would be terminated southwest of Potrero Mesa. Alternative 7 would have the least amount of permanent impacts to drainages and adjacent uplands providing potential habitat for the western spadefoot toad because of the pullback of facilities from the Santa Clara River and its tributaries and other changes to the Project footprint under Alternative 7 that would reduce impacts to suitable habitat for the western spadefoot toad compared to the other alternatives.

Although there would be some small differences in the amount of potential breeding and aestivation habitat permanently lost and temporarily impacted under Alternatives 3 through 7, impacts under all of the alternatives could have a substantial adverse effect on this species; interfere substantially with the movement of the species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Direct permanent and temporary impacts (Loss of Habitat) under Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Overall, build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would have similar impacts to western spadefoot

toad breeding and aestivation habitat to the impacts described above for Alternative 2. Because of various differences in the Project footprints for Alternatives 3 through 7, there would be some differences in the amount of habitat permanently lost. Alternatives 4 through 7 would result in fewer impacts to western spadefoot toad habitat than Alternative 3 because VCC would not be constructed under these alternatives. Alternatives 4 through 6 differ from each other through differences in the Entrada planning areas and Homestead East and Mission Village in the Specific Plan area. For example, Alternatives 5 and 6 have progressively smaller development footprints in Mission Village and the Entrada planning area compared to Alternative 4. Alternative 7 would have the smallest development footprint of all the alternatives because, in addition to VCC not being constructed, there would be reductions in the Entrada planning area, Mission Village, and Landmark Village, and Homestead East, adjacent to the Santa Clara River.

Although there would be some small to substantial differences in the amount of potential breeding and aestivation habitat permanently lost under Alternatives 3 through 7, impacts under all of the alternatives could have a substantial adverse effect on this species; interfere substantially with the movement of the species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Indirect permanent impacts (Loss of Habitat) under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

As described above for direct and indirect impacts under Alternatives 3 through 7, implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the permanent loss of western spadefoot toad breeding and aestivation habitat and likely would also result in the loss of individuals, including adults, juveniles, tadpoles, or egg masses. Although there would be some differences among the alternatives, the combined effect of the implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under any of the alternatives could have a substantial adverse effect on this species; interfere substantially with the movement of the species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Combined direct and indirect permanent impacts (Loss of Habitat) under Alternatives 3 through 7 would be significant, absent mitigation.

Impacts to Individuals

The potential impacts of construction and/or grading activities to known locations of western spadefoot toad observations or areas of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than those described above for Alternative 2. Implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would likely result in the loss of western spadefoot toad adults, juveniles, tadpoles, or egg masses. These impacts could have a substantial adverse effect on this species; interfere substantially with the movement of the species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Impacts to western spadefoot toad individuals under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

The potential short-term and long-term secondary effects to the western spadefoot toad and its habitat under Alternatives 3 through 7 would be similar to those described above for Alternative 2.

Short-term secondary effects include construction-related impacts, such as noise and ground vibration (which may cause premature emergence from burrows) and hydrologic or water quality alterations (including pollutants, sediments, and dust) of the Santa Clara River and its tributaries.

Long-term development-related impacts include the creation of impervious surfaces in the surrounding watershed, which could increase surface runoff into the Santa Clara River. Nighttime lighting adjacent to breeding habitat could affect nocturnal activities and increase predation by nocturnal predators. Western spadefoot toads would also be more vulnerable to predation by pet, stray, and feral cats and dogs and other mesopredators; exotic species; collecting; habitat degradation from increased human use and invasion by exotic plants; and increased risk of roadkill. Additionally, habitat fragmentation and isolation of some local populations of western spadefoot toads would occur, making them more vulnerable to extirpation.

These short-term and long-term secondary impacts could have a substantial adverse effect on this species; interfere substantially with the movement of the species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Therefore, both short-term secondary impacts associated with construction activities and long-term secondary impacts associated with the RMDP facilities and build-out of the Specific Plan, VCC,

and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to western spadefoot toad: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals, including adults, juveniles, metamorphs, egg masses, and tadpoles, could occur during construction as a result of vegetation clearing and grading and construction activities in breeding pools, including injury and mortality due to direct contact with construction equipment, entombment of hibernating and aestivating individuals, and increased exposure of individuals flushed from burrows or left without protective cover. Five occurrences of the western spadefoot toad have been identified in the Project area during focused surveys and by incidental observations. The build-out of the Specific Plan area would result in the loss of the known occurrences from the two breeding pools in the Mission Village development area and the one breeding pool in the Potrero Village development area; the other documented occurrences are either outside the development footprint and/or no longer support western spadefoot toads. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys within the proposed disturbance area and within will be conducted by a qualified biologist in possession of a scientific collecting permit. If western spadefoot toad is identified within a project site, a relocation site will be designed and created, as approved by CDFG, and all detected adults, tadpoles, and egg masses will be collected and relocated. General procedures to avoid and minimize impacts to western spadefoot toad during construction also will be implemented, and a qualified biologist will be present during construction in order to relocate any identified remaining individuals, further reducing impacts to the species. Several general measures will be implemented to protect wetland habitats that will reduce impacts to the western spadefoot toad. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities; biological monitoring during any stream diversions; restrictions on construction equipment operating in ponds or flowing water; design of bridges, culverts, and other structures so as not to impair the movement of aquatic species; and protection of water quality from mud, silt, and other pollutants.

The permanent loss of suitable habitat for the western spadefoot toad resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas will be mitigated through the preservation, restoration and enhancement, and management of suitable habitat, primarily in the River Corridor SMA, but also in riparian and wetland habitat and adjacent uplands in the High Country SMA and Salt Creek area. With regard to the River Corridor SMA, the Flood Hydraulics Impacts Assessment (PACE

2009) found that there would be no significant impacts in water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area over the long term as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue. Following build-out, the River Corridor floodplain would remain 1,000 to 2,000 feet wide and retain the mosaic of habitats that would support the life history of the western spadefoot toad.

With respect to secondary effects, any western spadefoot toads occupying habitat in close proximity to construction zones may be disturbed by construction activities, including ground vibration, dust, and nighttime lighting. Ground vibration could cause toads to emerge from burrows and expose them to predators, adverse environmental conditions (*e.g.*, hot, dry conditions), and increase their chance of injury or mortality from construction equipment and vehicles due to crushing. Lighting may increase their risk of predation from nocturnal predators and dust may adversely affect water quality and their insect prey. Potential breeding pools, including downstream pools, could be disturbed during construction by hydrological alterations and pollutants that impair water quality, thus adversely affecting egg masses and tadpoles. Biological monitoring during vegetation clearing and grading, as well as dust suppression measures, will help reduce the potential effects of ground vibration and dust. All lighting will be downcast away from habitat areas. Any western spadefoot toads detected emerging due to ground vibration will be relocated by a qualified biologist per a CDFG-approved relocation plan. Several general mitigation measures, as described above, will be implemented to protect on-site and downstream wetland and aquatic habitat quality, and in particular, protection of downstream water quality from mud, silt, and other pollutants. Potential long-term effects of development include increased human activity, including habitat degradation and collection; lighting; invasive species, including Argentine ant and invasive plants such as giant reed; pet, stray, and cats and feral dogs; vehicle collisions; and use of pesticides. The River Corridor SMA will provide adequate protected open space that will in large part offset these long-term impacts. Several specific mitigation measures will also be implemented to control human activities in the River Corridor SMA, including homeowner education and restrictions on recreational activities. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting along the open space-urban interface will be downcast. Pesticides will be controlled through an integrated pest management (IPM) plan. Argentine ant invasions of upland habitats in the open space system will be monitored and controlled to extent feasible. Implementation of these measures would allow this species to persist on site after development in the River Corridor SMA.

All mitigation measures for the western spadefoot toad are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-52 IMPACTS TO INDIVIDUALS – WESTERN SPADEFOOT TOAD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of western spadefoot toad individuals through pre-development surveys and conformance with state and federal permits related to wetlands and water quality.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that will reduce impacts to western spadefoot toad individuals. Most of these mitigation measures address impacts to potential breeding habitats, such as hydrologic alterations and water quality impacts that could adversely affect western spadefoot toads. Although western spadefoot toads usually breed in ephemeral pools in upland grasslands and mixed grassland/coastal sage scrub, they may also breed in riparian habitats with suitable pools (Holland and Goodman 1998). In addition, pre-construction coordination, focused surveys for western spadefoot toad, and biological monitoring will be conducted to reduce impacts.

The following three mitigation measures, BIO-46, BIO-48, and BIO-49, focus primarily on special-status fish, but they generally will also reduce impacts to the western spadefoot toad and other semi-aquatic species.

BIO-46 states that, during any stream diversion or culvert installation activity, a qualified biologist(s) shall be present, and shall patrol the areas within, upstream, and downstream of the work area. The biologists shall inspect the diversion and inspect for stranded spadefoot toads.

BIO-48 states that bridges, culverts, and other structures may not impair movement of fish and aquatic life and specifies relative depth requirements for temporary and permanent culverts.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-53 requires pre-construction surveys for western spadefoot toad within all portions of the Project site containing suitable breeding habitat. If western spadefoot toad is found on site, further measures include habitat creation at a 2:1 ratio, relocation of adults, tadpoles, and egg masses, and monitoring for five years.

BIO-70 is a more generally applicable mitigation measure that specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-53 LOSS OF HABITAT – WESTERN SPADEFOOT TOAD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for western spadefoot toad through habitat protection, restoration and enhancement, and management. SP-4.6-55 and SP-4.6-58, as described above, will also mitigate for loss of habitat by requiring compliance with state and federal permits related to wetlands and water quality.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 address habitat restoration in the River Corridor SMA and provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring

methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development. These transition areas provide potential upland aestivation habitat and also provide a buffer between development and suitable habitat in the River Corridor SMA.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system totaling approximately 6,100 acres that will reduce habitat fragmentation effects (**Figure 4.5-3**).

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the western spadefoot toad. These measures refer to habitat protection, restoration and enhancement, and management

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural

undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-53, described above, also requires creation of western spadefoot toad habitat within the Specific Plan area outside the proposed development area if the species is found in areas that would be developed.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the western spadefoot toad would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-54 SECONDARY IMPACTS – WESTERN SPADEFOOT TOAD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures to mitigate for short-term secondary impacts to the western spadefoot toad, such as altered hydrology and water quality and inadvertent impacts to suitable habitat adjacent to construction zones, as well as noise and ground vibration. Mitigation measures to offset long-term secondary impacts, such as habitat fragmentation, nighttime lighting, invasive plant species, increased human activity, increased predation by mesopredators, and other sources of habitat degradation (*e.g.*, grazing) were also identified.

In order to mitigate impacts from contact with chemical pollutants, increased sedimentation, increased turbidity, changes in flow, and changes in water temperature during construction, the Newhall Ranch Specific Plan Program EIR identified SP-4.6-55 and SP-4.6-58, as described above.

In order to avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These measures require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA. These measures, in combination with SP-4.6-53 and SP-4.6-59, which require pre-development surveys as described above, will also help reduce the effects of noise and ground vibration. However, these mitigation measures primarily are designed to minimize impacts to off-site resources and alone will not completely mitigate noise and ground vibration impacts. Because of the sporadic occurrence of the western spadefoot toad and the infeasibility of locating aestivating individuals prior to construction, long-term mitigation measures relating to habitat preservation and management will contribute to the persistence of the species on site and offset these short-term impacts from noise and ground vibration.

The following mitigation measures address the long-term secondary effects listed above. The Newhall Ranch Specific Plan Program EIR identified the several mitigation measures that primarily address habitat fragmentation, increased risk of predation by mesopredators, increased human populations and recreation in close proximity to open space and potential breeding and aestivation habitat for the western spadefoot toad, nighttime lighting, and other activities that could result in degradation of habitat, such as cattle grazing.

SP-4.6-1 through SP-4.6-16, SP-4.6-18, SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and which relate to the protection, restoration and enhancement, and management of the River Corridor SMA and High Country SMA, will prevent habitat fragmentation and increased predation by mesopredators (by maintaining the presence of top predators, such as coyotes) and will offset the impacts of increased human activity and grazing in the Project area.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-18 and SP-4.6-19, described above, address the transition area between development and the River Corridor SMA that will both buffer the River Corridor from adverse edge effects and provide potential aestivation habitat for the western spadefoot toad.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

In order to mitigate impacts from grazing, SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures that address potential short-term and long-term secondary effects to the western spadefoot toad, including impacts to hydrology and water quality; increased human activity; pet, stray, and feral cats and dogs; invasive plant and animal species; and use of pesticides.

In order to mitigate impacts from chemical pollution, increased sedimentation, increased turbidity, changes in flow, and changes in water temperature, BIO-46, BIO-48, BIO-49, and BIO-70, as summarized above, will be implemented. In addition, BIO-45, BIO-47, BIO-74, and BIO-77 will be implemented.

BIO-44 requires temporary bridges, culverts, or other feasible methods of providing access across the Santa Clara River. A Stream Crossing and Diversion Plan will be prepared that includes a description of diversion measures, such as berms, inflatable dams, sand bags, or other approved materials.

BIO-45 requires construction of bypass channels when the active wetted channel is within the work zone, in accordance with BIO-44. Equipment shall not be operated in areas of ponded or flowing water unless authorized by CDFG and USFWS.

BIO-74 requires installation of temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to construction within 200 feet of the spring and, if applicable, within 100 feet of flowing water in the Middle Canyon drainage. Permanent fencing and signage shall be erected along the bordering subdivision tract following construction. A qualified biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. Any upslope runoff from construction areas will be directed away from the Middle Canyon Spring. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

BIO-77 describes preparation of a plan and mitigation measures be implemented by the applicant specifically to maintain the populations of the undescribed snail and sunflower species, but these measures are also applicable to western spadefoot. The plan will provide guidelines for

collecting data on existing site conditions; developing a construction monitoring program and a post-development monitoring program; developing threshold parameters that activate adaptive management measures for water quality and water quantity issues; excluding unauthorized entry into the spring; and contingency measures. The plan shall be subject to the approval of CDFG prior to disturbance within 100 feet of flowing water in Middle Canyon Creek and/or 200 feet of Middle Canyon Spring.

In order to mitigate impacts from ground vibration, BIO-52, as summarized above, will be implemented.

In order to mitigate impacts from human activity (short term and long term), collection, and pet, stray, and feral cats and dogs and other mesopredators, BIO-1 through BIO-16, as summarized above, will be implemented. In addition, BIO-19 through BIO-21, BIO-63, BIO-64, BIO-69, and BIO-73 will be implemented.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. BIO-20 and BIO-21 provide for the preservation of coastal scrub within the High Country SMA, Salt Creek area, and River Corridor SMA as well as guidelines for development of a coastal scrub restoration plan. These three mitigation measure provide additional potential upland habitat for the western spadefoot toad that will be protected from adverse effects associated with an increased human population in the region.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent the pollution of suitable breeding habitat and potential toxic effects and loss of prey by pesticides and requires preparation of an IPM plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where

determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-72, BIO-80, BIO-85 and BIO-87 will mitigate impacts from non-native invasive plant and animal species that could degrade western spadefoot toad habitat and directly affect individuals, including adults, juveniles, tadpoles, and egg masses.

BIO-72 specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

BIO-80 states that the Project applicant shall retain a qualified biologist to develop and implement an Eradication Plan for bullfrog, African clawed frog, and crayfish. Following construction, monitoring shall be conducted at sentinel locations along the River Corridor SMA (and other potential habitat areas) annually for five years. After five years, monitoring shall be conducted bi-annually for 50 years.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the western spadefoot toad and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

ARROYO CHUB (CSC)

Life History

The arroyo chub (*Gila orcutti*) is designated a California Species of Special Concern (CSC) and is considered imperiled regionally and globally under the Natural Heritage Program methodology and is considered sensitive by the U.S. Forest Service. The arroyo chub is native to the Los Angeles, San Gabriel, San Luis Rey, Santa Ana, and Santa Margarita rivers and San Juan and Malibu creeks (CDFG 1995B). Arroyo chub are now rare within their native range and are only common in the upper Santa Margarita River and its tributary De Luz Creek in northern San Diego County; Trabuco Creek below O'Neill Regional Park and San Juan Creek (San Juan Creek drainage) in southern Orange County; and Malibu Creek (Swift *et al.* 1993) and West Fork San Gabriel River below Cogswell Reservoir in Los Angeles County (CDFG 1995B). The arroyo chub's range was artificially expanded as bait with trout or mosquitofish in the 1930s and 1940s (Swift *et al.* 1993). The arroyo chub was successfully introduced into the Santa Ynez, Santa Maria, Cuyama, and Mojave rivers, and is considered to be introduced within the Santa Clara River watershed (Swift *et al.* 1993; CDFG 1995B). If not for the introduced populations, the arroyo chub would likely be considered a threatened or endangered species (NatureServe 2007).

The arroyo chub is a small fish, typically about 70 to 100 millimeters in size. It occurs in slow-moving or backwater sections of warm to cool (10ºC to 24ºC) streams with mud or sand substrates (ENTRIX 2009); it thrives in low-gradient systems (Swift *et al.* 1993). This species may tolerate high temperatures and hypoxic conditions that occur in slow-flowing or stagnant streams and backwater pools in dry summers. The arroyo chub feeds primarily on algae but also feeds on insects and small crustaceans.

The arroyo chub can successfully reproduce after one year (CDFG 1995B). Arroyo chubs are fractional spawners that will breed from May to August, with the majority of breeding events taking place in June and July (CDFG 1995B), although others report spawning in March to April or May (NatureServe 2007). The arroyo chub breeding habitat requires slow-moving areas of water or pools. After hatching, the young spend the next three to four months in areas of quiet water, usually among vegetation or areas with cover (CDFG 1995B).

Survey Results

Arroyo chub have been documented within the Specific Plan area throughout the Santa Clara River. The focused special-status fish species habitat assessment and impact analysis for the Santa Clara River and tributary drainages conducted by ENTRIX (2009) found that the arroyo chub was common to abundant within the Specific Plan area and was the dominant species in the River during surveys. Surveys conducted in the summer of 2000 found this species within 500 meters (1,640 feet) upstream and downstream of the I-5 Bridge over the Santa Clara River (Impact Sciences 2003A, 2003B; Haglund and Baskin 2000). Haglund found the arroyo chub

during surveys for unarmored threespine stickleback in 1988 (Haglund 1989). Arroyo chub were also observed in the Entrada planning area (Aquatic Consulting Services 2002D; Haglund and Baskin 1995, 2000) and the VCC planning area (Haglund 1989). This species is not expected to occur in Salt Creek and other tributaries to the Santa Clara River due to lack of adequate hydrology.

During the ENTRIX (2009) surveys, the arroyo chub appears to have had a productive year (including numbers of young-of-the year) in spite of high levels of previous flood-related disturbances. This species is known to be widespread and common within perennial reaches of the Santa Clara River in Ventura and Los Angeles Counties.

Within the Project reach, arroyo chub only occurs within perennial aquatic habitat in the Santa Clara River, which comprises a small portion of the wetland/riparian habitat in the River and has high temporal variability, suitable aquatic habitat was not quantified for the purpose of the impact analysis in this EIS/EIR.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the proposed RMDP could result in permanent physical changes to the Santa Clara River corridor and surrounding watershed that could affect suitable arroyo chub habitat, including hydrology and fluvial processes. Implementation of the SCP would not directly affect this species.

Habitat variables evaluated by ENTRIX (2009) included potential changes in floodplain width, backwater refuge habitat area (flood condition aquatic refugia), and water velocity during various theoretical flood frequency events. ENTRIX (2009) conducted a study of Project-related hydrologic changes in the Santa Clara River and tributaries and their potential effects on special-status fish species, using the unarmored threespine stickleback as an indicator species because of its susceptibility to higher velocity

conditions. Parameters evaluated included potential changes in floodplain width, backwater refuge habitat (zero to two fps flow) area, and water velocity, and changes were evaluated during various theoretical flood frequency events including 20- and 100-year occurrences (**Figures 4.5-61a** and **4.5-61b**). The following summarizes the results of this analysis.

Implementation of the RMDP within the Project reach of the Santa Clara River would include 32,334 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch); the construction of bridges at Potrero Canyon, Long Canyon and Commerce Center Drive; and a Newhall Ranch Water Reclamation Plant (WRP) outfall in the Santa Clara River (**Figures 4.5-33-A1** through **4.5-33-D2**). The placement of bridge piers would be located within the Santa Clara River floodplain. This floodplain ranges in width from 980 to 1,550 feet at the bridge crossings and bridge footings would have the potential to occur in flowing portions of the River depending on stream hydrology. For example, the Potrero Canyon Bridge includes approximately 15 piers within the floodplain. During any given storm event, the number of piers subject to inundation may range from a single pier, to all of the piers. However, during summer low flows, the maximum number of piers to likely be in contact with the wetted channel would be two piers per bridge crossing. This would result in the direct loss of habitat occupied by arroyo chub. While the placement of bridge footings would result in the loss of River channel, the large width and hydrology of the River would maintain the formation of natural channels to support this species.

The primary effect of construction within the River channel is the alteration of natural stream hydrology and the quantity of stickleback habitat available. The ENTRIX report (2009) analyzed the hydrologic effects of the Project on the Santa Clara River for impacts to potential special-status fish species habitat. Based on an evaluation of velocity tolerance studies of stickleback fishes, ENTRIX inferred that unarmored threespine stickleback in the Santa Clara River require flood refugia velocities of two fps or less in natural river floodplain in order to avoid being washed downstream during flood events (ENTRIX 2009). Arroyo chub may be more tolerant of higher flow velocity conditions, however, this analysis uses the more conservative assumptions applied to unarmored threespine stickleback. Therefore, consistent with this approach, any areas maintaining velocities less than or equal to two fps would provide refuge for these species during storm events. Under existing conditions (dry and wet season conditions), most of the wetted channel of the Santa Clara River supports flows greater than two fps.

At the five- and 10-year flood events, frequency hydraulic modeling shows that there would be an increase in available area with less than two fps velocity of 1.3 acres and 5.5 acres, respectively, for special-status fish species. During the 20-, 50-, and 100-year

events, there is a decrease in area with less than two fps velocity at 12.5 acres, 11.1 acres, and 8.9 acres, respectively. This decrease is not expected to be significant, as the area lost during these flood events is in terraced agricultural land that is not suitable floodplain refugia habitat for the arroyo chub and other special-status fish species. Suitable floodplain refugia requires microhabitat elements, such as vegetative cover, substrate, and stream topography (ENTRIX 2009). Agricultural land is not considered as refuge as it presents a greater threat to fish stranding during high flood events. The ENTRIX report further indicates that the alteration of the stream hydrology would not significantly impact arroyo chub and other special-status fish access to flood plain refugia during flood events, since the general morphology of the Santa Clara River, adjacent rearing habitat, and high-flow floodplain refugia would not be substantially altered. This is illustrated on **Figures 4.5-61a** and **4.5-61b,** which indicate stream flow areas with less than two fps during the 20 and 100-year flood events, respectively (see entire set of graphics in ENTRIX 2009 report, **Appendix 4.5**).

Implementation of the RMDP in the Project reach of the Santa Clara River would include buried bank stabilization along the upland–riparian interface along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch), the construction of bridges at Potrero Canyon, Long Canyon, and Commerce Center Drive, and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-33-A1** through **4.5-33-D2**). ENTRIX (2009) evaluated the long-term effects of these facilities on special-status fish species habitat and concluded that no significant effects to fish habitat would occur because the general morphology of the Santa Clara River, adjacent rearing habitat, and high-flow riparian refugia would not be substantially altered.

There also would be no direct impacts to arroyo chub habitat resulting from modifications to tributaries to the Santa Clara River, due to the absence of fish in general, including special-status fish species. Most of the tributaries do not support perennial flows, and none of the tributaries have surface water connectivity with the Santa Clara River, except for Middle and Potrero canyons, which although they contain perennial flow, they have substantial blockages (bedrock headcuts or cascades) that are impassable to fish (ENTRIX 2009).

Although no substantial permanent impacts to arroyo chub habitat would occur through implementation of the RMDP, the Project would temporarily affect habitat when construction occurs directly in aquatic habitat, such as the active stream channel. Bridge construction, in particular, could directly affect aquatic habitat occupied by arroyo chub and other special-status fish through direct impacts to the flowing stream, stream diversion, and dewatering when construction is occurring within the River corridor. Direct impacts from temporary construction would be significant absent mitigation

primarily due to permanent and temporary disturbance to aquatic habitat from construction of RMDP facilities within the Santa Clara River.

With implementation of the RMDP, direct permanent and temporary impacts could substantially affect chub habitat; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct temporary impacts (Loss of Habitat) would be significant, absent mitigation. Implementation of the RMDP would not result in the significant alteration to stream hydrology or limit access to refugia during storm events and, therefore, direct permanent impacts would be adverse but not significant.

Indirect Permanent Impacts

Because the distribution of this species within the Project area is limited to aquatic habitats within the Santa Clara River, construction activities associated with build-out of the Specific Plan, VCC, and Entrada planning areas do not have potential to harm or eliminate occupied arroyo chub habitat because all activities would be outside the River corridor. Project build-out would not have a substantial adverse effect on chub habitat; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would not be significant because no impacts are expected to occur as a result of Specific Plan build-out and development outside of the River and aquatic habitat.

Combined Direct and Indirect Permanent Impacts

Only RMDP-related impacts would result in permanent impacts to suitable habitat for this species, and these impacts are considered to be adverse but not significant. Neither implementation of the RMDP nor build-out of the Specific Plan, VCC, and Entrada planning areas would result in permanent impacts that could have a substantial adverse effect on the species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Therefore, the combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The presence of arroyo chub and other special-status fish species is quite variable (ranging from rare or absent in certain reaches of the River, to locally abundant in any given year) in the Project reach, and the species is assumed to be present for this analysis. Implementation of the RMDP, including construction of buried bank structures and bridges, could adversely affect arroyo chub individuals during construction work within the River. The potential for impacts from installation of these structures is increased, as the construction is planned for marginal areas of the riparian zone and because this species is known to use lateral backwater refuge habitat and aquatic environments of emergent, fringe vegetation. Direct impacts to the species may occur during construction of RMDP components during the following anticipated activities: stream diversion and/or species exclusion; unauthorized entry of construction equipment into ponded or flowing water; placement of fill in occupied waters; construction dewatering activities; discharge of pollutants, including silt, sediment, fresh concrete, trash/debris, and petroleum or other deleterious materials or pollutants, and/or; unauthorized personnel entry into occupied waters.

These activities could result in the following impacts: inadvertently directing fish to unsuitable habitats, blocking fish passage, stranding of fish in unsuitable habitat, or directing fish into unsuitable flow regimes; causing water quality conditions unsuitable for the fish survival; direct mechanical crushing or entombment of fish; unauthorized collection of individuals; and/or physical disturbance of river edge habitats.

Implementation of the SCP would not directly impact this species within the Project reach or downstream. Implementation of the RMDP could have direct substantial adverse effects on the arroyo chub, interfere with the movement of the species, and substantially reduce the number of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

Because the distribution of this species within the Project area is limited to aquatic habitats within the Santa Clara River corridor, build-out of the Specific Plan, VCC, and Entrada planning areas would not result in the impacts to arroyo chub individuals. Project build-out would not have a substantial adverse effect on the arroyo chub; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or

substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would not be significant because physical onsite impacts are not expected to occur due to Specific Plan build-out.

Secondary Impacts

Implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas could result in both short-term secondary effects during construction and long-term effects due to use of RMDP facilities and build-out of the Project area. These impacts could affect the chub along the Santa Clara River corridor within the Project area and in downstream populations. Implementation of the SCP would not result in secondary impacts to this species.

Short-term construction-related effects include hydrologic and water quality effects. These short-term impacts could affect arroyo chub and other special-status fish species in the Santa Clara River within the Project area and in downstream populations (same as previously described for direct impacts to individuals).

Long-term effects associated with operation of RMDP facilities and build-out of the Project area due to potential physical changes in the River and increased discharges could include alterations in base flows, timing and duration of flood flows, biochemical changes, condition and composition of the substrate, aquatic and riparian vegetation (including exotic species), and water temperatures as well as increased pollutants from irrigation runoff and increased runoff from roadways. Additional secondary impacts associated with increased human presence include incidental litter and trash from recreation activity; impacts such as fecal material from pet, stray, and feral cats and dogs entering the aquatic system; and increased predation by exotic predators, such as bullfrogs and non-native fish.

These short-term and long-term secondary impacts could have a substantial adverse effect on the arroyo chub; substantially interfere with the movement of the species; reduce the species' habitat; or restrict the range of the species (significance criteria 1, 4, and 7). Secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Overall, implementation of the RMDP under Alternatives 3 through 7 would have similar types of impacts to arroyo chub habitat in the Santa Clara River corridor to those described above for Alternative 2 (**Figures 4.5-34-A1** through **4.5-38-D2**). Although no substantial permanent impacts to arroyo chub habitat would occur through implementation of the RMDP under Alternatives 3 through 7, the Project has the

potential to temporarily affect habitat when construction occurs directly in aquatic habitat, such as the active stream channel. Buried bank stabilization would be installed at the riparian–upland interface under all the alternatives, although under Alternative 7 it would be outside the 100-year floodplain and thus would have a substantially reduced risk of temporary impacts to arroyo chub habitat. Bridge construction, in particular, would directly affect aquatic habitat occupied by arroyo chub through direct impacts to the flowing stream, stream diversion, and dewatering when construction is occurring within the River corridor as previously described for Alternative 2. Three bridges would be constructed under Alternative 2. Bridges would also be constructed under Alternatives 3 through 7: two under Alternatives 3, 4, and 6; three under Alternative 5; and one under Alternative 7 (see **Table 4.5-23**, Key Components of Alternatives, for details). Thus, Alternatives 3, 4, 6, and 7 would have relatively reduced temporary impacts from bridge construction compared to Alternatives 2 and 5.

As described previously for Alternative 2, direct impacts from construction would be significant absent mitigation primarily due to permanent and temporary disturbance to aquatic habitat from construction of RMDP facilities within the Santa Clara River.

ENTRIX (2009) conducted a study of Project-related hydrologic changes in the Santa Clara River and tributaries and their potential effects on special status fish species (using stickleback as an indicator species due to its vulnerability to high flow velocities) for Alternatives 3, 4, 5, 6, and 7. Parameters evaluated included potential changes in floodplain width, floodplain refugia (zero to two fps flow) area, and water velocity, and changes were evaluated during various theoretical flood frequency events including five-, 10-, 20-, 50-, and 100-year occurrences. **Figures 4.5-62a** through **4.5-65b** show the range of floodplain effects for the 20- and 100-year flood events. The following summarizes the results of this analysis.

Alternatives 3 and 4

Implementation of the RMDP within the Project reach of the Santa Clara River would include 31,857 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of river (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch; the construction of bridges at Long Canyon and Commerce Center Drive; and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-34-A1** through **4.5-35-D2**). The ENTRIX report (2009) indicates that there would be the following impacts to potential arroyo chub floodplain refugia. At the five- and 10-year flood events, frequency hydraulic modeling shows that there would be an increase in available refugia of 2.1 and 8.9 acres, respectively, for chub with less than two fps flow. During the 20-, 50-, and 100-year events, there is a decrease in refugia with less than two fps flow at 7.3 acres, 5.3 acres and 5.7 acres, respectively.

The decrease in refugia is not expected to be significant as the area lost during these flood events is in terraced agricultural land that is not suitable floodplain refugia for the arroyo chub and other special-status fish species (ENTRIX 2009). The ENTRIX report (2009) further indicates that accessible floodplain refugia, would not be substantially altered, and therefore, any impact would be less than significant.

Alternatives 3 and 4 construct one less bridge (Potrero Canyon Road) than Alternative 2, however the direct impacts from construction would be similar to Alternative 2, and therefore would be significant absent mitigation.

Alternative 5

Implementation of the RMDP between Salt Creek and Middle Canyon would include 32,334 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch); the construction of bridges at Potrero Canyon, Long Canyon and Commerce Center Drive; and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-36-A1** through **4.5-36-D2**). The ENTRIX report (2009) indicates that there would be the following impacts to potential chub habitat (zero to two fps flow). At the five- and 10-year flood events, frequency hydraulic modeling shows that there would be an increase in available habitat of 1.3 and 5.5 acres, respectively, for the arroyo chub with less than two fps flow. During the 20-, 50-, and 100-year events, there is a decrease in habitat with less than two fps flow at 12.5 acres, 11.1 acres and 8.9 acres, respectively. The decrease in habitat is not expected to be significant as the habitat lost during these flood events is in terraced agricultural land that is not suitable habitat for arroyo chub and other special-status fish (ENTRIX 2009). The ENTRIX report (2009) further indicates that accessible floodplain refugia, would not be substantially altered, and therefore, any impact would be less than significant.

Alternatives 5 bridge construction (three bridges) would be similar to Alternative 2 and the direct impacts from construction would be the same with regard to arroyo chub, and therefore would be significant absent mitigation.

Alternative 6

Implementation of the RMDP between Salt Creek and Middle Canyon would include 29,293 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch); the construction of bridges at Potrero Canyon and Long Canyon; and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-37-A1** through **4.5-37-D2**). The ENTRIX report (2009)

indicates that there would be the following impacts to potential chub habitat (zero to two fps flow). At the five- and 10-year flood events, frequency hydraulic modeling shows that there would be an increase in available habitat of 1.3 and 10.7 acres, respectively, for the arroyo chub with less than two fps flow. During the 20-, 50-, and 100-year events there is a decrease in habitat with less than two fps flow at 7, 4.6, and 2.6 acres, respectively. The decrease in habitat is not expected to be significant as the habitat lost during these flood events is in terraced agricultural land that is not suitable habitat for the arroyo chub and other special-status fish (ENTRIX 2009). The ENTRIX report (2009) further indicates that accessible floodplain refugia, would not be substantially altered, and therefore, any impact would be less than significant.

Alternative 6 constructs one less bridge (Commerce Center Drive) than Alternative 2, however the direct impacts from construction would be similar to Alternative 2, and therefore would be significant absent mitigation.

Alternative 7

Implementation of the RMDP between Salt Creek and Middle Canyon would include the construction of one bridge at Long Canyon (with spans removed from the 100-year floodplain); the grading and conversion of 13,956 linear feet of ephemeral drainages to buried storm drains; and construction of a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-38-A1** through **4.5-38-D2**). Bank protection would be removed from the 100-year floodplain and built in upland areas. All jurisdictional streams and wetlands in the Santa Clara River, Potrero Canyon, Chiquito Canyon, and San Martinez Grande Canyon drainages would be preserved or avoided except where bridges are built to facilitate road crossings. The ENTRIX report (2009) indicates that there would be the following impacts to potential arroyo chub and other special-status fish habitat. The model predicts a projected increase of available refuge habitat (less flow during the five-, 10-, 20-, 50-, and 100-year flood events. The amount of available habitat would be 2.0, 13.3, 22.5, 41.7, and 25.2 acres, respectively. The ENTRIX report (2009) further indicates that there would be no impacts from the installation of these Project components, since the general morphology of the Santa Clara River, adjacent rearing habitat, and high-flow riparian refugia would not be substantially altered.

Alternatives 7 constructs two less bridges (Potrero Canyon Road and Commerce Center Drive) than Alternative 2, however the direct impacts from construction would be similar to Alternative 2, and therefore would be significant absent mitigation.

While implementation of the RMDP under Alternatives 3 through 7 would not have a substantial permanent adverse effect, temporary impacts could substantially affect arroyo chub; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-

sustaining levels; threaten to eliminate the species; or substantially reduce the number or restrict the range of the species. Direct permanent impacts (Loss of Habitat) under Alternatives 3 through 7 would not be significant because no impacts would occur but direct temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

The arroyo chub within the Project area is limited to aquatic habitats within the Santa Clara River. As with Alternative 2, construction activities associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas do not have the potential to harm or eliminate occupied chub habitat because all activities would be outside the River corridor. Project build-out would not have a substantial adverse effect on the arroyo chub; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Indirect permanent impacts (Loss of Habitat) under Alternatives 3 through 7 would not be significant because no impacts are expected to occur.

Combined Direct and Indirect Permanent Impacts

Alternatives 3 through 7, only RMDP-related impacts would result in permanent impacts to suitable habitat for this species, and these impacts are considered to be adverse but not significant. Neither implementation of the RMDP nor build-out of the Specific Plan, VCC, and Entrada planning areas would result in permanent impacts that could have a substantial adverse effect on the species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Therefore, the combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Similar to Alternative 2, implementation of the RMDP would require the construction of bridges and bank stabilization within the River corridor, although the number of bridges varies among the alternatives and bank stabilization under Alternative 7 would be constructed outside the 100-year floodplain, resulting in reduced risk of temporary impacts to arroyo chub habitat under this alternative. Implementation of the RMDP under Alternatives 3 through 7 may result in impacts to chub individuals if construction occurs during River flows adequate to support these species in

work zones in occupied habitat or if construction causes interruptions in water flows. Implementation of the SCP would not directly impact this species.

Implementation of the RMDP under Alternatives 3 through 7 could have a direct substantial adverse effect on the arroyo chub; interfere with the movement of the species; or substantially reduce the number of the species. Impacts to individuals under Alternatives 3 through 7 would be significant, absent mitigation.

Implementation of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7, would not result in indirect impacts to individuals.

Secondary Impacts

The potential short-term and long-term secondary impacts to the arroyo chub and its habitat under Alternatives 3 through 7 would be similar to those described above for Alternative 2.

Short-term construction-related effects include hydrologic and water quality effects, as described above, that could affect arroyo chub in the Santa Clara River within the Project area and in downstream populations.

Long-term effects associated with operation of RMDP facilities and build-out of the Project area could occur due to potential physical changes in the River and increased discharges and could affect base flows and flood flows and induce biochemical, substrate, temperature, and vegetative changes. Increased human activity could increase litter and trash, and fecal material from pet, stray, and feral cats and dogs may enter the aquatic system. In addition, increased predation by exotic predators, such as bullfrogs and non-native fish, may occur.

These short-term and long-term secondary impacts could have a substantial adverse effect on the arroyo chub; substantially interfere with the movement of the species; reduce the species' habitat; or restrict the range of the species. Secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to arroyo chub: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

The mitigation required by the Newhall Ranch Specific Plan Program EIR and the mitigation measures recommended by this EIS/EIR combined will prevent impacts to arroyo chub individuals. To prevent impacts to arroyo chub, protective measures will be implemented, such as pre-construction surveys, biological monitoring, exclusion of the species from construction

areas using temporary diversion channels, and protection of habitat through facilities design guidelines and BMPs, which will prevent impacts to arroyo chub individuals.

Impacts to individuals, including adults and fry (juvenile fish), could occur during construction as a result of heavy equipment operation for access and grading, or during diversion of Santa Clara River flows. The Project incorporates numerous elements to avoid and minimize potential impacts to individuals, such as injury or mortality, which would come as a result of direct contact with construction equipment or as an outcome of modification of River habitat, such as flow diversion activities. These measures include pre-construction surveys for any construction activity within 300 feet of River habitat to assure that arroyo chub individuals are avoided or excluded, particularly during the sensitive periods such as spawning or when fry are present. These measures also specify the methods to be used for excluded arroyo chub, as well as how temporary diversion channels will be constructed to assure that adequate rearing habitat is present for chub during construction. These measures also employ provisions for constructing permanent and temporary stream crossings in the Santa Clara River in a manner that will allow for unimpeded movement upstream and downstream. Numerous water quality measures, such as construction stormwater BMPs (*e.g.*, silt fencing, erosion control materials, sediment basins) and the installation of water quality treatment facilities are also included to minimize impacts from pollutants related to storm runoff during storm events.

The mitigation required by the Newhall Ranch Specific Plan Program EIR and the mitigation measures recommended by this EIS/EIR will reduce temporary impacts to arroyo chub habitat through facilities design requirements, which will avoid and minimize impacts to habitat, and conformance with state and federal permits to protect water quality.

The vast majority of chub habitat in Project reach of the Santa Clara River will be preserved under all of the alternatives. Arroyo chub habitat will be impacted through the construction of RMDP facilities, by bridge pier or column footings in particular. It is estimated that one to two pier or column footings would affect arroyo chub habitat at each of the three Santa Clara River bridge crossings (Commerce Center Drive, Long Canyon Road, Potrero Canyon Road) depending on the location of the active channel. The wetted channel of the River is typically between 30 and 50 feet wide, while the River floodplain ranges between 1,000 and 2,000 feet wide. The spacing between piers and columns will be 100 feet, thus approximately one to two pier or column footings per bridge could be placed in the flow of the River and affect arroyo chub habitat. Because River flow will deflect off of these structures and will become realigned, arroyo chub habitat will become re-established after bridge construction is completed. Temporary diversion for the construction of piers and columns will include the establishment of additional habitat downstream to allow for necessary arroyo chub spawning, rearing, and/or oversummering. Bank stabilization features (buried soil cement, rock riprap, or gunite lining) will impact chub habitat through floodplain alterations caused by changes to flood flows through the Project area. Under severe flood conditions, arroyo chub will seek slow-moving floodplain

areas as refugia from high velocity conditions. Although bank stabilization features will sometimes constrict flows through the Project reach, the amount of available flood refugia present during these events is adequate to protect arroyo chub from being flushed out of the Project area.

The mitigation required by the Newhall Ranch Specific Plan Program EIR and the mitigation measures recommended by this EIS/EIR combined will minimize secondary impacts from affecting the arroyo chub and its habitat. Impacts such as increased chemical pollutants, sedimentation, and increased human activity will be mitigated by measures such as the protection and management of the River Corridor SMA, creation of buffer areas between the River Corridor SMA and development, water quality requirements, and restrictions on public access. In addition, the technical studies conducted by ENTRIX (2009) concluded that suitable chub habitat would not be significantly affected by the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas under any of the alternatives. Further, the Flood Technical Report (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area over the long term as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County. The PACE study determined that the River would still retain sufficient width to allow natural fluvial processes to continue; as a result, the mosaic of habitats in the River that support various special-status fish species would be maintained and the populations of the species within and immediately adjacent to the River corridor would not be substantially affected.

All mitigation measures listed below are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-55 IMPACTS TO INDIVIDUALS – ARROYO CHUB

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the impacts to special-status fish species (primarily unarmored threespine stickleback) through facilities design requirements, pre-development surveys, consultation with USFWS, and conformance with state and federal permits related to wetlands and water quality.

SP-4.6-44 requires that drainages with flows greater than 2,000 cfs have soft bottoms. Bank protection will be of ungrouted rock or buried bank stabilization, except at bridge crossings and other areas where public health and safety considerations require concrete or other stabilization.

SP-4.6-53 requires updated surveys for special-status plants, animals, and vegetation communities as determined necessary by the County whenever construction maps are submitted. Based on the results of the surveys, additional conditions and mitigation measures may be required.

SP-4.6-54 requires that prior to development within or disturbance to occupied threespine stickleback habitat, a formal consultation with the USFWS shall occur.

SP-4.6-55 obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats.

SP-4.6-57 requires that, where bridge construction is proposed and water flow will be temporarily diverted, blocking nets and seines be used to control and remove fish from the area of activity. All fish captured during this operation will be stored in tubs and returned unharmed to the river after construction activities are complete.

SP-4.6-58 requires that in order to limit impacts to water quality, the Specific Plan shall conform to all provisions of required NPDES permits and water quality permits required by the RWQCB.

SP-4.6-59 requires consultations with the County of Los Angeles and CDFG before surveys, after surveys, at subdivision map approval, and prior to development or disturbance to habitats occupied by special-status species. Based on the results the consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that will mitigate the impacts to arroyo chub (and other special-status fish species) individuals. These mitigation measures include pre-development focused surveys for special-status fish, coordination with CDFG, channel diversion requirements, biological monitoring, avoidance of flowing water, design guidelines for bridges and culverts, and other BMPs. Additional mitigation measures are specified in other sections of the EIS/EIR that address water quality, riparian vegetation scour, and sedimentation. Specifically, Mitigation Measure WQ-1 in **Section 4.4,** Water Quality, and Mitigation Measures GRR-1 through GRR-7 in **Section 4.2**, Geomorphology and Riparian Resources, provide additional measures to reduce the impacts to arroyo chub and other special-status fish individuals. These mitigation measures include implementation of Project BMPs (including runoff control, conservation of natural areas, minimization of stormwater runoff pollutants of concern, prevention of slope and channel erosion, and education and signage to discourage illegal dumping to the storm drains), and other measures to minimize impacts to riparian resources and geomorphology (peak storm flow control, bridge span and clearance guidelines, maintenance minimization, channel design to minimize erosion potential, sediment

and debris control, reintroduction of sediments for beach replenishment, and a Geomorphology Monitoring and Management Plan).

BIO-43 provides for the biological surveying of aquatic habitats within 300 feet of construction sites and access roads for the presence of special-status fishes, at least 10 days prior to commencing construction, unless fish spawn has occurred or juvenile fishes are present; in which case, construction activities would be suspended.

BIO-44 requires that temporary crossings or access across the River be constructed outside of the winter season and not during spring periods when fish spawning is occurring, and be consistent with a Stream Crossing and Diversion Plan that outlines the following: the timing and methods for pre-construction fish surveys, a detailed description of the diversion methods, fish exclusion techniques, methods to maintain fish passage, channel habitat enhancement design, fish stranding surveys, and the techniques for the removal of temporary crossings prior to winter storm flows.

BIO-45 defines the timing and design of stream diversion bypass channels and dewatering activities and related restrictions to ensure that proper construction, operation, and abandonment diversion or dewatering will occur.

BIO-46 requires that a qualified biologist will inspect diversion or dewatering activities for stranded fish or other aquatic organisms.

BIO-47 provides for the construction of additional slow moving water habitats upstream and downstream of any river crossing or bridge construction area, to provide refuge for special-status fishes during construction.

BIO-48 requires the design and installation of bridges, culverts, or other structures to not impair the movement of fish and aquatic life, and requires provisions for a low flow channel where velocities are less than 2 feet per second to allow fish passage.

BIO-49 requires that pollutants from construction activities not be allowed to enter a flowing stream or be placed in locations that may be subjected to storm flows.

BIO-70 provides for construction plans that will include erosion control plans and dust control plans, specifications, and details, along with an overall Project stormwater pollution prevention plan (SWPPP). Together, these documents shall include measures to ensure that impacts (*e.g.*, the introduction of chemical pollutants, exposure to fugitive dust, contact with polluted runoff, and changes in hydrology) to vegetation communities and special-status plant species are avoided or minimized during construction.

BIO-71 requires that development areas have dust control measures implemented and maintained to prevent dust from impacting vegetation communities and aquatic wildlife species. Dust

control plans shall be prepared prior to initiation of construction activities and shall comply with SCAQMD Rule 403 (SCAQMD 2005).

Finding of Significance for Loss of or Harm to Individuals After Mitigation

After mitigation, impacts to arroyo chub individuals would be less than significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-56 LOSS OF HABITAT – ARROYO CHUB

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will mitigate the temporary impacts to habitat for special-status fish through RMDP facilities design requirements, consultation with the USFWS, and conformance with federal and state permits to protect water quality.

SP-4.6-44, SP-4.6-54, SP-4.6-55, and SP-4.6-58, as described above, will be implemented to mitigate impacts related to unarmored threespine stickleback through facilities design requirements, consultation with USFWS, and conformance with state and federal permits related to wetlands and water quality.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the temporary loss of habitat for the arroyo chub. These measures refer to stream diversions, BMPs, and facilities design. Additional mitigation measures are specified in other sections of the EIS/EIR that address water quality, riparian vegetation scour, and sedimentation as described above (Mitigation Measures WQ-1 and GRR-1 through GRR-7). These mitigation measures include implementation of Project BMPs and other measures to minimize impacts to riparian resources and geomorphology.

BIO-45, BIO-47 through BIO-49, BIO-70, and BIO-71, as described above, will be implemented to mitigate impacts from chemical pollution, increased sedimentation, increased turbidity, changes in flow, changes in water temperature, and dust.

Finding of Significance for Loss of Habitat After Mitigation

Permanent impacts (Loss of Habitat) would not be significant because impacts will be predominantly outside of the stream channel and be limited with respect to aquatic habitat. After

mitigation, temporary impacts to arroyo chub habitat would be less than significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-57 SECONDARY IMPACTS – ARROYO CHUB

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures to mitigate for both short-term secondary impacts to the arroyo chub, such as altered hydrology and water quality, and long-term secondary impacts, such as potential physical changes in the River; altered base and flood flows; biochemical, substrate, and temperature alterations; vegetative changes, such as invasive plant species; and increased human activity and impacts from pet, stray, and feral cats and dogs.

Most importantly, the River Corridor SMA will be protected and managed to preserve aquatic and riparian resources, including the arroyo chub and its habitat, through a series of mitigation measures. SP-4.6-1 through SP-4.6-16 and SP-4.6-63 address habitat restoration in the River Corridor SMA and provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats, including aquatic habitats used by the arroyo chub.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. These measures will provide a buffer between human activity and aquatic habitats supporting the arroyo chub. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-20 requires that all grading perimeters within the River Corridor SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to

avoid inadvertent impacts to riparian resources (including aquatic habitats) outside the grading area in the River Corridor SMA.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA.

SP-4.6-27 prohibits grazing in the River Corridor SMA except as a long-term resource management activity. Controls on grazing will help protect water quality in aquatic habitats used by the arroyo chub.

SP-4.6-44, SP-4.6-54, SP-4.6-55, and SP-4.6-58, as described above, will be implemented to mitigate impacts related to unarmored threespine stickleback through facilities design requirements, consultation with USFWS, and conformance with state and federal permits related to wetlands and water quality.

Measures Recommended by EIS/EIR

This EIS/EIR recommends additional mitigation measures to mitigate for secondary impacts to arroyo chub, including short-term impacts to hydrology and water quality and long-term impacts, such as effects on movement; increased human activities; pet, stray, and feral cat and dogs; habitat degradation from exotic plants; and increased predation from exotic predators. Additional mitigation measures are specified in other sections of the EIS/EIR that address water quality, riparian vegetation scour, and sedimentation as described above (Mitigation Measures WQ-1 and GRR-1 through GRR-7). These mitigation measures include implementation of Project BMPs and other measures to minimize impacts to riparian resources and geomorphology.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios. Although these measures primarily refer to riparian habitats, the riparian/aquatic communities in the River Corridor SMA will be addressed comprehensively in a manner that protects and enhances habitat for the arroyo chub, including management of invasive species, such as giant reed.

BIO-45, BIO-47 through BIO-49, BIO-70, and BIO-71, as described above, will be implemented to mitigate impacts from chemical pollution, increased sedimentation, increased turbidity, changes in flow, changes in water temperature, and dust.

BIO-63 will be implemented to mitigate impacts by pet, stray, and feral cats and dogs, such as fecal material entering the aquatic system. This measure requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-80 states that the Project applicant shall retain a qualified biologist to develop and implement an Eradication Plan for bullfrog, African clawed frog, and crayfish. Following construction, monitoring shall be conducted at sentinel locations along the River Corridor SMA (and other potential habitat areas) annually for five years. After five years, monitoring shall be conducted bi-annually for 50 years.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to the arroyo chub and its habitat would not be significant for Alternatives 2, 3, 4, 5, 6, and 7.

SANTA ANA SUCKER (CSC)

Life History

The Santa Ana sucker (*Catostomus santaanae*) is listed as a California Species of Special Concern (CSC) throughout its range. Outside the Newhall Ranch Specific Plan area, populations within the species' natural historic range, including the Los Angeles, San Gabriel, and Santa Ana river basins, are listed federally as Threatened. Populations within the Santa Clara River watershed are not listed as federally threatened. It is also considered sensitive by the U.S. Forest Service and is considered critically imperiled by the Natural Heritage Program and vulnerable by the IUCN World Conservation Union.

Santa Ana suckers are native to southwestern California and endemic to lower-elevation streams within the Los Angeles, San Gabriel, and Santa Ana river drainages (McGinnis 2006; Saiki 2000; Stephenson and Calcarone 1999). Natural history records for the Santa Ana sucker in California include three native, three historical, and four introduced populations. The remaining native populations are within the east, north, and west forks of the San Gabriel River inside the Angeles National Forest, the lower and middle Santa Ana River, and the lower Big Tujunga Creek in the Los Angeles River drainage. Historically, the Santa Ana sucker occurred in the upper Santa Ana River, Canyon and City creeks in the foothills of the San Bernardino Mountains, and Santiago Creek in the foothills of the Santa Ana Mountains. Finally, introduced populations are present in the Santa Clara River, Piru Creek, Sespe Creek, and San Francisquito Creek (Swift *et al.* 1993; Stephenson and Calcarone 1999; NEA 2004; NatureServe 2007). This species is known to hybridize with another introduced species (*C. fumeiventris*) in lower reaches of the Santa Clara River (Buth and Crabtree 1982). The Santa Clara River population is one of the largest (Moyle *et al.* 1995). Santa Ana suckers seem to have generalized stream habitat requirements, but they do not tolerate highly polluted or modified streams (Moyle *et al.* 1995; Baskin and Haglund 1999).

The Santa Ana sucker is reproductively mature the summer of its first year. The fish is short lived and usually survives two breeding seasons (Baskin and Haglund 1999). The Santa Ana sucker has a protracted spawning period that begins in March and can last through July (NatureServe 2007; Baskin and Haglund 1999). The Santa Ana sucker is known for its high fecundity. A female can produce between 4,000 and 16,000 eggs (NEA 2004; NatureServe 2007), which are spawned over gravel substrates. Due to its high fecundity, this species can quickly repopulate a stream after severe flooding and it appears to be reproductively adapted for rapid population recovery (NEA 2004; NatureServe 2007).

Survey Results

Santa Ana sucker has been documented within the Specific Plan area throughout the Santa Clara River. Most recently, ENTRIX (2009) found that the Santa Ana sucker was common within the

Specific Plan area of the RMDP. Surveys from Salt Creek Canyon upstream to The Old Road Bridge along the Santa Clara River, for example, collected approximately 100 Santa Ana suckers (ENTRIX 2009). Surveys conducted in 2000 found this species within 500 meters (1,640 feet) upstream and downstream of the I-5 Bridge over the Santa Clara River (Impact Sciences 2003A, 2003B; Haglund and Baskin 2000). This species is not expected to occur in tributaries to the Santa Clara River due to lack of hydrology and/or impassable barriers.

Other survey results include:

- In 1976, Bell recorded the occurrence of this species from I-5 downstream throughout the area of surface flow, but none from San Francisquito Creek downstream of Scott Road (SMEA 1995);
- In 1987 and 1989 respectively, Soltz and Haglund did not locate Santa Ana suckers from McBean Parkway downstream to I-5, from San Francisquito Creek downstream of Scott Road, or specimens between I-5 and Castaic Creek (SMEA 1995A);
- SMEA (1995A) did not find Santa Ana suckers located between The Old Road Bridge and the mouth of Castaic Creek, but did locate them between The Old Road Bridge and Bouquet Canyon Road Bridge and in San Francisquito Creek;
- No Santa Ana suckers were found along the Santa Clara River within the Castaic Junction Project Area by Aquatic Consulting Services, Inc. (2002A);
- No Santa Ana suckers were found along the Santa Clara River west of Commerce Center Bridge to the Ventura County Line, California by Aquatic Consulting Services, Inc. (2002B);
- No Santa Ana suckers were found along the Santa Clara River from the Ventura County Line to Las Brisas Bridge, Ventura County, California by Aquatic Consulting Services, Inc. (2002C);
- One location of Santa Ana suckers was found along the Santa Clara River from the Commerce Center Bridge Project Area by Aquatic Consulting Services, Inc. (2002D);
- Santa Ana suckers were identified at only one location, sample station 24, during Impact Sciences' (2002) fish survey;
- No Santa Ana suckers were found in Castaic Mesa, Castaic Creek by Impact Sciences (2003A);
- Two Santa Ana suckers were found in the Natural River Management Plan Area by Impact Sciences (2003B); and
- Santa Ana suckers were found within both reaches of Newhall Ranch by Impact Sciences (2003C).

This species is known to be generally common within perennial reaches of the Santa Clara River in Ventura and Los Angeles Counties. Within the Project area, Santa Ana suckers use only perennial aquatic habitat in the Santa Clara River, which comprises a small portion of the wetland/riparian habitat in the River and has high temporal variability; therefore, suitable aquatic habitat was not quantified for the purpose of the impact analysis in this EIS/EIR.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the proposed RMDP could result in permanent physical changes to the Santa Clara River corridor and surrounding watershed that could affect suitable Santa Ana sucker habitat, including hydrology and fluvial processes. Implementation of the SCP would not directly affect this species.

Habitat variables evaluated by ENTRIX (2009) included potential changes in floodplain width, backwater refuge habitat area (flood condition aquatic refugia), and water velocity during various theoretical flood frequency events. ENTRIX (2009) conducted a study of Project-related hydrologic changes in the Santa Clara River and tributaries and their potential effects on special-status fish species, using the unarmored threespine stickleback as an indicator species because of its susceptibility to higher velocity conditions. Parameters evaluated included potential changes in floodplain width, backwater refuge habitat (zero to two fps flow) area, and water velocity, and changes were evaluated during various theoretical flood frequency events including 20- and 100-year occurrences (**Figures 4.5-61a** and **4.5-61b**). The following summarizes the results of this analysis.

Implementation of the RMDP within the Project reach of the Santa Clara River would include 32,334 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch); the

construction of bridges at Potrero Canyon, Long Canyon and Commerce Center Drive; and a Newhall Ranch Water Reclamation Plant (WRP) outfall in the Santa Clara River (**Figures 4.5-33-A1** through **4.5-33-D2**). The placement of bridge piers would be located within the Santa Clara River floodplain. This floodplain ranges in width from 980 to 1,550 feet at the bridge crossings and bridge footings would have the potential to occur in flowing portions of the River depending on stream hydrology. For example, the Potrero Canyon Bridge includes approximately 15 piers within the floodplain. During any given storm event, the number of piers subject to inundation may range from a single pier, to all of the piers. However during summer low flows, the maximum number of piers to likely be in contact with the wetted channel would be two piers per bridge crossing. This would result in the direct loss of habitat occupied by Santa Ana sucker. While the placement of bridge footings would result in the loss of River channel, the large width and hydrology of the River would maintain the formation of natural channels to support this species.

The primary effect of construction within the River channel is the alteration of natural stream hydrology and the quantity of stickleback habitat available. The ENTRIX report (2009) analyzed the hydrological effects of the Project on the Santa Clara River for impacts to potential special-status fish species habitat. Based on an evaluation of velocity tolerance studies of stickleback fishes, ENTRIX inferred that unarmored threespine stickleback in the Santa Clara River require flood refugia velocities of two fps or less in natural river floodplain in order to avoid being washed downstream during flood events (ENTRIX, 2009). Santa Ana sucker may be more tolerant of higher flow velocity conditions, however, this analysis uses the more conservative assumptions applied to unarmored threespine stickleback. Therefore, consistent with this approach, any areas maintaining velocities less than or equal to two fps would provide refuge for these species during storm events. Under existing conditions (dry and wet season conditions), most of the wetted channel of the Santa Clara River supports flows greater than two fps

At the five- and 10-year flood events, frequency hydraulic modeling shows that there would be an increase in available area with less than two fps velocity of 1.3 acres and 5.5 acres, respectively, for special-status fish species. During the 20-, 50-, and 100-year events, there is a decrease in area with less than two fps velocity at 12.5 acres, 11.1 acres, and 8.9 acres, respectively. This decrease is not expected to be significant, as the area lost during these flood events is in terraced agricultural land that is not suitable floodplain refugia habitat for the Santa Ana sucker and other special-status fish species. Suitable floodplain refugia requires microhabitat elements, such as vegetative cover, substrate and stream topography (ENTRIX 2009). Agricultural land is not considered as refuge as it presents a greater threat to fish stranding during high flood events. The ENTRIX report further indicates that the alteration of the stream hydrology would not significantly impact Santa Ana sucker and other special-status fish access to flood plain refugia during flood events, since the general morphology of the Santa Clara River, adjacent rearing

habitat, and high-flow floodplain refugia would not be substantially altered. This is illustrated on **Figures 4.5-61a** and **4.5-61b,** which indicate stream flow areas with less than two fps during the 20 and 100-year flood events, respectively (see entire set of graphics in ENTRIX 2009 report, Appendix 4.5).

Implementation of the RMDP in the Project reach of the Santa Clara River would include buried bank stabilization along the upland-riparian interface along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch), the construction of bridges at Potrero Canyon, Long Canyon, and Commerce Center Drive, and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-33-A1** through **4.5-33-D2**). ENTRIX (2009) evaluated the long-term effects of these facilities on special-status fish species habitat and concluded that no significant effects to fish habitat would occur because the general morphology of the Santa Clara River, adjacent rearing habitat, and high-flow riparian refugia would not be substantially altered.

There also would be no direct impacts to Santa Ana sucker habitat resulting from modifications to tributaries to the Santa Clara River, due to the absence of fish in general, including special-status fish species. Most of the tributaries do not support perennial flows, and none of the tributaries have surface water connectivity with the Santa Clara River, except for Middle and Potrero canyons, which although they contain perennial flow, they have substantial blockages (bedrock headcuts or cascades) that are impassable to fish (ENTRIX 2009).

Although no substantial permanent impacts to Santa Ana sucker habitat would occur through implementation of the RMDP, the Project would temporarily affect habitat when construction occurs directly in aquatic habitat, such as the active stream channel. Bridge construction, in particular, could directly affect aquatic habitat occupied by Santa Ana sucker and other special-status fish through direct impacts to the flowing stream, stream diversion, and dewatering when construction is occurring within the River corridor. Direct impacts from temporary construction would be significant absent mitigation primarily due to permanent and temporary disturbance to aquatic habitat from construction of RMDP facilities within the Santa Clara River.

With implementation of the RMDP, direct temporary impacts could substantially affect sucker habitat; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct temporary impacts (Loss of Habitat) would be significant absent mitigation. Implementation of the RMDP would not result in the significant alteration to

stream hydrology or limit access to refugia during storm events and therefore direct permanent impacts would be adverse but not significant.

Indirect Permanent Impacts

Because the distribution of this species within the Project area is limited to aquatic habitats within the Santa Clara River, construction activities associated with build-out of the Specific Plan, VCC, and Entrada planning areas do not have potential to harm or eliminate occupied Santa Ana sucker habitat because all activities would be outside the River corridor. Project build-out would not have a substantial adverse effect on sucker habitat; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would not be significant because no impacts are expected to occur as a result of Specific Plan build-out and development outside of the River and aquatic habitat.

Combined Direct and Indirect Permanent Impacts

Only RMDP-related impacts would result in permanent impacts to suitable habitat for this species, and these impacts are considered to be adverse but not significant. Neither implementation of the RMDP nor build-out of the Specific Plan, VCC, and Entrada planning areas would result in permanent impacts that could have a substantial adverse effect on the species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Therefore, the combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The presence of Santa Ana sucker and other special-status fish species is quite variable (ranging from rare or absent in certain reaches of the River, to locally abundant in any given year) in the Project reach, and the species is assumed to be present for this analysis. Implementation of the RMDP, including construction of buried bank structures and bridges, could adversely affect individual Santa Ana suckers during construction work within the River. The potential for impacts from installation of these structures is

increased as the construction is planned for marginal areas of the riparian zone and because this species is known to use lateral backwater refuge habitat and aquatic environments of emergent, fringe vegetation. Direct impacts to the species may occur during construction of RMDP components during the following anticipated activities: stream diversion and/or species exclusion; unauthorized entry of construction equipment into ponded or flowing water; placement of fill in occupied waters; construction dewatering activities; discharge of pollutants, including silt, sediment, fresh concrete, trash/debris, and petroleum or other deleterious materials or pollutants, and/or; unauthorized personnel entry into occupied waters.

These activities could result in the following impacts: inadvertently directing fish to unsuitable habitats, blocking fish passage, stranding of fish in unsuitable habitat, or directing fish into unsuitable flow regimes; causing water quality conditions unsuitable for the fish survival; direct mechanical crushing or entombment of fish; unauthorized collection of individuals; and physical disturbance of river edge habitats

Implementation of the SCP would not directly impact this species within the Project reach or downstream. Implementation of the RMDP could have direct substantial adverse effects on the Santa Ana sucker, interfere with the movement of the species, and substantially reduce the number of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

Because the distribution of this species within the Project area is limited to aquatic habitats within the Santa Clara River corridor, build-out of the Specific Plan, VCC, and Entrada planning areas would not result in the impacts to Santa Ana sucker individuals. Project build-out would not have a substantial adverse effect on the Santa Ana sucker; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would not be significant because physical onsite impacts are not expected to occur due to Specific Plan build-out.

Secondary Impacts

Implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas could result in both short-term secondary effects during construction and long-term effects due to use of RMDP facilities and build-out of the Project area. These impacts could affect the

sucker along the Santa Clara River corridor within the Project area and in downstream populations. Implementation of the SCP would not result in secondary impacts to this species.

Short-term construction-related effects include hydrologic and water quality effects. These short-term impacts could affect Santa Ana sucker and other special-status fish species in the Santa Clara River within the Project area and in downstream populations (same as previously described for direct impacts to individuals).

Long-term effects associated with operation of RMDP facilities and build-out of the Project area due to potential physical changes in the River and increased discharges could include alterations in base flows, timing and duration of flood flows, biochemical changes, condition and composition of the substrate, aquatic and riparian vegetation (including exotic species), and water temperatures as well as increased pollutants from irrigation runoff and increased runoff from roadways. Additional secondary impacts associated with increased human presence include incidental litter and trash from recreation activity; impacts such as fecal material from pet, stray, and feral cats and dogs entering the aquatic system; and increased predation by exotic predators, such as bullfrogs and non-native fish.

These short-term and long-term secondary impacts could have a substantial adverse effect on the Santa Ana sucker; substantially interfere with the movement of the species; reduce the species' habitat; or restrict the range of the species (significance criteria 1, 4, and 7). Secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Overall, implementation of the RMDP under Alternatives 3 through 7 would have similar types of impacts to Santa Ana sucker habitat in the Santa Clara River corridor to those described above for Alternative 2. Although no substantial permanent impacts to Santa Ana sucker habitat would occur through implementation of the RMDP under Alternatives 3 through 7, the Project has the potential to temporarily affect habitat when construction occurs directly in aquatic habitat, such as the active stream channel. Buried bank stabilization would be installed at the riparian–upland interface under all the alternatives, although under Alternative 7 it would be outside the 100-year floodplain and thus would have a substantially reduced risk of temporary impacts to Santa Ana sucker habitat. Bridge construction, in particular, would directly affect aquatic habitat occupied by Santa Ana sucker through direct impacts to the flowing stream, stream diversion, and dewatering when construction is occurring within the River corridor as previously described for Alternative 2. Three bridges would be constructed under Alternative 2.

Bridges would also be constructed under Alternatives 3 through 7: two under Alternatives 3, 4, and 6; three under Alternative 5; and one under Alternative 7 (see **Table 4.5-23**, Key Components of Alternatives, for details). Thus, Alternatives 3, 4, 6, and 7 would have relatively reduced temporary impacts from bridge construction compared to Alternatives 2 and 5.

As described previously for Alternative 2, direct impacts from construction would be significant absent mitigation primarily due to permanent and temporary disturbance to aquatic habitat from construction of RMDP facilities within the Santa Clara River.

ENTRIX (2009) conducted a study of Project-related hydrologic changes in the Santa Clara River and tributaries and their potential effects on special status fish species (using stickleback as an indicator species due to its vulnerability to high flow velocities) for Alternatives 3, 4, 5, 6, and 7. Parameters evaluated included potential changes in floodplain width, floodplain refugia (zero to two fps flow) area, and water velocity, and changes were evaluated during various theoretical flood frequency events including five-, 10-, 20-, 50-, and 100-year occurrences. **Figures 4.5-62a** through **4.5-65b** show the range of floodplain effects for the 20- and 100-year flood events. The following summarizes the results of this analysis.

Alternatives 3 and 4

Implementation of the RMDP within the Project reach of the Santa Clara River would include 31,857 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of river (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch; the construction of bridges at Long Canyon and Commerce Center Drive; and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-34-A1** through **4.5-35-D2**). The ENTRIX report (2009) indicates that there would be the following impacts to potential Santa Ana sucker floodplain refugia. At the five- and 10-year flood events, frequency hydraulic modeling shows that there would be an increase in available refugia of 2.1 and 8.9 acres, respectively, for suckers with less than two fps flow. During the 20-, 50-, and 100-year events, there is a decrease in refugia with less than two fps flow at 7.3 acres, 5.3 acres and 5.7 acres, respectively. The decrease in refugia is not expected to be significant as the area lost during these flood events is in terraced agricultural land that is not suitable floodplain refugia for the Santa Ana sucker and other special-status fish species (ENTRIX 2009). The ENTRIX report (2009) further indicates that accessible floodplain refugia, would not be substantially altered, and therefore, any impact would be less than significant.

Alternatives 3 and 4 construct one less bridge (Potrero Canyon Road) than Alternative 2, however the direct impacts from construction would be similar to Alternative 2, and therefore would be significant absent mitigation.

Alternative 5

Implementation of the RMDP between Salt Creek and Middle Canyon would include 32,334 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch); the construction of bridges at Potrero Canyon, Long Canyon and Commerce Center Drive; and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-36-A1** through **4.5-36-D2**). The ENTRIX report (2009) indicates that there would be the following impacts to potential sucker habitat (zero to two fps flow). At the five- and 10-year flood events, frequency hydraulic modeling shows that there would be an increase in available habitat of 1.3 and 5.5 acres, respectively, for the Santa Ana sucker with less than two fps flow. During the 20-, 50-, and 100-year events, there is a decrease in habitat with less than two fps flow at 12.5 acres, 11.1 acres and 8.9 acres, respectively. The decrease in habitat is not expected to be significant as the habitat lost during these flood events is in terraced agricultural land that is not suitable habitat for Santa Ana sucker and other special-status fish (ENTRIX 2009). The ENTRIX report (2009) further indicates that accessible floodplain refugia, would not be substantially altered, and therefore, any impact would be less than significant.

Alternatives 5 bridge construction (three bridges) would be similar to Alternative 2 and the direct impacts from construction would be the same with regard to Santa Ana sucker, and therefore would be significant absent mitigation.

Alternative 6

Implementation of the RMDP between Salt Creek and Middle Canyon would include 29,293 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch); the construction of bridges at Potrero Canyon and Long Canyon; and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-37-A1** through **4.5-37-D2**). The ENTRIX report (2009) indicates that there would be the following impacts to potential sucker habitat (zero to two fps flow). At the five- and 10-year flood events, frequency hydraulic modeling shows that there would be an increase in available habitat of 1.3 and 10.7 acres, respectively, for the Santa Ana sucker with less than two fps flow. During the 20-, 50-, and 100-year events there is a decrease in habitat with less than two fps flow at 7, 4.6, and 2.6 acres, respectively. The decrease in habitat is not expected to be significant as

the habitat lost during these flood events is in terraced agricultural land that is not suitable habitat for the Santa Ana sucker and other special-status fish (ENTRIX 2009). The ENTRIX report (2009) further indicates that accessible floodplain refugia, would not be substantially altered, and therefore, any impact would be less than significant.

Alternative 6 constructs one less bridge (Commerce Center Drive) than Alternative 2, however the direct impacts from construction would be similar to Alternative 2, and therefore would be significant absent mitigation.

Alternative 7

Implementation of the RMDP between Salt Creek and Middle Canyon would include the construction of one bridge at Long Canyon (with spans removed from the 100-year floodplain); the grading and conversion of 13,956 linear feet of ephemeral drainages to buried storm drains; and construction of a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-38-A1** through **4.5-38-D2**). Bank protection would be removed from the 100-year floodplain and built in upland areas. All jurisdictional streams and wetlands in the Santa Clara River, Potrero Canyon, Chiquito Canyon, and San Martinez Grande Canyon drainages would be preserved or avoided except where bridges are built to facilitate road crossings. The ENTRIX report (2009) indicates that there would be the following impacts to potential Santa Ana sucker and other special-status fish habitat. The model predicts a projected increase of available refuge habitat (less flow during the five-, 10-, 20-, 50-, and 100-year flood events). The amount of available habitat would be 2.0, 13.3, 22.5, 41.7, and 25.2 acres, respectively. The ENTRIX report (2009) further indicates that there would be no impacts from the installation of these Project components, since the general morphology of the Santa Clara River, adjacent rearing habitat, and high-flow riparian refugia would not be substantially altered.

Alternatives 7 constructs two less bridges (Potrero Canyon Road and Commerce Center Drive) than Alternative 2, however the direct impacts from construction would be similar to Alternative 2, and therefore would be significant absent mitigation.

While implementation of the RMDP under Alternatives 3 through 7 would not have a substantial permanent adverse effect, temporary impacts could substantially affect Santa Ana sucker; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species; or substantially reduce the number or restrict the range of the species. Direct permanent impacts (Loss of Habitat) under Alternatives 3 through 7 would not be significant because no impacts would occur but direct temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

The Santa Ana sucker within the Project area is limited to aquatic habitats within the Santa Clara River. As with Alternative 2, construction activities associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas do not have the potential to harm or eliminate occupied sucker habitat because all activities would be outside the River corridor. Project build-out would not have a substantial adverse effect on the Santa Ana sucker; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Indirect permanent impacts (Loss of Habitat) under Alternatives 3 through 7 would not be significant because no impacts are expected to occur.

Combined Direct and Indirect Permanent Impacts

For Alternatives 3 through 7, only RMDP-related impacts would result in permanent impacts to suitable habitat for this species, and these impacts are considered to be adverse but not significant. Neither implementation of the RMDP nor build-out of the Specific Plan, VCC, and Entrada planning areas would result in permanent impacts that could have a substantial adverse effect on the species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Therefore, the combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Similar to Alternative 2, implementation of the RMDP would require the construction of bridges and bank stabilization within the River corridor, although the number of bridges varies among the alternatives and bank stabilization under Alternative 7 would be constructed outside the 100-year floodplain, resulting in reduced risk of temporary impacts to Santa Ana sucker habitat under this alternative. Implementation of the RMDP under Alternatives 3 through 7 may result in impacts to sucker individuals if construction occurs during River flows adequate to support these species in work zones in occupied habitat or if construction causes interruptions in water flows. Implementation of the SCP would not directly impact this species.

Implementation of the RMDP under Alternatives 3 through 7 could have a direct substantial adverse effect on the Santa Ana sucker; interfere with the movement of the species; or

substantially reduce the number of the species. Impacts to individuals under Alternatives 3 through 7 would be significant, absent mitigation.

Implementation of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7, would not result in indirect impacts to individuals.

Secondary Impacts

The potential short-term and long-term secondary impacts to the Santa Ana sucker and its habitat under Alternatives 3 through 7 would be similar to those described above for Alternative 2.

Short-term construction-related effects include hydrologic and water quality effects, as described above, that could affect Santa Ana sucker in the Santa Clara River within the Project area and in downstream populations.

Long-term effects associated with operation of RMDP facilities and build-out of the Project area could occur due to potential physical changes in the River and increased discharges and could affect base flows and flood flows and induce biochemical, substrate, temperature, and vegetative changes. Increased human activity could increase litter and trash, and fecal material from pet, stray, and feral cats and dogs may enter the aquatic system. In addition, increased predation by exotic predators, such as bullfrogs and non-native fish, may occur.

These short-term and long-term secondary impacts could have a substantial adverse effect on the Santa Ana sucker; substantially interfere with the movement of the species; reduce the species' habitat; or restrict the range of the species. Secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to Santa Ana sucker: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

The mitigation required by the Newhall Ranch Specific Plan Program EIR and the mitigation measures recommended by this EIS/EIR combined will prevent impacts to Santa Ana sucker individuals. To prevent impacts to Santa Ana sucker, protective measures will be implemented, such as pre-construction surveys, biological monitoring, exclusion of the species from construction areas using temporary diversion channels, and protection of habitat through facilities design guidelines and BMPs, which will prevent impacts to Santa Ana sucker individuals.

Impacts to individuals, including adults and fry (juvenile fish), could occur during construction as a result of heavy equipment operation for access and grading, or during diversion of Santa

Clara River flows. The Project incorporates numerous elements to avoid and minimize potential impacts to individuals, such as injury or mortality, which would come as a result of direct contact with construction equipment or as an outcome of modification of River habitat, such as flow diversion activities. These measures include pre-construction surveys for any construction activity within 300 feet of River habitat to assure that Santa Ana suckers are avoided or excluded, particularly during the sensitive periods such as spawning or when fry are present. These measures also specify the methods to be used for excluded Santa Ana sucker, as well as how temporary diversion channels will be constructed to assure that adequate rearing habitat is present for suckers during construction. These measures also employ provisions for constructing permanent and temporary stream crossings in the Santa Clara River in a manner that will allow for unimpeded movement upstream and downstream. Numerous water quality measures, such as construction stormwater BMPs (*e.g.*, silt fencing, erosion control materials, sediment basins) and the installation of water quality treatment facilities are also included to minimize impacts from pollutants related to storm runoff during storm events.

The mitigation required by the Newhall Ranch Specific Plan Program EIR and the mitigation measures recommended by this EIS/EIR will reduce temporary impacts to Santa Ana sucker habitat through facilities design requirements, which will avoid and minimize impacts to habitat, and conformance with state and federal permits to protect water quality.

The vast majority of sucker habitat in Project reach of the Santa Clara River will be preserved under all of the alternatives. Santa Ana sucker habitat will be impacted through the construction of RMDP facilities, by bridge pier or column footings in particular. It is estimated that one to two pier or column footings would affect Santa Ana sucker habitat at each of the three Santa Clara River bridge crossings (Commerce Center Drive, Long Canyon Road, Potrero Canyon Road) depending on the location of the active channel. The wetted channel of the River is typically between 30 and 50 feet wide, while the River floodplain ranges between 1,000 and 2,000 feet wide. The spacing between piers and columns will be 100 feet, thus approximately one to two pier or column footings per bridge could be placed in the flow of the River and affect Santa Ana sucker habitat. Because River flow will deflect off of these structures and will become realigned, Santa Ana sucker habitat will become re-established after bridge construction is completed. Temporary diversion for the construction of piers and columns will include the establishment of additional habitat downstream to allow for necessary Santa Ana sucker spawning, rearing, and/or oversummering. Bank stabilization features (buried soil cement, rock riprap, or gunite lining) will impact sucker habitat through floodplain alterations caused by changes to flood flows through the Project area. Under severe flood conditions, Santa Ana sucker will seek slow-moving floodplain areas as refugia from high velocity conditions. Although bank stabilization features will sometimes constrict flows through the Project reach, the amount of available flood refugia present during these events is adequate to protect Santa Ana sucker from being flushed out of the Project area.

The mitigation required by the Newhall Ranch Specific Plan Program EIR and the mitigation measures recommended by this EIS/EIR combined will minimize secondary impacts from affecting the Santa Ana sucker and its habitat. Impacts such as increased chemical pollutants, sedimentation, and increased human activity will be mitigated by measures such as the protection and management of the River Corridor SMA, creation of buffer areas between the River Corridor SMA and development, water quality requirements, and restrictions on public access. In addition, the technical studies conducted by ENTRIX (2009) concluded that suitable sucker habitat would not be significantly affected by the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas under any of the alternatives. Further, the Flood Technical Report (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area over the long term as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County. The PACE study determined that the River would still retain sufficient width to allow natural fluvial processes to continue; as a result, the mosaic of habitats in the River that support various special-status fish species would be maintained and the populations of the species within and immediately adjacent to the River corridor would not be substantially affected.

All mitigation measures listed below are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-58 IMPACTS TO INDIVIDUALS – SANTA ANA SUCKER

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the impacts to special-status fish species (primarily unarmored threespine stickleback) through facilities design requirements, pre-development surveys, consultation with USFWS, and conformance with state and federal permits related to wetlands and water quality.

SP-4.6-44 requires that drainages with flows greater than 2,000 cfs have soft bottoms. Bank protection will be of ungrouted rock or buried bank stabilization, except at bridge crossings and other areas where public health and safety considerations require concrete or other stabilization.

SP-4.6-53 requires updated surveys for special-status plants, animals, and vegetation communities as determined necessary by the County whenever construction maps are submitted. Based on the results of the surveys, additional conditions and mitigation measures may be required.

SP-4.6-54 requires that prior to development within or disturbance to occupied threespine stickleback habitat, a formal consultation with the USFWS shall occur.

SP-4.6-55 obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats.

SP-4.6-57 requires that, where bridge construction is proposed and water flow will be temporarily diverted, blocking nets and seines be used to control and remove fish from the area of activity. All fish captured during this operation will be stored in tubs and returned unharmed to the river after construction activities are complete.

SP-4.6-58 requires that in order to limit impacts to water quality, the Specific Plan shall conform to all provisions of required NPDES permits and water quality permits required by the RWQCB.

SP-4.6-59 requires consultations with the County of Los Angeles and CDFG before surveys, after surveys, at subdivision map approval, and prior to development or disturbance to habitats occupied by special-status species. Based on the results the consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that will mitigate the impacts to Santa Ana sucker (and other special-status fish species) individuals. These mitigation measures include pre-development focused surveys for special-status fish, coordination with CDFG, channel diversion requirements, biological monitoring, avoidance of flowing water, design guidelines for bridges and culverts, and other BMPs. Additional mitigation measures are specified in other sections of the EIS/EIR that address water quality, riparian vegetation scour, and sedimentation. Specifically, Mitigation Measure WQ-1 in **Section 4.4,** Water Quality, and Mitigation Measures GRR-1 through GRR-7 in **Section 4.2**, Geomorphology and Riparian Resources, provide additional measures to reduce the impacts to Santa Ana sucker and other special-status fish individuals. These mitigation measures include implementation of Project BMPs (including runoff control, conservation of natural areas, minimization of stormwater runoff pollutants of concern, prevention of slope and channel erosion, and education and signage to discourage illegal dumping to the storm drains), and other measures to minimize impacts to riparian resources and geomorphology (peak storm flow control, bridge span and clearance guidelines, maintenance minimization, channel design to minimize erosion potential, sediment and debris control, reintroduction of sediments for beach replenishment, and a Geomorphology Monitoring and Management Plan).

BIO-43 provides for the biological surveying of aquatic habitats within 300 feet of construction sites and access roads, for the presence of special-status fishes at least 10 days prior to

commencing construction unless fish spawn has occurred or juvenile fishes are present, then construction activities would be suspended.

BIO-44 requires that temporary crossings or access across the river be constructed outside of the winter season and not during spring periods when fish spawning is occurring and be consistent with a Stream Crossing and Diversion Plan that outlines the following: the timing and methods for pre-construction fish surveys; a detailed description of the diversion methods; fish exclusion techniques; methods to maintain fish passage; channel habitat enhancement design; fish stranding surveys; and the techniques for the removal of temporary crossings prior to winter storm flows.

BIO-45 defines the timing and design of stream diversion bypass channels and dewatering activities and related restrictions to ensure proper construction, operation, and abandonment diversion or dewatering will occur.

BIO-46 requires that a qualified biologist will inspect diversion or dewatering activities for stranded fish or other aquatic organisms.

BIO-47 provides for the construction of additional slow moving water habitats upstream and downstream of any river crossing or bridge construction area to provide refuge for special status fishes during construction.

BIO-48 requires the design and installation of bridges, culverts, or other structures to not impair the movement of fish and aquatic life and provisions for a low flow channel where velocities are less than 2 foot per second to allow fish passage.

BIO-49 requires that pollutants from construction activities not be allowed to enter a flowing stream or be placed in locations that may be subjected to storm flows.

BIO-70 provides for construction plans that will include erosion control plans and dust control plans, specifications, and details, along with an overall Project SWPPP. Together, these documents shall include measures to ensure that impacts (*e.g.*, the introduction of chemical pollutants, exposure to fugitive dust, contact with polluted runoff, and changes in hydrology) to vegetation communities and special-status plant species are avoided or minimized during construction.

BIO-71 requires that development areas have dust control measures implemented and maintained to prevent dust from impacting vegetation communities and aquatic wildlife species. Dust control plans shall be prepared prior to initiation of construction activities and shall comply with SCAQMD Rule 403 (SCAQMD 2005).

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to Santa Ana sucker individuals would be less than significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-59 LOSS OF HABITAT – SANTA ANA SUCKER

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will mitigate the temporary impacts to habitat for special-status fish (primarily unarmored threespine stickleback) through RMDP facilities design requirements, consultation with the USFWS, and conformance with federal and state permits to protect water quality.

SP-4.6-44, SP-4.6-54, SP-4.6-55, and SP-4.6-58, as described above, will be implemented to mitigate impacts related to unarmored threespine stickleback through facilities design requirements, consultation with USFWS, and conformance with state and federal permits related to wetlands and water quality.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the temporary impacts to habitat for the Santa Ana sucker. These measures refer to stream diversions, BMPs, and facilities design. Additional mitigation measures are specified in other sections of the EIS/EIR that address water quality, riparian vegetation scour, and sedimentation as described above (Mitigation Measures WQ-1 and GRR-1 through GRR-7). These mitigation measures include implementation of Project BMPs and other measures to minimize impacts to riparian resources and geomorphology.

BIO-45, BIO-47 through BIO-49, BIO-70, and BIO-71, as described above, will be implemented to mitigate impacts from chemical pollution, increased sedimentation, increased turbidity, changes in flow, changes in water temperature, and dust.

Finding of Significance for Loss of Habitat After Mitigation

Permanent impacts (Loss of Habitat) would not be significant because impacts will be predominantly outside of the stream channel and be limited with respect to aquatic habitat. After mitigation, temporary impacts to Santa Ana sucker habitat would be less than significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-60 SECONDARY IMPACTS – SANTA ANA SUCKER

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures to mitigate for both short-term secondary impacts to the Santa Ana sucker, such as altered hydrology and water quality, and long-term secondary impacts, such as potential physical changes in the River; altered base and flood flows; biochemical, substrate, and temperature alterations; vegetative changes, such as invasive plant species; increased human activity; and impacts from pet, stray, and feral cats and dogs.

Most importantly, the River Corridor SMA will be protected and managed to preserve aquatic and riparian resources, including the Santa Ana sucker and its habitat, through a series of mitigation measures. SP-4.6-1 through SP-4.6-16 and SP-4.6-63 address habitat restoration in the River Corridor SMA and provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats, including aquatic habitats used by the unarmored threespine stickleback.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. These measures will provide a buffer between human activity and aquatic habitats supporting the unarmored threespine stickleback. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-20 requires that all grading perimeters within the River Corridor SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian resources (including aquatic habitats) outside the grading area in the River Corridor SMA.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA.

SP-4.6-27 prohibits grazing in the River Corridor SMA except as a long-term resource management activity. Controls on grazing will help protect water quality in aquatic habitats used by the unarmored threespine stickleback.

In addition, SP-4.6-44 (drainage design), SP-4.6-55 (state and federal wetlands permits), and SP-4.6-58 (NPDES/RWQCB permits), as described above, will be implemented to protect natural flows and water quality, and SP-4.6-54 will require formal consultation with USFWS prior to impacts.

Measures Recommended by EIS/EIR

This EIS/EIR recommends additional mitigation measures to mitigate for secondary impacts to Santa Ana sucker, including short-term impacts to hydrology and water quality and long-term impacts, such as effects on movement; increased human activity; pet, stray, and feral cats and dogs; habitat degradation by exotic plants; and increased predation by exotic predators. Additional mitigation measures are specified in other sections of the EIS/EIR that address water quality, riparian vegetation scour, and sedimentation as described above (Mitigation Measures WQ-1 and GRR-1 through GRR-7). These mitigation measures include implementation of Project BMPs and other measures to minimize impacts to riparian resources and geomorphology.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. Although these measures primarily refer to riparian habitats, the riparian/aquatic communities in the River Corridor SMA will be addressed comprehensively in a manner that protects and enhances habitat for the unarmored threespine stickleback and other special-status fish, including management of invasive species, such as giant reed.

BIO-45, BIO-47 through BIO-49, BIO-70, and BIO-71, as described above, will be implemented to mitigate impacts from chemical pollution, increased sedimentation, increased turbidity, changes in flow, changes in water temperature, and dust.

BIO-63 will be implemented to mitigate impacts by pet, stray, and feral cats and dogs, such as fecal material entering the aquatic system. This measure requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas

within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-80 will mitigate for exotic predators. This measure states that the Project applicant shall retain a qualified biologist to conduct monitoring for bullfrog, African clawed frog, and crayfish every five years for 50 years to determine if control is necessary. If control is determined necessary, an eradication plan shall be developed and implemented.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to the Santa Ana sucker and its habitat would not be significant for Alternatives 2, 3, 4, 5, 6, and 7.

LOGGERHEAD SHRIKE (BCC, CSC)

Life History

The loggerhead shrike (*Lanius ludovicianus*) is widespread throughout the United States, Mexico, and portions of Canada. It is a year-long resident species in most of the United States, including from California east to Virginia, south to Florida, and in Mexico. It also summers and breeds in portions of southeast Alberta, southern Saskatchewan, southwest Manitoba, and southern Ontario in Canada; and in portions of Oregon and Washington east to Wisconsin, and portions of Ohio, Kentucky, and Indiana. Northerly breeding populations migrate to warmer locations during winter, including to the Atlantic and south Pacific coasts in Mexico (Small 1994; Yosef 1996). The loggerhead shrike is a resident species in foothills and lowlands throughout California, and remains in the southern portion of the state year round.

Preferred habitats for the loggerhead shrike are open areas that include scattered shrubs, trees, posts, fences, utility lines, or other structures that provide hunting perches with views of open ground, as well as nearby spiny vegetation or man-made structures (such as the top of chain-link fences or barbed wire) that provide a location to skewer prey items. Loggerhead shrikes occur most frequently in riparian areas along the woodland edge, grasslands with sufficient perch and butcher sites, scrublands, and open-canopied woodlands, although they can be quite common in agricultural and grazing areas, and can sometimes be found in mowed roadsides, cemeteries, and golf courses. Loggerhead shrikes occur only rarely in heavily urbanized areas. For nesting, the height of shrubs and presence of canopy cover are most important (Yosef 1996).

Loggerhead shrikes prey mainly on invertebrates and small to medium-sized reptiles, but will also take amphibians, fish, small birds and mammals, and carrion. In the west, their diet consists mostly of insects. They are opportunistic feeders and adjust their diet based on prey availability.

The loggerhead shrike's breeding territory is usually the same as its winter territory and it may defend territories year round (Yosef 1996). In Contra Costa and Kern counties in California, territories averaged 18.7 acres (Yosef 1996). Loggerhead shrikes are monogamous and individuals may remain paired during the winter in sedentary populations. In California, they lay four to eight eggs from March into May (Yosef 1996). Eggs hatch in 14 to 15 days and young are fledged after 18 to 19 days (Yosef 1996). The nest site location is chosen based more on the cover than the particular vegetation species. They are usually constructed in a dense shrub or tree well below the crown and are well concealed (Yosef 1996). The heights of the nests vary depending on the shrub or tree used for nesting, but the height of the nest increases as the breeding season progresses, probably due to weather conditions (Yosef 1996).

In addition to habitat loss, fragmentation, and degradation, other urban-related factors may be contributing to a decline in loggerhead shrike populations. Shrikes often prefer roadsides for foraging and sometimes nesting. The increase in roads and vehicular traffic since the 1940s has

been suggested to be a major factor in the population declines as a result of vehicle collisions (Yosef 1996). Additionally, predators are usually more abundant near roadsides, and loggerhead shrikes can be prey for domestic cats and urban-adapted mesopredators such as opossums and raccoons (Yosef 1996). Extensive areas of monoculture cultivation and associated heavy pesticide use also have contributed to the decline of loggerhead shrike populations (Bloom Biological 2007A). Adults and particularly juveniles are susceptible to ingestion of insecticides, such as dieldrin (banned in 1987), *via* invertebrate ingestion (Hall *et al.* 1997). Development-related increases in European starlings also may result in competition for resources, and red imported fire ants associated with increased water availability from development prey on nestlings (Yosef 1996). This impact by fire ants also suggests that nestlings may be vulnerable to Argentine ants.

Survey Results

The loggerhead shrike is a breeding resident on site (Bloom Biological 2007A, 2008). It has been observed to be fairly common within California sagebrush scrub and grasslands in the Specific Plan area (Guthrie 1993B, 1996A, 2000A, 2000B, 2002C, 2004A, 2004E, 2005B; Labinger *et al.* 1995; Lemons 2008; Bloom Biological 2007A, 2008) and has also been observed within the VCC planning area (Guthrie 1995A, 2004B), Salt Creek (Dudek and Associates 2006B), and the Entrada planning area (Guthrie 2000D, 2004G; Dudek and Associates 2006E). It was observed regularly in Potrero Canyon, Tapo Canyon, near Magic Mountain ranch gate, and Wolcott agricultural fields (Bloom Biological 2008). It was also observed nesting south of Potrero Mesa and west of the Ventura County line near an agriculture field adjacent to the Santa Clara River in 2007 (Bloom Biological 2007A), and it was thought to have nested within and adjacent to the Entrada planning area (southeast of Six Flags Magic Mountain Amusement Park) (Guthrie 2000D, 2004G).

Suitable nesting and foraging habitat on site includes alluvial scrub, arrow weed scrub, Mexican elderberry, herbaceous wetland, river wash, agriculture, big sagebrush scrub, chaparral (undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral), coastal scrub alliances and associations, California annual grassland, coyote brush scrub, *Eriodictyon* scrub, purple needlegrass, valley oak/grass, coast live oak woodland, valley oak woodland, and California walnut woodland vegetation communities. A total of 12,536 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use

practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 257 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 2.0% of these habitats on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats). A total of 133 acres would be temporarily impacted.

Because the loggerhead shrike is still a wide-ranging species and because the construction of RMDP facilities would be phased over a long period of time, thousands of acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. The permanent loss of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. These impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 4,292 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 34.2% of these habitats on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats).

A relatively large amount and percentage of suitable habitat on site for the loggerhead shrike would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. The removal of 34.2% of total nesting and foraging habitat on site would have the potential to have a substantial adverse effect *via* habitat modification; substantially reduce the habitat of the species on site or rangewide; and threaten to eliminate the species on site or rangewide (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 4,593 acres (36.3%). Because of the large amount and percentage of habitat loss, the combined direct and indirect impacts to suitable habitat would have a substantial adverse effect *via* habitat modification; substantially reduce the habitat of the species on site or rangewide; and threaten to eliminate the species on site or rangewide (significance criteria 1, 4, and 7). The combined permanent direct and indirect impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The loggerhead shrike is known to be a breeding resident in the Project area. Because these birds are highly mobile, it is unlikely that RMDP-related construction activities would result in injury or mortality of adult birds of this species. Construction/grading activities, such as vegetation clearing, occurring during the nesting season could result in destruction of nests and the resulting loss of eggs and/or young. In addition, construction activities could alter the loggerhead shrike's foraging behavior, potentially affecting provisioning of young, potentially reducing survivorship and reproductive success. Implementation of the SCP would not directly impact this species. Construction/grading activities such as vegetation clearing occurring during the nesting season could result in destruction of nests and the resulting loss of eggs and/or young or alteration of foraging behavior (significance criteria 1 and 4). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals, but over a much larger area. Construction and/or grading activities may occur during the nesting season and could result in impacts to eggs or young and alteration of foraging behavior (significance criteria 1 and 4). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Potential short-term secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, fugitive dust, nighttime lighting, and increased

human activity, which could modify essential behaviors, such as nesting, foraging, and care of young. These behaviors, in turn, could result in nest abandonment, lowered nest and egg production, and increased mortality of nestlings and juveniles.

Long-term secondary impacts could result from urbanization of lands within and adjacent to suitable nesting and foraging habitat in the Project site. Potential secondary effects include habitat fragmentation and reduced nest success due to nighttime lighting; noise disturbance; and harassment/disturbance by humans, especially if such disturbances occur during the nesting season; and predation by pet, stray, and feral cats and dogs as well as other mesopredators. The use of pesticides to control invertebrates and small mammals within and adjacent to open foraging areas could result in secondary poisoning and loss of prey for the species. An increase in traffic would likely result in increased incidence of vehicle collisions.

These short-term and long-term secondary effects would have a substantial adverse effect on the species; substantially reduce habitat quality on site or rangewide; and threaten to eliminate the species on site or rangewide (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts therefore would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the loggerhead shrike (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 233 acres (1.9%) of permanent loss and 171 acres of temporary loss;
- Alternative 4 – 225 acres (1.8%) of permanent loss and 172 acres of temporary loss;
- Alternative 5 – 267 acres (2.1%) of permanent loss and 167 acres of temporary loss;
- Alternative 6 – 252 acres (2.0%) of permanent loss and 172 acres of temporary loss; and
- Alternative 7 – 121 acres (1.0%) of permanent loss and 443 acres of temporary loss.

Compared to Alternative 2, which would result in 257 acres (2.0%) of permanent habitat loss and 133 acres of temporary impacts, the permanent loss of habitat under Alternatives

3, 5, and 6 would not be substantially different, Alternative 4 would be somewhat less, and Alternative 7 would be somewhat less. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be somewhat higher and Alternative 7 would be substantially higher. The large difference between Alternative 7 and the other alternatives for permanent and temporary loss of habitat is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and relatively more temporary impacts.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be less than or similar in magnitude compared to Alternative 2, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the loggerhead shrike (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 4,058 acres (32.4%) of permanent loss;
- Alternative 4 – 3,914 acres (31.1%) of permanent loss;
- Alternative 5 – 3,830 acres (30.6%) of permanent loss;
- Alternative 6 – 3,419 acres (27.3%) of permanent loss; and
- Alternative 7 – 2,908 acres (23.2%) of permanent loss.

Compared to Alternative 2, which would result in 4,292 acres (34.2%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different or would be somewhat less than Alternative 2, but still substantial, these impacts would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the loggerhead shrike:

- Alternative 3 – 4,291 acres (34.2%) of permanent loss;
- Alternative 4 – 4,140 acres (33.0%) of permanent loss;
- Alternative 5 – 4,097 acres (32.7%) of permanent loss;
- Alternative 6 – 3,671 acres (29.3%) of permanent loss; and
- Alternative 7 – 3,029 acres (24.2%) of permanent loss.

Compared to Alternative 2, which would result in 4,549 acres (36.3%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, as well as additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for the loggerhead shrike occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial and therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to loggerhead shrike individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual loggerhead shrikes occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term impacts include construction-related noise, ground vibration, fugitive dust, nighttime lighting, and increased human activity. These effects are more likely to occur during build-out of the Specific Plan, VCC, and Entrada planning areas than implementation of the RMDP and the SCP because of the much larger area of impact.

Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include habitat fragmentation, increased human activity, increased predation, secondary poisoning and loss of prey from pesticides, and increased incidence of vehicle collisions, as described above for Alternative 2.

These secondary impacts would permanently reduce the loggerhead shrike populations along the urban–open space edge and contribute to the reduction of the range and distribution of this species in the Project area. Short-term and long-term secondary impacts would be significant, absent mitigation, under Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to loggerhead shrike: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Nesting by loggerhead shrikes has been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, impacts to individuals could occur if active nests are disturbed during vegetation clearing and construction/grading activities, including destruction of nests and loss of eggs and/or fledglings. Construction activities may also cause abandonment of nests due to human activity and noise. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 500 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable habitat for the loggerhead shrike resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 3,029 acres (24.2%) under Alternative 7 to 4,549 acres (36.3%) under Alternative 2. This would be a substantial loss of suitable habitat for this species and will alter its use of the Project area for nesting and foraging. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable foraging habitat to support the loggerhead shrike in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 6,101 acres of suitable habitat for the loggerhead shrike in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With regard to secondary effects, nesting and foraging activities by the loggerhead shrike could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may cause adults to abandon nests due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to predators. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 500 feet and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include habitat fragmentation; increased noise; lighting; pesticides, which may cause secondary poisoning and loss of prey; human disturbances of nest sites; predation by pet, stray, and feral cats and dogs and other mesopredators; and increased vehicle collisions. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 6,101 acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area will provide loggerhead shrikes with relatively undisturbed habitat for nesting and foraging. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by nocturnal predators and reduce physiological stress. Limited recreational usage and access restrictions within the High Country SMA, control of pet, stray, and feral cats and dogs in or near open space areas, trail signage, and homeowner education regarding special-status resources in preserved natural habitat areas will help protect loggerhead shrikes by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of secondary poisoning and loss of prey.

The specific mitigation measures for the loggerhead shrike are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-61 IMPACTS TO INDIVIDUALS – LOGGERHEAD SHRIKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of loggerhead shrike individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to loggerhead shrike individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to loggerhead shrike individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-62 LOSS OF HABITAT – LOGGERHEAD SHRIKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the loggerhead shrike through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The River Corridor SMA will preserve and enhance at least 539 acres of suitable habitat for loggerhead shrike. The High Country SMA will preserve and enhance at least 4,112 acres of suitable habitat for the loggerhead shrike.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and that oak tree replacement occur as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA, including the following: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for loggerhead shrike through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site, providing suitable foraging habitat for the loggerhead shrike. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-22 states that the Oak Resource Management Plan shall incorporate the findings of the Draft Newhall Ranch Mitigation Feasibility Report (Dudek 2007A) and areas identified as being suitable for oak woodland enhancement and creation shall be used for mitigation.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the loggerhead shrike would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-63 SECONDARY IMPACTS – LOGGERHEAD SHRIKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on the loggerhead shrike associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as habitat fragmentation, abandonment of nests from human activity, greater vulnerability to nocturnal predators as a result of nighttime lighting, and vehicle collisions. Mitigation measures to minimize inadvertent impacts to habitat outside construction zones will also be implemented.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and which generally refer to habitat protection, restoration and enhancement, and management, will be implemented to mitigate for long-term habitat fragmentation effects, increased human activity, and increased vehicle collisions.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along the open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to loggerhead shrike, including short-term construction-related dust, noise, ground vibration, and increased human activity, as well as long-term habitat fragmentation edge-effects; increased human activity; increased vehicle collisions; and greater vulnerability to predation by pet, stray, and feral cats and dogs and other mesopredators.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 through BIO-21, as described above, will help reduce impacts to loggerhead shrike from habitat fragmentation, increased human activity, and increased vehicle collisions through the dedication of the 1,518-acre Salt Creek area to the public and management in conjunction with the 4,205-acre High Country SMA; preservation of coastal scrub within the High Country SMA, Salt Creek area, and River Corridor SMA, which includes at least 2,000 acres of coastal scrub foraging habitat for the loggerhead shrike; and coastal scrub restoration , if necessary.

BIO-42 requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities (County of Los Angeles 1988). Fencing shall extend to the root protection zone.

BIO-52 and BIO-56, as described above, will mitigate the effects of noise and ground vibration by identifying nest sites and providing for buffers between nests and construction activities.

BIO-63 and BIO-69 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-64 will be implemented to prevent poisoning and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the loggerhead shrike would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

LONG-EARED OWL (NESTING) (CSC)

Life History

The long-eared owl (*Asio otus*) occurs in North America, Europe, Asia, and northern Africa between elevations from near sea level to over 2,000 meters (6,560 feet) AMSL (Zeiner *et al.* 1990A). In North America, this species breeds from British Columbia east across Canada and the United States and south to southern California, southern Arizona, and northern Mexico. It also winters in most of its breeding range, except in the northernmost areas. The long-eared owl's wintering range extends from southern Canada and northern New England to the Gulf states and to the Jalisco, Michoacan, Guerrero, and Oaxaca states in Mexico (Marks *et al.* 1994).

The long-eared owl is an uncommon year-long resident throughout most of California, with the exception of the Central Valley and southern California desert regions, where is it generally a winter visitor (Zeiner *et al.* 1990A). Along the coastline of southern California, the long-eared owl may be a resident breeder (Marks *et al.* 1994; Bloom 1994) or a rare winter visitor (Garrett and Dunn 1981). It is known to nest successfully in the Santa Monica Mountains to the south of the Project area (Bloom Biological 2007A).

The long-eared owl primarily uses riparian habitat for roosting and nesting, but can also use live oak thickets and other dense stands of trees (Zeiner *et al.* 1990A). It appears to be more associated with forest edge habitat than with open habitat or forest habitat (Holt 1997). The long-eared owl usually does not hunt in the woodlands where it nests, but in open space areas such as fields, rangelands, and clearings. At higher elevations, the species is found in conifer stands that are usually adjacent to more open grasslands and shrublands (Marks *et al.* 1994). In California, long-eared owls also nest in dense or brushy vegetation amid open habitat (Bloom 1994). Long-eared owls have also been known to nest in caves, cracks in rock canyons, and in artificial wicker basket nests (Marks *et al.* 1994; Garner and Milne 1997).

The long-eared owl eats mostly voles and other rodents, though it also occasionally eats birds and other vertebrates (Armstrong 1958). It typically begins hunting before sunset, especially during the nesting season and while feeding its young (Bayldon 1978).

The long-eared owl uses abandoned crow, magpie, hawk, heron, and squirrel nests in a variety of trees with dense canopy (Call 1978; Marks 1986). The nest is usually three to 15 meters (9.8 to 49.2 feet) above the ground; rarely is the nest on the ground or in a tree cavity (Karalus and Eckert 1974). Breeding season extends from early March to late July (Call 1978). Pairs of long-eared owls have one brood per year with a clutch of three to eight eggs typically laid in April and May and incubated for 21 to 28 days (Zeiner *et al.* 1990A). Nestlings fledge in about 50 days or less and are usually independent from their parents by about two months.

In Wyoming, the breeding home range of this species in riparian habitat varied from 34 to 106 hectares (84.0 to 261.9 acres) and averaged 51 hectares (126.0 acres) (Craighead and Craighead 1956).

Resident populations of the long-eared owl in California have been declining since the 1940s, especially in southern California (Grinnell and Miller 1944; Remsen 1978; Bloom 1994). Habitat destruction, including grasslands used for foraging, fragmentation of riparian nesting habitat and live oak groves, and proximity to urban development are cited as major factors in the decline of populations in California (Marks *et al.* 1994; Bloom 1994; Remsen 1978). Nesting long-eared owls appear to be particularly sensitive to human activity. Human disturbance usually flushes females from active nests, and while females usually return within 10 minutes of the disturbance, eggs and hatchlings are vulnerable to predation while the nest is exposed (Marks 1986). Other urban-related factors that could affect long-eared owls are nighttime lighting, which may disrupt activity patterns and expose nests to nocturnal predators; use of pesticides, which may cause secondary poisoning and reduction or loss of prey; and predation and harassment by pet, stray, and feral cats and dogs.

Survey Results

Avian surveys were conducted in the riparian areas of the Santa Clara River and Castaic Creek from 1988 through 2008. These surveys were conducted by Guthrie from 1988 through 2006 along Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C); within portions of the Santa Clara River corridor by Labinger *et al.* and Labinger and Greaves in 1994 and 1996 through 1998 (Labinger *et al.* 1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A); within Castaic Creek, and portions of the River corridor adjacent to the Project site by Dudek and Associates in 2005 and 2006 (2006B, 2006D, 2006E); and within Castaic Creek and the Santa Clara River corridor from the I-5 bridge to Las Brisas Bridge west of the Ventura County line by Bloom Biological, Inc. in 2007 and (2007A, 2008). Surveys for upland bird species were conducted throughout the Project area and in nearby areas between 1995 and 2008. Surveys in the Specific Plan area were conducted by a variety of consulting firms and covered the Landmark Village, Mission Village, and Homestead East and West areas as well as Potrero, Long, and Chiquito canyons and the upland habitats along the Santa Clara River (Bloom Biological 2007A, 2008; Dudek and Associates 2006C; Guthrie 2000A, 2000B, 2004A, 2004D, 2004E; Impact Sciences 2000; RECON and Impact Sciences 1996; SAIC 2003). The High Country SMA and Salt Creek area (in the Specific Plan area) were surveyed by Dudek and Associates in 2005 (2006B). Bloom Biological Inc. surveyed along the Santa Clara River and in upland areas throughout the Project area in 2007 and 2008 (Bloom Biological 2008). Upland surveys have also been

conducted in the VCC planning area (Dudek and Associates 2006D; Guthrie 2004B) and Entrada planning area (Dudek and Associates 2006E; Guthrie 2004G).

The long-eared owl has been observed on site once during these surveys. Dudek and Associates observed a long-eared owl during wildlife transect surveys within the Specific Plan area in coast live oak woodland south of Via Canyon during the fall of 2005 (2006B). The observed individual was not nesting. Bloom Biological, Inc. (2007A) conducted focused surveys for the long-eared owl in the Landmark Village area of the Specific Plan area and failed to observe the species, although suitable nesting habitat was present.

Based on the numerous surveys in the Project area, the long-eared owl is expected to occur as a regular migrant and/or a winter visitor to the region, including the Project area, and could possibly breed on site within suitable habitat areas.

Suitable foraging habitat for the long-eared owl in the Project area includes agriculture, California annual grassland, purple needlegrass, and valley oak/grass, totaling 4,379 acres. Suitable nesting habitat includes oak woodlands (coast live oak woodland, mixed oak woodland, valley oak woodland), southern cottonwood–willow riparian, southern coast live oak riparian forest, and southern willow scrub, totaling 1,451 acres in the Project area. The combined suitable foraging and nesting habitat in the Project area totals 5,830 acres.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 189 acres of suitable foraging and nesting habitat would be permanently lost through implementation of the RMDP and the SCP, representing 3.2% of these habitats on site (**Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat, and **Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat). Of these impacts, 141 acres are foraging habitat, representing 3.2% the 4,379 acres of this habitat on site. The remaining 48 acres

of impact are nesting habitat, representing 3.3% of the 1,451 acres of this habitat on site. A total of 123 acres of suitable foraging and nesting habitat would be temporarily impacted, of which 77 acres are foraging habitat and 46 acres are nesting habitat.

The long-eared owl is still a widely distributed and common species throughout its range. It has been observed once on site, but has not been documented to nest. Because the construction of RMDP facilities would be phased over a long period of time, thousands of acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time**.** In addition, this species has not been documented to nest on site, and, therefore, nesting activities are unlikely to be disrupted. The loss of 3.2% of suitable foraging and nesting habitat as a result of construction/grading activities therefore would not be a substantial direct adverse effect on the habitat of a special-status species; impede the use of a native wildlife nursery site; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 2,283 acres of suitable foraging and nesting habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 39.2% of these habitats on site (**Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat, and **Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat). Of these impacts, 2,211 acres are foraging habitat, representing 50.5% of the 4,379 acres of this habitat on site. The remaining 73 acres of impact are nesting habitat, representing 5.0% of the 1,451 acres of this habitat on site.

The long-eared owl is still relatively widespread and common throughout its range. However, the overall loss of 39.2% of foraging and nesting habitat, including 50% of foraging habitat, would be a substantial habitat loss on site because the long-eared owl would be precluded from foraging in the substantial portion of the Project area. In particular, the loss of 50% of the 4,379 acres of foraging habitat would be considered a substantial adverse effect on the habitat of a special-status species; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Foraging Habitat) would be significant, absent

mitigation. The loss of 5% of the 1,451 acres of nesting habitat would be adverse, but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable foraging and nesting habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,472 acres (42.4%). Of these impacts, 2,351 acres are nesting and foraging habitat, representing 53.7% of this habitat on site. The remaining 120 acres of impact are nesting habitat, representing 8.3% of this habitat on site.

The combined direct and indirect loss of 42.4% of foraging and nesting habitat, including 53.7% of the 4,379 acres of foraging habitat and 8.3% of the 1,451 acres of nesting habitat, would be a substantial habitat loss on site. This impact would be considered a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Foraging and Nesting Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The long-eared owl is highly mobile, and, therefore, it is unlikely that RMDP-related construction activities would result in injury or mortality of adults. Although this species has not been observed nesting within the RMDP area, suitable nesting habitat for this species is present and the Project area is within its known breeding range. Therefore, construction and/or grading activities occurring during the nesting season could destroy active nests of this species, resulting in impacts to eggs and young. In addition, construction activities could cause temporary or permanent nest abandonment, resulting in increased vulnerability of active nests to predation and general exposure. Implementation of the SCP would not directly impact this species.

Impacts to young and/or eggs as a result of nest destruction or nest abandonment during construction/grading activities would be considered to have a substantial direct adverse effect on this species; impede the use of a native wildlife nursery site (nest); or threaten to eliminate the species on site (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of nesting habitat for this species, thus, construction and/or grading activities occurring during the nesting season could inadvertently destroy active nests of this species or cause nest abandonment, resulting in impacts to eggs and/or young.

The potential injury or mortality of individual birds, specifically loss of young and/or eggs during construction/grading activities as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Although the long-eared owl has not been observed to nest on site, there is suitable nesting habitat present and it is considered to have potential to nest in the Project area. Potential short-term secondary impacts associated with construction include noise, ground vibration, dust, nighttime lighting, and human activity. If the long-eared owl does nest on site and construction occurs during the nesting season, these impacts may decrease reproductive success by interfering with hunting, adult natal care, or by causing adults to abandon nests.

Potential long-term development-related secondary impacts include habitat fragmentation and isolation of some local populations of long-eared owls, making them more vulnerable to extirpation; disruption of nocturnal activities or a decrease in reproductive success due to nest abandonment caused by human disturbance; greater vulnerability to predation by pet, stray, and feral cats and dogs, and other mesopredators within approximately 200 feet of the urban–open space edge; and loss of prey and secondary poisoning from the use of pesticides.

Both these short-term and long-term secondary impacts would have a substantial adverse effect on this species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable foraging and nesting habitat for long-eared owl (**Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat, and **Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 161 acres (2.8%) permanent loss and 152 acres of temporary loss of foraging and nesting habitat, including
  - 127 acres (2.9%) of permanent loss and 107 acres of temporary loss of foraging habitat
  - 34 acres (2.3%) of permanent loss and 45 acres of temporary loss of nesting habitat;
- Alternative 4 – 151 acres (2.6%) permanent loss and 160 acres of temporary loss of foraging and nesting habitat, including
  - 117 acres (2.7%) of permanent loss and 118 acres of temporary loss of foraging habitat
  - 35 acres (2.4%) of permanent loss and 43 acres of temporary loss of nesting habitat;
- Alternative 5 – 195 acres (3.3%) permanent loss and 147 acres of temporary loss of foraging and nesting habitat, including
  - 151 acres (3.4%) of permanent loss and 99 acres of temporary loss of foraging habitat
  - 44 acres (3.0%) of permanent loss and 48 acres of temporary loss of nesting habitat;
- Alternative 6 – 183 acres (3.1%) permanent loss and 150 acres of temporary loss of foraging and nesting habitat, including
  - 150 acres (3.4%) of permanent loss and 107 acres of temporary loss of foraging habitat
  - 34 acres (2.3%) of permanent loss and 44 acres of temporary loss of nesting habitat; and

- Alternative 7 – 81 acres (1.4%) permanent loss and 381 acres of temporary loss of foraging and nesting habitat, including
  - 68 acres (1.6%) of permanent loss and 344 acres of temporary loss of foraging habitat
  - 13 acres (0.9%) of permanent loss and 37 acres of temporary loss of nesting habitat.

Compared to Alternative 2 for foraging and nesting habitat, which would result in 189 acres (3.2%) of permanent loss and 123 acres of temporary impacts, Alternatives 5 and 6 would not be substantially different compared to Alternative 2, Alternatives 3 and 4 would have somewhat reduced permanent impacts, and Alternative 7 would have substantially reduced impacts. For temporary impacts, Alternatives 3 through 6 would have somewhat higher impacts and Alternative 7 would have substantially higher impacts. This general pattern is similar for permanent impacts to foraging habitat. Compared to Alternative 2, which would have 141 acres of permanent impacts, Alternatives 3 and 4 would have somewhat reduced impacts, Alternatives 5 and 6 would have marginally higher impacts, and Alternative 7 would have substantially reduced impacts. For temporary impacts to foraging habitat, compared to Alternative 2, which would have 77 acres of impact, Alternatives 3 through 6 would have somewhat higher impacts and Alternative 7 would have substantially higher impacts. For nesting habitat, compared to Alternative 2, which would have 48 acres of permanent impact, Alternatives 3 through 6 would have somewhat reduced impacts and Alternative 7 would have substantially reduced impacts. For temporary impacts to nesting habitat, compared to Alternative 2, which would have 46 acres of impact, Alternatives 3 through 6 would have not substantially different to marginally different impacts and Alternative 7 would have somewhat reduced impacts.

The relatively greater difference between Alternative 7 and the other alternatives for foraging and nesting habitat is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and relatively more temporary impacts.

The overall direct permanent and temporary loss of foraging and nesting habitat resulting from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be less than or similar in magnitude compared to Alternative 2. The long-eared owl has been observed once on site, but has not been documented to nest. Because the construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable habitat would be available for this species in the River Corridor SMA, High Country SMA, and Salt Creek area at any given time**,** these impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable foraging and nesting habitat for long-eared owl (**Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat, and **Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 2,159 acres (37.0%) permanent loss of foraging and nesting habitat, including
  - 2,097 acres (47.9%) of permanent loss of foraging habitat
  - 62 acres (4.3%) of permanent loss of nesting habitat;
- Alternative 4 – 2,078 acres (35.6%) permanent loss of foraging and nesting habitat, including
  - 2,021 acres (46.1%) of permanent loss of foraging habitat
  - 57 acres (3.9%) of permanent loss of nesting habitat;
- Alternative 5 – 2,043 acres (35.0%) permanent loss of foraging and nesting habitat, including
  - 1,985 acres (45.3%) of permanent loss of foraging habitat
  - 57 acres (3.9%) of permanent loss of nesting habitat;
- Alternative 6 – 1,887 acres (32.4%) permanent loss of foraging and nesting habitat, including
  - 1,855 acres (42.4%) of permanent loss of foraging habitat
  - 32 acres (2.2%) of permanent loss of nesting habitat; and
- Alternative 7 – 1,549 acres (26.6%) permanent loss of foraging and nesting habitat, including
  - 1,515 acres (34.6%) of permanent loss of foraging habitat
  - 34 acres (2.3%) of permanent loss of nesting habitat.

Compared to Alternative 2 for foraging and nesting habitat, which would result in 2,283 acres (39.2%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. This general pattern is similar for separate permanent impacts to nesting and foraging habitat under Alternatives 3 through 7. Compared to Alternative 2, which would have 2,211 acres (50.5%) of permanent loss of foraging habitat, Alternatives 3 through 7 would have reduced impacts. Compared to Alternative 2, which would have

73 acres (5.0%) of permanent loss of nesting habitat, Alternatives 3 through 7 also would have reduced impacts. Overall for foraging and nesting habitat, Alternatives 4 through 7 would have fewer impacts than Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, and each would have successively fewer impacts due to other differences in the Project footprints. Alternative 7 would have the least amount of impact due to pullbacks from the Santa Clara River and its tributaries.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, all would result in impacts to nesting and foraging habitat and substantial impacts to foraging habitat in particular; impacts to foraging habitat would range from 34.6% for Alternative 7 to 47.9% for Alternative 3. These impacts would have a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species. Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable foraging and nesting habitat for long-eared owl:

- Alternative 3 – 2,320 acres (39.8%) permanent loss of foraging and nesting habitat, including
  - 2,224 acres (50.8%) of permanent loss of foraging habitat
  - 96 acres (6.6%) of permanent loss of nesting habitat;
- Alternative 4 – 2,229 acres (38.2%) permanent loss of foraging and nesting habitat, including
  - 2,137 acres (48.8%) of permanent loss of foraging habitat
  - 92 acres (6.3%) of permanent loss of nesting habitat;
- Alternative 5 – 2,237 acres (38.4%) permanent loss of foraging and nesting habitat, including
  - 2,136 acres (48.8%) of permanent loss of foraging habitat
  - 101 acres (7.0%) of permanent loss of nesting habitat;

- Alternative 6 – 2,070 acres (35.5%) permanent loss of foraging and nesting habitat, including
  - 2,004 acres (45.8%) of permanent loss of foraging habitat
  - 65 acres (4.5%) of permanent loss of nesting habitat; and
- Alternative 7 – 1,629 acres (27.9%) permanent loss of foraging and nesting habitat, including
  - 1,582 acres (36.1%) of permanent loss of foraging habitat
  - 47 acres (3.2%) of permanent loss of nesting habitat.

Compared to Alternative 2 for foraging and habitat, which would result in 2,472 acres (42.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. This general pattern is similar for permanent impacts to nesting and foraging habitat when considered separately. Compared to Alternative 2 for foraging habitat, which would have 2,351 acres (53.7%) of permanent loss, Alternatives 3 through 7 would have reduced impacts. Compared to Alternative 2 for nesting habitat, which would have 120 acres (8.3%) of permanent loss, Alternatives 3 through 7 also would have reduced impacts. Overall for foraging and nesting habitat, Alternatives 4 through 7 would have fewer combined direct and indirect permanent impacts than Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, and each would have successively fewer impacts (except for Alternatives 4 and 5 where Alternative 5 would be marginally higher) due to other differences in the Project footprints. Alternative 7 would have the least amount of impact due to pullbacks from the Santa Clara River and its tributaries and other differences in the Project footprint.

Although Alternatives 3 through 7 would have reduced combined direct and indirect permanent impacts compared to Alternative 2, all would result in impacts to nesting and foraging habitat and substantial impacts to foraging habitat in particular; combined impacts to foraging habitat would range from 36.1% for Alternative 7 to 50.8% for Alternative 3. These combined direct and indirect permanent impacts would have a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species. Combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to long-eared owl individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Suitable nesting habitat is present on site and construction/grading activities could result in impacts to eggs or young where long-eared owls are nesting as a result if nest destruction or abandonment of the nest. Impacts to long-eared owl individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative would have essentially the same construction activities and long-term effects.

Short-term effects include construction-related noise, ground vibration, lighting, and disturbance from human activity that could disrupt natal care and cause nest abandonment. Urban development could result in long-term secondary impacts, such as increased human activity; nighttime lighting; harassment by pet, stray, and feral cats and dogs; and secondary poisoning and loss of prey from use of pesticides.

These short-term and long-term secondary impacts therefore may interfere with the movement of this species on site, impede the use of nursery sites, or substantially reduce the number of this species or cause the species to drop below self-sustaining levels. Short-term and long-term secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to long-eared owl: (1) impacts to individuals; (2) loss of suitable nesting and foraging habitat; and (3) secondary impacts to individuals and suitable nesting and foraging habitat outside the Project footprint.

Although nesting by long-eared owls has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas, suitable nesting habitat (riparian, oak woodlands, and oak/grass) is present on site and it is assumed for the purpose of this analysis that nesting could occur. While adults are highly mobile and likely able to escape direct injury or

mortality from relatively slow-moving construction equipment, impacts to individuals could occur if active nests are disturbed during vegetation clearing and construction/grading activities, including destruction of nests and loss of eggs and/or fledglings or nest sites are abandoned due to construction-related activities. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 500 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable nesting and foraging habitat for the long-eared owl resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 1,629 acres (27.9%) under Alternative 7 to 2,422 acres (42.2%) under Alternative 2. This would be a substantial loss of suitable nesting and foraging habitat for this species and probably would alter its use of the Project area for nesting and foraging if present. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable nesting and foraging habitat to support the long-eared owl in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 2,474 acres of suitable nesting and foraging habitat for the long-eared owl in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With regard to secondary effects, nesting and foraging activities by the long-eared owl could be adversely affected in the short-term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may cause adults to abandon nests due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to predators and exposure. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 500 feet and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include habitat fragmentation; increased noise; lighting; pesticides that may cause secondary poisoning and loss of prey; human disturbances of nest sites; and predation by pet, stray, and feral cats and dogs and other mesopredators. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 2,474 acres of suitable nesting and foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area will provide long-eared owls with relatively undisturbed habitat for nesting and foraging. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by nocturnal predators and reduce physiological stress. Limited recreational usage and access restrictions within the High Country SMA, control of pet, stray, and feral cats and dogs in or near open space areas, trail signage, homeowner education and regarding special-status resources in preserved natural habitat areas will help protect long-eared owls by allowing to nest and forage without

disturbance. Controls on pesticides will reduce the chance of secondary poisoning and loss of prey.

The specific mitigation measures for the long-eared owl are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-64 IMPACTS TO INDIVIDUALS – LONG-EARED OWL

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of long-eared owl individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to long-eared owl individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to long-eared owl individuals would adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-65 LOSS OF HABITAT – LONG-EARED OWL

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for long-eared owl through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The River Corridor SMA will preserve and enhance at least 411 acres of suitable foraging and nesting habitat for long-eared owl**.** The High Country SMA will preserve and enhance 1,394 acres of suitable foraging and nesting habitat for long-eared owl.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and that oak tree replacement occur as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA, including the following: replacement oaks shall be

planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for long-eared owl through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-42 requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities (County of Los Angeles 1988). Fencing shall extend to the root protection zone.

BIO-55 requires that maps of suitable riparian habitat be updated for special-status avian species, and the creation or enhancement of habitat shall be similar to the habitat removed.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the long-eared owl would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-66 SECONDARY IMPACTS – LONG-EARED OWL

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on long-eared owl associated with build-out of the Specific Plan, VCC, and Entrada planning areas such as habitat fragmentation, increased human activity, and nighttime lighting. Mitigation measures to minimize inadvertent impacts to habitat outside construction zones will also be implemented.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and which generally refer to habitat protection, restoration and enhancement, and management, will be implemented to mitigate for the effects of habitat fragmentation and increased human activity.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These mitigation measures require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to long-eared owl, including short-term construction-related noise, ground vibration, dust, and increased human activity, as well as long-term habitat fragmentation; increased human activity;

harassment by pet, stray, and feral cats and dogs; and secondary poisoning and loss of prey due to the use of pesticides.

BIO-52 and BIO-56, as described above, will mitigate the effects of construction noise and increased human activity by identifying nest sites and providing for buffers between nests and construction activities.

BIO-1 through BIO-16 and BIO-19, as described above, will mitigate for habitat fragmentation and increased human activity in the Project area through habitat protection, restoration and enhancement, and management.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides (including rodenticides and insecticides) and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to long-eared owl would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

NORTHERN HARRIER (NESTING) (CSC)

Life History

The northern harrier (*Circus cyaneus*) has a wide geographic range throughout much of the northern continents. Its breeding range includes northern Alaska and Canada south to the northern Baja California peninsula in Mexico and east to the southern parts of Nevada, Utah, and the northern parts of New Mexico and Texas. It also breeds in southern Kansas, central Iowa, central Wisconsin, southern Michigan, southern Pennsylvania, southeast Virginia, and probably northeast North Carolina. The northern harrier is common along the west coast in mountain and desert regions. Northern harriers winter throughout much of Canada, the United States, and the Caribbean islands (Macwhirter and Bildstein 1996).

The northern harrier occurs throughout California from sea level to 3,000 meters (9,842 feet) AMSL as a widespread winter migrant (CDFG 2008A; Zeiner *et al.* 1990A). The northern harrier is also a permanent resident in coastal areas, the northeastern plateau, the Central Valley, and the Sierra Nevada, where its elevational range as a breeder reaches 1,700 meters (5,577 feet) AMSL (Zeiner *et al.* 1990A). Breeding populations are also known from around San Francisco Bay and in the Mono Lake area (Gaines 1977; CDFG 2008A). Most of the breeding population in California occurs in ungrazed parts of the state and in federal wildlife refuges (CDFG 2008A).

Northern harriers use a wide variety of open habitats in California, including deserts, coastal sand dunes, pasturelands, croplands, dry plains, grasslands, estuaries, flood plains, and marshes (Macwhirter and Bildstein 1996). The species also forages over coastal sage scrub and other open scrub communities (Bloom Biological 2007A). Nesting areas are associated with marshes, pastures, grasslands, prairies, croplands, desert shrub-steppe, and riparian woodland (Macwhirter and Bildstein 1996). Winter habitats similarly include a variety of open habitats dominated by herbaceous cover. Northern harrier populations are most concentrated in areas with low vegetation.

Northern harriers almost always forage on the wing, by flying slowly and low to the ground, sometimes hovering, sometimes soaring. They take small and medium-sized prey, including birds, rodents, reptiles, and frogs, but also some insects, such as beetles, grasshoppers, crickets, and locusts in small amounts (Macwhirter and Bildstein 1996).

Breeding occurs from March to May. Nests are located in patches of dense and tall vegetation, particularly wetlands and dense grasslands, and have a clutch size of four to six eggs that are incubated for 30 to 32 days. Chicks typically fledge at four to five weeks by making brief flights near the nest (Macwhirter and Bildstein 1996).

Harriers begin dispersing from breeding grounds in August through December (Cripe 2000), and migrate (if such migration occurs) north between late February and early May (Macwhirter and

Bildstein 1996). Their densities and territory size vary due to fluctuations in habitat type and local prey availability (Macwhirter and Bildstein 1996; Cripe 2000).

This species is primarily threatened by extensive loss of habitat (Cripe 2000), including freshwater and estuarine wetland breeding habitat and grasslands (Macwhirter and Bildstein 1996). In agricultural areas, nests are destroyed by livestock and other agricultural activities (Zeiner *et al.* 1990A). Overgrazing of pastures and pesticide use decreases prey abundance (Macwhirter and Bildstein 1996). Additionally, northern harriers have been heavily affected by widespread use of DDT, which causes eggshell thinning, and other chlorinated hydrocarbon pesticides (Terres 1980; Henny and Wight 1972). Predators of northern harriers' eggs and nestlings include crows and ravens, populations of which may increase during construction activities and over the long term in urbanized areas. Both nesting and wintering birds may avoid or abandon suitable habitat near areas of active use by humans (Macwhirter and Bildstein 1996). In addition, vehicle collisions may be a significant threat to northern harriers because they fly slowly and low to the ground during foraging.

Survey Results

Surveys for riparian and upland birds have been conducted for multiple years throughout most of the Project area. Riparian bird surveys were conducted by Guthrie from 1988 through 2006 along Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C); within portions of the Santa Clara River corridor by Labinger *et al.* in 1994 and 1996 through 1998 (1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A); within Castaic Creek, Salt Creek area, High Country SMA, and portions of the River corridor adjacent to the Project area by Dudek and Associates in 2005 and 2006 (2006B, 2006D, 2006E); and within Castaic Creek and the Santa Clara River corridor from the I-5 bridge to Las Brisas Bridge west of the Ventura County line by Bloom Biological, Inc. in 2007 and 2008 (2007A, 2008). Upland bird species surveys were conducted throughout the Project area and in nearby areas between 1995 and 2007 throughout the Specific Plan area (Bloom Biological 2007A, 2008; Dudek and Associates 2006C; Guthrie 2000A, 2000B, 2004A, 2004D, 2004E; Impact Sciences 2000; RECON and Impact Sciences 1996; SAIC 2003). The High Country SMA and Salt Creek area (in the Specific Plan area) were surveyed by Dudek and Associates in 2005 (2006B). Upland surveys have also been conducted in the VCC planning area (Dudek and Associates 2006D; Guthrie 2004B) and Entrada planning area (Dudek and Associates 2006E; Guthrie 2004G). Other areas near the Project area that have been surveyed for upland bird species include the Legacy Village area adjacent to the Project area on the south and east (Guthrie 2004C), the Castaic Junction area just north of the Entrada planning area (Guthrie 2004F, 2004I), the Riverpark site (now referred to as "River Village")

upstream of the Specific Plan area (Compliance Biology 2003A), and upland areas upstream of the VCC planning area, including the Castaic Mesa area (PCR 1998; Compliance Biology 2006A, 2006D).

The northern harrier has been observed in or near the Project area infrequently during the 20 years of surveys. Most of the observations of this species were probably of wintering and migrating individuals, and these surveys are considered adequate to establish that this species is at least an occasional winter migrant in the Project area. Although the northern harrier has never been documented breeding on the site, many populations in California are resident breeders (Cripe 2000; Macwhirter and Bildstein 1996), and the species is known to nest in coastal areas. The northern harrier is a local breeder in the region and has the potential to nest on site (Bloom Biological 2007A). Because the breeding population is much reduced in the southern California coastal areas (Zeiner *et al.* 1990A), it is possible that individuals breeding in the Project area were never observed despite extensive surveys.

The Project area provides both foraging and nesting habitat for the species. Agriculture, bulrush–cattail wetland, California annual grassland, cismontane alkali marsh, coastal and valley freshwater marsh, herbaceous wetland, valley oak/grass, and purple needlegrass are both suitable nesting and foraging habitats for the northern harrier. There is a total of 4,585 acres of suitable nesting and foraging habitat within the Project area. Additional suitable foraging habitat in the Project area for the northern harrier includes alluvial scrub, big sagebrush scrub, coastal scrub alliances and associations, and river wash. There is a total of 5,737 acres of additional suitable foraging habitat within the Project area. The combined suitable nesting and foraging habitat in the Project area totals 10,322 acres.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 236 acres of suitable nesting and/or foraging habitat would be permanently lost through implementation of the RMDP and the SCP, representing 2.3% of these habitats

on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat, and **Figure 4.5-125**, Alternative 2 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat). Of these impacts, 153 acres are nesting and foraging habitat (*i.e.*, habitat suitable for both nesting and foraging, including agriculture, bulrush–cattail wetland, California annual grassland, cismontane alkali marsh, coastal and valley freshwater marsh, herbaceous wetland, valley oak/grass, and purple needlegrass), representing 3.3% of this habitat on site. The remaining 82 acres of impact are foraging habitat only (*i.e.*, habitat suitable only for foraging, including alluvial scrub, big sagebrush scrub, coastal scrub alliances and associations, and river wash), representing 1.4% of this habitat on site. A total of 130 acres of suitable nesting and/or foraging habitat would be temporarily impacted, of which 82 acres are nesting and foraging habitat and 49 acres are foraging habitat only.

The northern harrier is still relatively widespread and common throughout its range, and uses a variety of habitats for foraging. The construction of RMDP facilities would be phased over a long period of time and thousand of acres of foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek would be available for this species at any given time. At the completion of temporary disturbances, these areas would be restored. Furthermore, although the northern harrier potentially nests on site, it has not been observed to nest and no known nesting areas would be affected. Therefore, the overall loss of 2.3% of nesting and/or foraging habitat as a result of construction/grading activities, including 3.3% of foraging and nesting habitat and 1.4% foraging habitat only, would not be a substantial adverse effect on the habitat of a special-status species; would not impede the use of a native wildlife nursery site; would not have the potential to substantially reduce the habitat of the species on site or rangewide; would not potentially cause the species to drop below self-sustaining levels on site or rangewide; would not threaten to eliminate the species on site or rangewide; and would not substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,799 acres of suitable nesting and/or foraging habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 36.8% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat, and **Figure 4.5-125**, Alternative 2 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat). Of these impacts, 2,213 acres are nesting and foraging habitat, representing 48.3% of this habitat on site. The remaining 1,585 acres of impact are foraging habitat only, representing 27.6% of this habitat on site.

The northern harrier is still relatively widespread and common throughout its range. However, the overall loss of 36.8% of nesting and/or foraging habitat, including 48.3% of foraging and nesting habitat and 27.6% foraging habitat only, would be a substantial habitat loss on site. This impact would be considered a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable nesting and/or foraging habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 4,034 acres (39.1%). Of these impacts, 2,366 acres are nesting and foraging habitat, representing 51.6% of this habitat on site. The remaining 1,668 acres of impact are foraging habitat only, representing 29.1% of this habitat on site.

The combined loss of 39.1% of nesting and/or foraging habitat, including 51.6% of foraging and nesting habitat and 29.1% foraging habitat only, would be a substantial habitat loss on site. This impact would be considered a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Although the northern harrier has never been documented nesting on site, the species is known to be a local breeder in the Project region and it is possible that pairs of northern harriers could nest in the Project area. Because northern harriers are highly mobile, implementation of the RMDP would not result in injury or mortality of adult individuals occupying this habitat during construction and/or grading activities. However, the proposed Project could result in destruction of young or eggs of this species as a result of

destruction of nests from any construction and/or grading activities occurring during the nesting season. In addition, disturbances in close proximity to nest sites could result in abandonment of nests, increasing the risk of predation (*e.g.*, by crows and ravens that are attracted to construction areas) and general exposure. Implementation of the SCP would not directly impact this species.

Injury or mortality of individual birds, specifically the loss of young and/or eggs as a result of nest destruction or nest abandonment during construction/grading activities, would have a substantial direct adverse effect on this species; would impede the use of a native wildlife nursery site; would cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

As described above for direct permanent and temporary impacts, adult northern harriers are highly mobile and are unlikely to be directly affected by build-out of the Specific Plan, VCC, and Entrada planning areas. However, nesting habitat for this species would be lost; thus, construction and/or grading activities occurring during the nesting season could inadvertently destroy active nests, resulting in impacts to eggs and/or young. Construction disturbances could also cause nest abandonment.

Injury or mortality of individual birds, specifically loss of young and/or eggs during construction/grading activities as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

In the short-term, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would have the potential to affect northern harriers in areas adjacent to construction zones. Secondary impacts could include exposure to construction-related dust, noise, ground vibration, nighttime lighting, increased human activity, increased predation (*e.g.*, by crows and ravens attracted to construction sites), and impaired water quality (*e.g.*, turbidity and other pollutants) resulting from construction

within or in proximity to wetland habitats used for nesting and foraging. The northern harrier has been documented avoiding or leaving suitable habitat near areas of active use by humans and in response to direct human interference (Serrentino 1992; Bildstein 1987; Macwhirter and Bildstein 1996). Construction occurring near active nest sites therefore could result in direct impacts to young or generally reduce reproductive success due to reduced foraging efficiency and caretaking of young.

Long-term secondary impacts from the close proximity of urban development to suitable nesting and/or foraging habitat could include disturbance-caused nest abandonment and disruptions associated with increased human activity, noise, nighttime lighting, and vehicle collisions. As noted above, human activity near nest sites can cause nest abandonment. Lighting could increase the northern harrier's vulnerability to nest predation by pet, stray, and feral cats and dogs, and other mesopredators. Use of pesticides could result in loss of prey and secondary poisoning. Wetland nesting habitats also would be vulnerable to degradation of water quality, including sedimentation and other pollutants of concern such as petroleum products, chemicals, and heavy metals.

Both these short-term and long-term secondary impacts would have a substantial adverse effect on this species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable nesting and/or foraging habitat for the northern harrier (Figures **4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat, and **Figures 4.5-126** through **4.5-130**, Alternatives 3 through 7 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat):

- Alternative 3 – 209 acres (2.0%) permanent loss and 169 acres of temporary loss of nesting and/or foraging habitat, including
    - 135 acres (2.9%) of permanent loss and 112 acres of temporary loss of nesting and foraging habitat

  - 74 acres (1.3%) of permanent loss and 57 acres of temporary loss of foraging habitat only;
- Alternative 4 – 199 acres (1.9%) permanent loss and 171 acres of temporary loss of nesting and/or foraging habitat, including
  - 124 acres (2.7%) of permanent loss and 122 acres of temporary loss of nesting and foraging habitat
  - 75 acres (1.3%) of permanent loss and 48 acres of temporary loss of foraging habitat only;
- Alternative 5 – 238 acres (2.3%) permanent loss and 166 acres of temporary loss of nesting and/or foraging habitat, including
  - 160 acres (3.5%) of permanent loss and 105 acres of temporary loss of nesting and foraging habitat
  - 78 acres (1.4%) of permanent loss and 61 acres of temporary loss of foraging habitat only;
- Alternative 6 – 222 acres (2.2%) permanent loss and 170 acres of temporary loss of nesting and/or foraging habitat, including
  - 158 acres (3.4%) of permanent loss and 111 acres of temporary loss of nesting and foraging habitat
  - 64 acres (1.1%) of permanent loss and 59 acres of temporary loss of foraging habitat only; and
- Alternative 7 – 100 acres (1.0%) permanent loss and 422 acres of temporary loss of nesting and/or foraging habitat, including
  - 68 acres (1.5%) of permanent loss and 348 acres of temporary loss of nesting and foraging habitat
  - 32 acres (0.6%) of permanent loss and 74 acres of temporary loss of foraging habitat only.

Compared to Alternative 2 for nesting/and or foraging habitat, which would result in 236 acres (2.3%) of permanent loss and 130 acres of temporary impacts, Alternatives 5 and 6 would have not substantially different permanent impacts, Alternatives 3 and 4 would have somewhat reduced impacts, and Alternative 7 would have substantially reduced impacts. For temporary impacts to nesting and/or foraging habitat, Alternatives 3 through 6 would have somewhat higher impacts and Alternative 7 would have substantially higher impacts compared to Alternative 2.

Compared to Alternative 2 for nesting and foraging habitat, which would result in 153 acres (3.3%) of permanent loss and 82 acres of temporary impacts, Alternatives 5 and 6 would have not substantially to marginally different permanent impacts, Alternatives 3 and 4 would have somewhat reduced impacts, and Alternative 7 would have substantially reduced impacts. For temporary impacts to nesting and foraging habitat, Alternatives 3 through 6 would have somewhat higher impacts and Alternative 7 would have substantially higher impacts compared to Alternative 2.

Compared to Alternative 2 for foraging habitat only, which would result in 82 acres (1.4%) of permanent loss and 49 acres of temporary impacts, Alternatives 3 through 5 would have not substantially different permanent impacts and Alternatives 6 and 7 would have somewhat reduced impacts. For temporary impacts to foraging habitat only, Alternatives 3 through 6 would have not substantially to marginally different impacts and Alternative 7 would have somewhat higher impacts compared to Alternative 2.

The relatively greater difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and relatively more temporary impacts.

The overall permanent loss of nesting and/or foraging habitat resulting from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be less than or similar in magnitude compared to Alternative 2. This impact would not be a substantial adverse effect on the habitat of a special-status species; would not impede the use of a native wildlife nursery site; would not have the potential to substantially reduce the habitat of the species on site or rangewide; would not cause the species to drop below self-sustaining levels on site or rangewide; would not threaten to eliminate the species on site or rangewide; and would not substantially reduce the number or restrict the range of the species. The direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant under Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the northern harrier (Figures **4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat, and **Figures 4.5-126** through **4.5-130**, Alternatives 3 through 7 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat):

- Alternative 3 – 3,586 acres (34.7%) permanent loss of nesting and/or foraging habitat, including

  - 2,098 acres (45.7%) of permanent loss of nesting and foraging habitat
  - 1,488 acres (25.9%) of permanent loss of foraging habitat only;
- Alternative 4 – 3,454 acres (33.5%) permanent loss of nesting and/or foraging habitat, including
  - 2,022 acres (44.1%) of permanent loss of nesting and foraging habitat
  - 1,432 acres (25.0%) of permanent loss of foraging habitat only;
- Alternative 5 – 3,367 acres (32.6%) permanent loss of nesting and/or foraging habitat, including
  - 1,985 acres (43.3%) of permanent loss of nesting and foraging habitat
  - 1,381 acres (24.1%) of permanent loss of foraging habitat only;
- Alternative 6 – 2,984 acres (28.9%) permanent loss of nesting and/or foraging habitat, including
  - 1,855 acres (40.5%) of permanent loss of nesting and foraging habitat
  - 1,129 acres (19.7%) of permanent loss of foraging habitat only; and
- Alternative 7 – 2,550 acres (24.7%) permanent loss of nesting and/or foraging habitat, including
  - 1,515 acres (33.0%) of permanent loss of nesting and foraging habitat
  - 1,035 acres (18.0%) of permanent loss of foraging habitat only.

Compared to Alternative 2 for nesting/and or foraging habitat, which would result in 3,799 acres (36.8%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. This general pattern is similar for permanent impacts to nesting and foraging habitat. Compared to Alternative 2, which would result in 2,213 acres (48.3%) of permanent loss of nesting and foraging habitat, Alternatives 3 through 7 would have reduced impacts. Compared to Alternative 2 for permanent loss of foraging habitat only, which would result in 1,568 acres (27.3%) of permanent loss, Alternatives 3 through 6 would have reduced impacts. Overall for nesting and/or foraging habitat, Alternatives 4 through 7 would have fewer impacts than Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, and each would have successively fewer impacts due to other differences in the Project footprints. Alternative 7 would have the least amount of impact due to pullbacks from the Santa Clara River and its tributaries.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, all would result in substantial impacts to nesting and/or foraging habitat, ranging from 24.7% for Alternative 7 to 34.7% for Alternative 3. These impacts would have a substantial adverse effect on the habitat of a special-status species; would impede the use

of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species. Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the northern harrier:

- Alternative 3 – 3,794 acres (36.8%) permanent loss of nesting and/or foraging habitat, including
  - 2,233 acres (48.7%) of permanent loss of nesting and foraging habitat
  - 1,562 acres (27.2%) of permanent loss of foraging habitat only;
- Alternative 4 – 3,653 acres (35.4%) permanent loss of nesting and/or foraging habitat, including
  - 2,146 acres (46.8%) of permanent loss of nesting and foraging habitat
  - 1,507 acres (26.3%) of permanent loss of foraging habitat only;
- Alternative 5 – 3,604 acres (34.9%) permanent loss of nesting and/or foraging habitat, including
  - 2,145 acres (46.8%) of permanent loss of nesting and foraging habitat
  - 1,459 acres (25.4%) of permanent loss of foraging habitat only;
- Alternative 6 – 3,206 acres (31.1%) permanent loss of nesting and/or foraging habitat, including
  - 2,013 acres (43.9%) of permanent loss of nesting and foraging habitat
  - 1,193 acres (20.8%) of permanent loss of foraging habitat only; and
- Alternative 7 – 2,650 acres (25.7%) permanent loss of nesting and/or foraging habitat, including
  - 1,583 acres (34.5%) of permanent loss of nesting and foraging habitat
  - 1,067 acres (18.6%) of permanent loss of foraging habitat only.

Compared to Alternative 2 for nesting/and or foraging habitat, which would result in 4,034 acres (39.1%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. This general pattern is similar for permanent impacts to nesting and foraging habitat. Compared to Alternative 2, which would result in 2,366 acres (51.6%) of permanent loss to nesting and foraging habitat, Alternatives 3 through 7 would have reduced impacts. Compared to Alternative 2 for the combined direct and indirect permanent loss of foraging habitat only, which would result in 1,668 acres (29.1%) of permanent loss, Alternatives 3 through 6 would have reduced impacts. Overall for nesting and/or foraging habitat, Alternatives 4 through 7 would have fewer combined direct and indirect impacts than Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, and each would have successively fewer impacts due to other differences in the Project footprints. Alternative 7 would have the least amount of impact due to pullbacks from the Santa Clara River and its tributaries and other differences in the Project footprint.

Although Alternatives 3 through 7 would have reduced combined direct and indirect permanent impacts compared to Alternative 2, all would result in substantial impacts to nesting and/or foraging habitat, ranging from 25.7% for Alternative 7 to 36.8% for Alternative 3. These combined direct and indirect permanent impacts would have a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species. Combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to northern harrier individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Although adults are unlikely to be directly affected, suitable nesting habitat is present on site and construction/grading activities could result in impacts to eggs or young where northern harriers are nesting as a result of direct destruction of nests or abandonment of nest sites. Impacts to northern harrier individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative would have similar construction activities and long-term effects.

Short-term effects include construction-related dust, noise, ground vibration, nighttime lighting, impaired water quality, and disturbance from human activity that could cause nest abandonment. Urban development could result in long-term secondary impacts such as increased human activity; nighttime lighting; harassment by pet, stray, and feral cats and dogs; secondary poisoning and loss of prey from use of pesticides; vehicle collisions; and impaired water quality.

These short-term and long-term secondary impacts therefore may interfere with the movement of this species on site, impede the use of nursery sites, or substantially reduce the number of this species or cause the species to drop below self-sustaining levels. Short-term and long-term secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to northern harrier: (1) impacts to individuals; (2) loss of suitable nesting and/or foraging habitat; and (3) secondary impacts to individuals and suitable nesting and/or foraging habitat outside the Project footprint.

Although nesting by northern harriers has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas, suitable nesting habitat is present on site and it is assumed for the purpose of this analysis that nesting could occur. Impacts to individuals could occur if active nests are disturbed during construction, including destruction of nests and loss of eggs and/or fledglings, or abandonment of nests as a result of human activity and construction activities. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 500 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of nesting and/or foraging habitat resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,650 acres (25.7%) under Alternative 7 to 4,034 acres (39.1%) under Alternative 2. This would be a substantial loss of suitable foraging and/or nesting habitat. Although the northern harrier has not been documented to nest in the Project disturbance area, if it were to nest on site, both the loss of nesting and foraging habitat would substantially alter its distribution on site. As mitigation for this loss of habitat, the combined Newhall Ranch Specific

Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable foraging habitat to support the northern harrier in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 4,682 acres of suitable nesting and/or foraging habitat for the northern harrier in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With regard to secondary effects, any foraging and/or nesting activities by the northern harrier could be adversely affected in the short-term by increased human activity, dust, noise, ground vibration, increased predation (*e.g.*, by crows and ravens), and water quality impacts. Nighttime lighting also may cause adults to abandon nests due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to nocturnal predators. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 500 feet and by retaining a qualified biologist during all grading and construction activities. Nighttime lighting will be downcast away from natural habitat areas. Water quality will be protected through several general measures, including obtaining pertinent state and federal wetland permits and authorizations prior to construction activities, biological monitoring during any stream diversions, restrictions on construction equipment operating in ponds or flowing water, and protection of water quality from mud, silt, and other pollutants.

Long-term development-related impacts include increased noise; lighting; pesticides that may cause secondary poisoning and loss of prey; human disturbances of foraging individuals and nest sites; pet, stray, and feral cats and dogs; vehicle collisions; and impaired water quality that may affect nesting habitat. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of nesting and/or foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area will provide northern harriers with relatively undisturbed habitat for foraging and potentially nesting. Long-term hydrology and water quality will be protected through several general measures, including obtaining pertinent state and federal wetland permits and authorizations. Lighting restrictions along the perimeter of natural areas would help avoid impacts to potential nest sites. Limited recreational usage and access restrictions within the High Country SMA, control of pet, stray, and feral cats and dogs in or near open space areas, trail signage, and homeowner education regarding special-status resources in preserved natural habitat areas will help protect northern harriers during foraging activities and at potential nest sites. Controls on pesticides (including rodenticides) will prevent accidental poisoning and potential loss of prey.

The specific mitigation measures for the northern harrier are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-67 IMPACTS TO INDIVIDUALS – NORTHERN HARRIER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of northern harrier individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to northern harrier individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to northern harrier individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-68 LOSS OF HABITAT – NORTHERN HARRIER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for northern harrier through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The River Corridor SMA will preserve and enhance at least 524 acres of suitable nesting and/or foraging habitat for northern harrier**.** The High Country SMA will preserve and enhance 3,005 acres of suitable nesting and/or foraging habitat for northern harrier.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for northern harrier through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation

ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the northern harrier would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-69 SECONDARY IMPACTS – NORTHERN HARRIER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for short-term construction-related impacts to northern harrier, such as impaired water quality and lighting, and long-term secondary effects associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as increased human activity, lighting, and impaired

water quality. Mitigation measures to minimize inadvertent impacts to habitat outside construction zones will also be implemented.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and which generally refer to habitat protection, restoration and enhancement, and management, will be implemented to mitigate for the effects of increased human activity and the increase in incidence of vehicle collisions.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These mitigation measures require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along the open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. These mitigation measures will address avoidance and minimization of downstream hydrology and water quality effects that could adversely affect potential nesting habitat for the northern harrier.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to northern harrier, including short-term construction-related, dust, noise, ground vibration,

increased human activity, and impaired water quality, as well as long-term secondary effects, such as increased human activity; harassment by pet, stray, and feral cats and dogs; vehicle collisions; and secondary poisoning and loss of prey due to the use of pesticides.

BIO-52 and BIO-56, as described above, will mitigate the effects of construction noise and increased human activity by identifying nest sites and providing for buffers between nests and construction activities.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, will mitigate for increased human activity and increased incidence of vehicle collisions in the Project area through habitat protection, restoration and enhancement, and management.

BIO-47 requires that slow moving water habitats shall be constructed up stream and down stream of any river crossing or bridge construction area that will provide refuge for northern harrier during construction.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-70 is a more generally applicable mitigation measure that specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides (including rodenticides and insecticides) and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to northern harrier would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

SHORT-EARED OWL (NESTING) (USBC, CSC)

Life History

The short-eared owl (*Asio flammeus*) is a ground-dwelling owl that lives on every continent except Australia (Terres 1980). In North America, its range extends from northern Alaska east to Newfoundland and south to central California. The species may winter in some of its United States breeding range, but individuals from Canada and other colder areas migrate to areas further south of their nesting range when snow affects access to rodent prey (Terres 1980). The wintering range of the species includes all of the United States and most of Mexico (Wiggins *et al.* 2006). The short-eared owl feeds primarily on voles and other small mammals, such as shrews, moles, rabbits, and pocket gophers (Bent 1938; Earhart and Johnson 1970; Wiggins *et al.* 2006). Individuals tend to congregate in areas where vole or other small mammal populations are high. The distribution and abundance of short-eared owls therefore may fluctuate in relation to rodent populations, and nomadic individuals may shift wintering and breeding sites based on spatial and temporal variation in prey abundance.

Short-eared owls are found throughout California as an uncommon but widespread winter migrant, although they may be year-round residents and breeders in northern California. Migrants usually arrive in California in September or October and leave in April (Zeiner *et al.* 1990A). The species has been known to winter in the Central Valley, in the western Sierra Nevada foothills, in the southern desert region, and in the Channel Islands (Zeiner *et al.* 1990A; Dixon and Bond 1937). With only one recent breeding record within the desert regions, the species is considered primarily a non-breeder in southern California (Garrett and Dunn 1981; Terres 1980).

The short-eared owl usually occurs in open mixed and tall grass habitats with few trees, such as annual and perennial grasslands, prairies, tundra, dunes, meadows, agricultural lands, and saline and fresh emergent wetlands (Zeiner *et al.* 1990A; Terres 1980). It commonly uses fence posts and small mounds as perches in open treeless areas (Zeiner *et al.* 1990A). Short-eared owls typically nest on the ground, though they may roost in individual trees or groves near agriculture fields in the winter (Wiggins *et al.* 2006; Terres 1980).

Short-eared owls breed from early March through July (Bent 1938). Eggs are laid in April and May, and clutch size is four to 14 eggs (but usually five to seven), with higher numbers in years with higher prey population (Murray 1976). The female incubates the eggs for 28 to 30 days (Pitelka *et al.* 1955A) and cares for the young while the male brings food to the female (Zeiner *et al.* 1990A). The male also defends the nest with distraction displays and vocalizations (Wiggins *et al.* 2006). Young birds fledge between 24 and 36 days of age (Wiggins *et al.* 2006; Urner 1923).

The relatively large tracts of open habitat required by short-eared owls are increasingly being converted to agricultural, grazing, recreational, and development uses. Numbers of short-eared owl have declined over most of their North American range in recent decades due to the destruction and fragmentation of grassland and wetland habitats (Remsen 1978). Short-eared owls are vulnerable to mesopredators that are associated with urban, rural, and agricultural areas, such as red fox and striped skunk, and domestic dogs. They are also likely vulnerable to pesticides, particularly rodenticides, which may reduce their prey or cause secondary poisoning, and like many other raptors, may be vulnerable to vehicle collisions. This species also often hunts around dusk and dawn and may be affected by artificial lighting, which may affect the behavior of its prey and make it more vulnerable to predators.

Survey Results

Surveys for upland bird species were conducted throughout the Project area and in nearby areas between 1995 and 2008 by a variety of consulting firms and covered the Landmark Village, Mission Village, and Homestead East and West areas as well as Potrero, Long, and Chiquito canyons and the upland habitats along the Santa Clara River (Bloom Biological 2007A, 2008; Dudek and Associates 2006C; Guthrie 2000A, 2000B, 2004A, 2004D, 2004E; Impact Sciences 2000; RECON and Impact Sciences 1996; SAIC 2003). The High Country SMA and Salt Creek area (in the Specific Plan area) were surveyed by Dudek and Associates in 2005 (2006B). Upland surveys have also been conducted in the VCC (Dudek and Associates 2006D; Guthrie 2004B) and Entrada (Dudek and Associates 2006E; Guthrie 2004G) planning areas. Areas near the Project site that have been surveyed for upland bird species include the Legacy Village area adjacent to the Project site on the south and east (Guthrie 2004C), the Castaic Junction area just north of the Entrada planning area (Guthrie 2004F, 2004I), the Riverpark site (now referred to as "River Village") upstream of the Specific Plan area (Compliance Biology 2003A), and upland areas upstream of the VCC planning area, including the Castaic Mesa area (PCR 1998; Compliance Biology 2006A, 2006D).

Short-eared owls have never been observed in the defined Project area. Most of these surveys, however, were conducted in the spring and summer for nesting species and would not have reliably observed migrant or wintering individuals. An individual was observed just outside the Project area boundary in the Salt Creek area just west of the Ventura/Los Angeles County line in the fall of 2005 (Dudek and Associates 2006B). In December 2006, a freshly dead individual was found at the edge of a cultivated field just west of I-5 (off site) during the Santa Clarita bird count (Olson 2007). Based on these two observations, it is assumed for the purpose of this analysis that the short-eared owl at least occurs in the Project area as an occasional migrant and uses the site for foraging.

Suitable foraging habitat for the short-eared owl in the Project area includes agriculture, bulrush–cattail and herbaceous wetland, California annual grassland, purple needlegrass, and valley oak/grass. A total of 4,564 acres of suitable foraging habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 142 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 3.1% of suitable habitat on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat, and **Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat). A total of 82 acres would be temporarily impacted.

The short-eared owl is still a wide-ranging species and likely only occurs on site as an occasional migrant. Because it uses a variety of habitats for foraging, the construction of RMDP facilities would be phased over a long period of time, and approximately 1,500 acres of suitable foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species, the loss of foraging habitat used during migration and temporary impacts that would occur as a result of construction and/or grading activities would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 2,212 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 48.5% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat, and **Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat).

Because the short-eared owl is still a wide-ranging species, likely only occurs on site as an occasional migrant, uses a variety of habitat for foraging, and approximately 1,500 acres of foraging habitat would be preserved in the River Corridor SMA, High Country SMA, and Salt Creek area, this permanent loss of habitat as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,353 acres (51.6%).

Because the short-eared owl is still a wide-ranging species, likely only occurs on site as an occasional migrant, uses a variety of habitat for foraging, and approximately 1,500 acres of foraging habitat would be preserved in the River Corridor SMA, High Country SMA, and Salt Creek area, this combined loss of habitat would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Short-eared owls are highly mobile; therefore, it is unlikely that RMDP-related construction activities would result in injury or mortality of adult birds migrating through the Project area. However, foraging behavior of migrants may be somewhat disrupted because of human activity, noise, and other factors discussed under secondary effects below. Vegetation clearing and grading would not result in destruction of young or eggs of this species because, as a migrant, this species is not expected to nest on site. Implementation of the SCP also would not directly impact this species. Because the Project area supports a large amount of suitable foraging habitat that would not be disturbed, construction and grading activities related to implementation of the RMDP would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is similar to that described above for direct permanent and temporary impacts. Injury or mortality of migrating individuals is expected to be a rare occurrence (*e.g.,* from vehicle collisions or predation), and this species is not expected to nest on site. Therefore, build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would be short term. These potential construction-related secondary effects, such as fugitive dust, ground vibration, noise, nighttime illumination, and increased human activity, would affect a small proportion of short-eared owls migrating through the Project area. Most of these factors would cause short-eared owls to avoid construction areas

during foraging, but lighting could increase their risk of predation or affect the behavior of their prey.

Similarly, potential long-term development-related secondary effects resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas, such as nighttime illumination; noise, increased human activity, predation by pet, stray, and feral cats and dogs and other mesopredators, and vehicle collisions may disrupt foraging behavior and increase injury and mortality rates over existing conditions. Also, pesticides (particularly rodenticides) could reduce prey or cause secondary poisoning. However, because very few individuals apparently use the Project area, these impacts would rarely occur. Furthermore, there would be adequate foraging habitat for migrant individuals well away from development edges; a total of 1,521 acres of suitable foraging habitat would be protected in the River Corridor SMA, High Country SMA, and Salt Creek areas.

These potential short-term and long-term secondary impacts would not have a substantial adverse effect on this species; cause the species to drop below self-sustaining levels on site or rangewide; interfere with the movement of the species between important habitat areas; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the short-eared owl (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat, and **Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 127 acres (2.8%) of permanent loss and 111 acres of temporary loss;
- Alternative 4 – 117 acres (2.6%) of permanent loss and 122 acres of temporary loss;
- Alternative 5 – 152 acres (3.3%) of permanent loss and 103 acres of temporary loss;

- Alternative 6 – 150 acres (3.3%) of permanent loss and 110 acres of temporary loss; and
- Alternative 7 – 68 acres (1.5%) of permanent loss and 347 acres of temporary loss.

Compared to Alternative 2, which would result in 142 acres (3.1%) of permanent habitat loss and 82 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 and 4 would be somewhat reduced, would be marginally increased under Alternatives 5 and 6, and would be substantially reduced under Alternative 7. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be somewhat increased and would be substantially increased under Alternative 7. The difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in substantially fewer permanent impacts and substantially greater temporary impacts under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, these impacts associated with Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the short-eared owl (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat, and **Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 2,098 acres (46.0%) of permanent loss;
- Alternative 4 – 2,021 acres (44.3%) of permanent loss;
- Alternative 5 – 1,985 acres (43.5%) of permanent loss;
- Alternative 6 – 1,855 acres (40.6%) of permanent loss; and
- Alternative 7 – 1,515 acres (33.2%) of permanent loss.

Compared to Alternative 2, which would result in 2,212 acres (48.5%) of permanent loss of habitat, Alternatives 3 through 7 would have successively reduced impacts. Alternative 7 would have substantially reduced impacts due to the much reduced development of agricultural land in Landmark Village and Homestead East (Onion Fields) adjacent to the Santa Clara River. Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under

Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the short-eared owl:

- Alternative 3 – 2,225 acres (48.8%) of permanent loss;
- Alternative 4 – 2,138 acres (46.8%) of permanent loss;
- Alternative 5 – 2,137 acres (46.8%) of permanent loss;
- Alternative 6 – 2,005 acres (43.9%) of permanent loss; and
- Alternative 7 – 1,583 acres (34.7%) of permanent loss.

Compared to Alternative 2, which would result in 2,353 acres (51.6%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have successively reduced impacts. Alternative 7 would have substantially reduced impacts due to the much reduced development of agricultural land in Landmark Village and Homestead East (Onion Fields) adjacent to the Santa Clara River. Because the combined direct and indirect permanent loss of suitable habitat occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Impacts to Individuals

The potential for impacts to short-eared owl individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Injury or mortality of migrating individuals is expected to be a rare occurrence (*e.g.,* from vehicle collisions or predation) and this species is not expected to nest on site. Individuals may be displaced from foraging habitat within and in proximity to construction and development areas. However, because substantial foraging habitat would still be available, construction and/or grading activities would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate

the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Impacts to short-eared owl individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term impacts include construction-related dust, noise, ground vibration, and nighttime illumination, resulting in displacement from foraging habitat and increased risk of predation. These effects are more likely to occur during build-out of the Specific Plan, VCC, and Entrada planning areas than during implementation of the RMDP and the SCP because of the much larger area of impact associated with build-out of the Specific Plan, VCC, and Entrada planning areas.

Potential long-term secondary impacts associated with implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas include increased human activity, increased predation, increased risk of vehicle collisions, and reduction of prey or potential secondary poisoning from use of pesticides, as described above for Alternative 2.

Because the short-eared owl is a migrant, very few individuals likely would be affected, and there would be adequate suitable habitat well away from development edges, these potential short-term and long-term secondary effects would not have a substantial adverse effect on the species or contribute to the reduction of its range and distribution. These secondary impacts would be adverse but not significant.

Mitigation Strategy and Summary

No mitigation is required for impacts to the short-eared owl because all impacts were determined to be adverse but not significant. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA, High Country SMA and Salt Creek area—areas that will form a large, contiguous open space system containing approximately 1,488 acres of foraging habitat for this species. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction because individuals will have access to foraging habitat in undisturbed open space. Mitigation measures also include

biological monitoring during construction and controls on lighting. Long-term effects, such as habitat degradation; increased human activity, pet, stray, and feral cats and dogs; dust, lighting, and pesticides will also be mitigated through a variety of measures.

WESTERN BURROWING OWL (BURROW SITES AND SOME WINTERING SITES) (BCC, CSC)

Life History

The burrowing owl (*Athene cunicularia*) breeds from southern interior British Columbia, southern Alberta, southern Saskatchewan, and southern Manitoba, south through eastern Washington, central Oregon, and California to Baja California, east to western Minnesota, northwestern Iowa, eastern Nebraska, central Kansas, Oklahoma, eastern Texas, and Louisiana, the southern portion of Florida, and south to central Mexico. The species is also locally distributed throughout suitable habitat in Central and South America to Tierra del Fuego, and in Cuba, Hispaniola, the northern Lesser Antilles, Bahama Islands, and in the Pacific Ocean off the west coast of Mexico (County of Riverside 2008). The western subspecies, western burrowing owl (*A. c. hypugaea*), occurs throughout North and Central America west of the eastern edge of the Great Plains south to Panama (County of Riverside 2008). The winter range of the western burrowing owl is much the same as the breeding range, except that most individuals apparently vacate the northern areas of the Great Plains and the Great Basin (County of Riverside 2008). The majority of western burrowing owls that breed in Canada and the northern United States are believed to migrate south during September and October and north during March and April, and into the first week of May. These individuals winter within the breeding habitat of more southern-located populations. Thus, winter observations may include both the migrant individuals as well as the resident population (County of Riverside 2008). Western burrowing owls occurring in Florida are predominantly non-migratory, as are populations in southern California (Thomsen 1971). Western burrowing owls in northern California are believed to migrate (Coulombe 1971). In many parts of the United States, the western burrowing owl's breeding range has been reduced and it has been extirpated from certain areas, including western Minnesota, eastern North Dakota, Nebraska, and Oklahoma (Bates 2006).

In California, western burrowing owls are yearlong residents of flat, open, dry grassland and desert habitats at lower elevations (Bates 2006). They typically inhabit annual and perennial grasslands and scrublands characterized by low-growing vegetation and also may occur in areas that include trees and shrubs if the cover is less than 30% (Bates 2006); however, they prefer treeless grasslands. Although western burrowing owls prefer large, contiguous areas of treeless grasslands, they have also been observed in fallow agriculture fields, golf courses, cemeteries, road allowances, airports, vacant lots in residential areas and university campuses, and fairgrounds when nest burrows are present (Bates 2006; County of Riverside 2008). The availability of numerous small mammal burrows, such as those of California ground squirrel (*Spermophilus beecheyi*), is a major factor in determining whether an area with apparently suitable habitat supports western burrowing owls (Coulombe 1971). Western burrowing owls rarely use areas without colonies of burrowing mammals (Zarn 1974). They can excavate holes where burrowing mammals are absent but rarely do so (Thomsen 1971). County of Riverside

(2008) suggest that western burrowing owls exhibit high site-fidelity and reuse burrows year after year.

Western burrowing owls are opportunistic feeders, primarily feeding on arthropods, small mammals, and birds, and often need short grass, mowed pastures, or overgrazed pastures for foraging (County of Riverside 2008). Western burrowing owls are primarily crepuscular in their foraging habits but hunting has been observed throughout the day (Thomsen 1971; Marti 1974). Insects are often taken during daylight, whereas small mammals are taken more often after dark (County of Riverside 2008).

Western burrowing owls breed from March through August, with a peak in April and May. Migrants arrive on the breeding areas either singly or paired. Non-migrants retain their pair bonds throughout the year (County of Riverside 2008). Clutch size is six to 11 eggs, with an average of seven to nine eggs. Young emerge from burrows at about two weeks, and fly after about four weeks (Zarn 1974). Martin (1973) reported 95% of young fledging, with a mean reproductive success of 4.9 young per pair.

Factors related to declines in western burrowing owl populations include the loss of natural habitat due to urban development and agriculture; other habitat destruction; predators, including domestic dogs; collisions with vehicles; and pesticides/poisoning of ground squirrels (Grinnell and Miller 1944; Zarn 1974; Remsen 1978). A ranking of the most important threats to the species included loss of habitat, reduced burrow availability due to rodent control, and pesticides (James and Espie 1997). Adjacency to development also is a threat to the western burrowing owl due to damaged burrows caused by dogs and humans. Collision with vehicles is a frequent cause of mortality because of the owl's behavior of sitting and hunting on roads at night. Use of pesticides may have direct toxic effects; for example, when carbofuran, a carbamate insecticide, is sprayed over nest burrows (County of Riverside 2008). Secondary poisoning due to contaminated prey may also be a factor. On pastures where strychnine-coated grain is used to control ground squirrels, owl weights were significantly lower than on control pastures, suggesting a sublethal effect or less available food (County of Riverside 2008).

Survey Results

Numerous bird surveys have been conducted between 1996 and 2008 in the Project area in areas with suitable burrowing owl habitat (agriculture and grasslands), but no CDFG burrowing owl protocol surveys have been conducted in the Project area. General bird surveys have been conducted in Landmark Village; Mission Village; and Homestead East and West areas; Potrero, Long, and Chiquito canyons; and the upland habitats along the Santa Clara River (Bloom Biological2007A, 2008; Dudek and Associates 2006C; Guthrie 2000A, 2000B, 2004A, 2004D, 2004E; Impact Sciences 2000; RECON and Impact Sciences 1996; SAIC 2003). The High Country SMA and Salt Creek area (in the Specific Plan area) were surveyed by Dudek and Associates in 2005 (2006B). Upland surveys have also been conducted in the VCC (Dudek and

Associates 2006D; Guthrie 2004B) and Entrada planning areas (Dudek and Associates 2006E; Guthrie 2004G). Areas near the Project area that have been surveyed for upland bird species include the Legacy Village area adjacent to the Project area on the south and east (Guthrie 2004C); the Castaic Junction area just north of the Entrada planning area (Guthrie 2004F, 2004I); the Riverpark site (now referred to as River Village) upstream of the Specific Plan area (Compliance Biology 2003A); and upland areas upstream of the VCC planning area, including the Castaic Mesa area (PCR 1998; Compliance Biology 2006A, 2006D).

The western burrowing owl was not observed during these surveys. The surveys frequently passed through uplands and open grassland areas and documented all observed special-status species. While these surveys were not focused on western burrowing owl, this species is highly detectable and would have been detected if present. Furthermore, surveys conducted by Bloom Biological, Inc. in 2007 and 2008 emphasized agriculture fields and abandoned fields in the Project area during dawn and dusk when the western burrowing owl is most active (2007A, 2008).

Surveys have also been conducted within the River Corridor SMA for riparian birds from 1988 to 2006, including within Castaic Creek and the Santa Clara River from the I-5 bridge to the Las Brisas Bridge, west of the Ventura County line (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C; Labinger *et al.* 1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A). These surveys included the riparian vegetation in the River corridor and also adjacent upland habitat and likely would have resulted in the detection of western burrowing owl if present within these areas. However, the western burrowing owl was not observed during these surveys.

The western burrowing owl has been incidentally observed at two locations (**Figure 4.5-6,** RMDP/SCP– Special-Status Wildlife Species Occurrences). A single western burrowing owl individual was observed twice at the same location within a four-week period (November and December 2006) in the northern portion of Middle Canyon, east of Airport Mesa, in ruderal habitat (Babcock 2007). Another individual was observed in December 2006 in Middle Canyon, and again on April 11, 2007 (Miller 2007). It was observed on the upslope portion of a hill with relatively bare coverage, adjacent to the road near coastal scrub, utilizing a small mammal burrow, which it appeared to have only recently occupied. Given the timing of the sightings (winter of 2006 and spring of 2007) and the fact that there have been no other observations of the western burrowing owl during the numerous spring and summer surveys, the observed individuals likely were wintering on site or temporarily using the site during migration.

The available information indicates that the western burrowing owl occasionally uses the site for wintering or during migration, but is unlikely to nest on site. However, the Project area is within

its breeding range and thus it is considered to have potential to breed on site, and is analyzed in that context. The Project area supports suitable habitat for the western burrowing owl, including California annual grassland, purple needlegrass, disturbed land, and agriculture (where the agriculture is not continuously or frequently tilled). A total of 5,118 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 212 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 4.1% of these habitats on site (**Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat). A total of 94 acres would be temporarily impacted.

The observation of two western burrowing owls between 1988 and 2007 indicates that the Project area is occasionally used for wintering or during migration. Due to the lack of CDFG protocol burrowing owl surveys in the Project area, the likelihood of this species using dens for nesting or wintering on site is unknown. If burrowing owl were to use dens on site for nesting or over-wintering, the loss of the dens as the result of construction activities would have a substantial adverse effect; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 3,079 acres of suitable habitat would be permanently loss through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 60.2% of suitable habitats on site (**Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat).

Because the western burrowing owl is known to use the Project area for wintering or during migration, and has at least some potential to nest on site, the loss of 60.2% of suitable habitat would substantially reduce the available habitat on site for this species. Therefore, this loss of habitat would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,291 acres (64.3%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the western burrowing owl in the Project area and substantially restrict its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because the western burrowing owl is highly mobile, it is unlikely that implementation of the RMDP would result in mortality of adult birds of this species. However, foraging adult birds would be expected to leave construction areas and nearby areas, thus affecting their distribution on site. Also, because there is some potential for the western burrowing owl to nest on site, implementation of the RMDP could result in destruction of natal dens, young, or eggs if construction/grading activities occurred during the nesting season. Implementation of the SCP would not directly impact this species.

Because of the special status of this bird species and the potential for impacts to individual birds, specifically loss of, young, and/or eggs as a result of nest destruction or

nest abandonment during construction/grading activities, the implementation of the RMDP could have a substantial direct adverse effect on this species; impede the use of a native wildlife nursery site; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The western burrowing owl is a mobile species and it is unlikely that build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of individual adult birds. However, foraging adult birds would be expected to leave construction areas and nearby areas, thus affecting their distribution on site. Also, mortality of young and/or eggs due to destruction of nests could occur if construction/grading activities occurred during the nesting season of this species. Impacts to eggs or young would be a substantial adverse effect on a special-status species (significance criterion 1). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, fugitive dust, increased human activity, and nighttime illumination. Because this species uses ground burrows for nesting and during wintering and migration, they are more susceptible to harassment by humans and disturbances from ground vibration, noise, and dust. Because this species often forages around dusk and dawn, nighttime lighting could increase its risk of predation and affect the behavior of its prey. Although construction would be short term in nature, these construction-related disturbances therefore could result in impacts to individuals, abandonment of winter and breeding burrows, or a decrease in nesting success of western burrowing owl.

Potential long-term secondary impacts from the build-out of the Specific Plan, VCC, and Entrada planning areas include abandonment of winter and nesting burrow sites due to nighttime lighting; noise disturbance; harassment by humans; increased harassment and predation by pet, stray, and feral cats and dogs; as well as other mesopredators. The use of pesticides within and adjacent to open foraging areas could result in direct and secondary poisoning to the western burrowing owls, a reduction in prey, and a loss of potential burrow sites created by ground squirrels. In addition, the increase in traffic associated with urban development may result in an increased incidence of vehicle collisions.

Short-term and long-term secondary impacts would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for western burrowing owl (**Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 197 acres (3.8%) of permanent loss and 132 acres of temporary loss;
- Alternative 4 – 179 acres (3.5%) of permanent loss and 142 acres of temporary loss;
- Alternative 5 – 234 acres (4.6%) of permanent loss and 118 acres of temporary loss;
- Alternative 6 – 238 acres (4.6%) of permanent loss and 132 acres of temporary loss; and
- Alternative 7 – 112 acres (2.2%) of permanent loss and 438 acres of temporary loss.

Compared to Alternative 2, which would result in 212 acres (4.1%) of permanent habitat loss and 94 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 and 4 would be somewhat less, somewhat more under Alternatives 5 and 6, and substantially less under Alternative 7. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be somewhat more and would be substantially more under Alternative 7. The difference between Alternative 7 (substantially less permanent impacts and substantially more temporary impacts) is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Although the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be less than or similar in magnitude compared to Alternative 2, if the burrowing owl were to use dens for nesting or over-wintering, the permanent loss of these dens would be significant, absent mitigation, under Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for western burrowing owl (**Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 2,955 acres (57.7%) of permanent loss;
- Alternative 4 – 2,821 acres (55.1%) of permanent loss;
- Alternative 5 – 2,767 acres (54.1%) of permanent loss;
- Alternative 6 – 2,548 acres (49.8%) of permanent loss; and
- Alternative 7 – 2,087 acres (40.8%) of permanent loss.

Compared to Alternative 2, which would result in 3,079 acres (60.2%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 6 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries, as well as other changes in the Project footprint under Alternative 7 compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, but still substantial, these impacts would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for western burrowing owl:

- Alternative 3 – 3,152 acres (61.6%) of permanent loss;
- Alternative 4 – 3,000 acres (58.6%) of permanent loss;
- Alternative 5 – 3,001 acres (58.6%) of permanent loss;
- Alternative 6 – 2,785 acres (54.4%) of permanent loss; and
- Alternative 7 – 2,200 acres (43.0%) of permanent loss.

Compared to Alternative 2, which would result in 3,291 acres (64.3%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, there would also be generally successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7 (Alternatives 4 and 5 would have nearly identical impacts), and there would be additional pullbacks from the Santa Clara River and its tributaries, as well as other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for western burrowing owl occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial and therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to western burrowing owl individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Migrating and wintering adults could be displaced from suitable foraging habitat and there is some potential for impacts to eggs and/or young as a result of destruction of nest burrows if breeding occurred on site. Impacts to individual western burrowing owls occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented

above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term impacts include construction-related dust, noise, ground vibration, increased human activity, and nighttime illumination. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas include noise; nighttime illumination; pesticides; increased human activity; predation by pet, stray, and feral cats and dogs and mesopredators; and increased incidence of vehicle collisions, as described above for Alternative 2.

These potential short-term and long-term secondary effects would have a substantial adverse effect on the species and contribute to the reduction of its range and distribution. These long-term and short-term secondary impacts would be significant, absent mitigation, for Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to western burrowing owl: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

There are a few incidental observations of western burrowing owls on site that were determined to be wintering or migrating individuals. Nesting by this species has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. However, for the purpose of this analysis, it is assumed that western burrowing owls could nest on site. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, individuals could be displaced from suitable foraging habitat by construction activities. Impacts to individuals also could occur if western burrowing owls were to nest on site and active nests were disturbed during vegetation clearing and construction/grading activities, resulting in the destruction of the nests and loss of eggs and/or young. Construction activities may also cause abandonment of nests due to human activity, noise, and ground vibration. In order to avoid these impacts, focused surveys for western burrowing owls and assessment of their nesting status, if present, will be conducted 30 days prior to construction activities. Non-breeding individuals will be evacuated from the site using CDFG-approved burrow closure procedures and, in the case of breeding individuals, construction work within 500 feet of the nest will be delayed until fledglings have left the nest. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable habitat for the western burrowing owl resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,200 acres (43.0%) under Alternative 7 to

3,291 acres (64.3%) under Alternative 2. This would be a substantial loss of suitable habitat for this species and will alter its use of the Project area for foraging, and potentially nesting. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a permanent open space system that will provide suitable habitat to support both foraging and breeding by the western burrowing owl in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 896 acres of suitable habitat for the western burrowing owl in the High Country SMA and the Salt Creek area (**Figure 4.5-3**), as well as 100 acres in the River Corridor SMA.

With regard to secondary effects, foraging, and potentially nesting, activities by the western burrowing owl could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may cause adults to vacate foraging areas and abandon nests, if breeding were to occur, due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to predators, such as domestic dogs. These short-term construction-related secondary impacts will be minimized by conducting pre-construction surveys to determine if burrowing owl dens, including active nests, are present in the disturbance zone or within 500 feet and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-term development-related impacts include habitat fragmentation; increased noise; lighting; pesticides, which may cause direct and secondary poisoning, loss of prey, and loss of ground squirrel burrow sites; human disturbances of nest sites; predation and harassment by pet, stray, and feral cats and dogs and other mesopredators; and increased vehicle collisions. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 896 acres of suitable habitat in the High Country SMA and Salt Creek area and 100 acres in the River Corridor SMA will provide western burrowing owls with relatively undisturbed habitat for foraging and potentially nesting. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by predators and reduce behavioral disturbances and physiological stress. Limited recreational usage and access restrictions within the High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect western burrowing owls by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of direct and secondary poisoning, loss of prey, and loss of burrow sites.

The specific mitigation measures for the western burrowing owl are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-70 IMPACTS TO INDIVIDUALS – WESTERN BURROWING OWL

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of western burrowing owl individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two mitigation measures to reduce impacts to western burrowing owl individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-57 requires a survey for the presence of burrowing owls and nesting status of the individuals at the site 30 days prior to construction activities. Surveys shall be conducted in areas dominated by field crops, disturbed habitat, and grasslands; and along levee locations, or if such habitats occur within 500 feet of a construction zone. If the burrowing owl is detected but nesting is not occurring, construction work can proceed after any owls have been evacuated from the site using CDFG-approved burrow closure procedures and after alternative nest sites have been provided. If nesting is occurring, construction work within 500 feet shall be delayed until fledglings have left the nest. Surveys shall only be conducted in areas dominated by field crops and grassland, or if such habitats occur within 500 feet of a construction zone.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to western burrowing owl individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-71 LOSS OF HABITAT – WESTERN BURROWING OWL

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for western burrowing owl through habitat protection, restoration and enhancement, and management.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The High Country SMA will protect and manage at least 571 acres of suitable habitat for the western burrowing owl.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measure to mitigate for the loss of habitat for the western burrowing owl through habitat protection, restoration and enhancement, and management.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. The Salt Creek area includes 324 acres of suitable habitat for the western burrowing owl.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the western burrowing owl would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-72 SECONDARY IMPACTS – WESTERN BURROWING OWL

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Measures Recommended by EIS/EIR

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on the western burrowing owl associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such noise, increased human activity, and greater vulnerability to predators and disturbances of behavior and increased physiological stress as a result of nighttime lighting. These mitigation measures provide for protection, restoration, enhancement, and management of habitat in open space for western burrowing owl that will offset secondary impacts by providing high-quality habitat away from development areas.

Mitigation measures to minimize inadvertent impacts to habitat outside construction zones will also be implemented.

SP-4.6-53 and SP-4.6-59, as described above, will be implemented to mitigate impacts from increased short-term human activity associated with construction.

SP-4.6-36 through SP-4.6-42, as described above and which generally refer to habitat protection in the High Country SMA, will be implemented to mitigate for long-term habitat fragmentation effects and increased human activity.

SP-4.6-29 through SP-4.6-32 will be implemented to mitigate for impacts related to increased human activity in the High Country SMA through limiting access to daytime use of the designated trail system; prohibiting pets (with the exception of horses on established trails); prohibiting hunting, fishing, and motor or off-trail bike riding; and providing trail design guidelines to minimize impacts to native habitats.

SP-4.6-33 will be implemented to mitigate potential adverse edge effects by permitting construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-34 and SP-4.6-35 require that all grading perimeters within High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Previously Incorporated Measures

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to western burrowing owl, including short-term construction-related dust, noise, ground vibration, and increased human activity, as well as long-term habitat fragmentation; increased human activity; greater vulnerability to predation by pet, stray, and feral cats and dogs; direct and secondary poisoning and loss of prey and burrows from pesticide use; and increased incidence of vehicle collisions.

BIO-52 and BIO-57, as described above, will mitigate the effects of noise and ground vibration by identifying nest sites and providing for buffers between nests and construction activities.

BIO-19, as described above, will mitigate for habitat fragmentation effects and increased human activity in the Project area through habitat protection and management in the Salt Creek area.

BIO-63 and BIO-69 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-64 will be implemented to prevent poisoning, loss of prey, and loss of burrows and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the western burrowing owl would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

SUMMER TANAGER (NESTING) (CSC)

Life History

The summer tanager (*Piranga rubra*) is found in the eastern and southwestern United States, Central America, and South America, and regularly occurs north of Mexico. It primarily breeds in the eastern United States from New Jersey south to Florida, west to southern Illinois, and south to Texas. It also breeds in portions of New Mexico, Arizona, California, and Baja California. It winters in Central Mexico, south through Central America, and as far south as Bolivia and Brazil. Summer tanagers migrate from their breeding grounds to their wintering grounds in September and October (Robinson 1996).

The summer tanager was once a common summer resident and breeder in the desert riparian areas along the Colorado River Valley. It now occurs less commonly in the Colorado River Valley and can be found in isolated populations in southern California desert habitats. It may also nest near the City of Weldon on the south fork of the Kern River (Garrett and Dunn 1981). During migration, it can be found along the coast south of Los Angeles County as a rare but regular migrant (Zeiner *et al.* 1990A; Garrett and Dunn 1981).

Western populations of summer tanagers occupy riparian woodlands dominated by willows (*Salix* spp.) and cottonwoods (*Populus* spp.) at lower elevations (Robinson 1996; Rosenberg *et al.* 1982, 1991) and mesquite (*Prosopis* spp.) and tamarisk (*Tamarix* spp.) habitats at higher elevations (Robinson 1996). During the winter, the summer tanager occurs in open and second-growth habitats within its range, typically below 1,200 meters (3,937 feet) AMSL (Robinson 1996). In Mexico, it occurs in humid evergreen forest and tropical deciduous forest, especially along forest edges (Robinson 1996). Elsewhere, it is typically found along forest edges, within second-growth woodlands, and in shrubby clearings, as well as in parks and gardens in towns, and in woodland thinned for coffee plantations (Robinson 1996).

The summer tanager commonly feeds on bees and wasps, often foraging for larvae from hives and nests (Robinson 1996). It feeds on other insects, spiders, and small fruits and berries. It also captures flying insects during short sallies from a perch and gleans insects and fruits from leaf and bark surfaces of trees and shrubs (Robinson 1996).

The males begin to arrive to the breeding grounds in April, slightly before the females. Nests are constructed on a large, horizontal limb of a tree within riparian vegetation, usually a cottonwood or willow tree, approximately 3 to 6 meters (10 to 20 feet) above the ground (Zeiner *et al.* 1990A). The nest is constructed in an open-cup shape from dried herbaceous vegetation, and is usually placed among or under leaves (Robinson 1996).

There is little specific threat information for summer tanager. Robinson (1996) describes habitat destruction as the largest effect of human activities on the summer tanager. In the southwest,

particularly in southern California and the Colorado River valley, populations of summer tanagers have declined, due the elimination of riparian willow and cottonwood forest. Nest parasitism by brown-headed cowbirds may also be a factor contributing to declining populations. However, as discussed below, this species is not expected to nest on site and nest parasitism therefore would not be a potential impact of the proposed Project. Like other riparian bird species, however, several other potential human- or development-related factors may affect summer tanager. Construction related impacts include dust; noise and ground vibration; diminished water quality and altered hydrology; increased human activity in close proximity to foraging areas; and lighting, which may alter foraging behavior, induce physiological stress, and increase predation risk. Long-term effects related to development include increased human activity; noise; lighting; diminished water quality and altered hydrology; predation and harassment by pet, stray, and feral cats and dogs and other mesopredators; and pesticides, which may reduce insect prey or cause secondary poisoning.

Survey Results

Suitable nesting and foraging habitat for the summer tanager exists in riparian woodland habitat along the Santa Clara River and Castaic Creek in the Project area. However, no individuals have been observed within the Project area during annual riparian bird surveys conducted from 1988 to 2007 along the Santa Clara River (Bloom Biological 2007A; Guthrie 1988, 1989, 1990, 1991A, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2005A, 2005B, 2006A, 2006C; Labinger *et al.* 1995, 1997B; Labinger and Greaves 1999A). This species occurs only rarely in coastal southern California as a breeding bird. Bloom Biological, Inc (2007A) describes this species as not being known to breed within the Santa Clara River watershed, but reports that it may be found on the site occasionally in migration. Because the majority of the surveys in riparian areas were conducted during the spring and summer breeding season, migrating individuals may have been missed.

Southern cottonwood–willow riparian, southern coast live oak riparian forest, and southern willow scrub are suitable habitat for this species. It is assumed for the purpose of this analysis that the summer tanager may occur as a migrant but that it does not breed on site. A total of 445 acres of suitable habitat that could be used by summer tanagers during migration is present within the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use

practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 39 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 8.7% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). A total of 44 acres would be temporarily impacted.

The summer tanager is a wide-ranging species that uses a variety of riparian-associated habitats. The construction of RMDP facilities would be phased over a long period of time, and hundreds of acres of suitable riparian habitat in the River Corridor SMA and associated tributaries would be available for individuals of this species migrating through the Project area at any given time. Therefore, the permanent loss of 39 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 7.8 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 1.8% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat).

Because the summer tanager is a wide-ranging species that may only occur on site as an occasional migrant and is not expected to nest in the Project area, the loss of 7.9 acres of habitat that would occur as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the

movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 47 acres (10.4%). Because the summer tanager is a wide-ranging species that may only occur on site as an occasional migrant and is not expected to nest in the Project area, the loss of 47 acres of habitat from the combined direct and indirect permanent impacts of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The summer tanager is a mobile species that may occasionally occur on site as a migrant and is not expected to nest in the Project area. It is highly unlikely that construction activities associated with implementation of the RMDP would result in the injury or mortality of individual adult birds. Foraging and resting behavior, however, may be somewhat disrupted by construction activities because individuals would probably avoid or leave construction areas for other undisturbed habitat areas. The summer tanager is not expected to breed on site, so nests with eggs or young would not be affected. Implementation of the SCP would not directly impact this species. Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

The summer tanager is a mobile species and it is highly unlikely that build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of individual adult birds. Foraging and resting behavior, however, may be somewhat disrupted by construction activities because individuals would probably avoid or leave construction

areas for other undisturbed habitat areas. The summer tanager is not expected to breed on site, so nests with eggs or young would not be affected. Indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, fugitive dust, increased human activity, nighttime illumination, and diminished water quality and altered hydrology. These effects may disturb summer tanagers that use the site for resting and foraging during migration, causing them to avoid or leave areas near construction, or reducing habitat quality and affecting prey abundance.

Potential long-term secondary impacts associated with urban development include traffic noise; nighttime illumination; invasion of suitable habitat by exotic species, such as giant reed and tamarisk; increased litter; pesticide use resulting in loss of prey and/or secondary poisoning; increased human activity; harassment and predation by pet, stray, and feral cats and dogs; and increased mesopredators as a result of increased habitat fragmentation. These secondary impacts may result in migrating summer tanagers avoiding or leaving areas subject to these effects and there would be increased potential for predation of individuals.

Altered hydrology and geomorphology in the Santa Clara River corridor as a result of urban development in the watershed and resulting impacts to suitable habitat for the summer tanager, are also potential long-term secondary effects of the build-out of the Specific Plan, VCC, and Entrada planning areas. However, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County over the long term. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue. As a result, the mosaic of habitats in the River that support various special-status species would be maintained and would not be significantly affected.

Because the summer tanager is a wide-ranging species that may only occasionally use habitat in the Project area during migration, these short-term and long-term secondary impacts would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the summer tanager (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitats):

- Alternative 3 – 25 acres (5.6%) of permanent loss and 43 acres of temporary loss;
- Alternative 4 – 26 acres (5.8%) of permanent loss and 41 acres of temporary loss;
- Alternative 5 – 31 acres (7.0%) of permanent loss and 47 acres of temporary loss;
- Alternative 6 – 17 acres (3.9%) of permanent loss and 43 acres of temporary loss; and
- Alternative 7 – 7.9 acres (1.8%) of permanent loss and 24 acres of temporary loss.

Compared to Alternative 2, which would result in 39 acres (8.7%) of permanent habitat loss and 44 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 through 7 would be substantially reduced. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 and 6 would be marginally different, Alternatives 4 and 5 would be somewhat different, and Alternative 7 would be substantially reduced. The difference for direct permanent and temporary impacts under Alternative 7 compared to the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Because the overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be substantially reduced compared to Alternative 2, and temporary impacts would be similar in magnitude to substantially reduced, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the summer tanager (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitats):

- Alternative 3 – 6.9 acres (1.6%) of permanent loss;
- Alternative 4 – 3.5 acres (0.8%) of permanent loss;

- Alternative 5 – 2.6 acres (0.6%) of permanent loss;
- Alternative 6 – 1.3 acres (0.3%) of permanent loss; and
- Alternative 7 – 0.7 acre (0.1%) of permanent loss.

Compared to Alternative 2, which would result in 7.8 acres (1.8%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts; Alternative 3 would have marginally reduced impacts and Alternatives 4 through 7 would have successively greater reductions compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the summer tanager:

- Alternative 3 – 32 acres (7.2%) of permanent loss;
- Alternative 4 – 29 acres (6.5%) of permanent loss;
- Alternative 5 – 34 acres (7.5%) of permanent loss;
- Alternative 6 – 19 acres (4.2%) of permanent loss; and
- Alternative 7 – 8.5 acres (1.9%) of permanent loss.

Compared to Alternative 2, which would result in 47 acres (10.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. There would generally be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 3, 4, 6, and 7. Alternative 5 would have the next largest impact compared to Alternative 2. Because the combined direct and indirect permanent loss of suitable habitat for the summer tanager occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Impacts to Individuals

The potential for impacts to summer tanager individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada

planning areas under Alternatives 3 through 7 would be similar to Alternative 2. Adult birds would likely avoid impacts during construction activities by avoiding or leaving construction areas, resulting in potential impacts to foraging and resting. Because the species does not nest on site, nests with eggs and young would not be affected. Because the summer tanager is a wide-ranging species and may only occur on site as an occasional migrant, direct and indirect permanent impacts (Impacts to Individuals) would be adverse but not significant under Alternatives 3 through 7.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term impacts include construction-related dust; noise and ground vibration; increased human activity; nighttime illumination; and diminished water quality and altered hydrology. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas include increased human activity; diminished water quality; traffic noise; nighttime illumination; exotic plant species; litter; pesticides; and predation by pet, stray, and feral cats and dogs and mesopredators, as described above for Alternative 2.

Because the summer tanager is a wide-ranging species and may only occasionally occur on site during migration, these potential short-term and long-term secondary effects would not have a substantial adverse effect on the species and would not contribute to the reduction of its range and distribution. These long-term and short-term secondary impacts would be adverse but not significant for Alternatives 3 through 7.

Mitigation Strategy and Summary

No mitigation is required for impacts to the summer tanager because all impacts were determined to be adverse but not significant. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of approximately 321 acres of suitable riparian habitat in the River Corridor SMA, as well as drainages in the Salt Creek area and High Country SMA that contain riparian habitats. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction, because individuals will have access to foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction and controls on lighting. Long-term effects, such as

habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; and pesticides, will also be mitigated through a variety of measures.

TRICOLORED BLACKBIRD (NESTING COLONY) (BCC, CSC)

Life History

The tricolored blackbird (*Agelaius tricolor*) is almost endemic to California. Approximately 99% of tricolored blackbirds occur in California, but their range includes small portions of Oregon and Washington, eastern Nevada, northern Baja California, and Mexico (County of Riverside 2008). Populations in California generally inhabit the same area all year round, and do not need additional wintering sites, but most populations have been restricted to the Central Valley and surrounding foothills and coastal and some inland localities in southern California. In California, the tricolored blackbird breeds locally west of the Cascade Range, Sierra Nevada, and southeastern deserts from Humboldt and Shasta counties south to extreme southwestern San Bernardino County, western Riverside County, and western and southern San Diego County. In central California, breeding colonies extend east into the foothills of the Sierra Nevada. It also breeds in the marshes of Klamath Basin in Siskiyou and Modoc counties and Honey Lake Basin in Lassen County (County of Riverside 2008).

The tricolored blackbird usually breeds in freshwater marshes with dense growths of emergent vegetation dominated by cattails (*Typha* spp.) or bulrushes (*Schoenoplectus* spp.), but breeding colonies also occur in willows (*Salix* spp.), blackberries (*Rubus* spp.), thistles (*Cirsium* and *Centaurea* spp.), and nettles (*Urtica* sp.). More recently, breeding habitat has included diverse upland and agricultural areas. Many colonies have been reported in Himalayan blackberries (*Rubus discolor*) and some of the largest colonies are in silage and grain fields in the San Joaquin Valley. Other nesting habitats include giant reed (*Arundo donax*), safflower (*Carthamus tinctorius*), mustard (*Brassica nigra*), stinging nettle (*Urtica dioica*), tamarisk (*Tamarix* spp.), riparian scrublands and forests (*e.g.*, willows and Fremont cottonwood (*Populus fremontii*), California ash (*Fraxinus latifolia*), and mulefat (*Baccharis salicifolia*)), a desert olive (*Forestiera neomexicana*) grove, wheat (*Triticum* spp.), barley (*Hordeum* spp.), and thistles. Dairies and feedlots are components of many tricolored blackbird breeding habitats. The tricolored blackbird usually forages in open habitats such as grassland, woodland, and croplands (County of Riverside 2008). Most foraging occurs within 3.1 miles of colony sites (County of Riverside 2008).

As colonial nesters, tricolored blackbirds generally construct their nests within 12 inches or less of one another. Colonies are "itinerant," changing nesting locations from year to year, and often nesting at more than one location during the breeding season; two broods per year may be raised (County of Riverside 2008). Although they often change nesting locations, they require secure nesting substrates, water, and suitable foraging habitats for breeding (County of Riverside 2008). Breeding occurs mid-April and extends into late July. Clutch size is typically three or four eggs, with clutches of two and five eggs occasionally observed (Emlen 1941). Incubation is about 11 days, and young are fledged at about 13 days (County of Riverside 2008).

The tricolored blackbird primarily feeds on seeds and invertebrates, and requires an abundant, concentrated supply of insects for successful breeding colonies. Observations of tricolored blackbirds indicate that they require some free water in addition to insects. Opportunistic foragers, tricolored blackbirds consume any locally abundant insect resource, including grasshoppers, grains (maturing and ripe seeds), snails, and small clams, often exploiting concentrated agricultural food resources (County of Riverside 2008).

The main threats to the tricolored blackbird are a result of human activity related to habitat loss and alteration; most of the Central Valley has been converted from suitable nesting and foraging habitat for the species to non-suitable conditions by agriculture and urbanization (County of Riverside 2008). Population studies have shown a decline in population of 37% between 1994 and 1997, with the number and size of colonies shrinking. Colonies with fewer than 1,000 adults had increased from 25% in the 1930s to almost 67% in the 1980s, and colonies with more than 10,000 adults had dropped from 12% to 3% (County of Riverside 2008).

Various reports also noted unexplained abandonment of entire colonies at advanced stages of nesting. One factor may be insufficient food supplies to support the young (County of Riverside 2008). Another factor may be human activities, because localized abandonment of active nests have been observed where colonies were entered and human-related activities were adjacent to the colony for several hours (Beedy and Hayworth 1992). Also, because nests are colonial, tricolored blackbirds are susceptible to massive nest destruction and failure from predators (Beedy *et al.* 1991).

Tricolored blackbirds have shown reproductive failure as a result of pesticides and other toxins. During 1986, Beedy and Hayworth (1992) observed almost complete nesting failure of a large colony (about 47,000 adults) at Kesterson Reservoir, Merced County, an area contaminated by selenium deposited from agricultural drainage water. At a Kern County colony, all eggs sprayed with mosquito abatement oil failed to hatch (County of Riverside 2008). The loss of at least two colonies has been attributed to aerial herbicide applications (County of Riverside 2008).

As with other wetland and riparian species, tricolored blackbirds may be sensitive to several other human- or development-related impacts. Construction-related dust; noise and ground vibration; nighttime lighting; and diminished water quality and altered hydrology are all factors that could affect tricolored blackbirds in the short term. Noise; lighting; diminished water quality and altered hydrology (*e.g.*, groundwater pumping and dewatering); increased human activity; and predation by pet, stray, and feral cats and dogs and other mesopredators are all factors that could affect tricolored blackbirds over the long term. Overgrazing of pastures and grassland may reduce important prey for tricolored blackbirds, such as grasshoppers.

Survey Results

Surveys for riparian species have been conducted over multiple years along the Santa Clara River within suitable habitat for the tricolored blackbird. These surveys were conducted from 1988 through 2006 within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C); within portions of the Santa Clara River by Labinger *et al.* in 1994, 1996, and 1997 (1995, 1996, 1997A, 1997B) and Labinger and Greaves in 1998 (1999A); within Castaic Creek, Salt Creek, High Country SMA, and portions of the Santa Clara River adjacent to the Project site by Dudek and Associates (2006B, 2006D, 2006E); and within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line by Bloom Biological, Inc. in 2007 and 2008 (2007A, 2008). These surveys generally included both the riparian habitat within the River corridor and adjacent fields, both of which are suitable breeding and foraging habitat for the tricolored blackbird.

This species has been observed on the Project site during focused bird surveys. Migrants have also been observed within the Specific Plan area (Guthrie 1996B, 1999B), the VCC planning area (Guthrie 1999A, 2006C), and off site in Castaic Junction (Guthrie 1995A, 2000E, 2001A, 2006C; Dudek and Associates 2006E) during surveys. Except for 1994, no breeding colonies have been observed, despite annual surveys from 1988 to 2007. According to Guthrie (1994A), a colony of about 200 breeding pairs was observed in a small marsh area along the side of the Santa Clara River at the Castaic Junction east of the RMDP Project area and another smaller colony of about 20 breeding pairs was observed in a pond beside Castaic Creek within the SCP boundary, which appeared to be an old borrow pit left over from work on the flood control dikes. Neither of the colonies had been observed in previous survey years, and Guthrie (1994A) suggested that rains in 1994 resulted in standing water and lush growth of cattails in both locations. Guthrie stated that "a small number of tricolored blackbirds appeared in April and May and inspected the Castaic Creek site. However, the birds apparently found the site unsuitable and did not attempt to breed." (Guthrie 1995A).

It is unknown why tricolored blackbirds apparently attempted nesting in the Project vicinity only in 1994. On site, there is some suitable nesting habitat within marsh habitat that may be present during wet periods within the Santa Clara River and Castaic Creek. There are also agriculture areas and some grassland areas adjacent to portions of the river in the RMDP area and the VCC planning area that are suitable foraging habitat. As noted above, however, colonies may change nesting locations from year to year, and they require secure nesting sites (County of Riverside 2008). It is possible that the increased urbanization in the area over the last decade, including increased traffic and noise, has resulted in nesting habitats not being secure enough to attract

breeding colonies. Tricolored blackbirds are easily disturbed during settlement, egg-laying, and early incubation (County of Riverside 2008).

Nesting habitat in the Project area for the tricolored blackbird includes bulrush–cattail wetland and coastal and valley freshwater marsh, which total 3.4 acres. Foraging habitat includes cismontane alkali marsh, herbaceous wetland, grasslands (California annual grassland, purple needlegrass), agriculture, and disturbed land, which total 5,320 acres. A total of 5,324 acres of nesting and foraging habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 224 acres of suitable nesting and foraging habitat would be permanently lost through implementation of the RMDP and the SCP, representing 4.2% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat, and **Figure 4.5-66**, Alternative 2 Impacts to California Annual Grassland, Agriculture, and Disturbed Land Wildlife Habitat). Of these impacts, 1.6 acres are to nesting habitat, representing 47.0% of this habitat on site. The remaining 222 acres of impact are to foraging habitat, representing 4.2% of this habitat on site. A total of 98 acres of suitable foraging habitat would be temporarily impacted, but no nesting habitat would be temporarily impacted.

The tricolored blackbird may occur on site as a migrant or during the winter and also was recorded nesting on site in 1994, as noted above. However, currently there is little suitable nesting habitat in the Project area (3.4 acres), and because the tricolored blackbird has not been observed nesting on site since 1994, conditions may no longer be suitable for nesting. Therefore, the permanent loss of 1.6 acres of nesting habitat, 222 acres of suitable foraging habitat, and temporary impacts to foraging habitat that would occur as a result of construction/grading activities would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species

on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,081 acres of suitable nesting and foraging habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 57.9% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat, and **Figure 4.5-66**, Alternative 2 Impacts to California Annual Grassland, Agriculture, and Disturbed Land Wildlife Habitat). Of these impacts, 0.3 acre is nesting habitat, representing 8.8% of this habitat on site. The remaining 3,081 acres of impact are foraging habitat, representing 57.9% of this habitat on site.

There is little suitable nesting habitat for the tricolored blackbird in the Project area, and no nesting colonies have been observed on site since 1994. Therefore, the loss of 0.3 acre of nesting habitat would not have a substantial adverse effect on the tricolored blackbird. However, this species has been observed using this site as foraging habitat during migration. In addition, foraging habitat is important for the nesting success of colonies even if the nesting colony is not specifically located in the Project area. A relatively large amount and percentage of on-site foraging habitat for the tricolored blackbird would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from foraging in approximately 57.9% of suitable habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable nesting and foraging habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,305 acres (62.1%). Of these impacts, 2.0 acres are nesting habitat, representing 55.8% of this habitat on site. The remaining 3,304 acres of impact are foraging habitat, representing 62.1% of this habitat on site.

There is little suitable nesting habitat for the tricolored blackbird in the Project area, and no nesting colonies have been observed on site since 1994. Therefore, the combined

direct and indirect permanent loss of 1.9 acres of nesting habitat would not have a substantial adverse effect on the tricolored blackbird. However, this species has been observed using this site as foraging habitat during migration. In addition, foraging habitat is important for the nesting success of colonies even if the nesting colony is not specifically located in the Project area. A relatively large amount and percentage of on-site foraging habitat for the tricolored blackbird would be permanently lost as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from foraging in approximately 62.1% of suitable habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The tricolored blackbird is a relatively mobile species, and it is unlikely that Project-related construction activities would result in injury or mortality of individual adult birds. However, foraging birds may be displaced from suitable foraging habitat or disturbed during foraging activities. Also, because the species has potential to nest on site in habitat that would be directly affected, implementation of the RMDP could result in loss of young or eggs of this species as a result of destruction of nests from any construction/grading activities that occur during the nesting season. Construction activities may also cause nest abandonment and consequent loss of the nest to exposure, starvation, or predation. Implementation of the SCP would not directly impact this species. Because of the special status of this species and the potential for foraging disruptions or injury or mortality of individual birds, including the loss of young and/or eggs as a result of nest destruction or abandonment during construction/grading activities, implementation of the RMDP would have a substantial adverse effect on this species; impede the use of a native wildlife nursery site; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. Because the species has potential to forage and nest on site in habitat that would be directly affected, build-out of the Specific Plan, VCC, and Entrada planning areas could result in disruption of foraging activities or

loss of young or eggs of this species as a result of destruction or abandonment of nests from any construction/grading activities that occur during the nesting season. The build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on this species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Potential short-term construction-related secondary impacts to the tricolored blackbird include disruptions of essential behaviors associated with noise, ground vibration, dust, and nighttime illumination. Breeding habitat may be affected by diminished water quality and altered hydrology (*e.g.*, dewatering). Tricolored blackbirds that are foraging on site may be inhibited from foraging in areas in close proximity to construction activities. In addition, nesting colonies are highly sensitive to human disturbance (*e.g.*, Beedy and Hayworth 1992) and construction activities occurring in proximity to nesting areas could cause nest failure and abandonment of the nesting site. Long-term secondary impacts include traffic noise; nighttime illumination; increased human activity; pesticide use that could result in loss of prey, secondary poisoning, and direct toxic effects on eggs (County of Riverside 2008); harassment and predation by pet, stray, and feral cats and dogs; increased predation by mesopredators; and diminished water quality and altered hydrology.

RMDP facilities include a public trail and viewing platforms adjacent to and along the northern edge of the Santa Clara River corridor, as shown in **Figure 4.5-88**, Special-Status Riparian Bird Observations in Relation to Viewing Platforms. The trail and viewing platforms will be used by the public during daytime hours. There is a potential for secondary impacts to tricolored blackbirds that could nest in areas that are adjacent to the trail and viewing platforms. Secondary impacts primarily would include noise and general increases in human activity that could disrupt behavioral activities, such as foraging, territory defense, and nesting, or increase physiological stress. In addition, there is the potential for increased trash along the trail that could enter the River Corridor SMA. Due to the very close proximity of viewing platforms and trails to riparian habitats, there is potential for unauthorized trespass by the public into sensitive habitat areas. Although there would be no lighting provided for evening use of the trail and viewing platforms, public access during the nighttime hours may still occur and could introduce fugitive light and noise. These impacts have the potential to affect the health of young, and potentially reduce survivorship and reproductive success if tricolored blackbirds attempted to nest near trails and viewing platforms.

If tricolored blackbirds attempt to breed on site, both short-term and long-term secondary impacts may prevent successful nesting, which would permanently reduce the number of tricolored blackbirds. In addition, the secondary impacts may permanently reduce the foraging that occurs on site, interfere with the movement of the tricolored blackbird in the Project vicinity, and contribute to the reduction of the range and distribution of the tricolored blackbird in the Project area (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable nesting and foraging habitat for the tricolored blackbird (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat, and **Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to California Annual Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 205 acres (3.9%) permanent loss and 137 acres of temporary loss of nesting and foraging habitat, including
  - 1.1 acres (32.3%) of permanent loss and 0.5 acre temporary loss of nesting habitat
  - 204 acres (3.8%) of permanent loss and 137 acres of temporary loss of foraging habitat;
- Alternative 4 – 187 acres (3.5%) of permanent loss and 147 acres of temporary loss of nesting and foraging habitat, including
  - 1.1 acres (32.3%) of permanent loss and 0.4 acre of temporary loss of nesting habitat
  - 186 acres (3.5%) of permanent loss and 146 acres of temporary loss of foraging habitat;
- Alternative 5 – 243 acres (4.6%) of permanent loss and 124 acres of temporary loss of nesting and foraging habitat, including
  - 1.1 acres (32.3%) of permanent loss and 0.8 acre of temporary loss of nesting habitat
  - 241 acres (4.5%) of permanent loss and 123 acres of temporary loss of foraging habitat;

- Alternative 6 – 246 acres (4.6%) of permanent loss and 136 acres of temporary loss of nesting and foraging habitat, including
  - 1.2 acres (35.3%) of permanent loss and 0.3 acre of temporary loss of nesting habitat
  - 245 acres (4.6%) of permanent loss and 136 acres of temporary loss of foraging habitat; and
- Alternative 7 – 113 acres (2.1%) of permanent loss and 442 acres of temporary loss of nesting and foraging habitat, including
  - No permanent loss and 0.2 acre of temporary loss of nesting habitat
  - 113 acres (2.1%) of permanent loss and 442 acres of temporary loss of foraging habitat.

Compared to Alternative 2 for nesting and foraging habitat, which would result in 224 acres (4.2%) of permanent loss and 98 acres of temporary impacts, Alternatives 3 and 4 would have somewhat reduced permanent impacts, Alternatives 5 and 6 would have somewhat higher impacts, and Alternative 7 would have substantially reduced impacts. Alternatives 3 through 6 would have somewhat higher temporary impacts compared to Alternative 2, and Alternative 7 would have substantially higher temporary impacts. Alternative 7 has substantially lower permanent impacts and substantially higher temporary impacts compared to the other alternatives because of the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Alternatives 3 through 6 would have substantially reduced permanent impacts to nesting habitat compared to Alternative 2, which would impact 1.6 acres. Alternative 7 would have no permanent impacts to nesting habitat due to the pullback of RMDP facilities from the Santa Clara River and its tributaries. However, Alternatives 3 through 7 would have temporary impacts to nesting habitat, compared to no temporary impacts under Alternative 2.

For foraging habitat, the comparison of alternatives is similar to that described above for overall impacts because foraging habitat comprises the vast majority (99%+) of the total habitat for the tricolored blackbird in the Project area.

As concluded for Alternative 2, the permanent loss of 0.0 to 1.2 acres of nesting habitat under Alternatives 3 through 7 would not have a substantial adverse effect on the tricolored blackbird because of the small amount (3.4 acres) of suitable nesting habitat on site and the lack of breeding activity in the Project area. Also, a relatively small percentage of foraging habitat (2.1% to 4.6%) would be permanently lost under all the alternatives as a result of implementation of the RMDP. These impacts would not be

considered a substantial adverse effect on the habitat of a special-status species; would not impede the use of a native wildlife nursery site; would not have the potential to substantially reduce the habitat of the species on site or rangewide; would not cause the species to drop below self-sustaining levels on site or rangewide; would not threaten to eliminate the species on site or rangewide; and would not substantially reduce the number or restrict the range of the species. The direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant under Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the tricolored blackbird (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat, and **Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to California Annual Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 2,996 acres (55.5%) permanent loss of foraging habitat and no loss of nesting habitat;
- Alternative 4 – 2,822 acres (53.0%) permanent loss of foraging habitat and 0.2 acre (5.9%) of nesting habitat;
- Alternative 5 – 2,767 acres (52.0%) permanent loss of foraging habitat and no loss of nesting habitat;
- Alternative 6 – 2,548 acres (47.9%) permanent loss of foraging habitat and no loss of nesting habitat; and
- Alternative 7 – 2,087 acres (39.2%) permanent loss of foraging habitat and no loss of nesting habitat.

Compared to Alternative 2 for nesting and foraging habitat, which would result in 3,081 acres (57.9%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 6 would have substantially reduced impacts compared to Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions under Alternatives 4 through 7 due to reduced Project footprints, and Alternative 7 would be substantially reduced compared to the other alternatives because large agricultural areas along the Santa Clara River associated with Landmark Village and Homestead East (the Onion Fields) would not be developed.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, they would result in substantial impacts to foraging habitat, ranging from 39.2% under Alternative 7 to 55.5% under Alternative 3. These impacts would have a substantial

adverse effect on the habitat of a special-status species; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species. Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following combined direct and indirect permanent impacts to suitable habitat for the tricolored blackbird:

- Alternative 3 – 3,161 acres (59.4%) permanent loss of nesting and foraging habitat, including
  - 1.1 acres (32.3%) of permanent loss of nesting habitat
  - 3,160 acres (59.4%) of permanent loss of foraging habitat;
- Alternative 4 – 3,009 acres (56.5%) permanent loss of nesting and foraging habitat, including
  - 1.3 acres (38.2%) of permanent loss of nesting habitat
  - 3,008 acres (56.5%) of permanent loss of foraging habitat;
- Alternative 5 – 3,009 acres (56.5%) permanent loss of nesting and foraging habitat, including
  - 1.1 acres (32.3%) of permanent loss of nesting habitat
  - 3,008 acres (56.5%) of permanent loss of foraging habitat;
- Alternative 6 – 2,794 acres (52.5%) permanent loss of nesting and foraging habitat, including
  - 1.2 acres (35.3%) of permanent loss of nesting habitat
  - 2,793 acres (52.5%) of permanent loss of foraging habitat; and
- Alternative 7 – 2,200 acres (41.3%) permanent loss of nesting and foraging habitat, including
  - No permanent loss of nesting habitat
  - 2,200 acres (41.3%) of permanent loss of foraging habitat;

Compared to Alternative 2 for nesting and foraging habitat, which would result in 3,305 acres (62.1%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 6 would have substantially reduced impacts compared to Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions under Alternatives 4 through 7 due to reduced Project footprints, and Alternative 7 would be substantially reduced compared to the other alternatives because large agricultural areas along the Santa Clara River associated with Landmark Village and Homestead East (the Onion Fields) would not be developed.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, they would result in substantial impacts to foraging habitat, ranging from 41.3% under Alternative 7 to 59.4% under Alternative 3. These impacts would have a substantial adverse effect on the habitat of a special-status species; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species. Combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation under Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to tricolored blackbird individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Suitable foraging and nesting habitat is present on site and there is potential for the species to nest on site. Foraging behavior may be disrupted by construction/grading activities, and if construction occurs during the breeding season, these activities could result in impacts to eggs or young where the species is nesting. Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative would have similar construction activities and long-term effects.

Short-term effects include construction-related noise, lighting, and disturbance from human activity that could cause nest site abandonment by a colony, and dust, diminished water quality, and altered hydrology that could affect breeding habitat quality. Urban development could result in long-term secondary effects, such as traffic noise; increased human activity; nighttime lighting; diminished water quality and altered hydrology; harassment and predation by pet, stray, and feral cats and dogs; increased mesopredators; and effects of pesticides such as loss of prey, direct toxic effects on eggs, and secondary poisoning.

There would be no viewing platforms constructed in the River Corridor SMA under Alternatives 3 through 7.

These short-term and long-term secondary impacts therefore may cause habitat degradation, impede use of nursery sites, or substantially reduce the number of this species or cause the species to drop below self-sustaining levels. Short-term and long-term secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to tricolored blackbird: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Nesting by tricolored blackbirds has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. However, the tricolored blackbird has nested in the Project vicinity outside of the affected area in the Santa Clara River and Castaic Creek in the past and it is assumed that the species could nest in the Project area in the future. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, impacts to individuals could occur if colonies and active nests are disturbed during vegetation clearing and other construction/grading activities in suitable breeding habitat, including destruction of nests and loss of eggs and/or fledglings. Construction activities may also alter foraging behavior and thus potentially reduce the health of young and result in lower reproductive success. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nesting colonies and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable nesting and foraging habitat for the tricolored blackbird resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,200 acres (41.4%) for foraging habitat (no impact to nesting habitat) under Alternative 7 to 3,305 acres (62.1%) under Alternative 2, of which 3,304 acres are foraging habitat and 2.0 acres are nesting habitat.

The loss of foraging habitat would be a substantial loss of suitable habitat for this species and could alter its use of the Project area for foraging. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide both suitable nesting and foraging habitat to support the tricolored blackbird in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 1,181 acres of suitable habitat for the tricolored blackbird in the River Corridor SMA, High Country SMA, and the Salt Creek area. Although all but about 2.0 acres of this habitat is currently foraging habitat composed of California annual grassland, agriculture, and disturbed land, the River Corridor SMA provides riparian and wetland communities that may become suitable for nesting (e.g., development of marsh) at times in relation to dynamic changes in the River system.

With regard to secondary effects, nesting and foraging activities by the tricolored blackbird could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, lighting, and diminished water quality and altered hydrology. These secondary effects may alter foraging, cause adults to abandon nests and otherwise disrupt normal behavioral patterns and cause nests to be more vulnerable to predators. Short-term effects of dust and diminished water quality and altered hydrology may affect nesting habitat quality for the tricolored blackbird. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 300 feet and by retaining a qualified biologist during all vegetation clearing and grading activities. Several general measures will be implemented to protect wetland habitats that will reduce impacts to the tricolored blackbird. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities, biological monitoring during any stream diversions, restrictions on construction equipment operating in ponds or flowing water, and protection of water quality from mud, silt, and other pollutants. Long-term development-related impacts include noise; increased traffic noise; introduction of secondary effects related to viewing platforms and trails along the River Corridor SMA (under Alternative 2 only); diminished water quality, affecting habitat quality; lighting; pesticides, which may have toxic effects on eggs or secondary poisoning and loss of prey; human disturbances of nest sites; and predation by pet, stray, and feral cats and dogs and other mesopredators. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of about 1,181 acres of suitable foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek, area will provide tricolored blackbirds with relatively undisturbed habitat for foraging (**Figure 4.5-3**). Protection of the River Corridor SMA will provide potential nesting habitat in areas where marsh habitats may develop. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by nocturnal predators and reduce physiological stress. Limited recreational usage and access restrictions within the River Corridor SMA and High Country SMA, control of pet, stray, and feral cats and dogs in or near open space areas, trail signage, and homeowner education

regarding special-status resources in preserved natural habitat areas will help protect tricolored blackbirds by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of toxic impacts on eggs, secondary poisoning, and loss of prey.

The specific mitigation measures for the tricolored blackbird are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-73 IMPACTS TO INDIVIDUALS – TRICOLORED BLACKBIRD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, or mitigate impacts to tricolored blackbird individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to tricolored blackbird individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall

continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to tricolored blackbird individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-74 LOSS OF HABITAT – TRICOLORED BLACKBIRD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for tricolored blackbird through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system (**Figure 4.5-3**). The River Corridor SMA will preserve and enhance at least 281 acres of suitable foraging habitat for the tricolored blackbird**.** The High Country SMA will preserve and enhance 576 acres of suitable habitat for the tricolored blackbird, including 575 acres of foraging habitat and 1.4 acres of nesting habitat.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the tricolored blackbird through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. The Salt Creek area supports 324 acres of suitable foraging habitat for the tricolored blackbird.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the tricolored blackbird would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-75 SECONDARY IMPACTS – TRICOLORED BLACKBIRD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on the tricolored blackbird associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as increased human activity, increased traffic noise, and nighttime lighting. Mitigation measures to avoid and minimize impacts to water quality and hydrology and inadvertent impacts to habitat outside disturbance zones during construction will also be implemented.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and which generally refer to habitat protection, restoration and enhancement, and management, will be implemented to mitigate for the effects of increased human activity and increased traffic noise.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These mitigation measures require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along the open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. These mitigation measures will address avoidance and minimization of downstream hydrology and water quality effects that could adversely affect tricolored blackbird nesting habitat and/or breeding populations.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to the tricolored blackbird, including short-term construction-related noise, ground vibration, dust, increased human activity, and diminished water quality, and long-term impacts, such as long-term increased human activity; harassment and predation by pet, stray, and feral cats and

dogs; and toxic effects on eggs, secondary poisoning, and loss of prey due to the use of pesticides.

BIO-52 and BIO-56, as described above, will mitigate the effects of construction noise and increased human activity by identifying nest areas and providing for buffers between nests and construction activities.

Three mitigation measures, BIO-47, BIO-49, and BIO-70, will reduce impacts to the tricolored blackbird nesting habitat during construction activities by protecting water quality.

BIO-47 requires that slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area that will provide refuge for tricolored blackbird during construction.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. This will reduce impacts to the tricolored blackbird by protecting habitat quality, including water quality, and by minimizing impacts on its insect prey. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-1 through BIO-16 and BIO-19, as described above, will mitigate for increased human activity and traffic noise in the Project area through habitat protection, restoration and enhancement, and management.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity, and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the tricolored blackbird would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

VERMILION FLYCATCHER (NESTING) (CSC)

Life History

The vermilion flycatcher (*Pyrocephalus rubinus*) is a common breeder in southern Arizona, New Mexico, and Texas (Wolf and Jones 2000). It breeds in Arizona from the northwest and Mogollon Rim south throughout the state, is common along the base of the Huachuca Mountains and is a locally common breeder on the lower Verde and Salt rivers in Maricopa County, Arizona. It also commonly breeds in southern New Mexico in the Pecos, San Francisco, Gila, and lower–middle Rio Grande valleys. In Texas, the vermilion flycatcher breeds in the western and central portions of the state, mainly in central and southern Trans-Pecos and Edwards Plateau, and north into areas south of the panhandle and southeast to the lower Texas coast (Wolf and Jones 2000). It is a rare and local breeder along the Salt and Colorado rivers (Wolf and Jones 2000). The vermilion flycatcher is normally a year-round resident throughout all but the northernmost portion of the breeding range in the United States, Mexico, and Central America. Its range during the winter fluctuates with winter conditions; in some winters, the species wanders along river corridors outside its normal range (Grinnell and Miller 1944). The vermilion flycatcher may winter outside of its breeding range throughout the coastal plain of Texas (Wolf and Jones 2000), in deserts of southeastern California north to southern Inyo County (Garrett and Dunn 1981), in southwestern Arizona (Wolf and Jones 2000), and into portions of Mexico (Wolf and Jones 2000). A few individuals winter regularly along the California coast north to Ventura County and occasionally to San Luis Obispo County, along the Gulf Coast of Texas, rarely north to southern Arkansas, throughout the mainland of Florida, and along the Atlantic Coast of Mexico (Wolf and Jones 2000).

In California, the vermilion flycatcher was formerly considered a more common and widespread breeder along the lower Colorado River, Imperial Valley, Coachella Valley, upper Mojave River drainage, and San Diego County (Grinnell and Miller 1944; Garrett and Dunn 1981), but its breeding range has declined throughout this area (Wolf and Jones 2000). Currently, in California, there are some isolated breeding populations in the lowlands in the south central and southeast portions of the state, including San Bernardino, Riverside, San Diego, Santa Barbara, Ventura, and Kern counties (Wolf and Jones 2000). Zeiner *et al.* (1990A) state that there are sporadic breeding populations in desert oases west and north of the Morongo Valley and Mojave Narrows in San Bernardino County. It has been recorded in summer along the Santa Clara River near Castaic and at Frazier Park, Kern County; however, there has been no evidence of breeding, and these observations are likely vagrants (Garrett and Dunn 1981).

The vermilion flycatcher appears to be a strict insectivore with no records of plant material being consumed. It has been recorded eating insects and other arthropods, honeybees, grasshoppers, beetles, and crickets (Wolf and Jones 2000).

Although the vermilion flycatcher is largely a resident species, where it does show migratory movements, the male arrives to the breeding locations in February or March and females arrive afterwards, typically in March or April, depending on location (Wolf and Jones 2000). Males play a large role in determining the nest site, which is built in a horizontal fork or branch under a canopy in an area free of leaves, about eight to 20 feet above ground (Wolf and Jones 2000; Tinkham 1949). The nest is a shallow open cup, loosely constructed out of small twigs, forbs, rootlets, grasses, fibers, or other similar materials and is lined with feathers and hair (Wolf and Jones 2000).

This species primarily is threatened by the degradation and loss of habitat. The abundance and distribution of this species has been drastically reduced over the last 50 years in the lower Colorado River Valley. Water management, such as groundwater pumping and damming, can reduce and degrade riparian habitat and remove vegetation, such as cottonwoods and willows, that is critical to its breeding. Urbanization and human development have also degraded or reduced vermilion flycatcher habitat. Like other riparian bird species, however, several other potential human- or development-related factors may affect the vermilion flycatcher. Construction-related impacts include dust; noise and ground vibration; diminished water quality and altered hydrology; increased human activity in close proximity to foraging areas; and lighting, which may alter foraging behavior, induce physiological stress, and increase predation risk. Long-term effects related to development include increased human activity; noise; lighting; diminished water quality and altered hydrology; predation and harassment by pet, stray, and feral cats and dogs and other mesopredators; and pesticides, which may reduce insect prey or cause secondary poisoning.

Survey Results

Suitable nesting and foraging habitat for the vermilion flycatcher exists in riparian woodland habitat along the Santa Clara River and Castaic Creek in the Project area. However, only one observation of a vermilion flycatcher has been documented during annual riparian bird surveys conducted from 1988 to 2007 along the Santa Clara River (Bloom Biological 2007A; Guthrie 1988, 1989, 1990, 1991A, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2005A, 2005B, 2006A, 2006C; Labinger *et al.* 1995, 1997B; Labinger and Greaves 1999A). The single observation of vermilion flycatcher in the Santa Clara River was by Guthrie in 1993 and was characterized as an "immature and possibly a post-breeding wanderer" (Guthrie 1993B).

Because the vermilion flycatcher has only been observed once in the Project area over multiple years of surveys it is assumed for the purpose of this analysis that this species occurs only rarely as a vagrant. Southern cottonwood–willow riparian, southern coast live oak riparian forest,

Mexican elderberry, and southern willow scrub are suitable habitat for this species when it does occur on site. A total of 458 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 40 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 8.8% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). A total of 44 acres would be temporarily impacted.

The vermilion flycatcher is a wide-ranging species that may only occur on site as an occasional vagrant and uses a variety of riparian-associated habitats. The construction of RMDP facilities would be phased over a long period of time, and hundreds of acres of suitable riparian habitat in the River Corridor SMA and associated tributaries would be available for individuals of this species occasionally using the Project area at any given time. Therefore, the permanent loss of 40 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 14 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 3.1% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat).

Because the vermilion flycatcher is a wide-ranging species that may only occur on site as an occasional vagrant and is not expected to nest in the Project area, the loss of 14 acres would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 54 acres (11.9%). Because the vermilion flycatcher is a wide-ranging species that may only occur on site as an occasional vagrant and is not expected to nest in the Project area, the loss of 54 acres of habitat from the combined direct and indirect permanent impacts of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The vermilion flycatcher is a mobile species that may only occasionally occur on site as a vagrant and is not expected to nest in the Project area because it has not been observed on site in over 10 years. It is highly unlikely that construction activities associated with implementation of the RMDP would result in the direct loss of individual adult birds. Foraging and resting behavior, however, may be somewhat disrupted by construction activities because individuals would probably avoid or leave construction areas for other undisturbed habitat areas. The vermilion flycatcher is not expected to breed on site so

nests with eggs or young would not be affected. Implementation of the SCP would not directly impact this species. Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

The vermilion flycatcher is a mobile species and it is highly unlikely that build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of individual adult birds. Foraging and resting behavior, however, may be somewhat disrupted by construction activities because individuals would probably avoid or leave construction areas for other undisturbed habitat areas. The vermilion flycatcher is not expected to breed on site so nests with eggs or young would not be affected. Indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, fugitive dust, increased human activity, nighttime illumination, and diminished water quality and altered hydrology. These effects may disturb vermilion flycatchers that use the site for resting and foraging, causing them to avoid or leave areas near construction, or reducing habitat quality and affecting prey abundance.

Potential long-term secondary impacts associated with urban development include traffic noise, nighttime illumination, invasion of suitable habitat by exotic species such as giant reed and tamarisk; increased litter; pesticide use resulting in loss of prey and/or secondary poisoning; increased human activity; harassment and predation by pet, stray, and feral cats and dogs; and increased mesopredators as a result of increased habitat fragmentation. These secondary impacts may result in vermilion flycatchers avoiding or leaving areas subject to these effects and there would be increased potential for predation of individuals.

Altered hydrology and geomorphology in the Santa Clara River corridor as a result of urban development in the watershed, and thus impacts to suitable habitat for the vermilion flycatcher, are also potential long-term secondary effects of the build-out of the Specific Plan, VCC, and Entrada planning areas. However, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County over the long term. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue.

As a result, the mosaic of habitats in the River that support various special-status species would be maintained, and would not be significantly affected.

Because the vermilion flycatcher is a wide-ranging species that may only occasionally use habitat in the Project area, these short-term and long-term secondary impacts would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the vermilion flycatcher (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitats):

- Alternative 3 – 27 acres (5.8%) of permanent loss and 43 acres of temporary loss;
- Alternative 4 – 27 acres (5.8%) of permanent loss and 41 acres of temporary loss;
- Alternative 5 – 33 acres (7.1%) of permanent loss and 47 acres of temporary loss;
- Alternative 6 – 18 acres (4.0%) of permanent loss and 43 acres of temporary loss; and
- Alternative 7 – 7.9 acres (1.7%) of permanent loss and 24 acres of temporary loss.

Compared to Alternative 2, which would result in 40 acres (8.8%) of permanent habitat loss and 44 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 through 7 would be substantially reduced. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be marginally to somewhat different and Alternative 7 would be substantially reduced. The difference for permanent and temporary impacts under Alternative 7 compared to the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Because the overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be substantially reduced compared to

Alternative 2, and temporary impacts would range from similar in magnitude to substantially reduced, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the vermilion flycatcher (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitats):

- Alternative 3 – 13 acres (2.8%) of permanent loss;
- Alternative 4 – 9.6 acres (2.1%) of permanent loss;
- Alternative 5 – 8.6 acres (1.9%) of permanent loss;
- Alternative 6 – 6.0 acres (1.3%) of permanent loss; and
- Alternative 7 – 4.5 acres (1.0%) of permanent loss.

Compared to Alternative 2, which would result in 14 acres (3.1%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternative 3 would have somewhat reduced impacts compared to Alternative 2, and Alternatives 4 through 7 would have successively reduced impacts compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the vermilion flycatcher:

- Alternative 3 – 40 acres (8.6%) of permanent loss;
- Alternative 4 – 37 acres (8.1%) of permanent loss;
- Alternative 5 – 41 acres (9.0%) of permanent loss;
- Alternative 6 – 24 acres (5.3%) of permanent loss; and
- Alternative 7 – 12 acres (2.7%) of permanent loss.

Compared to Alternative 2, which would result in 54 acres (11.9%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced

impacts. There would generally be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 3, 4, 6, and 7. Alternative 5 would have the next largest impact compared to Alternative 2. Because the combined direct and indirect permanent loss of suitable habitat for the vermilion flycatcher occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than under Alternative 2, these impacts would be adverse but not significant.

Impacts to Individuals

The potential for impacts to vermilion flycatcher individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2. Adult birds would likely avoid impacts during construction activities by avoiding or leaving construction areas, resulting in potential impacts to foraging and resting. Because the species does not nest on site, nests with eggs and young would not be affected. Because the vermilion flycatcher is a wide-ranging species and may only occur on site as an occasional vagrant, direct and indirect permanent impacts (Impacts to Individuals) would be adverse but not significant under Alternatives 3 through 7.

Secondary Impacts

Short-term impacts include construction-related dust; noise and ground vibration; increased human activity; nighttime illumination; and diminished water quality and altered hydrology. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas include increased human activity; diminished water quality; traffic noise; nighttime illumination; exotic plant species; litter; pesticides; and predation by pet, stray, and feral cats and dogs and mesopredators, as described above for Alternative 2.

Because the vermilion flycatcher is a wide-ranging species and may only occasionally occur on site as a vagrant, these potential short-term and long-term secondary effects would not have a substantial adverse effect on the species and would not contribute to the reduction of its range and distribution. These long-term and short-term secondary impacts would be adverse but not significant for Alternatives 3 through 7.

Mitigation Strategy and Summary

No mitigation is required for impacts to the vermilion flycatcher because all impacts were determined to be adverse but not significant. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and

management of approximately 326 acres of suitable riparian habitat in the River Corridor SMA, as well as drainages in the Salt Creek area and High Country SMA that contain riparian habitats. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction, because individuals will have access to foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction, and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; and pesticides, will also be mitigated through a variety of measures.

YELLOW-BREASTED CHAT (NESTING) (CSC)

Life History

The yellow-breasted chat (*Icteria virens*) has a broad geographic range occurring in several disjunct areas in the United States, southwestern portions of Canada, and Mexico. Its breeding range includes the eastern United States from Wisconsin south to the Gulf coast, and east to the Atlantic Coast. Western breeding populations occur along the Pacific Coast, within the Great Basin valleys, lower montane portions of the Rocky Mountains, and south into Arizona and New Mexico, with isolated populations in Texas (Dunn and Garrett 1997). The yellow-breasted chat is an uncommon summer resident and migrant in coastal California and in the foothills of the Sierra Nevada (Zeiner *et al.* 1990A). The yellow-breasted chat is found at elevations up to 1,450 meters (4,800 feet) AMSL in valley foothill riparian habitat and up to 2,050 meters (6,500 feet) AMSL east of the Sierra Nevada in desert riparian habitat (Gaines 1977; DeSante and Ainley 1980; Garrett and Dunn 1981). The yellow-breasted chat is uncommon along the coast of northern California and occurs locally only south of Mendocino County (McCaskie *et al.* 1979). In southern California, the yellow-breasted chat breeds locally on the coast and very locally inland at lower elevations throughout the region (Garrett and Dunn 1981).

In the western United States, the yellow-breasted chat requires riparian thickets and riparian woodlands with a dense understory for nesting (Eckerle and Thompson 2001). In southern California, the yellow-breasted chat nests in dense, relatively wide riparian woodlands and thickets of willows, vine tangles, and dense brush with well-developed understories. Nesting areas are associated with streams, swampy ground, and the borders of small ponds (Zeiner *et al.* 1990A). Grinnell and Miller (1944) suggested that plant cover in breeding habitat must be dense to provide shade and concealment. During the spring and fall migration, the yellow-breasted chat uses the same low, dense vegetation used as breeding and wintering grounds, although spring migrants are occasionally found in suburban habitats (Parnell 1969). Winter habitat is similar in structure to that used for breeding and migration with dense, low cover of woody vegetation (Eckerle and Thompson 2001).

The yellow-breasted chat feeds on small invertebrates, including insects and spiders, during the summer and forages for berries and fruits from shrubs and low trees when available (Bent 1953). It forages in low, dense shrubs and thickets, gleaning individual prey from the foliage (Whitmore 1977). Young are fed soft-bodied insects such as grasshoppers and crickets and insect larvae (Eckerle and Thompson 2001).

Yellow-breasted chat pairs typically build nests 0.6 to 2.4 meters (2.0 to 7.9 feet) above ground in dense shrubs along streams or rivers. The yellow-breasted chat is a neotropical migrant that usually arrives in the United States and Canada in April to breed and leaves for wintering grounds in Mexico and Guatemala in late September (Zeiner *et al.* 1990A). During the breeding season, the male maintains and defends an individual territory. In a low-density population in

southern Indiana, territory size ranged from 1.1 to 1.6 hectares (2.7 to 3.9 acres) with rare male–male confrontations (Thompson and Nolan 1973). In a high-density population, territory size ranged from 0.5 to 1.0 hectare (1.2 to 2.5 acres), with frequent male–male confrontations (Zeiner *et al.* 1990A).

The yellow-breasted chat is primarily threatened by loss of riparian habitat. In California, this species has declined due to the loss of riparian habitats and parasitism by brown-headed cowbirds (Zeiner *et al.* 1990A). The loss, fragmentation, and degradation of riparian habitat in California coastal lowlands as a result of development, agriculture, and channeling of rivers are factors have led to the decline of the yellow-breasted chat in southern California. Heavy cattle grazing may cause a decline of dense, shrubby areas used for nesting (Johnston and Odum 1956). Garrett and Dunn (1981) concluded that the clearing of dense riparian thickets and brushy tangles in southern California caused a noticeable decline in the number of breeding birds, with cowbird parasitism possibly contributing to their decline (Remsen 1978). The frequency of cowbird parasitism varies from 5% to 91% across the breeding range (Eckerle and Thompson 2001). However, Thompson and Nolan (1973) found that, following hatching, nestlings are able to compete with cowbird nestlings and then survive to fledge. Like other riparian bird species, several other potential human- or development-related factors may affect yellow-breasted chats. Construction-related impacts include dust; noise and ground vibration; diminished water quality and altered hydrology; increased human activity in close proximity to nesting and foraging areas; and lighting, which may alter behavior, induce physiological stress, and increase predation risk. Long-term effects related to development include invasive plant species such as giant reed and tamarisk, which degrade habitat quality; increased human activity; noise; lighting; diminished water quality and altered hydrology; predation and harassment by pet, stray, and feral cats and dogs and other mesopredators; and Argentine ants, which are especially attracted to riparian areas and may prey on nestlings.

Survey Results

Surveys for riparian birds have been conducted for multiple years along the Santa Clara River within suitable habitat for the yellow-breasted chat. On site, this species was observed nesting in riparian thickets in 2007 (Bloom Biological 2007A) and has also been observed over multiple years during the bird surveys conducted from 1988 through 2006 along the Santa Clara River within the riparian scrub and woodland habitat (Guthrie 1988, 1989, 1990, 1991A, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2005A, 2005B, 2006A, 2006C; Labinger *et al.* 1995, 1997B; Labinger and Greaves 1999A). Other recent observations were made along the Santa Clara River within the Specific Plan area and in Castaic Creek in the VCC planning area in 2006 (specific locations not mapped), where yellow-breasted chats were observed calling from territories in the riparian woodland (Guthrie 2006A, 2006C). There is suitable nesting habitat within the riparian scrub

and woodland habitats on site along the Santa Clara River in the Specific Plan area and along Castaic Creek in the VCC planning area.

Southern cottonwood–willow riparian, southern coast live oak riparian forest, and southern willow scrub are suitable nesting and foraging habitat for the yellow-breasted chat. There is a total of 445 acres of suitable habitat in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 39 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 8.7% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). A total of 44 acres would be temporarily impacted.

The yellow-breasted chat is still a wide-ranging species and uses a variety of riparian associated habitats. The construction of RMDP facilities would be phased over a long period of time, and hundreds of acres of suitable riparian habitat in the River Corridor SMA and associated tributaries would be available for this species at any given time. Therefore, the permanent loss of 39 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 7.8 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 1.8% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat).

Because the yellow-breasted chat is still a wide-ranging species and uses a variety of riparian associated habitats, the permanent loss of 7.8 acres of habitat as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 47 acres (10.4%). Because the yellow-breasted chat is still a wide-ranging species, uses a variety of riparian associated habitat, and because the construction activities would be phased over a long period of time, hundreds of acres of suitable riparian habitat in the River Corridor SMA and associated tributaries would be available for this species at any given time. Therefore, the combined permanent loss of 47 acres of habitat that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction. These impacts would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The yellow-breasted chat is a relatively mobile species and it is unlikely that construction activities associated with implementation of the RMDP would result in injury or mortality of individual adult birds. However, implementation of the RMDP could result

in injury or mortality of yellow-breasted chats due to destruction of nests and loss of young if such construction/grading activities occurred during the nesting season. In addition, construction activities could alter the yellow-breasted chat's foraging behavior, potentially affecting the health of young and potentially reducing survivorship and reproductive success. Implementation of the SCP would not directly impact this species. Construction/grading activities, such as vegetation clearing, occurring during the nesting season could result in destruction of nests and the resulting loss of eggs and/or young (significance criteria 1 and 4). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. Because the species has potential to nest on site in habitat that would be directly affected, build-out of the Specific Plan, VCC, and Entrada planning areas could result in loss of young or eggs of this species as a result of destruction of nests from any construction/grading activities that occur during the nesting season or alteration of foraging behavior. Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, fugitive dust, and nighttime illumination. These impacts could alter essential behaviors such as foraging and breeding, induce physiological stress, and increase predation rates. Fugitive dust, diminished water quality, and altered hydrology (*e.g.*, runoff, erosion, sedimentation) could reduce habitat quality, including insect prey. Although construction would be short term in nature, if these activities occurred during the breeding season they could have a substantial direct adverse effect on this species due to potential disruption of breeding and nesting activities.

Potential long-term secondary impacts associated with urban development include traffic noise (similar to the noise effects discussed in detail above for least Bell's vireo); nighttime illumination; invasion by exotic species such as giant reed and tamarisk and Argentine ants which are attracted to riparian areas and may prey on nestlings; increased litter; cowbird nest parasitism; pesticide use resulting in loss of prey and/or secondary poisoning; increased human activity; harassment and predation by pet, stray, and feral cats and dogs; and increased mesopredators as a result of increased habitat fragmentation. These secondary impacts may result in abandonment of nests and lower reproductive success along the urban–open space edge over the long term.

Altered hydrology and geomorphology in the Santa Clara River corridor as a result of urban development in the watershed, and thus impacts to nesting habitat for the yellow-breasted chat, are also potential long-term secondary effects of the build-out of the Specific Plan, VCC, and Entrada planning areas. However, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County over the long term. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue. As a result, the mosaic of habitats in the River that support various special-status species would be maintained, and the population of the species within and immediately adjacent to the River corridor would not be significantly affected.

RMDP facilities include a public trail and viewing platforms adjacent to and along the northern edge of the Santa Clara River corridor, as shown in **Figure 4.5-88**, Special-Status Riparian Bird Observations in Relation to Viewing Platforms. The trail and viewing platforms will be used by the public during daytime hours. There is a potential for secondary impacts to yellow-breasted chat nesting in areas that are adjacent to the trail and viewing platforms. Secondary impacts primarily would include noise and general increases in human activity that could disrupt behavioral activities such as foraging, territory defense, and nesting, or increase physiological stress. In addition, there is the potential for increased trash along the trail that could enter the River Corridor SMA. Due to the very close proximity of viewing platforms and trails to riparian habitats, there is potential for unauthorized trespass by the public into sensitive habitat areas. Although there would be no lighting provided for evening use of the trail and viewing platforms, public access during the nighttime hours may still occur and could introduce fugitive light and noise. These impacts have the potential to affect the health of young, and potentially reduce survivorship and reproductive success.

Short-term and long-term secondary impacts would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the yellow-breasted chat (**Figures 4.5-55** through **4.5-59,** Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 25 acres (5.6%) of permanent loss and 43 acres of temporary loss;
- Alternative 4 – 26 acres (5.8%) of permanent loss and 41 acres of temporary loss;
- Alternative 5 – 31 acres (7.0%) of permanent loss and 47 acres of temporary loss;
- Alternative 6 – 17 acres (3.9%) of permanent loss and 43 acres of temporary loss; and
- Alternative 7 – 7.9 acres (1.8%) of permanent loss and 24 acres of temporary loss.

Compared to Alternative 2, which would result in 39 acres (8.7%) of permanent habitat loss and 44 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 through 7 would be substantially reduced. Compared to Alternative 2, the temporary loss of habitat would be marginally reduced under Alternatives 3 and 6, somewhat reduced under Alternative 4, somewhat greater under Alternative 5, and substantially reduced under Alternative 7. The difference for permanent and temporary impacts under Alternative 7 compared to the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Because the overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be substantially reduced compared to Alternative 2, and temporary impacts would be similar in magnitude to substantially reduced, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the yellow-breasted chat (**Figures 4.5-55** through **4.5-59,** Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 6.9 acres (1.6%) of permanent loss;
- Alternative 4 – 3.5 acres (0.8%) of permanent loss;

- Alternative 5 – 2.6 acres (0.6%) of permanent loss;
- Alternative 6 – 1.3 acres (0.3%) of permanent loss; and
- Alternative 7 – 0.7 acre (0.1%) of permanent loss.

Compared to Alternative 2, which would result in 7.8 acres (1.8%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 and 5 would have somewhat reduced impacts compared to Alternative 3 (which is marginally different than Alternative 2) and Alternatives 6 and 7 would have additional reductions compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the yellow-breasted chat:

- Alternative 3 – 32 acres (7.2%) of permanent loss;
- Alternative 4 – 29 acres (6.5%) of permanent loss;
- Alternative 5 – 34 acres (7.5%) of permanent loss;
- Alternative 6 – 19 acres (4.2%) of permanent loss; and
- Alternative 7 – 8.5 acres (1.9%) of permanent loss.

Compared to Alternative 2, which would result in 47 acres (10.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. There would generally be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 3, 4, 6, and 7. Alternative 5 would have the next largest impact compared to Alternative 2. Because the combined direct and indirect permanent loss of suitable habitat for the yellow-breasted chat occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Impacts to Individuals

The potential for impacts to yellow-breasted chat individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would essentially be the same as for Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. The yellow-breasted chat is known to nest on site. Construction/grading activities such as vegetation clearing conducted during the breeding season could result in destruction of nests and loss of eggs and/or young where the species is nesting, and foraging behavior could be altered such that the health of young and survivorship and overall reproductive success would be reduced. Permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Potential short-term impacts include construction-related dust, noise, ground vibration, nighttime illumination, diminished water quality and altered hydrology. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas include traffic noise; nighttime illumination; diminished water quality; exotic plant and animal species; litter; cowbird nest parasitism; pesticides; increased human activity; and predation by pet, stray, and feral cats and dogs and mesopredators, as described above for Alternative 2. All of these impacts occurring under Alternatives 3 through 7 could result in lower reproductive success of the yellow-breasted chat in the Project area.

Riparian habitat along the Santa Clara River would not be substantially affected over the long term by altered hydrology or geomorphology under Alternatives 3 through 7 (PACE 2009).

There would be no viewing platforms constructed in the River Corridor SMA under Alternatives 3 through 7.

These potential short-term and long-term secondary effects would have a substantial adverse effect on the species and would contribute to the reduction of its range and distribution. These long-term and short-term secondary impacts would be significant, absent mitigation for Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to yellow-breasted chat: (1) impacts to individuals; and (2) secondary impacts to individuals and suitable habitat outside the Project footprint. Direct and indirect impacts to habitat were determined to be adverse but not significant.

Nesting by yellow-breasted chat has been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, impacts to individuals could occur if active nests are disturbed during vegetation clearing and construction/grading activities, including destruction of nests and loss of eggs and/or fledglings. Construction activities may also alter foraging behavior and thus potentially reduce the health of young and result in lower reproductive success. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

With regard to secondary effects, nesting and foraging activities by the yellow-breasted chat could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, lighting, and diminished water quality and altered hydrology. These secondary effects may alter foraging and nest defense behavior, cause adults to abandon nests due to stress, and otherwise disrupt normal behavioral patterns, and cause nests to be more vulnerable to predators. Short-term effects of dust and diminished water quality and altered hydrology may affect habitat quality and the insect prey base for the yellow-breasted chat, thus adversely affecting foraging behavior and provisioning of young. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 300 feet, and by retaining a qualified biologist during all vegetation clearing and grading activities. Several general measures will be implemented that will reduce impacts to yellow-breasted chat. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities; biological monitoring during any stream diversions; restrictions on construction equipment operating in ponds or flowing water; and protection of water quality from mud, silt, and other pollutants. Long-term development-related impacts include habitat fragmentation; increased traffic noise; introduction of secondary effects related to viewing platforms and trails along the River Corridor SMA (under Alternative 2 only); invasive species such as giant reed and tamarisk and Argentine ants which may prey on nestlings; cowbird parasitism; increased noise; diminished water quality, affecting prey and nesting habitat quality; lighting; pesticides that may cause secondary poisoning and loss of prey; human disturbances of nest sites; and predation by pet, stray, and feral cats and dogs and other mesopredators. These long-term secondary impacts will be

minimized through several mitigation measures. Protection, restoration and enhancement, and management of 314 acres of suitable habitat, primarily in the River Corridor SMA, but also the High Country SMA and Salt Creek area, will provide yellow-breasted chats with relatively undisturbed habitat for nesting and foraging. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by nocturnal predators and reduce physiological stress. Limited recreational usage and access restrictions within the River Corridor SMA and High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect yellow-breasted chats by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of secondary poisoning and loss of prey. Cowbird surveys will be conducted and trapping will be implemented if necessary. Controls on Argentine ants will help reduce impacts on young in nests.

The specific mitigation measures for the yellow-breasted chat are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-76 IMPACTS TO INDIVIDUALS – YELLOW-BREASTED CHAT (NESTING)

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate impacts to yellow-breasted chat individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to yellow-breasted chat individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife;

review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity..

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to yellow-breasted chat individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-77 SECONDARY IMPACTS – YELLOW-BREASTED CHAT (NESTING)

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on the yellow-breasted chat associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such traffic noise, invasion by exotic plant species, abandonment of nests from human activity, and greater vulnerability to nocturnal predators as a result of nighttime lighting. These mitigation measures provide for protection, restoration, enhancement, and management of habitat in open space for yellow-breasted chat that will offset secondary impacts by providing high-quality habitat away from development areas. Mitigation measures to avoid and minimize impacts to water quality and hydrology and inadvertent impacts to habitat outside disturbance zones during construction will also be implemented.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

Additionally, SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA that will preserve and enhance at least 314 acres of suitable habitat for the yellow-breasted chat (**Figure 4.5-12**).

SP-4.6-17 will control public access to the River Corridor SMA and states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20 states that any grading activities within or adjacent to the River Corridor SMA shall have grading perimeters clearly marked and inspected prior to grading. The Project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. These mitigation measures will address avoidance and minimization of downstream hydrology and water quality effects that could adversely affect yellow-breasted chat habitat and/or breeding populations.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to yellow-breasted chat, including short-term construction-related dust, noise, ground vibration, and diminished water quality; and long-term impacts such as invasive species (including exotic plants, cowbirds, and Argentine ants); increased human activity; greater vulnerability to predation by pet, stray, and feral cats and dogs; and impacts of pesticides such as indirect poisoning and loss of prey.

Secondary effects of noise and ground vibration during construction will be addressed by BIO-52 and BIO-56, as described above, which will mitigate these effects by identifying nest sites and providing for buffers between nests and construction activities.

Three mitigation measures, BIO-47, BIO-49, and BIO-70, will reduce impacts to the yellow-breasted chat during construction activities by protecting water quality.

BIO-47 requires that slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area that will provide refuge for arroyo toad during construction.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. This will reduce impacts to yellow-breasted chat by protecting habitat quality, including water quality, and by minimizing impacts on its insect prey. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-55 requires that existing maps of suitable riparian habitat for the least Bell's vireo, willow flycatcher/southwestern willow flycatcher, and western yellow-billed cuckoo be updated as needed and submitted to the Corps and CDFG. The removal of any riparian habitat suitable for

these species from the Project footprint shall be mitigated through the creation or enhancement of similar riparian habitat at an approved mitigation site or by the removal of exotic species from an area of existing similar habitat. Because the yellow-breasted chat uses the same habitat as these species, it will benefit from this mitigation measure.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-78 requires implementation of a cowbird trapping program once vegetation clearing begins. The program shall be implemented each day beginning April 1 and concluding on or about November 1, through the construction, maintenance, and monitoring period of the riparian restoration sites. In the event that trapping is terminated after the first few years of development, subsequent phases of the RMDP development shall trigger initiation of trapping surveys.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed

within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impacts to yellow-breasted chat by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant from riparian areas is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the yellow-breasted chat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

YELLOW-HEADED BLACKBIRD (NESTING) (CSC)

Life History

The yellow-headed blackbird (*Xanthocephalus xanthocephalus*) occurs throughout the United States and in parts of Canada. Its breeding range occurs in the central and western United States, including eastern portions of Oregon and Washington. The eastern boundary of its breeding range lies within portions of Michigan and extends west and south toward western Texas. In Canada, this species breeds in central British Columbia, northern Alberta, central Saskatchewan, southern Manitoba, and southwest Ontario. Its wintering range extends from western and southern Arizona, southern New Mexico, and southern Texas through Mexico. Small numbers winter locally in Florida and California (Twedt and Crawford 1995).

In California, the yellow-headed blackbird is a common breeder along the lower Colorado River and the north and south ends of the Salton Sea. It occurs as a fairly common transient and local breeder in the Antelope Valley, and also has been recorded to breed occasionally in northern Kern and Ventura counties, western Riverside County, San Diego County, and possibly in Orange County (Garrett and Dunn 1981). It also breeds in the Klamath Basin, Modoc Plateau, Mono Basin, and Owens Valley. Generally, within the coastal regions of southern California, which include most of Los Angeles County, the yellow-headed blackbird is considered an uncommon to fairly common spring transient (Garrett and Dunn 1981).

The yellow-headed blackbird nests, roosts, and does much foraging within fresh emergent wetland habitat, and its overall distribution is limited based on the availability of this habitat (Twedt and Crawford 1995). It primarily occurs in prairie wetlands, but it is also found commonly in wetlands associated with quaking aspen parks, mountain meadows, and arid regions. The males arrive in breeding areas first to establish territories, and females select nest sites after selecting a territory, usually from mid-April to late July. Nests are placed close together in the colony in emergent wetlands over deeper water, usually in cattails, bulrushes, or reeds, and occasionally willows (Twedt and Crawford 1995; Zeiner *et al.* 1990A). Clutches range from two to five eggs (Zeiner *et al.* 1990A; Twedt and Crawford 1995) and are incubated for 10 to 13 days (Fautin 1941; Zeiner *et al.* 1990A). The young fledge and leave the nest after nine to 12 days although they do not fly until about 20 days (Zeiner *et al.* 1990A).

In California, most of the breeding population migrates south for the winter, but some individuals occur irregularly in the southern coastal areas, and more commonly in Imperial Valley (Zeiner *et al.* 1990A).

Foraging occurs within the wetland habitat when food is available, but yellow-headed blackbirds often forage in nearby open fields (*e.g.*, grasslands, croplands, or savannahs), preferably on moist ground. After breeding, they forage mostly in cropland and grassland (Twedt and Crawford 1995; Zeiner *et al*. 1990A).

Yellow-headed blackbirds mostly forage for insects during the breeding season and for seeds and grains during the post-breeding season (Twedt *et al*. 1991). During breeding, they feed on aquatic insects within the wetland territories and travel to grasslands and agriculture areas (*e.g.*, pastures and croplands) where invertebrate populations are abundant, sometimes feeding on snails and spiders (Zeiner *et al.* 1990A; Twedt and Crawford 1995). They forage as far as 1.6 kilometers (1 mile) from the nesting colony (Twedt and Crawford 1995). During this time, they probably require drinking water, and they return to the emergent wetlands at night to roost (Twedt and Crawford 1995).

The yellow-headed blackbird is vulnerable to habitat loss or degradation and to pesticide and herbicide use. For example, marsh drainage eliminated breeding populations in the San Fernando Valley (Small 1994). Aerial pesticides used in agriculture may drift into nearby wetland breeding colonies causing direct mortality of nestlings, or indirect mortality through a reduction in aquatic invertebrate food sources (Twedt and Crawford 1995). The use of herbicides may reduce suitable nesting habitat by removing nesting vegetation in the wetlands. Because these birds are colonial nesters, they are vulnerable to local extirpation, and pesticide use could devastate local breeding populations (Twedt and Crawford 1995). This species also may be affected by flooding of nests in areas with high water-level fluctuations, resulting in nest failure and nestling mortality. When adults are disturbed from the nest, unguarded eggs may be preyed upon by other birds, snakes, and mammals. In urbanized areas, predators may include cats and dogs and other mesopredators such as skunks, raccoons, and opossums. As with other wetland and riparian species, yellow-headed blackbirds may be sensitive to several other human- or development-related impacts. Construction-related dust, noise and ground vibration, nighttime lighting, and diminished water quality and altered hydrology are all factors that could affect yellow-headed blackbirds in the short term. Noise, lighting, diminished water quality and altered hydrology (*e.g.*, groundwater pumping and dewatering), and increased human activity are all factors that could affect yellow-headed blackbirds over the long term.

Survey Results

Surveys for riparian birds have been conducted for multiple years along the Santa Clara River and other portions of the Project area within suitable habitat for the yellow-headed blackbird. These surveys were conducted from 1988 through 2006 within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C); within portions of the Santa Clara River by Labinger *et al.* or Labinger and Greaves in 1994, 1996, 1997 and 1998 (Labinger *et al.* 1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A); within Castaic Creek, Salt Creek, High Country SMA, and portions of the Santa Clara River adjacent to the Project site by Dudek and Associates (2006B, 2006D, 2006E);

and within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line by Bloom Biological, Inc. in 2007 and 2008 (2007A, 2008). These surveys generally included both the riparian habitat within the River corridor and adjacent fields, which provide suitable breeding and/or foraging habitat for the yellow-headed blackbird.

This species has occasionally been observed within the Specific Plan area (Guthrie 1996B, 1997B, 1999B, 2001B; Bloom Biological 2007A), in the VCC planning area (Guthrie 1997A, 2006C), and off site in Castaic Junction (Guthrie 1988, 2000E). The most recent observation was on April 1, 2007, of a single individual in a flock of red-winged blackbirds in agricultural fields (Bloom Biological 2007A). No nesting colonies (which would have been highly conspicuous given the colonial nesting behavior of this species) have been observed within the Project areas. Thus, while suitable nesting and foraging habitat occurs on the Project site, based on survey results, this species is expected to occur occasionally on site and only as a migrant or vagrant that uses the Project area for foraging; it is not expected to nest on site. For this reason, this EIS/EIR analyzes impacts to suitable foraging habitat only and does not address nesting habitat separately.

Suitable foraging habitat for the yellow-headed blackbird in the Project area includes agriculture, disturbed land, California annual grasslands, purple needlegrass, bulrush–cattail wetland, cistmontane alkali marsh, coastal and valley freshwater marsh, herbaceous wetland, and river wash, totaling 5,656 acres.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 245 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 4.3% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat for nesting habitat and **Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and

Disturbed Land Wildlife Habitat for foraging habitat). A total of 136 acres would be temporarily impacted.

The yellow-headed blackbird is a wide-ranging species that may only occur on site as an occasional migrant or vagrant and forages in a variety of habitats. The construction of RMDP facilities would be phased over a long period of time, and approximately 1,486 of acres of suitable foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek and associated tributaries would be available for individuals of this species occasionally using the Project area at any given time. Therefore, the permanent loss of 245 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,116 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 55.1% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat for nesting habitat and **Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat for foraging habitat). After build-out of the Project area, 1,486 acres of suitable habitat for this species would remain in the Project area.

Because the yellow-headed blackbird is a wide-ranging species that occurs on site as an occasional migrant or vagrant and 1,486 acres of suitable foraging habitat would remain after build-out, this permanent loss of habitat that would occur as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,361 acres (59.4%). Because the yellow-headed blackbird is a wide-ranging species that occurs on site as an occasional migrant or vagrant and approximately 1,486 acres of suitable habitat would remain after build-out, the permanent loss of habitat from the combined direct and indirect permanent impacts of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The yellow-headed blackbird is a mobile species that occasionally occurs on site as an occasional migrant or vagrant. It is highly unlikely that construction activities associated with implementation of the RMDP would result in injury or mortality of individual adult birds. Some foraging or resting individuals may be displaced or disturbed by construction activities, but there would be adequate alternative habitat elsewhere in the Project area for these individuals. The yellow-headed blackbird is not expected to breed on site so nests with eggs or young would not be affected. Implementation of the SCP would not directly impact this species. Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

The yellow-headed blackbird is a mobile species and it is highly unlikely that build-out of the Specific Plan, VCC, and Entrada planning areas would result in injury or mortality of individual adult birds. Some foraging or resting individuals may be displaced or disturbed by construction activities, but there would be adequate alternative habitat elsewhere in the Project area for these individuals. The yellow-headed blackbird is not expected to breed on site so nests with eggs or young would not be affected. Indirect permanent impacts would be adverse but not significant.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, fugitive dust, and nighttime illumination. These effects may disturb yellow-headed blackbirds that use the site for foraging, causing them to avoid or leave areas near construction.

Potential long-term secondary impacts associated with urban development include traffic noise; nighttime illumination; invasion of suitable habitat by exotic species; increased litter; pesticide use resulting in loss of prey and/or secondary poisoning; increased human activity; harassment and predation by pet, stray, and feral cats and dogs; and increased mesopredators as a result of increased habitat fragmentation. These secondary impacts may result in yellow-headed blackbirds avoiding or leaving areas subject to these effects and there is some potential for predation of individuals.

Altered hydrology and geomorphology in the Santa Clara River corridor as a result of urban development in the watershed, and thus impacts to suitable habitat for the yellow-headed blackbird, are also potential long-term secondary effects of the build-out of the Specific Plan, VCC, and Entrada planning areas. However, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County over the long term. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue. As a result, the mosaic of habitats in the River that support various special-status species would be maintained, and the population of the species within and immediately adjacent to the River corridor would not be significantly affected.

Because the yellow-headed blackbird is a wide-ranging species that occasionally uses habitat in the Project area for foraging, these short-term and long-term secondary impacts would only affect occasional migrants or vagrants. These impacts would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the yellow-headed blackbird (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat for nesting habitat and **Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat for foraging habitat):

- Alternative 3 – 224 acres (4.0%) of permanent loss and 179 acres of temporary loss;
- Alternative 4 – 207 acres (3.7%) of permanent loss and 183 acres of temporary loss;
- Alternative 5 – 260 acres (4.6%) of permanent loss and 169 acres of temporary loss;
- Alternative 6 – 261 acres (4.6%) of permanent loss and 176 acres of temporary loss; and
- Alternative 7 – 118 acres (2.1%) of permanent loss and 475 acres of temporary loss.

Compared to Alternative 2, which would result in 245 acres (4.3%) of permanent habitat loss and 136 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 and 4 would be somewhat reduced, Alternatives 5 and 6 would be somewhat higher, and Alternative 7 would be substantially less. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be somewhat higher and Alternative 7 would be substantially higher. The difference for permanent and temporary impacts under Alternative 7 compared to the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Because the yellow-headed blackbird is a wide-ranging species and is expected to occasionally use the Project area for foraging, and because the overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be somewhat higher and lower, and substantially reduced under Alternative 7 compared to Alternative 2, permanent loss of habitat would not be substantially adverse. Temporary impacts under Alternatives 3 through 7 would be somewhat to substantially higher, but because of their temporary nature also would not be substantially adverse.

Permanent and temporary loss of habitat under Alternatives 3 through 7 therefore would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the yellow-headed blackbird (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat for nesting habitat and **Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat for foraging habitat):

- Alternative 3 – 2,985 acres (52.8%) of permanent loss;
- Alternative 4 – 2,838 acres (50.2%) of permanent loss;
- Alternative 5 – 2,780 acres (49.2%) of permanent loss;
- Alternative 6 – 2,556 acres (45.2%) of permanent loss; and
- Alternative 7 – 2,093 acres (37.0%) of permanent loss.

Compared to Alternative 2, which would result in 3,361 acres (59.4%) of permanent loss of habitat, Alternatives 3 through 6 would have reduced impacts. Alternatives 4 through 7 would have substantially reduced impacts compared to Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions under Alternatives 4 through 7 due to reduced Project footprints, and Alternative 7 would be further substantially reduced compared to the other alternatives because large agricultural areas along the Santa Clara River associated with Landmark Village and Homestead East (the Onion Fields) would not be developed.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the yellow-headed blackbird:

- Alternative 3 – 3,209 acres (56.7%) of permanent loss;
- Alternative 4 – 3,044 acres (53.8%) of permanent loss;

- Alternative 5 – 3,040 acres (53.8%) of permanent loss;
- Alternative 6 – 2,817 acres (49.8%) of permanent loss; and
- Alternative 7 – 2,211 acres (39.1%) of permanent loss.

Compared to Alternative 2, which would result in 3,361 acres (59.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons cited above for indirect permanent impacts. Because the combined direct and indirect permanent loss of suitable habitat for the yellow-headed blackbird occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Impacts to Individuals

The potential for impacts to yellow-headed blackbird individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2. Adult birds would likely avoid impacts during construction activities by avoiding or leaving construction areas. It is unlikely that adults would be injured or killed, but foraging and resting may be disrupted by construction activities. Because the species does not nest on site, nests with eggs and young would not be affected. Combined direct and indirect permanent impacts (Impacts to Individuals) would be adverse but not significant under Alternatives 3 through 7.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term impacts include construction-related dust, noise, ground vibration, and nighttime illumination. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas include traffic noise; nighttime illumination; exotic plant species; litter; pesticides; increased human activity; and predation by pet, stray, and feral cats and dogs and mesopredators, as described above for Alternative 2.

Because the yellow-headed blackbird is a wide-ranging species and only occasionally occurs on site to forage, these potential short-term and long-term secondary effects would not have a substantial adverse effect on the species and contribute to the reduction of its range and

distribution. These long-term and short-term secondary impacts would be adverse but not significant for Alternatives 3 through 7.

Mitigation Strategy and Summary

No mitigation is required for impacts to the yellow-headed blackbird because all impacts were determined to be adverse but not significant. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of approximately 1,418 acres of suitable foraging habitat in the River Corridor SMA, Salt Creek area, and High Country SMA. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction because individuals will have access to foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; and pesticides, will also be mitigated through a variety of measures.

YELLOW WARBLER (NESTING) (CSC)

Life History

The yellow warbler (*Dendroica petechia brewsteri*) is widely distributed, with a breeding range from northern Alaska eastward to Newfoundland and southward to northern Baja California and Georgia. This species is a migrant throughout much of North America and winters from southern California, Arizona, and the Gulf Coast southward to central South America (AOU 1998). Zeiner *et al.* (1990A) describes its distribution, abundance, and seasonality in California as an uncommon to common summer resident in the north and as a locally common resident in the south. It breeds in riparian woodlands southward from the northern border of the state, generally west of the Sierra Nevada to the coastal slopes of southern California, and from coastal and desert lowlands up to 2,700 meters (8,860 feet) AMSL in the Sierra Nevada and other montane chaparral and forest habitats (Lowther *et al.* 1999; Grinnell and Miller 1944). The yellow warbler primarily winters from northern Mexico to South America (mostly east of the Andes) to the Amazon lowlands of northern Bolivia and Amazonian Brazil, including most insular areas within this range, and to central Peru. Winter populations occur in lesser numbers in California, southwestern Arizona, southern Florida, and the Greater Antilles (Lowther *et al.* 1999). Small numbers regularly overwinter in southern California lowlands (Garrett and Dunn 1981). It is also a common migrant on the Channel Islands and Farallon Islands in spring and fall (DeSante and Ainley 1980; Garrett and Dunn 1981).

The yellow warbler usually nests in wet, deciduous thickets, especially those dominated by willows (*Salix* spp.), and in disturbed and early successional habitats (Lowther *et al.* 1999). In southern California, it nests in lowland and foothill riparian woodlands dominated by cottonwoods (*Populus* spp.), alders (*Alnus* spp.), or willows and other small trees and shrubs typical of low, open-canopy riparian woodland (Garrett and Dunn 1981). Nest trees most often are willows, hawthorns (*Crataegus* spp.), raspberry (*Rubus* spp.), northern white cedar (*Thuja occidentalis)*, honeysuckle (*Lonicera* spp.), and Spiraea (*Spiraea* spp.) (Lowther *et al.* 1999). It also nests in montane chaparral, open ponderosa pine and mixed conifer habitats with substantial amounts of brush (Zeiner *et al.* 1990A), but nesting in these habitats is perhaps relatively recent (Gaines 1977). Nests are usually located at intermediate heights (six to eight feet above the ground) and shrub density in an upright fork or crotch of a large tree, or sometimes a sapling or bush. Territories are established as soon as the males arrive in the spring (Lowther *et al.* 1999). Territories and home ranges are small, varying from 0.03 to 0.2 hectare (0.08 to 0.5 acre) (Lowther *et al.* 1999). Peak densities measured in southeast Arizona reached 48 birds per hectare (Lowther *et al.* 1999).

During migration, yellow warblers occur in lowland and foothill woodland habitats such as desert oases, riparian woodlands, oak woodlands, mixed deciduous–coniferous woodlands,

shrublands, forests, suburban and urban gardens and parks, groves of exotic trees, farmyard windbreaks, and orchards (Small 1994).

The yellow warbler forages for insects and spiders in the upper canopy of deciduous trees and shrubs, and occasionally hawks insects from the air or eats berries (Bent 1953; Ehrlich *et al.* 1988). Foraging typically occurs between 0.3 and 16.8 meters (1 to 55 feet) above the ground at the top of vegetation.

While no large-scale rangewide changes have been documented for the yellow warbler, populations in the southwestern United States have declined dramatically in recent decades in many lowland areas (*e.g.*, southern coast, Colorado River, San Joaquin and Sacramento valleys) (Lowther *et al.* 1999). Yellow warbler is now rare to uncommon in many lowland areas where formerly it was common (McCaskie *et al.* 1979; Garrett and Dunn 1981). Major continuing threats to the species include habitat destruction and fragmentation, and nest parasitism by brown-headed cowbirds (Garrett and Dunn 1981). Habitat fragmentation, especially when caused by intense grazing where willow growth along riparian habitats is reduced or removed, has had a major impact on populations in the western United States (Taylor and Littlefield 1986). Populations along the stretch of the Salinas River in Monterey County declined 50% in the 1980s, attributed to loss of riparian habitat and an increase of brown-headed cowbirds (Lowther *et al.* 1999). Management of cattle grazing in the western United States to maintain willow borders of riparian habitats helped to maintain yellow warbler populations (Taylor and Littlefield 1986). In southeastern Arizona, the yellow warbler population density increased six-fold within two to three years after the cessation of livestock grazing in riparian habitat (Lowther *et al.* 1999). Brood parasitism by brown-headed cowbirds is heavy and apparently has been a major cause of the drastic decline in numbers in lowland localities in recent decades (Lowther *et al.* 1999; Garrett and Dunn 1981; Remsen 1978). For example, parasitism occurred in nine of 25 nests or family groups in the Sierra Nevada where cowbirds were common (Lowther *et al.* 1999; Rothstein *et al.* 1980). Like other riparian bird species, several other potential human- or development-related factors may affect yellow warblers. Construction-related impacts include dust; noise and ground vibration; diminished water quality and altered hydrology; increased human activity in close proximity to nesting and foraging areas; and lighting, which may alter behavior, induce physiological stress, and increase predation risk. Long-term effects related to development include invasive plant species such as giant reed and tamarisk, which degrade habitat quality; increased human activity; noise; lighting; diminished water quality and altered hydrology; predation and harassment by pet, stray, and feral cats and dogs and other mesopredators; and Argentine ants, which are especially attracted to riparian areas and may prey on nestlings.

Survey Results

Surveys for riparian birds have been conducted for multiple years along the Santa Clara River in suitable habitat for the yellow warbler. This species was observed within the Specific Plan area during avian surveys from 1992 through 2007 (Guthrie 1992, 1993B, 1994B, 1995B, 1996B, 1997B, 1998A, 1999B, 2000C, 2001B, 2002C, 2003B, 2004H, 2005B, 2006A; Labinger *et al.* 1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A; Bloom Biological 2007A); in the VCC planning area from 1988 to 1989 and 1991 to 2006 (Guthrie 1988, 1989, 1991A, 1992, 1993A, 1994A, 1995A, 1996A, 1997A, 1998B, 1999A, 2000E, 2001A, 2002A, 2003A, 2004F, 2005A, 2006C); in the Entrada planning area in 2000 (Guthrie 2000D); and off site in Castaic Junction north of the Entrada planning area (Guthrie 1988, 1989, 1990, 1991A, 1992, 1993A, 1994A, 1995A, 1996A, 1997A, 1998B, 1999A, 2000E, 2000F, 2001A, 2002A, 2003A, 2004F, 2005A, 2006C; Haglund and Baskin 2000; Dudek and Associates 2006E; Bloom Biological 2007A). The species is considered to be a relatively common breeder in the Project area.

Southern cottonwood–willow riparian, southern coast live oak riparian forest, and southern willow scrub are suitable nesting and foraging habitat for the yellow warbler. There is a total of 445 acres of suitable habitat in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 39 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 8.7% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). A total of 44 acres would be temporarily impacted.

The yellow warbler is still a wide-ranging species that uses a variety of riparian habitats. The construction of RMDP facilities would be phased over a long period of time, and hundreds of acres of suitable riparian habitat in the River Corridor SMA and associated

tributaries would be available for this species at any given time. The permanent loss of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. These permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 7.8 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 1.8% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat).

Because the yellow warbler is still a wide-ranging species and uses a variety of riparian associated habitats, the permanent loss of 7.8 acres of habitat that would occur as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 47 acres (10.4%). Because the yellow warbler is still a wide-ranging species, uses a variety of riparian-associated habitat, and because the construction activities would be phased over a long period of time, hundreds of acres of suitable riparian habitat in the River Corridor SMA and associated tributaries would be available for this species at any given time. Therefore, the permanent loss of 47 acres of habitat that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction. These impacts would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of

the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The yellow warbler is a relatively mobile species and it is unlikely that construction activities associated with implementation of the RMDP would result in the direct loss of individual adult birds. However, implementation of the RMDP could result in injury or mortality of yellow warblers due to destruction of nests and loss of young if such construction/grading activities occurred during the nesting season. In addition, construction activities could alter the yellow warbler's foraging behavior, potentially affecting the health of young and reducing survivorship and reproductive success. Implementation of the SCP would not directly impact this species. Construction/grading activities, such as vegetation clearing, occurring during the nesting season could result in destruction of nests and resulting loss of eggs and/or young or alteration of foraging behavior (significance criteria 1 and 4). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. Because the species has potential to nest on site in habitat that would be directly affected, build-out of the Specific Plan, VCC, and Entrada planning areas could result in loss of young or eggs of this species as a result of destruction of nests (from any construction/grading activities that occur during the nesting season) or alteration of foraging behavior. Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, ground vibration, fugitive dust, and nighttime illumination. These impacts could alter essential behaviors such as foraging and breeding, induce physiological stress, and increase predation rates. Fugitive dust and diminished water quality and altered hydrology (*e.g.*, runoff, erosion, sedimentation) could reduce habitat quality, including insect prey. Although construction would be short term in nature, if these activities occurred during the

breeding season they could have a substantial direct adverse effect on this species due to potential disruption of breeding and nesting activities.

Potential long-term secondary impacts associated with urban development include traffic noise (similar to the noise effects discussed in detail above for least Bell's vireo); nighttime illumination; invasion by exotic species such as giant reed and tamarisk and Argentine ants which are attracted to riparian areas and may prey on nestlings; increased litter; cowbird nest parasitism; pesticide use resulting in loss of prey and/or secondary poisoning; increased human activity; harassment and predation by pet, stray, and feral cats and dogs; and increased mesopredators as a result of increased habitat fragmentation. These secondary impacts may result in abandonment of nests and lower reproductive success along the urban–open space edge over the long term.

Altered hydrology and geomorphology in the Santa Clara River corridor as a result of urban development in the watershed, and thus impacts to nesting habitat for the yellow warbler, are also potential long-term secondary effects of the build-out of the Specific Plan, VCC, and Entrada planning areas. However, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County over the long term. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue. As a result, the mosaic of habitats in the River that support various special-status species would be maintained and the population of the species within and immediately adjacent to the River corridor would not be significantly affected.

RMDP facilities include a public trail and viewing platforms adjacent to and along the northern edge of the Santa Clara River corridor, as shown in **Figure 4.5-88**, Special-Status Riparian Bird Observations in Relation to Viewing Platforms. The trail and viewing platforms will be used by the public during daytime hours. There is a potential for secondary impacts to yellow warbler nesting in areas that are adjacent to the trail and viewing platforms. Secondary impacts primarily would include noise and general increases in human activity that could disrupt behavioral activities such as foraging, territory defense, and nesting, or increase physiological stress. In addition, there is the potential for increased trash along the trail that could enter the River Corridor SMA. Due to the very close proximity of viewing platforms and trails to riparian habitats, there is potential for unauthorized trespass by the public into sensitive habitat areas. Although there would be no lighting provided for evening use of the trail and viewing platforms, public access during the nighttime hours may still occur and could introduce fugitive light and noise. These impacts have the potential to affect the health of young, and potentially reduce survivorship and reproductive success.

Short-term and long-term secondary impacts would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the yellow warbler (**Figures 4.5-55** through **4.5-59,** Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 25 acres (5.6%) of permanent loss and 43 acres of temporary loss;
- Alternative 4 – 26 acres (5.8%) of permanent loss and 41 acres of temporary loss;
- Alternative 5 – 31 acres (7.0%) of permanent loss and 47 acres of temporary loss;
- Alternative 6 – 17 acres (3.9%) of permanent loss and 43 acres of temporary loss; and
- Alternative 7 – 7.9 acres (1.8%) of permanent loss and 24 acres of temporary loss.

Compared to Alternative 2, which would result in 39 acres (8.7%) of permanent habitat loss and 44 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 through 7 would be substantially less. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be marginally to somewhat different and Alternative 7 would be substantially reduced. The difference for permanent and temporary impacts under Alternative 7 compared to the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Because the overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be substantially reduced compared to Alternative 2, and temporary impacts would range from similar in magnitude to substantially reduced, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the yellow warbler (**Figures 4.5-55** through **4.5-59,** Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 6.9 acres (1.6%) of permanent loss;
- Alternative 4 – 3.5 acres (0.8%) of permanent loss;
- Alternative 5 – 2.6 acres (0.6%) of permanent loss;
- Alternative 6 – 1.3 acres (0.3%) of permanent loss; and
- Alternative 7 – 0.7 acre (0.1%) of permanent loss.

Compared to Alternative 2, which would result in 7.8 acres (1.8%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 3 and 4 would have marginally to somewhat reduced impacts compared to Alternatives 5, 6, and 7, which would have additional reductions compared to the other alternatives.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the yellow warbler:

- Alternative 3 – 32 acres (7.2%) of permanent loss;
- Alternative 4 – 29 acres (6.5%) of permanent loss;
- Alternative 5 – 34 acres (7.5%) of permanent loss;
- Alternative 6 – 19 acres (4.2%) of permanent loss; and
- Alternative 7 – 8.5 acres (1.9%) of permanent loss.

Compared to Alternative 2, which would result in 47 acres (10.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. There would generally be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 3, 4, 6, and 7. Alternative 5 would have the next

largest impact compared to Alternative 2. Because the combined direct and indirect permanent loss of suitable habitat for the yellow warbler occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than under Alternative 2, these impacts would be adverse but not significant.

Impacts to Individuals

The potential for impacts to yellow warbler individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would essentially be the same as for Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. The yellow warbler is known to nest on site. Construction/grading activities, such as vegetation clearing, conducted during the breeding season could result in destruction of nests and loss of eggs and/or young where the species is nesting, and foraging behavior could be altered such that the health of young and survivorship and overall reproductive success would be reduced. Permanent impacts (Impacts to Individuals) would be significant, absent mitigation under Alternatives 3 through 7.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Potential short-term impacts include construction-related dust, noise, ground vibration, nighttime illumination, diminished water quality and altered hydrology. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas include traffic noise; nighttime illumination; diminished water quality; exotic plant and animal species; litter; cowbird nest parasitism; pesticides; increased human activity; and predation by pet, stray, and feral cats and dogs and mesopredators, as described above for Alternative 2. All of these impacts occurring under Alternatives 3 through 7 could result in lower reproductive success of the yellow warbler in the Project area.

Riparian habitat along the Santa Clara River would not be substantially affected over the long term by altered hydrology or geomorphology under Alternatives 3 through 7 (PACE 2009).

There would be no viewing platforms constructed in the River Corridor SMA under Alternatives 3 through 7.

These potential short-term and long-term secondary effects would have a substantial adverse effect on the species and would contribute to the reduction of its range and distribution. These long-term and short-term secondary impacts would be significant, absent mitigation for Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to yellow warbler: (1) impacts to individuals; and (2) secondary impacts to individuals and suitable habitat outside the Project footprint. Direct and indirect impacts to habitat were determined to be adverse but not significant.

Nesting by yellow warbler has been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, impacts to individuals could occur if active nests are disturbed during vegetation clearing and construction/grading activities, including destruction of nests and loss of eggs and/or fledglings. Construction activities may also alter foraging behavior and thus potentially reduce the health of young and result in lower reproductive success. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

With regard to secondary effects, nesting and foraging activities by the yellow warbler could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, lighting, and diminished water quality and altered hydrology. These secondary effects may alter foraging and nest defense behavior, cause adults to abandon nests due to stress, and otherwise disrupt normal behavioral patterns, and cause nests to be more vulnerable to predators. Short-term effects of dust and diminished water quality and altered hydrology may affect habitat quality and the insect prey base for the yellow warbler, thus adversely affecting foraging behavior and provisioning of young. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 300 feet, and by retaining a qualified biologist during all vegetation clearing and grading activities. Several general measures will be implemented that will reduce impacts to yellow warbler. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities, biological monitoring during any stream diversions, restrictions on construction equipment operating in ponds or flowing water, and protection of water quality from mud, silt, and other pollutants. Long-term development-related impacts include habitat fragmentation; increased traffic noise; introduction of secondary effects related to viewing platforms and trails along the River Corridor SMA (under Alternative

2 only); invasive species such as giant reed and tamarisk and Argentine ants, which may prey on nestlings; cowbird parasitism; increased noise; diminished water quality, affecting prey and nesting habitat quality; lighting; pesticides that may cause secondary poisoning and loss of prey; human disturbances of nest sites; and predation by pet, stray, and feral cats and dogs and other mesopredators. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 314 acres of suitable habitat, primarily in the River Corridor SMA, but also in the High Country SMA and Salt Creek area, will provide yellow warblers with relatively undisturbed habitat for nesting and foraging. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by nocturnal predators and reduce physiological stress. Limited recreational usage and access restrictions within the River Corridor SMA and High Country SMA; control of pet, stray, and feral cats and dogs in or near open space areas; trail signage; and homeowner education regarding special-status resources in preserved natural habitat areas will help protect yellow warblers by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of secondary poisoning and loss of prey. Cowbird surveys will be conducted and trapping will be implemented if necessary. Controls on Argentine ants will help reduce impacts on young in nests.

The specific mitigation measures for the yellow warbler are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-78 IMPACTS TO INDIVIDUALS – YELLOW WARBLER (NESTING)

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of yellow warbler individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to yellow warbler individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to yellow warbler individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-79 SECONDARY IMPACTS – YELLOW WARBLER (NESTING)

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on the yellow warbler associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such traffic noise, invasion by exotic plant species, abandonment of nests from human activity, and greater vulnerability to nocturnal predators as a result of nighttime lighting. These mitigation measures provide for protection, restoration, enhancement, and management of habitat in open space for yellow warbler that will offset secondary impacts by providing high-quality habitat away from development areas. Mitigation measures to avoid and minimize impacts to water quality and hydrology and inadvertent impacts to habitat outside disturbance zones during construction will also be implemented.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor

SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

Additionally, SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA that will preserve and enhance at least 314 acres of suitable habitat for the yellow warbler (**Figure 4.5-12**).

SP-4.6-17 will control public access to the River Corridor SMA and states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20 states that any grading activities within or adjacent to the River Corridor SMA shall have grading perimeters clearly marked and inspected prior to grading. The Project biologist shall work with the grading contractor to avoid inadvertent impacts to riparian resources.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. These mitigation measures will address avoidance and minimization of downstream hydrology and water quality effects that could adversely affect yellow warbler habitat and/or breeding populations.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to yellow warbler, including short-term construction-related dust, noise, ground vibration, and diminished water quality; and long-term impacts such as invasive species (including exotic plants, cowbirds, and Argentine ants); increased human activity; greater vulnerability to

predation by pet, stray, and feral cats and dogs; and impacts of pesticides such as indirect poisoning and loss of prey.

Secondary effects of noise and ground vibration during construction will be addressed by BIO-52 and BIO-56, as described above, which will mitigate these effects by identifying nest sites and providing for buffers between nests and construction activities.

Three mitigation measures, BIO-47, BIO-49, and BIO-70, will reduce impacts to the yellow warbler during construction activities by protecting water quality.

BIO-47 requires that slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area that will provide refuge for arroyo toad during construction.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. This will reduce impacts to yellow warbler by protecting habitat quality, including water quality, and by minimizing impacts on its insect prey. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-55 requires that existing maps of suitable riparian habitat for the least Bell's vireo, willow flycatcher/southwestern willow flycatcher, and western yellow-billed cuckoo be updated as needed and submitted to the Corps and CDFG. The removal of any riparian habitat suitable for these species from the Project footprint shall be mitigated through the creation or enhancement of similar riparian habitat at an approved mitigation site or by the removal of exotic species from an area of existing similar habitat. Because the yellow warbler uses the same habitat as these species, it will benefit from this mitigation measure.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-78 requires implementation of a cowbird trapping program once vegetation clearing begins. The program shall be implemented each day beginning April 1 and concluding on or about November 1, through the construction, maintenance, and monitoring period of the riparian restoration sites. In the event that trapping is terminated after the first few years of development, subsequent phases of the RMDP development shall trigger initiation of trapping surveys.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also reduce impacts to yellow warbler by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant from riparian areas is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the yellow warbler would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

GRASSHOPPER SPARROW (NESTING) (CSC)

Life History

The grasshopper sparrow (*Ammodramus savannarum*) is a neotropical migrant that breeds from eastern Washington eastward to southern Maine, and southward to southern California, northernmost Mexico, and Virginia. It is a breeding resident east of the Rocky Mountains from Canada to the southern states and the wintering ranges south into Florida and Mexico. Grasshopper sparrows winter from California to North Carolina and south through Central America to Costa Rica (County of Riverside 2008). It is a year-round resident in the western states and in the southern portions of the southeastern states (County of Riverside 2008). In southern California, the grasshopper sparrow occurs in appropriate habitats west of the deserts (Garrett and Dunn 1981).

Grasshopper sparrows in California breed (and primarily winter) on slopes and mesas containing grasslands of varying compositions (Grinnell and Miller 1944; Garrett and Dunn 1981). The grasshopper sparrow uses dense, dry, or well-drained grassland, especially native grassland with a mix of grasses and forbs for foraging and nesting, and requires fairly continuous native grassland areas with occasional taller grasses, forbs, or shrubs for song perches (Garrett and Dunn 1981). Grasshopper sparrows tend to avoid grassland areas with extensive shrub cover and the presence of native grasses is less important than the absence of trees (Smith 1963; County of Riverside 2008). They may also occur in fallow agricultural fields, especially those periodically planted with oats and barley.

Grasshopper sparrows forage for insect prey on the ground and in low foliage within the interstitial bare ground among relatively dense, short to medium height bunchgrass, sometimes scraping in the litter. It feeds primarily on insects in the summer and grass and forb seeds in winter (County of Riverside 2008).

Grasshopper sparrows breed from early April to mid-July, with a peak in May and June. Nests are difficult to detect and are composed of grasses and forbs and are located in slight depressions in the ground or hidden at the base of an overhanging clump of grasses or forbs (Zeiner *et al.* 1990A). Clutch size is four to five eggs that incubate in 11 to 12 days. The chicks fledge about nine days after hatching (Harrison 1978).

Threats to the grasshopper sparrow include habitat loss, degradation, and fragmentation. A decline in population was observed in the mid-1900s because of increased development on open, hillside areas (Garrett and Dunn 1981). Development-related fragmentation of native habitat in southern California has also been shown to contribute to rapid local native species extirpations, particularly passerine birds (Soulé *et al.* 1988; Soulé *et al.* 1992; Crooks *et al.* 2001). Vickery (County of Riverside 2008) suggested that declines in the population were also due to extensive grazing in western North America and brown-headed cowbird nest parasitism. An additional

threat to this species is increased nest failures resulting from nest predation where nests are located in short grasses and weedy edges of wooded habitats associated with habitat fragmentation (County of Riverside 2008). General human presence and domestic animals have fairly obvious potential adverse effects on native habitats and species along the urban–wildland edge. Human activity may result in increased trampling of native vegetation, trash dumping, off-road vehicles, *etc.*, that degrade habitats and harass wildlife. Cats and dogs may prey on native species along the urban–wildland edge and can have a significant impact on local populations (Crooks *et al.* 2001). Several other potential human- or development-related factors may affect grasshopper sparrows. Construction-related impacts include dust; noise and ground vibration; increased human activity in close proximity to nesting and foraging areas; and lighting, which may alter behavior, induce physiological stress, and increase predation risk. Additional long-term effects related to development include lighting and Argentine ants, which may occur in moist edge areas and prey on nestlings.

Survey Results

The Project area is just south of the southern edge of the portion of this species' summer breeding range, which occurs at approximately the Los Angeles/Kern County boundary. Therefore, grasshopper sparrows likely use the Project area during migration between breeding areas to the north and southern wintering areas. There is potential for this species to breed in grasslands and some agricultural areas, which occur mostly in the central portion of the Specific Plan area, San Martinez Grande, along portions of the Santa Clara River and Castaic Creek, and some portions of the VCC and Entrada planning areas. Although suitable grassland breeding and wintering habitat for the grasshopper sparrow occurs in the Project area, multiple avian surveys conducted since 1988 have not detected this species. Bird surveys were conducted by Daniel Guthrie from 1988 through 2007 within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line (1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C). The surveys were focused in riparian areas in the Santa Clara River corridor and on both sides of the River but also included uplands adjacent to the River. Other avian surveys were conducted in portions of the Santa Clara River by Labinger *et al.* and Labinger and Greaves in 1994, 1996, 1997, and 1998 (Labinger *et al.*1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A); within Castaic Creek, Salt Creek, High Country SMA, and portions of the Santa Clara River adjacent to the Project site by Dudek and Associates (2006B, 2006D, 2006E); and within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line by Bloom Biological, Inc. in 2007 and 2008 (2007A, 2008).

The presence of the grasshopper sparrow is easily confirmed by its characteristic call, although nests are difficult to find. These surveys generally were conducted during the April to June

breeding seasons, and, if the grasshopper sparrow was a common nesting bird on site, it would have been detected. These surveys therefore are considered adequate to conclude that the grasshopper sparrow does not commonly occur on site, but they do not demonstrate absence from the Project area. This EIS/EIR thus analyzes the potential impact of the implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas on this species. California annual grassland and purple needlegrass are suitable breeding and wintering habitat for this species. A total of 2,300 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 24 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.1% of these habitats on site (**Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat). A total of 9.7 acres would be temporarily impacted.

The grasshopper sparrow is still a wide-ranging species, but it was determined to not commonly occur on site (it has not been detected during surveys). The construction of RMDP facilities would be phased over a long period of time, and approximately 660 of acres of grassland habitat in the High Country SMA, Salt Creek area, River Corridor SMA would be available for this species at any given time if it were to occur on site. The permanent loss of 24 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the

species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 1,042 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 45.3% of these habitats on site (**Figure 4.5-66,** Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat).

Although a relatively large amount and percentage of suitable habitat on site for the grasshopper sparrow would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas, this species is considered unlikely to breed or winter on site based on negative survey results over multiple years. This species is wide-ranging and it was determined to not commonly occur on site. If it were to occur, approximately 660 of acres of grassland habitat in the High Country SMA, Salt Creek area, and River Corridor SMA would be available for this species. This loss of habitat, therefore, would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 1,067 acres (46.4%). Although a relatively large amount and percentage of suitable habitat on site for the grasshopper sparrow would be permanently lost from the combined direct and indirect permanent impacts of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas, this species is considered unlikely to breed or winter on site based on negative survey results over multiple years. This species is wide-ranging and it was determined to not commonly occur on site**.** If it were to occur, approximately 660 of acres of grassland habitat in the High Country SMA, Salt Creek area, and River Corridor SMA would be available for this species. This loss of habitat, therefore, would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to

eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Based on the negative results from past surveys, the grasshopper sparrow is unlikely to breed in the Project area. Also, because these birds are highly mobile, it is unlikely that RMDP-related construction activities would result in injury or mortality of adult grasshopper sparrows. Construction activities, however, could disrupt foraging by wintering birds by displacing them from construction areas. Implementation of the SCP would not directly impact this species. If the species occasionally attempted to nest on site, vegetation clearing or grading activities occurring during the nesting season could result in destruction of nests and eggs and injury or mortality of young, and/or disrupt foraging and provisioning of young (significance criteria 1 and 4). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent and temporary impacts to individuals, but over a much larger area. Although wintering adults would not be injured or killed, foraging could be disrupted. If the species attempted to nest on site, vegetation clearing and grading activities occurring during the nesting season could result in destruction of nests and eggs, injury or mortality of young, and/or disruption of foraging and provisioning of young (significance criteria 1 and 4). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

In the short term, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would have the potential to impact grasshopper sparrows in areas adjacent to construction zones. These impacts could include exposure to construction-related dust, noise, ground vibration, nighttime illumination, and increased human activity. These impacts could affect both wintering birds foraging on site and nesting birds, if nesting were to occur on site. Construction activities associated with RMDP implementation and build-out of the Specific Plan, VCC, and Entrada planning areas, however, would be short term and because of the low potential for grasshopper sparrow to occur on site, these impacts would not have a substantial adverse effect on this species.

Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include habitat fragmentation; abandonment of nests from human activity; greater vulnerability to nocturnal predators as a result of nighttime lighting; noise from roadways; nest parasitism by cowbirds; greater vulnerability to predation by pet, stray, and feral cats and dogs and other mesopredators; and loss of prey or secondary poisoning due to the use of pesticides. Although these effects could occur, because the grasshopper sparrow is unlikely to nest or winter on site in large numbers, these impacts would not have a substantial adverse effect on the species.

These potential short-term and long-term secondary impacts would not have a substantial adverse effect on the species and would not contribute to the reduction of the range and/or distribution of this species (significance criteria 1 and 7). Short-term and long-term secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the grasshopper sparrow (**Figures 4.5-67** through **4.5-71,** Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 32 acres (1.4%) of permanent loss and 14 acres of temporary loss;
- Alternative 4 – 24 acres (1.1%) of permanent loss and 10 acres of temporary loss;
- Alternative 5 – 42 acres (1.8%) of permanent loss and 16 acres of temporary loss;
- Alternative 6 – 66 acres (2.8%) of permanent loss and 18 acres of temporary loss; and
- Alternative 7 – 19 acres (0.8%) of permanent loss and 55 acres of temporary loss.

Compared to Alternative 2, which would result in 24 acres (1.1%) of permanent habitat loss and 9.7 acres of temporary impacts, the permanent loss of habitat under Alternatives 3, 4, and 5 would be not substantially different to somewhat more; Alternative 6 would be substantially more, and Alternative 7 would be somewhat less. Compared to Alternative 2, the temporary loss of habitat under Alternative 4 would be not substantially different; Alternatives 3, 5, and 6 would be marginally to somewhat more; and Alternative 7 would be substantially more. The difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and relatively more temporary impacts.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would not be substantially different than Alternative 2, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the grasshopper sparrow (**Figures 4.5-67** through **4.5-71,** Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 966 acres (42.0%) of permanent loss;
- Alternative 4 – 911 acres (39.6%) of permanent loss;
- Alternative 5 – 880 acres (38.3%) of permanent loss;
- Alternative 6 – 846 acres (36.8%) of permanent loss; and
- Alternative 7 – 722 acres (31.4%) of permanent loss.

Compared to Alternative 2, which would result in 1,042 acres (45.3%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the grasshopper sparrow:

- Alternative 3 – 998 acres (43.4%) of permanent loss;
- Alternative 4 – 935 acres (40.6%) of permanent loss;
- Alternative 5 – 922 acres (40.1%) of permanent loss;
- Alternative 6 – 911 acres (39.6%) of permanent loss; and

- Alternative 7 – 741 acres (32.2%) of permanent loss.

Compared to Alternative 2, which would result in 1,067 acres (46.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect permanent impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, there would also be successive reductions in the Specific Plan and Entrada planning areas under these alternatives. Because the combined direct and indirect permanent loss of suitable habitat for the grasshopper sparrow occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Impacts to Individuals

The potential for impacts to grasshopper sparrow individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Wintering birds foraging on site could be displaced by construction activities. Although the grasshopper sparrow has a low potential to breed or nest on site, if it attempted to nest on site, impacts to individual grasshopper sparrows, including destruction of nests and eggs, injury or mortality of young, or disruption of foraging and provisioning of young, occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term impacts include construction-related dust, noise, ground vibration, and nighttime illumination. These effects are more likely to occur during build-out of the Specific Plan, VCC, and Entrada planning areas than implementation of the RMDP and the SCP because of the much larger area of impact.

Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas, include increased human activity, highway noise, increased predation, and use of pesticides, as described above for Alternative 2.

Because the grasshopper sparrow has a low potential to breed or winter on site, these potential short-term and long-term secondary impacts would not have a substantial adverse effect on the species or contribute to the reduction of its range and distribution. These secondary impacts would be adverse but not significant.

Mitigation Strategy and Summary

The Project could result in significant impacts to the grasshopper sparrow as a result of impacts to individuals.

Wintering and nesting by the grasshopper sparrow has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. However, for the purpose of this analysis, it is assumed that grasshopper sparrows could both winter and nest on site. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, both wintering and nesting individuals could be displaced from suitable habitat by construction activities. Although impacts to winter visitors foraging on site would not be significant because substantial alternative habitat would be available, impacts to nesting individuals would be significant if vegetation clearing and grading activities resulted in the destruction of nests and eggs, injury or mortality of young, or disruption of foraging and provisioning of young. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 300 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

Loss of suitable habitat and secondary impacts to individuals would be adverse but not significant and no mitigation is required for these impacts. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts due to habitat loss and secondary effects to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of approximately 659 acres of grassland habitat in the Salt Creek area, High Country SMA, and River Corridor SMA. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction, because individuals will have access to foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; and pesticides; will also be mitigated through a variety of measures.

IMPACT 4.5-80 IMPACTS TO INDIVIDUALS – GRASSHOPPER SPARROW

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of grasshopper sparrow individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to grasshopper sparrow individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to grasshopper sparrow individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

PALLID BAT (CSC)

Life History

The pallid bat (*Antrozous pallidus*) is widespread throughout the western United States; southern British Columbia, Canada; and mainland and Baja California, Mexico (Hermanson and O'Shea 1983; Hall 1981). Within the United States, it ranges east into southern Nebraska, western Oklahoma, and western Texas. In California, the CNDDB (CDFG 2007A) contains 378 records for this species. The pallid bat occurs throughout California, except for the highest elevations of the Sierra Nevada. A large number of the records are from southern California counties, including Los Angeles (14 records), San Bernardino (24 records), San Diego (26 records), Riverside (14 records), Orange (three records), and Ventura (four records).

The pallid bat is locally common in arid deserts (especially the Sonoran life zone) and grasslands throughout the western United States and also occurs in shrublands, woodlands, and forests at elevations up to 2,440 meters (8,000 feet) (Hermanson and O'Shea 1983; Hall 1981). Although this species prefers rocky outcrops, cliffs, and crevices with access to open habitats for foraging, it has been observed far from such areas (Hermanson and O'Shea 1983).

Pallid bat day roosts of single- or mixed-sex colonies, often including greater than 20 individuals and sometimes more than 200 individuals, usually are established in crevices or man-made structures, with colonies (Hermanson and O'Shea 1983). The selection of crevices may vary seasonally in relation to "adaptive hypothermia" in the species.

Pallid bats forage for a variety of insects, including flightless arthropods picked up from the ground (*e.g.*, scorpions and ground crickets), insects gleaned from vegetation (*e.g.*, cicadas), insects taken in flight, and small vertebrates such as horned lizards and pocket mice that are taken on the ground. Although the species is capable of flying more than 18 miles, most foraging occurs within about two miles of the diurnal roost (Hermanson and O'Shea 1983). They probably are not "migratory" in the sense of moving long distances between summer and winter roosts, but they appear to move to different roosting areas in the cooler months. They probably hibernate in the winter, but some winter activity has been observed (Hermanson and O'Shea 1983).

Pallid bats typically give birth from May through June in the southwestern United States. The young are born relatively undeveloped, but they mature rapidly and achieve full adult flight capability by about 49 days of age and full adult weight by 56 days of age (Hermanson and O'Shea 1983).

Bats in general are very sensitive to human disturbance of roost sites, including exploration of caves, mines and old buildings, vandalism, collection at roost sites and watering sites, and extermination. Even a small amount of activity can cause bats to permanently abandon roost

sites, particularly day roosts that may be used as maternity sites during the breeding season and winter roosts that are used during hibernation and torpid periods. The pallid bat is particularly vulnerable to terrestrial predators and collection by humans while pallid bat individuals are on the ground taking prey (Hermanson and O'Shea 1983). Plausible impacts to pallid bat resulting from construction activities include disturbances of day roosts from human activity, noise, and dust, as well as effects of dust on insect prey. Potential long-term impacts from urban development also include human and pet, stray, and feral animals' disturbances of roost sites; roost site and foraging habitat degradation, such as trampling and invasive species; and pesticides that may cause secondary poisoning and affect prey abundance.

Survey Results

Two focused bat surveys have been conducted in the Project area. Impact Sciences (2005) conducted acoustic surveys using the Anabat II Bat Detector in 2004 and conducted surveys using both the Anabat detector and mist netting in 2006 (Johnson 2006).

Figure 4.5-131 shows the 25 survey locations from 2004 and the six survey locations from 2006 (Impact Sciences 2005; Johnson 2006). The 2004 surveys were scattered throughout the Project area, as well as in two locations on the Legacy Village site. The 2006 surveys were more concentrated, with three locations in Potrero Canyon, two locations along the Santa Clara River, and one location in upper Long Canyon.

The results of these surveys demonstrate that the pallid bat is present and has both day and nocturnal roosts in the Project area. There is at least one maternity colony in a metal storage building in middle Potrero Canyon, and a nocturnal roost in a wooden shed was documented along Potrero Creek. Because of the general foraging behavior of this species and its ability to forage several miles from roost sites, it is assumed that most natural habitats within the Project area provide potential foraging habitat. Suitable foraging (shrublands and grasslands) or roosting habitat (woodlands) for the pallid bat includes alluvial scrub, arrow weed scrub, southern cottonwood–willow riparian forest, Mexican elderberry scrub, mulefat scrub, southern coast live oak riparian forest, southern willow scrub, river wash, big sagebrush scrub, California sagebrush scrub, coyote brush scrub, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, California annual grassland, *Eriodictyon* scrub, purple needlegrass, coast live oak woodland, valley oak woodland, valley oak/grass, mixed oak woodland, and California walnut woodland. A total of 10,919 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of

Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total 173 acres of suitable foraging habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.6% of these communities on site. **Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats shows impacts to all vegetation communities because the pallid bat is a foraging habitat generalist and thus potentially forages throughout the Project area. A total of 75 acres would be temporarily impacted. In addition, a documented nocturnal roost site in a wooden shed in Potrero Creek would be removed.

The pallid bat forages in a broad variety of habitats that comprise more than 10,000 acres in the Project area. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 173 acres of foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). However, the loss of the nocturnal roost site along Potrero Creek would have a substantial direct adverse effect on this species and would affect the pattern of its movement and habitat use on site (significance criteria 1 and 4). Direct permanent and temporary impacts (Loss of Habitat) are therefore significant, absent mitigation.

Indirect Permanent Impacts

Approximately 3,123 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 28.6% of suitable habitat on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats).

A relatively large amount and percentage of on-site roosting and foraging habitat for the pallid bat would be permanently removed as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from approximately 28.6% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,296 acres (30.2%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of the pallid bat on site, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Pallid bats are highly mobile, and it is unlikely that the proposed Project would result in direct mortality of adults occupying this habitat during construction and/or grading activities. However, if adults are flushed from a day roost site during construction activities, these individuals could become disoriented and unable to safely relocate to another roost site, resulting in an increased risk of injury or mortality. In addition, if construction activities directly impacted a colonial maternity site, young could be injured or killed. Furthermore, even if young escaped direct impacts, the loss of a maternity site resulting from implementation of the RMDP before young are independent of the mother likely would result in mortality of the young due to their likely inability to safely relocate to another roost site. The documented 2006 maternity site in the storage building in Potrero Canyon is located approximately 300 feet north of the RMDP construction zone and would not be directly impacted during construction activities; thus, there would not be direct impacts to pallid bats using this maternity site. However, because of the pallid bat's presence in the Project area, there is the potential for maternity sites to be established elsewhere, and those sites could be directly impacted by construction activities. Implementation of the SCP would not directly impact this species. A nocturnal roost in the wooden shed along Potrero Creek would be removed, but direct impacts to pallid bats at this site are not anticipated. However, if a day roost site were established elsewhere prior to construction activities in the Project footprint, direct impacts to the

roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent loss of the maternity site in the storage building north of Potrero Canyon. If construction occurred while the site was occupied, impacts to both adults and young would occur because of their likely disorientation from being flushed from the roost and their likely inability to safely relocate to another day roost. Although other day roosts, including maternity sites, were not documented in the 2004 and 2006 surveys (Impact Sciences 2005; Johnson 2006), any day roost sites established in construction zones could also result in impacts to pallid bat individuals.

The loss of the maternity site in Potrero Canyon would have a substantial adverse effect on a special-status species (significance criterion 1). Furthermore, if a day roost site were established elsewhere in the Project area prior to construction activities, impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). Because of the loss of a documented maternity site, indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect pallid bats in areas adjacent to construction zones. As noted above, increased human activity, noise, and dust associated with construction activities could cause pallid bats to abandon day roosts, exposing both adults and young to injury and mortality due to their likely inability to safely relocate to another day roost. Although bats are highly mobile and could alter their foraging behavior to avoid construction areas, construction-generated dust may adversely affect foraging habitat by reducing their insect prey. Lighting in construction areas may also alter foraging behavior due to changing the distribution of insect prey attracted to lights and potentially causing increased competition among bats.

A maternity site in a storage building is located approximately 300 feet north of the proposed road in Potrero Canyon. Although this site would be permanently lost due to construction of Potrero Village, prior to build-out, it also could be disturbed as a result of construction of RMDP facilities in Potrero Canyon. No other maternity sites were detected during focused surveys in 2004 and 2006 (Impact Sciences 2005; Johnson 2006). The documented maternity site and any other day roosts (including maternity sites) that become established in proximity to construction

zones therefore could be temporarily or permanently impacted as a result of short-term construction activities.

Long-term impacts of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would also increase potential secondary impacts through increased human activity, noise, and lighting for the same reason described above for construction impacts, but over the long term. Furthermore, pallid bats taking prey on the ground are vulnerable to collection by humans and to predation by pet, stray, and feral cats and dogs. Use of pesticides for agriculture or in landscaped areas may result in secondary poisoning and reduction of prey.

Both short-term and long-term secondary impacts to a roost site and impacts to foraging bats would result in a substantial adverse effect on a special-status species (significance criterion 1) and would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to suitable habitat for the pallid bat (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 158 acres (1.4%) of permanent loss and 85 acres of temporary loss;
- Alternative 4 – 153 acres (1.4%) of permanent loss and 74 acres of temporary loss;
- Alternative 5 – 185 acres (1.7%) of permanent loss and 91 acres of temporary loss;
- Alternative 6 – 187 acres (1.7%) of permanent loss and 91 acres of temporary loss; and
- Alternative 7 – 77 acres (0.7%) of permanent loss and 152 acres of temporary loss.

Compared to Alternative 2, which would result in 173 acres (1.6%) of permanent loss and 75 acres of temporary impacts, the combined direct permanent and temporary loss of habitat under Alternative 3 would not be substantially different, Alternatives 4 and 7 would be marginally smaller, and Alternatives 5 and 6 would be marginally greater. The relatively greater reduction in permanent loss of habitat and increase in temporary impacts for Alternative 7 compared to Alternative 2 is primarily due to the pullback of

RMDP facilities from the Santa Clara River and its tributaries under Alternative 7; however, the larger amount of temporary impacts under Alternative 7 is offset by the substantial reduction in permanent impacts.

The overall loss of foraging habitat from implementation of the RMDP and the SCP under Alternative 3 through 7 would be similar in magnitude compared to Alternative 2. As described above, the loss of habitat alone under Alternative 2 would not be a substantial adverse impact, but the associated loss of the maternity site in Potrero Canyon results in a finding for Alternative 2 of significant, absent mitigation. The maternity site would also be lost under Alternatives 3 through 7; therefore, this impact (Loss of Habitat) for Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the pallid bat (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 2,919 acres (26.7%) of permanent loss;
- Alternative 4 – 2,808 acres (25.7%) of permanent loss;
- Alternative 5 – 2,728 acres (25.0%) of permanent loss;
- Alternative 6 – 2,415 acres (22.1%) of permanent loss; and
- Alternative 7 – 2,122 acres (19.4%) of permanent loss.

Compared to Alternative 2, which would result in 3,123 acres (28.6%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that reduce impacts to pallid bat suitable habitat compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the pallid bat occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the pallid bat:

- Alternative 3 – 3,077 acres (28.2%) of permanent loss;
- Alternative 4 – 2,961 acres (27.1%) of permanent loss;
- Alternative 5 – 2,914 acres (26.7%) of permanent loss;
- Alternative 6 – 2,602 acres (23.8%) of permanent loss; and
- Alternative 7 – 2,199 acres (20.1%) of permanent loss.

Compared to Alternative 2, which would result in 3,296 acres (30.2%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussion of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the development footprint in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the pallid bat occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual pallid bats as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. The impacts to individual pallid bats occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada

planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as increased human activity; dust; noise (from construction and traffic on road and bridges); lighting; pesticides; and pet, stray, and feral cats and dogs. The loss or degradation of suitable habitat and impacts to individual pallid bats due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to pallid bat: (1) impacts to individuals; (2) loss of roosting and foraging habitat; and (3) secondary impacts to individuals and roosting sites and foraging habitat outside the Project footprint.

Impacts to individuals could occur if day roosting sites are disturbed during construction as a result of increased human activity, noise, dust, and lighting. As noted above, bats are very sensitive to disturbances and may permanently abandon roost sites with a single disturbance event. If individuals, including adults and young, are flushed from a day roost during construction, they would likely become disoriented and unable to safely relocate to another roost, resulting in increased risk of injury or mortality. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active bat roost sites and postpone work within 300 feet of any active maternity roost until young have fledged, and will create alternative roost sites to mitigate for any roost sites disturbed during construction, including creation of roosts under bridges and in culverts, where practicable, in consultation with CDFG.

The combined permanent loss of foraging habitat result from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,199 acres (20.1%) under Alternative 7 to 3,296 acres (30.2%) under Alternative 2. This would be a substantial loss of suitable foraging habitat and will alter the foraging behavior of the pallid bat in the Project area. A maternity roost would also be lost due to development in Potrero Canyon, and other day roosts may be present in development areas in the future. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable foraging habitat to support the pallid bat in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 5,819 acres of suitable foraging habitat, as well as potential roosting sites, for the pallid bat. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, bats are very sensitive to disturbances and thus roost sites outside of the construction zone could be adversely affected during construction due to increased human activity, dust, noise, and lighting. Dust may also affect their insect prey base. Impacts to active maternity sites in or within 300 feet of construction zones will be avoided until young have fledged, as noted above. Construction-generated dust will be controlled using standard measures such as chemical suppression and screening fencing where determined to be necessary. Potential long-term effects of development include lighting; increased human activity; pet, stray, and feral cats and dogs, which may cause roost abandonment; and use of pesticides, which may cause secondary poisoning or affect the prey base. The large open space system will provide adequate areas for roosting and foraging that will in part offset these impacts. Several specific mitigation measures will also be implemented to control human activities in open space areas where bats may roost, including homeowner education and restrictions on recreational activities. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting along the edge of natural habitat areas will be downcast. Pesticides will be controlled through an integrated pest management (IPM) plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

The specific mitigation measures for the pallid bat are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-81 IMPACTS TO INDIVIDUALS – PALLID BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid, minimize, or mitigate impacts to pallid bat individuals.

Measures Recommended by EIS/EIR

This EIS/EIR recommends three mitigation measures to reduce impacts to pallid bat individuals. These mitigation measures primarily are designed to avoid impacts to active day roosts.

BIO-61 requires a pre-construction survey to determine if active roosts of special-status bats are present within 300 feet of the Project disturbance boundaries. If an active maternity roost is found, all work within 300 feet shall be postponed until the roost is vacated and juveniles have fledged. If a maternity roost is impacted, substitute roosting habitat shall be provided. Non-breeding bat hibernacula shall be vacated the evening between initial disturbance and clearing and grading activities.

BIO-68 requires creation of artificial roost sites to mitigate day roost sites found during pre-construction surveys conducted per BIO-61.

BIO-84 states that the culvert and bridge designs, where practicable, shall provide roosting habitat for bats. A qualified biologist shall work with the Project engineer in identifying and incorporating structures into the design that provide suitable roosting habitat for bat species occurring in the Project area.

BIO-52 will also be implemented as a general measure to avoid and minimize impacts to general wildlife during construction, including bats. BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to pallid bat individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-82 LOSS OF HABITAT – PALLID BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures that will mitigate for the permanent loss of habitat for the pallid bat. These mitigation measures primarily relate to the establishment and management of a large open space system that will provide adequate suitable roosting and foraging habitat to support the pallid bat and allow for its persistence in the Project area.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 relate to habitat restoration and management of the River Corridor SMA, which is an important foraging habitat resource for the pallid bat. These measures provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects and will provide potential roosting and adequate foraging habitat in the Project area for the pallid bat.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA. This measure will help enhance foraging habitat quality for the pallid bat because insect diversity and abundance, as well as small vertebrates would be enhanced.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA are the same as required for the River Corridor SMA and oak tree replacement occurs as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines. These measures will help enhance foraging habitat quality for the pallid bat and also will provide potential roost sites.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures to mitigate for the loss of habitat for the pallid bat that relate to the establishment and management of a large open space system.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for pallid bat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-83 SECONDARY IMPACTS – PALLID BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Secondary impacts during construction include increased human activity, dust, noise, and lighting. Dust may also affect their insect prey base. Potential long-term effects of development include increased lighting; human activity; pet, stray, and feral cats and dogs that may prey on foraging pallid bats and disturb roost sites; and use of pesticides.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-56 to control lighting in natural areas that could affect pallid bat roosting and foraging behavior. This measure requires that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several mitigation measures to reduce short-term and long-term secondary impacts to a level that is adverse but not significant. BIO-61 and BIO-68, described above, will mitigate for short-term construction-related disturbance and human activity. BIO-61,

BIO-68, and BIO-84, described above, will also mitigate for the impacts from long-term disturbance associated with roads, bridges, lighting, and human activity.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an IPM plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to pallid bat individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

POCKETED FREE-TAILED BAT (CSC)

Life History

The pocketed free-tailed bat (*Nyctinomops femorosaccus*) is widespread and fairly common in the deserts of the southwestern United States; Baja California, Mexico; and mainland Mexico (Hall 1981). In the United States, it occurs in southern California, central Arizona, southern Mexico, and western Texas (Hall 1981). Although common throughout much of its range, it is considered rare in California (Zeiner *et al.* 1990B). In California, the CNDDB (CDFG 2007A) contains 46 records for this species, including San Diego County (27 records), Riverside County (nine records), Imperial County (five records), Los Angeles County (three records), and Orange and San Bernardino counties (one record each).

The pocketed free-tailed bat primarily occurs in desert habitats but may forage over most available habitats where it occurs (Kumirai and Jones 1990). It occurs at elevations from sea level to 2,500 meters (7,380 feet). Day roosts usually are in crevices in rocky outcrops, steep slopes, and rugged cliffs that are relatively inaccessible to humans (Kumirai and Jones 1990), but the pocketed free-tailed bat also may roost in buildings and under roof tiles (NatureServe 2007).

The pocketed free-tailed bat is probably a moth specialist (Zeiner *et al.* 1990B), but it also forages for a variety of other insects, including true bugs, beetles, ants, wasps, bees, true flies, gnats, midges, and mosquitoes.

Pocketed free-tailed bats form small colonies in day roosts up to about 100 individuals, in crevices in canyons and cliffs and sometimes in man-made structures (Kumirai and Jones 1990; Wilson and Ruff 1999). Births occur in late June and July, and young have been observed flying by August. This species is a yearlong resident of California, and there is no evidence of migration (Zeiner *et al.* 1990B).

No documented threats to pocketed free-tailed bat colonies have been reported in the scientific literature (*e.g.*, Kumirai and Jones 1990) and, because this species uses relatively inaccessible areas for day roosts (crevices in rocky outcrops, steep slopes, and rugged cliffs), most of its colonies probably are not directly threatened. However, like most bats, this species is likely very sensitive to human disturbance and, because it may also roost in man-made structures, it is vulnerable to vandalism, extermination, or inadvertent disturbance of roost sites. Other plausible threats to pocketed free-tailed bats resulting from construction activities include disturbances of day roosts from human activity, noise, and dust, as well as effects of dust on insect prey. Potential long-term impacts from urban development also include human and pet, stray, and feral animals' disturbances of roost sites; roost site and foraging habitat degradation, such as trampling and invasive species; and pesticides that may cause secondary poisoning and affect prey abundance.

Survey Results

Two focused bat surveys have been conducted in the Project area. Impact Sciences (2005) conducted acoustic surveys using the Anabat II Bat Detector in 2004 and conducted surveys using both the Anabat detector and mist netting in 2006 (Johnson 2006).

Figure 4.5-131 shows the 25 survey locations from 2004 and the six survey locations from 2006 (Impact Sciences 2005; Johnson 2006). The 2004 surveys were scattered through the Project area as well as in two locations on the Legacy Village site. The 2006 surveys were more concentrated, with three locations in Potrero Canyon, two locations along the Santa Clara River, and one location in upper Long Canyon.

The pocketed free-tailed bat was acoustically detected in 2006 in lower Potrero Creek (Johnson 2006). This species was not detected in Anabat surveys in 2004 (Impact Sciences 2005). The Project area is at the extreme northwestern part of pocketed free-tailed bat range in California and does not contain the desert habitats typically used by this species. Though present on site, the species is likely rare. Where it occurs, it probably uses all available habitats supporting prey. Foraging habitat for the pocketed free-tailed bat includes alluvial scrub, arrow weed scrub, bulrush–cattail wetland, cismontane alkali marsh, southern cottonwood–willow riparian, Mexican elderberry, giant reed, coastal and valley freshwater marsh, herbaceous wetland, mulefat scrub, southern coast live oak riparian forest, southern willow scrub, shrub tamarisk, river wash, big sagebrush scrub, California sagebrush scrub, coyote brush scrub, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, California annual grassland, *Eriodictyon* scrub, purple needlegrass, coast live oak woodland, valley oak woodland, valley oak/grass, mixed oak woodland, and California walnut woodland. A total of 11,466 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 207 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.8% of these communities on site. **Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats shows impacts to all vegetation communities because the pocketed free-tailed bat is a foraging habitat generalist and thus potentially forages throughout the Project area. A total of 118 acres would be temporarily impacted.

The pocket free-tailed bat forages in a broad variety of habitats that comprise more than 11,000 acres in the Project area. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 207 acres of foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,161 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 27.6% of suitable habitat on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats).

A relatively large amount and percentage of on-site roosting and foraging habitats for the pocketed free-tailed bat would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from 27.6% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,367 acres (29.4%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of the pocketed free-tailed bat on site, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Pocketed free-tailed bats are highly mobile, and it is unlikely that the proposed Project would result in direct mortality of adults occupying this habitat during construction and/or grading activities. However, if adults are flushed from a day roost site during construction activities, these individuals could become disoriented and unable to safely relocate to another roost site, resulting in an increased risk of injury or mortality. In addition, if construction activities directly impacted a colonial maternity site, young could be harassed, injured, or killed. Furthermore, even if young escaped direct impacts, the loss of a maternity site resulting from implementation of the RMDP before young are independent of the mother likely would result in injury or mortality of the young due to their likely inability to safely relocate to another roost site. Implementation of the SCP would not directly impact this species. If a day roost site were established prior to construction activities in the Project footprint, direct impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. If a day roost site were established prior to construction activities in the Project footprint, impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, indirect permanent impacts (Impacts Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect pocketed free-tailed bats in areas adjacent to construction zones. There is no evidence of existing pocketed free-tailed bat day roost sites, including maternity sites, in the Project area, based on focused bat surveys in 2004 and 2006 (Impact Sciences 2005; Johnson 2006). However, if a day roost site were established prior to construction activities in proximity to the construction zones, both short-term secondary impacts associated with construction activities and long-term secondary impacts to a roost site could occur. As noted above, increased human activity, noise, and dust associated with construction activities could cause pocketed free-tailed bats to abandon day roosts, exposing both adults and young to injury and mortality due to their likely inability to safely relocate to another day roost. Although bats are highly mobile and could alter their foraging behavior to avoid construction areas, construction-generated dust may adversely affect foraging habitat by reducing their insect prey. Lighting in construction areas may also alter foraging behavior due to changing the distribution of insect prey attracted to lights and potentially causing increased competition among bats.

Long-term impacts of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would also increase potential secondary impacts through increased human activity, noise, and lighting for the same reason described above for construction impacts, but over the long term. Use of pesticides for agriculture or in landscaped areas may result in secondary poisoning and reduction of prey. Pet, stray, and feral cats and dogs may disturb roost sites.

Both short-term and long-term secondary impacts to a roost site and impacts to foraging bats would result in a substantial adverse effect on a special-status species (significance criterion 1) and would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the pocketed free-tailed bat (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 185 acres (1.6%) of permanent loss and 132 acres of temporary loss;

- Alternative 4 – 180 acres (1.6%) of permanent loss and 115 acres of temporary loss;
- Alternative 5 – 212 acres (1.8%) of permanent loss and 141 acres of temporary loss;
- Alternative 6 – 211 acres (1.8%) of permanent loss and 136 acres of temporary loss; and
- Alternative 7 – 82 acres (0.7%) of permanent loss and 190 acres of temporary loss.

Compared to Alternative 2, which would result in 207 acres (1.8%) of permanent loss and 118 acres of temporary impacts, the combined direct permanent and temporary loss of foraging habitat under Alternative 3 would not be substantially different than Alternative 2, Alternative 4 would be marginally less and Alternative 6 marginally greater, Alternative 5 would be somewhat greater, and Alternative 7 would be somewhat less. The difference between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternative 3 through 7 would be similar in magnitude compared to Alternative 2, these impacts for Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to suitable habitat for the pocketed free-tailed bat (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 2,949 acres (25.7%) of permanent loss;
- Alternative 4 – 2,825 acres (24.6%) of permanent loss;
- Alternative 5 – 2,742 acres (23.9%) of permanent loss;
- Alternative 6 – 2,423 acres (21.1%) of permanent loss; and
- Alternative 7 – 2,128 acres (18.6%) of permanent loss.

Compared to Alternative 2, which would result in 3,161 acres (27.6%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be

constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that reduce impacts to pocketed free-tailed bat suitable habitat compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the pocketed free-tailed bat occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the pocketed free-tailed bat:

- Alternative 3 – 3,134 acres (27.3%) of permanent loss;
- Alternative 4 – 3,005 acres (26.2%) of permanent loss;
- Alternative 5 – 2,953 acres (25.8%) of permanent loss;
- Alternative 6 – 2,633 acres (23.0%) of permanent loss; and
- Alternative 7 – 2,210 acres (19.3%) of permanent loss.

Compared to Alternative 2, which would result in 3,367 acres (29.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the pocketed free-tailed bat occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual pocketed free-tailed bats as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to the potential for loss under Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. The impacts to individual pocketed free-tailed bats occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as increased human activity; dust; noise (from construction and traffic on roads and bridges); pet, stray, and feral cats and dogs; pesticides; and lighting. The loss or degradation of suitable habitat and the impacts to individual pocketed free-tailed bats due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to pocketed free-tailed bat: (1) impacts to individuals; (2) loss of roosting and foraging habitat; and (3) secondary impacts to individuals, roosting sites, and foraging habitat outside the Project footprint.

Impacts to individuals could occur if day roosting sites are disturbed during construction as a result of increased human activity, noise, dust, and lighting. As noted above, bats are very sensitive to disturbances and may permanently abandon roost sites with a single disturbance event. If individuals, including adults and young, are flushed from a day roost during construction they would likely become disoriented and unable to safely relocate to another roost, resulting in increased risk of injury or mortality. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active bat roost sites and postpone work within 300 feet of any active maternity roost until young have fledged, and will create alternative roost sites to mitigate for any roost sites disturbed during construction, including creation of roosts under bridges and in culverts, where practicable, in consultation with CDFG.

The combined permanent loss of foraging habitat resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,210 acres (19.3%) under Alternative 7 to 3,367 acres (29.4%) under Alternative 2. This would be a substantial loss of suitable foraging habitat and will alter the foraging behavior of the pocketed free-tailed bat in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable foraging habitat to support the pocketed free-tailed bat in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 6,250 acres of suitable foraging habitat, as well as potential roosting sites, for the pocketed free-tailed bat. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, bats are very sensitive to disturbances and thus roost sites outside of the construction zone could be adversely affected during construction due to increased human activity, dust, noise, and lighting. Dust may also affect their insect prey base. Impacts to active maternity sites in or within 300 feet of construction zones will be avoided until young have fledged, as noted above. Construction-generated dust will be controlled using standard measures such as chemical suppression and screening fencing where determined to be necessary. Potential long-term effects of development include lighting increased human activity and pet, stray, and feral cats and dogs, which may cause roost abandonment, and use of pesticides, which may cause secondary poisoning or affect the prey base. The large open space system will provide adequate areas for roosting and foraging that will in part offset these impacts. Several specific mitigation measures will also be implemented to control human activities in open space areas where bats may roost, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting along the edge of natural habitat areas will be downcast. Pesticides will be controlled through an integrated pest management (IPM) plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

The specific mitigation measures for the pocketed free-tailed bat are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-84 IMPACTS TO INDIVIDUALS – POCKETED FREE-TAILED BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid, minimize, or mitigate the impacts to pocketed free-tailed bat individuals.

Measures Recommended by EIS/EIR

This EIS/EIR recommends three mitigation measures to reduce impacts to pocketed free-tailed bat individuals. These mitigation measures primarily are designed to avoid impacts to active day roosts.

BIO-61 requires a pre-construction survey to determine if active roosts of special-status bats are present within 300 feet of the Project disturbance boundaries. If an active maternity roost is found, all work within 300 feet shall be postponed until the roost is vacated and juveniles have fledged. If a maternity roost is impacted, substitute roosting habitat shall be provided. Non-breeding bat hibernacula shall be vacated the evening between initial disturbance and clearing and grading activities.

BIO-68 requires creation of artificial roost sites to mitigate day roost sites found during pre-construction surveys conducted per BIO-61.

BIO-84 states that the culvert and bridge designs, where practicable, shall provide roosting habitat for bats. A qualified biologist shall work with the Project engineer in identifying and incorporating structures into the design that provide suitable roosting habitat for bat species occurring in the Project area.

BIO-52 will also be implemented as a general measure to avoid and minimize impacts to general wildlife during construction, including bats. BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

Finding of Significance for Impacts Individuals After Mitigation

After mitigation, impacts pocketed free-tailed bat individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-85 LOSS OF HABITAT – POCKETED FREE-TAILED BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures that will mitigate for the permanent loss of habitat for the pocketed free-tailed bat. These mitigation measures primarily relate to the establishment and management of a large open space system that will provide adequate suitable roosting and foraging habitat to support the pocketed free-tailed bat and allow for its persistence in the Project area.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 relate to habitat restoration and management of the River Corridor SMA, which is an important foraging habitat resource for the pocketed free-tailed bat. These measures provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects and will provide potential roosting and adequate foraging habitat in the Project area for the pocketed free-tailed bat.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA. This measure will help enhance foraging habitat quality for the pocketed free-tailed bat because insect diversity and abundance would be enhanced.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA are the same as required for the River Corridor SMA and oak tree replacement occurs as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines. This measure will help enhance foraging habitat quality for the pocketed free-tailed bat and also will provide potential roost sites.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures to mitigate for the loss of habitat for the pocketed free-tailed bat that relate to the establishment and management of a large open space system.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for pocketed free-tailed bat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-86 SECONDARY IMPACTS – POCKETED FREE-TAILED BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Secondary impacts during construction include increased human activity, dust, noise, and lighting. Dust may also affect the insect prey base of pocketed free-tailed bat. Potential long-term effects of development include increased human activity; pet, stray, and feral cats and dogs that may disturb roost sites; and use of pesticides.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-56 to control lighting in natural areas that could affect pocketed free-tailed bat roosting and foraging behavior. This measure requires that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several mitigation measures to reduce short-term and long-term secondary impacts to roost sites to a level that is adverse but not significant. BIO-61 and BIO-68, described above, will mitigate for short-term construction-related disturbance and human activity. BIO-61, BIO-68, and BIO-84, described above, will also mitigate for the impacts from long-term disturbance associated with roads, bridges, lighting, and human activity.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an IPM plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to pocketed free-tailed bat individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

TOWNSEND'S BIG-EARED BAT (CSC)

Life History

The Townsend's big-eared bat (*Corynorhinus townsendii*) (big-eared bat) ranges throughout the western United States, British Columbia, Canada, and Mexico (Kunz and Martin 1982). In the United States, it occurs in a continuous distribution in all the western states and east into western South Dakota, northwestern Nebraska, southwestern Kansas, western Oklahoma, and western Texas (Kunz and Martin 1982). It also is known from isolated gypsum caves in northeast Texas, Oklahoma, and Kansas and from limestone areas in Arkansas, Missouri, Oklahoma, Kentucky, Virginia, and West Virginia (Kunz and Martin 1982). These relict populations are thought to reflect post-pleistocene climates (Kunz and Martin 1982). In California, the CNDDB (CDFG 2007A) contains 212 records for this species, of which 52 are from four counties in southern California: San Bernardino (33 records), San Diego (10 records), Riverside (five records) and Imperial (four records). There are no records for Los Angeles, Orange, or Ventura counties.

The big-eared bat is primarily associated with mesic habitats characterized by coniferous and deciduous forests, although it also occurs in xeric areas (Kunz and Martin 1982). In California, this species was historically associated with limestone caves and lava tubes located in coastal lowlands, agricultural valleys, and hillsides with mixed vegetation; it occurs in all parts of California, with the exception of alpine and subalpine areas of the Sierra Nevada (Zeiner *et al*. 1990B). The species also occurs in man-made structures and tunnels (Kunz and Martin 1982), and it has been suggested that the big-eared bat has become more common in the western United States due to the availability of man-made structures (Kunz and Martin 1982).

Big-eared bats are relatively sedentary and are not known to disperse or migrate large distances. The longest recorded movement of a big-eared bat in California is 20 miles (Kunz and Martin 1982). Females show high maternity roost fidelity (Kunz and Martin 1982). Maternity roosts are established in the warm parts of caves, mines, and buildings, with one or more clusters of females numbering up to about 100 individuals. Summer roosts of males are solitary. Young are born from late spring to early summer and are fully weaned by 42 days of age. First flight occurs by about 18 to 21 days.

Big-eared bats take a variety of prey on the wing from the edge of forested habitats but also glean prey from vegetation to forage, including small moths, beetles, flies, lacewings, wasps, bees, and ants.

Big-eared bats are very sensitive to human disturbances, and a single disturbance of a maternity roost or hibernation site may cause abandonment (Zeiner *et al*. 1990B). All known limestone cave sites in California, for example, have been abandoned (Zeiner *et al*. 1990B). Other plausible threats to big-eared bats resulting from construction activities include disturbances of day roosts from human activity, noise, and dust, as well as effects of dust on insect prey. Potential long-

term impacts from urban development also include human and pet, stray, and feral animals' disturbances of roost sites, roost site and foraging habitat degradation, such as trampling and invasive species, and pesticides that may cause secondary poisoning and affect prey abundance.

Survey Results

Two focused bat surveys have been conducted in the Project area. Impact Sciences (2005) conducted acoustic surveys using the Anabat II Bat Detector in 2004 and conducted surveys using both the Anabat detector and mist netting in 2006 (Johnson 2006).

Figure 4.5-131 shows the 25 survey locations from 2004 and the six survey locations from 2006 (Impact Sciences 2005; Johnson 2006). The 2004 surveys were scattered through the Project area, as well as in two locations on the Legacy Village site. The 2006 surveys were more concentrated, with three locations in Potrero Canyon, two locations along the Santa Clara River, and one location in upper Long Canyon.

The big-eared bat was not detected during the year 2004 and 2006 surveys (Impact Sciences 2005; Johnson 2006). This species is more effectively sampled by capture methods than by acoustic methods because they have a relatively low-intensity call and can only be detected at distances of less than five meters (16 feet) from the Anabat detector (O'Farrell and Gannon 1999). Therefore, the failure to detect this species on site should not be considered absence from the Project area. Because the big-eared bat occurs throughout California, except at the highest elevations, and because the Project area supports substantial suitable habitat for the species, for the purpose of the impact analysis, the big-eared bat is considered to have moderate potential to occur on site.

The big-eared bat is known to use a variety of habitats throughout its range; therefore, it is assumed to potentially use most of the natural vegetation communities on site, including alluvial scrub, arrow weed scrub, bulrush–cattail wetland, cismontane alkali marsh, southern cottonwood–willow riparian, Mexican elderberry, giant reed, coastal and valley freshwater marsh, herbaceous wetland, mulefat scrub, southern coast live oak riparian forest, southern willow scrub, shrub tamarisk, river wash, big sagebrush scrub, California sagebrush scrub, coyote brush scrub, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, California annual grassland, *Eriodictyon* scrub, purple needlegrass, coast live oak woodland, valley oak woodland, valley oak/grass, and California walnut woodland. A total of 11,466 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 207 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.8% of these communities on site. **Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats, shows impacts to all vegetation communities because the big-eared bat is a foraging habitat generalist and thus potentially forages throughout the Project area. A total of 118 acres would be temporarily impacted.

The Townsend's big-eared bat forages in a broad variety of habitats that comprise more than 11,000 acres in the Project area. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 207 acres of foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,161 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 27.6% of suitable habitat on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats).

A relatively large amount and percentage of on-site roosting and foraging habitat for the big-eared bat would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from 27.6% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,367 acres (29.4%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of the big-eared bat on site, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Big-eared bats are highly mobile, and it is unlikely that the proposed Project would result in direct mortality of adults occupying this habitat during construction and/or grading activities. However, if adults are flushed from a day roost site during construction activities, these individuals could become disoriented and unable to safely relocate to another roost site, resulting in an increased risk of injury or mortality. In addition, if construction activities directly impacted a colonial maternity site, young could be injured or killed. Furthermore, even if young escaped direct impacts, the loss of a maternity site resulting from implementation of the RMDP before young are independent of the mother likely would result in mortality of the young due to their likely inability to safely relocate to another roost site. Implementation of the SCP would not directly impact this species. If a day roost site were established prior to construction activities in the Project footprint, direct impacts to the roost site would result in a substantial adverse effect on a special-

status species (significance criterion 1). If this occurred, direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. If a day roost site were established prior to construction activities in the Project footprint, impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect big-eared bats in areas adjacent to construction zones. There is no evidence of existing big-eared bat day roost sites, including maternity sites, in the Project area, based on focused bat surveys in 2004 and 2006 (Impact Sciences 2005; Johnson 2006). However, if a day roost site were established prior to construction activities in proximity to the construction zones, both short-term secondary impacts associated with construction activities and long-term secondary impacts to a roost could occur. As noted above, increased human activity, noise, and dust associated with construction activities could cause big-eared bats to abandon day roosts, exposing both adults and young to injury and mortality due to their likely inability to safely relocate another day roost. Although bats are highly mobile and could alter their foraging behavior to avoid construction areas, construction-generated dust may adversely affect foraging habitat by reducing their insect prey. Lighting in construction areas may also alter foraging behavior due to changing the distribution of insect prey attracted to lights and potentially causing increased competition among bats.

Long-term impacts of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would also increase potential secondary impacts through increased human activity, noise, and lighting for the same reason described above for construction impacts, but over the long term. Use of pesticides for agriculture or in landscaped areas may result in secondary poisoning and reduction of prey. Pet, stray, and feral cats and dogs may disturb roost sites.

Both short-term and long-term secondary impacts to a roost site and impacts to foraging bats would result in a substantial adverse effect on a special-status species (significance criterion 1) and would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to suitable habitat for the big-eared bat (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 185 acres (1.6%) of permanent loss and 132 acres of temporary loss;
- Alternative 4 – 180 acres (1.6%) of permanent loss and 115 acres of temporary loss;
- Alternative 5 – 212 acres (1.8%) of permanent loss and 141 acres of temporary loss;
- Alternative 6 – 211 acres (1.8%) of permanent loss and 136 acres of temporary loss; and
- Alternative 7 – 82 acres (0.7%) of permanent loss and 190 acres of temporary loss.

Compared to Alternative 2, which would result in 207 acres (1.8%) of permanent loss and 118 acres of temporary impacts, the combined direct permanent and temporary loss of foraging habitat under Alternative 3 would not be substantially different, Alternative 4 would be marginally less overall, and Alternatives 5 and 6 would be marginally more overall. The difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts under this alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, impacts for Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to suitable habitat for the big-eared bat (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 2,949 acres (25.7%) of permanent loss;
- Alternative 4 – 2,825 acres (24.6%) of permanent loss;
- Alternative 5 – 2,742 acres (23.9%) of permanent loss;
- Alternative 6 – 2,423 acres (21.1%) of permanent loss; and
- Alternative 7 – 2,128 acres (18.6%) of permanent loss.

Compared to Alternative 2, which would result in 3,161 acres (27.6%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and other changes in the Project footprint under Alternative 7 that reduce impacts to big-eared bat suitable habitat compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the big-eared bat occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the big-eared bat:

- Alternative 3 – 3,134 acres (27.3%) of permanent loss;
- Alternative 4 – 3,005 acres (26.2%) of permanent loss;
- Alternative 5 – 2,953 acres (25.8%) of permanent loss;
- Alternative 6 – 2,633 acres (23.0%) of permanent loss; and
- Alternative 7 – 2,210 acres (19.3%) of permanent loss.

Compared to Alternative 2, which would result in 3,367 acres (29.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed

under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the big-eared bat occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual big-eared bats as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. The impacts to individual big-eared bats occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as increased human activity; dust; noise (from construction and traffic on roads and bridges); pet, stray, and feral cats and dogs; pesticides; and lighting. The loss or degradation of suitable habitat and impacts to individual big-eared bats due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to big-eared bat: (1) impacts to individuals; (2) loss of roosting and foraging habitat; and (3) secondary impacts to individuals and roosting sites and foraging habitat outside the Project footprint.

Impacts to individuals could occur if day roosting sites are disturbed during construction as a result of increased human activity, noise, dust, and lighting. As noted above, bats are very sensitive to disturbances and may permanently abandon roost sites with a single disturbance

event. If individuals, including adults and young, are flushed from a day roost during construction, they would likely become disoriented and unable to safely relocate to another roost, resulting in increased risk of injury or mortality. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active bat roost sites and postpone work within 300 feet of any active maternity roost until young have fledged and will create alternative roost sites to mitigate for any roost sites disturbed during construction, including creation of roosts under bridges and in culverts, where practicable, in consultation with CDFG.

The combined permanent loss of foraging habitat resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,210 acres (19.3%) under Alternative 7 to 3,367 acres (29.4%) under Alternative 2. This would be a substantial loss of suitable foraging habitat and will alter the foraging behavior of the big-eared bat in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable foraging habitat to support the big-eared bat in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 6,250 acres of suitable foraging habitat, as well as potential roosting sites, for the big-eared bat. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, bats are very sensitive to disturbances and thus roost sites outside of the construction zone could be adversely affected during construction due to increased human activity, dust, noise, and lighting. Dust may also affect their insect prey base. Impacts to active maternity sites in or within 300 feet of construction zones will be avoided until young have fledged, as noted above. Construction-generated dust will be controlled using standard measures such as chemical suppression and screening fencing where determined to be necessary. Potential long-term effects of development include lighting; increased human activity; pet, stray, and feral cats and dogs, which may cause roost abandonment; and use of pesticides, which may cause secondary poisoning or affect the prey base. The large open space system will provide adequate areas for roosting and foraging that will in part offset these impacts. Several specific mitigation measures will also be implemented to control human activities in open space areas where bats may roost, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting along the edge of natural habitat areas will be downcast. Pesticides will be controlled through an integrated pest management (IPM) plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

The specific mitigation measures for the Townsend's big-eared bat are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-87 IMPACTS TO INDIVIDUALS – TOWNSEND'S BIG-EARED BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid, minimize, or mitigate impacts to big-eared bat individuals.

Measures Recommended by EIS/EIR

This EIS/EIR recommends three mitigation measures to reduce impacts to big-eared bat individuals. These mitigation measures primarily are designed to avoid impacts to active day roosts.

BIO-61 requires a pre-construction survey to determine if active roosts of special-status bats are present within 300 feet of the Project disturbance boundaries. If an active maternity roost is found, all work within 300 feet shall be postponed until the roost is vacated and juveniles have fledged. If a maternity roost is impacted, substitute roosting habitat shall be provided. Non-breeding bat hibernacula shall be vacated the evening between initial disturbance and clearing and grading activities.

BIO-68 requires creation of artificial roost sites to mitigate day roost sites found during pre-construction surveys conducted per BIO-61.

BIO-84 states that the culvert and bridge designs, where practicable, shall provide roosting habitat for bats. A qualified biologist shall work with the Project engineer in identifying and incorporating structures into the design that provide suitable roosting habitat for bat species occurring in the Project area.

BIO-52 will also be implemented as a general measure to avoid and minimize impacts to general wildlife during construction, including bats. BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to big-eared bat individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-88 LOSS OF HABITAT – TOWNSEND'S BIG-EARED BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures that will mitigate for the permanent loss of habitat for the big-eared bat. These mitigation measures primarily relate to the establishment and management of a large open space system that will provide adequate suitable roosting and foraging habitat to support the big-eared bat and allow for its persistence in the Project area.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 relate to habitat restoration and management of the River Corridor SMA, which is an important foraging habitat resource for the big-eared bat. These measures provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects and will provide potential roosting and adequate foraging habitat in the Project area for the big-eared bat because insect diversity and abundance would be enhanced.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA. This measure will help enhance foraging habitat quality for the big-eared bat because insect diversity and abundance would be enhanced.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA are the same as required for the River Corridor SMA and oak tree replacement occurs as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic

stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines. This measure will help enhance foraging habitat quality for the big-eared bat and also will provide potential roost sites.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures to mitigate for the loss of habitat for the big-eared bat that relate to the establishment and management of a large open space system.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Suitable Habitat After Mitigation

After mitigation, the loss of habitat for big-eared bat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-89 SECONDARY IMPACTS – TOWNSEND'S BIG-EARED BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Secondary impacts during construction include increased human activity, dust, noise, and lighting. Dust may also affect the insect prey base of big-eared bat. Potential long-term effects of development include lighting; increased human activity; pet, stray, and feral cats and dogs that may disturb roost sites; and use of pesticides.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-56 to control lighting in natural areas that could affect big-eared bat roosting and foraging behavior. This measure requires that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several mitigation measures to reduce short-term and long-term secondary impacts to roost sites to a level that is adverse but not significant. BIO-61 and BIO-68, described above, will mitigate for short-term construction-related disturbance and human activity. BIO-61, BIO-68, and BIO-84, described above, will also mitigate for the impacts from long-term disturbance associated with roads, bridges, lighting, and human activity.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to big-eared bat individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

WESTERN MASTIFF BAT (CSC)

Life History

The western mastiff bat (*Eumops perotis californicus*) is widespread in the southwestern United States; the northern portion of Baja California, Mexico; and south into central mainland Mexico (Hall 1981). In the United States, it occurs in northern, central, and southern California; the southern portion of Nevada; the southwestern half of Arizona; and the extreme southwestern portions of New Mexico and Texas (Hall 1981). In California, its yearlong range includes the San Joaquin Valley, the coastal region from the San Francisco Bay area south to San Diego, and the Transverse and Peninsular mountain ranges and Mojave and Colorado deserts of southern California (Zeiner *et al.* 1990B). It is absent in California from the agricultural regions of the Central Valley, northwestern California, and the Great Basin Desert of northeastern California (Zeiner *et al.* 1990B). In California, the CNDDB (CDFG 2007A) contains 251 records for this species. Records are scattered around the state, but many of the records are from counties in southern California, including Los Angeles (28 records), San Diego (27 records), Orange and Riverside (18 records each), San Bernardino and Imperial (10 records each), and Ventura (four records).

The western mastiff bat occurs in a wide variety of chaparral, coastal scrub, coniferous and deciduous forest and woodland, and desert scrub habitats (Best *et al.* 1996; Zeiner *et al.* 1990B). Day roosts are established in crevices in rocky canyons and cliffs where the canyon or cliff is vertical or nearly vertical (Best *et al.* 1996) as well as in trees and tunnels (Zeiner *et al.* 1990B). This species has also adapted to roosting in buildings and has been observed hanging from various other kinds of man-made structures, including awnings, ledges over doors and windows, large cracks in masonry, and rafters (Best *et al.* 1996). Although western mastiff bats are yearlong residents in California and are known to shift day roosts throughout the year, whether they are seasonally migratory is unknown.

This species exhibits yearlong nocturnal activity and emerges from the day roost within about 40 to 50 minutes after sundown (Zeiner *et al.* 1990B). It forages for a variety of small to large low- and weak-flying insects that it catches in flight from near ground level to the tops of trees, including dragonflies, damselflies, grasshoppers, crickets, mantids, walking sticks, true bugs, beetles, moths, ants, wasps, and bees.

Western mastiff bats form small colonies in day roosts up to about 100 individuals in crevices in canyons and cliffs and man-made structures. Maternity colonies include both males and females.

Young are born from June to possibly September. The maturation period of the young is unknown, and it is unknown when young are first able to fly.

No specific threats to western mastiff bat colonies have been reported in the scientific literature (*e.g.*, Best *et al.* 1996) but, because it has adapted to roosting in man-made structures, it is vulnerable to vandalism, extermination, or inadvertent disturbance of roost sites in buildings. Human collection of this species likely is not a risk because western mastiff bat attempts to bite when handled (Best *et al.* 1996). Other plausible threats to western mastiff bats resulting from construction activities include disturbances of day roosts from human activity, noise, and dust, as well as effects of dust on insect prey. Potential long-term impacts from urban development also include human and pet, stray, and feral animals' disturbances of roost sites, roost site and foraging habitat degradation, such as trampling and invasive species, and pesticides that may cause secondary poisoning and affect prey abundance.

Survey Results

Two focused bat surveys have been conducted in the Project area. Impact Sciences (2005) conducted acoustic surveys using the Anabat II Bat Detector in 2004 and conducted surveys using both the Anabat detector and mist netting in 2006 (Johnson 2006).

Figure 4.5-131 shows the 25 survey locations from 2004 and the six survey locations from 2006 (Impact Sciences 2005; Johnson 2006). The 2004 surveys were scattered throughout the Project area as well as in two locations on the Legacy Village site. The 2006 surveys were more concentrated, with three locations in Potrero Canyon, two locations along the Santa Clara River, and one location in upper Long Canyon.

The western mastiff bat was audibly detected (mastiff bat signals are detectable by humans) in 2006 along the Santa Clara River at Walcott Road (Johnson 2006). The species is known to use a variety of habitats throughout its range; therefore, it is assumed to potentially use most of the natural vegetation communities on site, including alluvial scrub, arrow weed scrub, bulrush–cattail wetland, cismontane alkali marsh, southern cottonwood–willow riparian, Mexican elderberry, giant reed, coastal and valley freshwater marsh, herbaceous wetland, mulefat scrub, southern coast live oak riparian forest, southern willow scrub, shrub tamarisk, river wash, big sagebrush scrub, California sagebrush scrub, coyote brush scrub, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, California annual grassland, *Eriodictyon* scrub, purple needlegrass, coast live oak woodland, valley oak woodland, valley oak/grass, and California walnut woodland. A total of 11,466 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of

Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 207 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.8% of these communities on site. **Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats, shows impacts to all vegetation communities because the western mastiff bat is a foraging habitat generalist and thus potentially forages throughout the Project area. A total of 118 acres would be temporarily impacted.

The western mastiff bat forages in a broad variety of habitats that comprise more than 11,000 acres in the Project area. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 207 acres of foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,161 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 27.6% of suitable habitat on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats).

A relatively large amount and percentage of on-site roosting and foraging habitats for the western mastiff bat would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial

adverse effect on the distribution of this species on site by eliminating it from 27.6% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,367 acres (29.4%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of the western mastiff bat on site, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Western mastiff bats are highly mobile, and it is unlikely that the proposed Project would result in direct mortality of adults occupying this habitat during construction and/or grading activities. However, if adults are flushed from a day roost site during construction activities, these individuals could become disoriented and unable to safely relocate to another roost site, resulting in an increased risk of injury or mortality. In addition, if construction activities directly impacted a colonial maternity site, young could be harassed, injured, or killed. Furthermore, even if young escaped direct harm, the loss of a maternity site resulting from implementation of the RMDP before young are independent of the mother likely would result in injury or mortality of the young due to their likely inability to safely relocate to another roost site. Implementation of the SCP would not directly impact this species. If a day roost site were established prior to construction activities in the Project footprint, direct impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. If a day roost site were established prior to construction activities in the Project footprint, impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1).

If this occurred, indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect western mastiff bats in areas adjacent to construction zones. There is no evidence of existing western mastiff bat day roost sites, including maternity sites, in the Project area, based on focused bat surveys in 2004 and 2006 (Impact Sciences 2005; Johnson 2006). However, if a day roost site were established prior to construction activities in proximity to the construction zones, both short-term secondary impacts associated with construction activities and long-term secondary impacts to a roost site could occur. As noted above, increased human activity, noise, and dust associated with construction activities could cause western mastiff bats to abandon day roosts, exposing both adults and young to injury and mortality due to their likely inability to safely relocate another day roost. Although bats are highly mobile and could alter their foraging behavior to avoid construction areas, construction-generated dust may adversely affect foraging habitat by reducing their insect prey. Lighting in construction areas may also alter foraging behavior due to changing the distribution of insect prey attracted to lights and potentially causing increased competition among bats.

Long-term impacts of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would also increase potential secondary impacts through increased human activity, noise, and lighting for the same reason described above for construction impacts, but over the long term. Use of pesticides for agriculture or in landscaped areas may result in secondary poisoning and reduction of prey. Pet, stray, and feral cats and dogs may disturb roost sites.

Both short-term and long-term secondary impacts to a roost site and impacts to foraging bats would result in a substantial adverse effect on a special-status species (significance criterion 1) and would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to suitable habitat for the western mastiff bat (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 185 acres (1.6%) of permanent loss and 132 acres of temporary loss;

- Alternative 4 – 180 acres (1.6%) of permanent loss and 115 acres of temporary loss;
- Alternative 5 – 212 acres (1.8%) of permanent loss and 141 acres of temporary loss;
- Alternative 6 – 211 acres (1.8%) of permanent loss and 136 acres of temporary loss; and
- Alternative 7 – 82 acres (0.7%) of permanent loss and 190 acres of temporary loss.

Compared to Alternative 2, which would result in 207 acres (1.8%) of permanent loss and 118 acres of temporary impacts, the combined direct permanent and temporary loss of foraging habitat under Alternative 3 would not be substantially different, Alternative 4 would be marginally less overall, and Alternatives 5 and 6 would be marginally to somewhat more overall. The difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, impacts for Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to suitable habitat for the western mastiff bat (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 2,949 acres (25.7%) of permanent loss;
- Alternative 4 – 2,825 acres (24.6%) of permanent loss;
- Alternative 5 – 2,742 acres (23.9%) of permanent loss;
- Alternative 6 – 2,423 acres (21.1%) of permanent loss; and
- Alternative 7 – 2,128 acres (18.6%) of permanent loss.

Compared to Alternative 2, which would result in 3,161 acres (27.6%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the

development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and other changes in the Project footprint under Alternative 7 that reduce impacts to western mastiff bat suitable habitat compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the western mastiff bat occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the western mastiff bat:

- Alternative 3 – 3,134 acres (27.3%) of permanent loss;
- Alternative 4 – 3,005 acres (26.2%) of permanent loss;
- Alternative 5 – 2,953 acres (25.8%) of permanent loss;
- Alternative 6 – 2,633 acres (23.0%) of permanent loss; and
- Alternative 7 – 2,210 acres (19.3%) of permanent loss.

Compared to Alternative 2, which would result in 3,367 acres (29.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the western mastiff bat occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual western mastiff bats as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual western mastiff bats occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as increased human activity, noise, roads, bridges, and lighting. The loss or degradation of suitable habitat and impacts to individual western mastiff bats due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to western mastiff bat: (1) impacts to individuals; (2) loss of roosting and foraging habitat; and (3) secondary impacts to individuals and roosting sites and foraging habitat outside the Project footprint.

Impacts to individuals could occur if day roosting sites are disturbed during construction as a result of increased human activity, noise, dust, and lighting. As noted above, bats are very sensitive to disturbances and may permanently abandon roost sites with a single disturbance event. If individuals, including adults and young, are flushed from a day roost during construction, they would likely become disoriented and unable to safely relocate to another roost, resulting in increased risk of injury or mortality. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active bat roost sites and postpone work within 300 feet of any active maternity roost until young have fledged and create alternative roost sites to mitigate for any roost sites disturbed during construction, including creation of roosts under bridges and in culverts, where practicable, in consultation with CDFG.

The combined permanent loss of foraging habitat resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas

would range from 2,210 acres (19.3%) under Alternative 7 to 3,367 acres (29.4%) under Alternative 2. This would be a substantial loss of suitable foraging habitat and will alter the foraging behavior of the western mastiff bat in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable foraging habitat to support the western mastiff bat in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 6,250 acres of suitable foraging habitat, as well as potential roosting sites, for the western mastiff bat. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, bats are very sensitive to disturbances and thus roost sites outside of the construction zone could be adversely affected during construction due to increased human activity, dust, noise, and lighting. Dust may also affect their insect prey base. Impacts to active maternity sites in or within 300 feet of construction zones will be avoided until young have fledged, as noted above. Construction-generated dust will be controlled using standard measures, such as chemical suppression and screening fencing, where determined to be necessary. Potential long-term effects of development include lighting; increased human activity; pet, stray, and feral cats and dogs, which may cause roost abandonment; and use of pesticides, which may cause secondary poisoning or affect the prey base. The large open space system will provide adequate areas for roosting and foraging that will in part offset these impacts. Several specific mitigation measures will also be implemented to control human activities in open space areas where bats may roost, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting along the edge of natural habitat areas will be downcast. Pesticides will be controlled through an integrated pest management (IPM) plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

The specific mitigation measures for the western mastiff bat are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-90 IMPACTS TO INDIVIDUALS – WESTERN MASTIFF BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid, minimize, or mitigate impacts to western mastiff bat individuals.

Measures Recommended by EIS/EIR

This EIS/EIR recommends three mitigation measures to reduce impacts to western mastiff bat individuals. These mitigation measures primarily are designed to avoid impacts to active day roosts.

BIO-61 requires a pre-construction survey to determine if active roosts of special-status bats are present within 300 feet of the Project disturbance boundaries. If an active maternity roost is found, all work within 300 feet shall be postponed until the roost is vacated and juveniles have fledged. If a maternity roost is impacted, substitute roosting habitat shall be provided. Non-breeding bat hibernacula shall be vacated the evening between initial disturbance and clearing and grading activities.

BIO-68 requires creation of artificial roost sites to mitigate day roost sites found during pre-construction surveys conducted per BIO-61.

BIO-84 states that the culvert and bridge designs, where practicable, shall provide roosting habitat for bats. A qualified biologist shall work with the Project engineer in identifying and incorporating structures into the design that provide suitable roosting habitat for bat species occurring in the Project area.

BIO-52 will also be implemented as a general measure to avoid and minimize impacts to general wildlife during construction, including bats. BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to western mastiff bat individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-91 LOSS OF HABITAT – WESTERN MASTIFF BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures that will mitigate for the permanent loss of habitat for the western mastiff bat. These mitigation measures primarily relate to the establishment and management of a large open space system that will provide adequate suitable roosting and foraging habitat to support the western mastiff bat and allow for its persistence in the Project area.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 relate to habitat restoration and management of the River Corridor SMA, which is an important foraging habitat resource for the western mastiff bat. These measures provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects and will provide potential roosting and adequate foraging habitat in the Project area for the western mastiff bat.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA. This measure will help enhance foraging habitat quality for the western mastiff bat because insect diversity and abundance would be enhanced.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA are the same as required for the River Corridor SMA and oak tree replacement occurs as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines. This measure will help enhance foraging habitat quality for the western mastiff bat and also will provide potential roost sites.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures to mitigate for the loss of habitat for the western mastiff bat that relate to the establishment and management of a large open space system.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for western mastiff bat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-92 SECONDARY IMPACTS – WESTERN MASTIFF BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Secondary impacts during construction include increased human activity, dust, noise, and lighting. Dust may also affect the insect prey base of western mastiff bat. Potential long-term effects of development include lighting; increased human activity; pet, stray, and feral cats and dogs that may disturb roost sites; and use of pesticides.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-56 to control lighting in natural areas that could affect western mastiff bat roosting and foraging behavior. This measure requires that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several mitigation measures to reduce short-term and long-term secondary impacts to roost sites to a level that is adverse but not significant. BIO-61 and BIO-68, described above, will mitigate for short-term construction-related disturbance and human activity. BIO-61, BIO-68, and BIO-84, described above, will also mitigate for the impacts from long-term disturbance associated with roads, bridges, lighting, and human activity.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to western mastiff bat individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

WESTERN RED BAT (CSC)

Life History

The western red bat (*Lasiurus blossevillii*) occurs in California from Shasta County and Mendocino County in the north, and through the central coastal region and the Central Valley west of the Sierra Nevada/Cascade ranges to coastal southern California (Cryan 2003; Zeiner *et al.* 1990B), east into Arizona and New Mexico, and south into Baja California and mainland Mexico to South America (Cryan 2003). The species does not occur in desert regions. The western red bat had been considered a subspecies of the red bat (*L. borealis teliotis*) (Shump and Shump 1982), but more recent genetic studies separated the red bat into two species: the western red bat and the eastern red bat (*L. borealis*) (Baker *et al.* 1988; Morales and Bickham 1995). Morales and Bickham (1995) used mitochondrial DNA (mtDNA) to support the separation of the two species. The western red bat is considered locally common. The species inhabits California year-round but makes seasonal movements within the state and, possibly, to Arizona and New Mexico (Cryan 2003).

There is little ecological information specifically for the western red bat; most studies are based on the red bat before it was separated into the western and eastern species. This species account is, therefore, based primarily on information for the red bat before it was separated into the two species.

Red bats (*Lasiurus* spp.) typically roost in trees, occasionally in shrubs, and even on the ground (Shump and Shump 1982). They are usually solitary, but different bats may use different roosts on different days, and they occasionally form nursery colonies. Day roosts are commonly located in edge habitats adjacent to streams, open fields, and urban areas (Shump and Shump 1982).

Red bats take a variety of prey, including moths, crickets, flies, true bugs, beetles, and cicadas (Shump and Shump 1982). They generally forage in grasslands, shrublands, open woodlands, and croplands, but they also take advantage of congregations of insects attracted to streetlights and building floodlights.

Births occur in about mid-June and young develop rapidly, with flight occurring by 21 to 42 days of age (Shump and Shump 1982).

Like other bats, western red bats probably are generally vulnerable to human activity and related impacts. Unlike many other bat species, due to their use of day roosts in trees, shrubs, and sometimes on the ground, western red bats are especially vulnerable to predation by domestic cats, as well as opossums, great horned owls, kestrels, and roadrunners. Other plausible threats to western red bats resulting from construction activities include disturbances of day roosts from human activity, noise, and dust, as well as effects of dust on insect prey. Potential long-term

impacts from urban development, in addition to pet, stray, and feral animals, include human disturbances of roost sites, roost site and foraging habitat degradation, such as trampling and invasive species, and pesticides that may cause secondary poisoning and affect prey abundance.

Survey Results

Two focused bat surveys have been conducted in the Project area. Impact Sciences (2005) conducted acoustic surveys using the Anabat II Bat Detector in 2004 and conducted surveys using both the Anabat detector and mist netting in 2006 (Johnson 2006).

Figure 4.5-131 shows the 25 survey locations from 2004 and the six survey locations from 2006 (Impact Sciences 2005; Johnson 2006). The 2004 surveys were scattered throughout the Project area as well as in two locations on the Legacy Village site. The 2006 surveys were more concentrated, with three locations in Potrero Canyon, two locations along the Santa Clara River, and one location in upper Long Canyon.

There were three acoustic detections of the western red bat in the Project area. Two 2004 detections (Impact Sciences 2005) were in willow riparian habitat, and the 2006 detection was under The Old Road Bridge (Johnson 2006). The species is known to use a variety of habitats throughout its range; therefore, it is assumed to potentially use most of the natural vegetation communities on site, including alluvial scrub, arrow weed scrub, bulrush–cattail wetland, cismontane alkali marsh, southern cottonwood–willow riparian, Mexican elderberry, giant reed, coastal and valley freshwater marsh, herbaceous wetland, mulefat scrub, southern coast live oak riparian forest, southern willow scrub, shrub tamarisk, river wash, big sagebrush scrub, California sagebrush scrub, coyote brush scrub, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, California annual grassland, *Eriodictyon* scrub, purple needlegrass, coast live oak woodland, valley oak woodland, valley oak/grass, and California walnut woodland. A total of 11,466 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 207 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.8% of these communities on site**. Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats, shows impacts to all vegetation communities because the western red bat is a foraging habitat generalist and thus potentially forages throughout the Project area. A total of 118 acres would be temporarily impacted.

The western red bat forages in a broad variety of habitats that comprise more than 11,000 acres in the Project area. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 207 acres of foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,161 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 27.6% of suitable habitat on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats).

A relatively large amount and percentage of on-site roosting and foraging habitats for the western red bat would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from 27.6% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,367 acres (29.4%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of the western red bat on site, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Western red bats are highly mobile, and it is unlikely that the proposed Project would result in direct mortality of adults occupying this habitat during construction and/or grading activities. However, if adults are flushed from a day roost site during construction activities, these individuals could become disoriented and unable to safely relocate to another roost site, resulting in an increased risk of injury or mortality. In addition, if construction activities directly impacted a colonial maternity site, young could be harassed, injured, or killed. Furthermore, even if young escaped direct harm, the loss of a maternity site resulting from implementation of the RMDP before young are independent of the mother likely would result in injury or mortality of the young due to their likely inability to safely relocate to another roost site. Implementation of the SCP would not directly impact this species. If a day roost site were established prior to construction activities in the Project footprint, direct impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals. If a day roost site were established prior to construction activities in the Project footprint, impacts to the roost site would result in a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect western red bats in areas adjacent to construction zones. There is no evidence of existing western red bat day roost sites, including maternity sites, in the Project area, based on focused bat surveys in 2004 and 2006 (Impact Sciences 2005; Johnson 2006). However, if a day roost site were established prior to construction activities in proximity to the construction zones, both short-term secondary impacts associated with construction activities and long-term secondary impacts to a roost site could occur. As noted above, increased human activity, noise, and dust associated with construction activities could cause western red bats to abandon day roosts, exposing both adults and young to injury and mortality due to their likely inability to safely relocate another day roost. Although bats are highly mobile and could alter their foraging behavior to avoid construction areas, construction-generated dust may adversely affect foraging habitat by reducing their insect prey. Lighting in construction areas may also alter foraging behavior due to changing the distribution of insect prey attracted to lights and potentially causing increased competition among bats.

Long-term impacts of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would also increase potential secondary impacts through increased human activity, noise, and lighting for the same reason described above for construction impacts, but over the long term. Use of pesticides for agricultural or in landscaped areas may result in secondary poisoning and reduction of prey. Pet, stray, and feral cats and dogs may disturb roost sites or prey on bats.

Both short-term and long-term secondary impacts to a roost site and impacts to foraging bats would result in a substantial adverse effect on a special-status species (significance criterion 1) and would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to suitable habitat for the western red bat (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 185 acres (1.6%) of permanent loss and 132 acres of temporary loss;
- Alternative 4 – 180 acres (1.6%) of permanent loss and 115 acres of temporary loss;

- Alternative 5 – 212 acres (1.8%) of permanent loss and 141 acres of temporary loss;
- Alternative 6 – 211 acres (1.8%) of permanent loss and 136 acres of temporary loss; and
- Alternative 7 – 82 acres (0.7%) of permanent loss and 190 acres of temporary loss.

Compared to Alternative 2, which would result in 207 acres (1.8%) of permanent loss and 118 acres of temporary impacts, the combined direct permanent and temporary loss of foraging habitat under Alternative 3 would not be substantially different, Alternative 4 would be marginally less overall, and Alternatives 5 and 6 would be marginally to somewhat more overall. The difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, impacts for Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the western red bat (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 2,949 acres (25.7%) of permanent loss;
- Alternative 4 – 2,825 acres (24.6%) of permanent loss;
- Alternative 5 – 2,742 acres (23.9%) of permanent loss;
- Alternative 6 – 2,423 acres (21.1%) of permanent loss; and
- Alternative 7 – 2,128 acres (18.6%) of permanent loss.

Compared to Alternative 2, which would result in 3,161 acres (27.6%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara

River and other changes in the Project footprint under Alternative 7 that reduce impacts to western red bat suitable habitat compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the western red bat occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the western red bat:

- Alternative 3 – 3,134 acres (27.3%) of permanent loss;
- Alternative 4 – 3,005 acres (26.2%) of permanent loss;
- Alternative 5 – 2,953 acres (25.8%) of permanent loss;
- Alternative 6 – 2,633 acres (23.0%) of permanent loss; and
- Alternative 7 – 2,210 acres (19.3%) of permanent loss.

Compared to Alternative 2, which would result in 3,367 acres (29.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the western red bat occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual western red bats as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the

relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual western red bats occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as increased human activity; dust; noise (from construction and traffic on roads and bridges); pet, stray, and feral cats and dogs; pesticides; and lighting. The loss or degradation of suitable habitat and impacts to individual western red bats due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to western red bat: (1) impacts to individuals; (2) loss of roosting and foraging habitat; and (3) secondary impacts to individuals and roosting sites and foraging habitat outside the Project footprint.

Impacts to individuals could occur if day roosting sites are disturbed during construction as a result of increased human activity, noise, dust, and lighting. As noted above, bats are very sensitive to disturbances and may permanently abandon roost sites with a single disturbance event. If individuals, including adults and young, are flushed from a day roost during construction, they would likely become disoriented and unable to safely relocate to another roost, resulting in increased risk of injury or mortality. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active bat roost sites and postpone work within 300 feet of any active maternity roost until young have fledged and will create alternative roost sites to mitigate for any roost sites disturbed during construction, including creation of roosts under bridges and in culverts, where practicable, in consultation with CDFG.

The combined permanent loss of foraging habitat resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,210 acres (19.3%) under Alternative 7 to 3,367 acres (29.4%) under Alternative 2. This would be a substantial loss of suitable foraging habitat and will alter the foraging behavior of the western red bat in the Project area. The combined Newhall Ranch

Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable foraging habitat to support the western red bat in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 6,250 acres of suitable foraging habitat, as well as potential roosting sites, for the western red bat. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, bats are very sensitive to disturbances and thus roost sites outside of the construction zone could be adversely affected during construction due to increased human activity, dust, noise, and lighting. Dust may also affect their insect prey base. Impacts to active maternity sites in or within 300 feet of construction zones will be avoided until young have fledged, as noted above. Construction-generated dust will be controlled using standard measures, such as chemical suppression and screening fencing, where determined to be necessary. Potential long-term effects of development include lighting; increased human activity; pet, stray, and feral cats and dogs, which may cause roost abandonment; and use of pesticides, which may cause secondary poisoning or affect the prey base. The large open space system will provide adequate areas for roosting and foraging that will in part offset these impacts. Several specific mitigation measures will also be implemented to control human activities in open space areas where bats may roost, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting along the edge of natural habitat areas will be downcast. Pesticides will be controlled through an integrated pest management (IPM) plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

The specific mitigation measures for the western red bat are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-93 IMPACTS TO INDIVIDUALS – WESTERN RED BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid, minimize, or mitigate impacts to western red bat individuals.

Measures Recommended by EIS/EIR

This EIS/EIR recommends three mitigation measures to reduce impacts to western red bat individuals. These mitigation measures primarily are designed to avoid impacts to active day roosts.

BIO-61 requires a pre-construction survey to determine if active roosts of special-status bats are present within 300 feet of the Project disturbance boundaries. If an active maternity roost is found, all work within 300 feet shall be postponed until the roost is vacated and juveniles have fledged. If a maternity roost is impacted, substitute roosting habitat shall be provided. Non-breeding bat hibernacula shall be vacated the evening between initial disturbance and clearing and grading activities.

BIO-68 requires creation of artificial roost sites to mitigate day roost sites found during pre-construction surveys conducted per BIO-61.

BIO-84 states that the culvert and bridge designs, where practicable, shall provide roosting habitat for bats. A qualified biologist shall work with the Project engineer in identifying and incorporating structures into the design that provide suitable roosting habitat for bat species occurring in the Project area.

BIO-52 will also be implemented as a general measure to avoid and minimize impacts to general wildlife during construction, including bats. BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, loss of or harm to western red bat individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-94 LOSS OF HABITAT – WESTERN RED BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures that will mitigate for the permanent loss of habitat for the western red bat. These mitigation measures primarily relate to the establishment and management of a large open space system that will provide adequate suitable roosting and foraging habitat to support the western red bat and allow for its persistence in the Project area.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 relate to habitat restoration and management of the River Corridor SMA, which is an important foraging habitat resource for the western red bat. These measures provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects and will provide potential roosting and adequate foraging habitat in the Project area for the western red bat.

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA. This measure will help enhance foraging habitat quality for the western red bat because insect diversity and abundance would be enhanced.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA are the same as required for the River Corridor SMA and oak tree replacement occurs as described in SP-4.6-48.SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area, including: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines. This measure will help enhance foraging habitat quality for the western red bat and also will provide potential roost sites.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures to mitigate for the loss of habitat for the western red bat that relate to the establishment and management of a large open space system.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for western red bat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-95 SECONDARY IMPACTS – WESTERN RED BAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Secondary impacts during construction include increased human activity, dust, noise, and lighting. Dust may also affect the insect prey base of western red bat. Potential long-term effects of development include lighting, increased human activity, pet, stray, and feral cats and dogs that may disturb roost sites and prey on bats, and use of pesticides.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified Mitigation Measure SP-4.6-56 to control lighting in natural areas that could affect western red bat roosting and foraging behavior. This measure requires that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several mitigation measures to reduce short-term and long-term secondary impacts to roost sites to a level that is adverse but not significant. BIO-61 and BIO-68, described above, will mitigate for short-term construction-related disturbance and human activity. BIO-61, BIO-68, and BIO-84, described above, will also mitigate for the impacts from long-term disturbance associated with roads, bridges, lighting, and human activity.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to western red bat individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

SAN DIEGO DESERT WOODRAT (CSC)

Life History

The desert woodrat (*Neotoma lepida*) is widespread throughout central and southern California and the Great Basin, Mojave, and Colorado deserts. Marginal records for the San Diego desert woodrat (*N. l. intermedia*) in the United States include San Luis Obispo, San Fernando in Los Angeles County, the San Bernardino Mountains and Redlands in San Bernardino County, and Julian in San Diego County (Hall 1981).

Desert woodrats are found in a variety of shrub and desert habitats and are primarily associated with rock outcroppings, boulders, cacti, or areas of dense undergrowth (Bleich 1973; Bleich and Schwartz 1975; Brown *et al*. 1972; Cameron and Rainey 1972; Thompson 1982). Desert woodrats are noted for their flexibility or plasticity in utilizing various materials, such as twigs and other debris (sticks, rocks, dung), to build elaborate dens or "middens," which typically include several chambers for nesting and food as well as several entrances. Middens may be used by several generations of woodrats (Cameron and Rainey 1972).

Desert woodrats are primarily herbivorous, and their diet may include leaves, seeds, berries, parts of flowers, and yucca shoots (Cameron and Rainey 1972).

The desert woodrat is a relatively sedentary species with patterns of movement and spatial activity primarily determined by habitat structure (Thompson 1982). Den sites tend to be on the periphery of the home range; woodrats move between loci along distinct routes. Home ranges of desert woodrats are relatively small, with observed male and female home ranges in north-coastal San Diego County of 371 square meters (0.09 acre) and 433 square meters (0.11 acre), respectively (Bleich and Schwartz 1975). Average moves by males and females were 13.2 meters (43 feet) and 14.5 meters (48 feet) (Bleich and Schwartz 1975).

The breeding season of desert woodrats probably is related to local climate conditions and available resources to support reproduction that may vary from year to year. The peak breeding season in north-coastal San Diego appears to be from November to April, but breeding can occur year-round (Bleich 1973).

Desert woodrats are vulnerable to at least two long-term effects related to urbanization. First, increased fire frequency may cause type conversion of coastal scrub and chaparral habitats to California annual grassland, making recolonization of such areas unlikely. Cactus patches destroyed by fire, in particular, require a long period of recovery to become suitable for woodrats. Second, increased predation of native rodents, including woodrats, by cats and other mesopredators in habitat edges also may occur with urbanization (Bolger *et al.* 1997). Compounding this problem is a decline in coyote population numbers in fragmented habitats, resulting in the "mesopredator release" effect because coyotes are no longer preying on

mesopredators (Crooks and Soulé 1999). Declines in the coyote population result in an increase in the abundance of mesopredators, such as domestic cat, raccoon, opossum, and fox, which are the principal predators of small mammals such as woodrats. Finally, use of rodenticides for pest management is a potential threat to this species.

Survey Results

Small mammal live-trapping found that the San Diego desert woodrat is a relatively common rodent within the Specific Plan portion of the Project area (Impact Sciences 2005). The highest frequency of captures of the desert woodrat was in coastal scrub, with fewer captures in mixed scrub, coast live oak woodland, dry wash, willow riparian, and mulefat scrub. Although some captures were in oak woodland and riparian scrubs, the primary habitat for this species is considered to be shrublands (coastal scrubs and chaparral). Alluvial scrub, big sagebrush scrub, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, coastal scrub alliances and associations, and *Eriodictyon* scrub are considered suitable habitats for the San Diego desert woodrat. A total of 6,575 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 80 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.2% of these habitats on site (**Figure 4.5-102**, Alternative 2 Impacts to Scrub and Chaparral Wildlife Habitat). A total of 9.0 acres would be temporarily impacted.

Although this species is still widespread and relatively common throughout its range, due to landscape habitat fragmentation and type conversion of coastal scrub and chaparral to grasslands through much of its range, resulting in local extirpations, the loss of 80 acres of habitat for the San Diego desert woodrat would have a substantial direct adverse effect

on a special-status species (significance criterion 1). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 1,971 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 30.0% of the habitat on site (**Figure 4.5-102**, Alternative 2 Impacts to Scrub and Chaparral Wildlife Habitat).

A relatively large amount and percentage of on-site shrub communities providing habitat for the San Diego desert woodrat would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from approximately 30.0% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,052 acres (31.2%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of the San Diego desert woodrat on site, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because desert woodrats are not highly mobile, the proposed Project would result in injury and mortality of individuals occupying suitable habitat during construction and/or grading activities as a result of implementation of the RMDP. These impacts would occur as result of direct contact with construction equipment or entombment during vegetation clearing and grading. Animals flushed from dens during construction would likely be disoriented and may be unable to find safe refuge, resulting in exposure, increased predation, and increased vehicle collisions. Implementation of the SCP would not directly impact this species.

Although this species is still widespread and relatively common throughout its range, due to landscape habitat fragmentation and type conversion of coastal scrub and chaparral to

grasslands throughout much of its range, resulting in local extirpations, these impacts to individual San Diego desert woodrats would have a substantial direct adverse effect on a special-status species (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is similar to that described above for direct permanent impacts because San Diego desert woodrats are not highly mobile. The number of San Diego desert woodrat individuals that would be injured or killed during construction as a result of build-out of the Specific Plan, VCC, and Entrada planning areas is potentially much greater than injured or killed during implementation of the RMDP because of the much greater loss of suitable habitat. This loss of individuals would have a substantial adverse effect on this species, thus substantially reducing its number and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would have the potential to affect San Diego desert woodrats in areas adjacent to construction zones. These impacts could include collapsed burrows and middens due to ground vibration; abandonment of burrows or middens; and disruptions associated with increased human activity, noise, and nighttime illumination—the latter of which may disrupt the woodrats' nocturnal behavior and make them more vulnerable to predation by nocturnal predators, such as owls and coyotes. Implementation of the SCP would not affect this species.

Potential long-term secondary impacts would primarily stem from build-out of the Specific Plan, VCC, and Entrada planning areas. These impacts include habitat fragmentation and isolation of some local populations of San Diego desert woodrats, making them more vulnerable to extirpation, as well as increased human activity in open space areas. Several other long-term secondary effects could occur from the close proximity of urban development to suitable San Diego desert woodrat habitat: abandonment of burrows and middens; disruption of nocturnal activities; greater vulnerability to predation by nocturnal predators (*e.g.*, owls and coyotes) as a result of nighttime lighting; greater vulnerability to predation by pet, stray, and feral cats and dogs as well as other mesopredators (see Crooks and Soulé 1999); and vulnerability to rodenticides that may be used to control pest rodents (*e.g.*, ground squirrels in landscaped areas or golf courses).

Short-term secondary impacts would have a substantial adverse effect on a special-status species (significance criterion 1). Long-term secondary impacts would also have a substantial adverse effect on a special-status species and permanently reduce San Diego desert woodrat populations

along the urban–open space edge and contribute to the reduction of the range and distribution of the San Diego desert woodrat in the Project area (significance criteria 1 and 7). Overall, short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the San Diego desert woodrat **(Figures 4.5-103** through **4.5-107**, Alternatives 3 through 7 Impacts to Scrub and Chaparral Wildlife Habitat**)**:

- Alternative 3 – 76 acres (1.2%) of permanent loss and 12 acres of temporary loss;
- Alternative 4 – 77 acres (1.2%) of permanent loss and 8.7 acres of temporary loss;
- Alternative 5 – 82 acres (1.2%) of permanent loss and 14 acres of temporary loss;
- Alternative 6 – 68 acres (1.0%) of permanent loss and 16 acres of temporary loss; and
- Alternative 7 – 42 acres (0.6%) of permanent loss and 43 acres of temporary loss.

Compared to Alternative 2, which would result in 80 acres (1.2%) of permanent loss and 9.0 acres of temporary impacts, the permanent and temporary loss of habitat under Alternatives 3 through 5 would not be substantially different, while the impacts under Alternative 6 would be marginally different compared to Alternative 2. The difference between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries and other changes to the Project footprint under Alternative 7 that would result in fewer permanent impacts and relatively more temporary impacts to suitable habitat for San Diego desert woodrat compared to the other alternatives.

Because of the loss and fragmentation of habitat for the San Diego desert woodrat throughout its range, and because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is similar in magnitude compared to the loss of habitat under Alternative 2, the impacts would significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the San

Diego desert woodrat **(Figures 4.5-103** through **4.5-107**, Alternatives 3 through 7 Impacts to Scrub and Chaparral Wildlife Habitat**)**:

- Alternative 3 – 1,866 acres (28.4%) of permanent loss;
- Alternative 4 – 1,814 acres (27.6%) of permanent loss;
- Alternative 5 – 1,767 acres (26.9%) of permanent loss;
- Alternative 6 – 1,517 acres (23.1%) of permanent loss; and
- Alternative 7 – 1,349 acres (20.5%) of permanent loss.

Compared to Alternative 2, which would result in 1,971 acres (30.0%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would reduce impacts to suitable habitat for the San Diego desert woodrat compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the San Diego desert woodrat occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the San Diego desert woodrat:

- Alternative 3 – 1,942 acres (29.5%) of permanent loss;
- Alternative 4 – 1,892 acres (28.8%) of permanent loss;
- Alternative 5 – 1,849 acres (28.1%) of permanent loss;
- Alternative 6 – 1,586 acres (24.1%) of permanent loss; and
- Alternative 7 – 1,391 acres (21.2%) of permanent loss.

Compared to Alternative 2, which would result in 2,052 acres (31.2%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7; there would also be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 that would reduce impacts to suitable habitat for the San Diego desert woodrat compared to the other alternatives. Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for the San Diego desert woodrat occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial and therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual San Diego desert woodrats as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual San Diego desert woodrats occurring as a result of implementation of the RMDP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as increased human activity, noise, habitat fragmentation, ground vibration, nighttime lighting, and rodenticides. Therefore, the loss or degradation of suitable habitat and impacts to individual San Diego desert woodrats due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to San Diego desert woodrat: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur if dens are disturbed during construction, including direct destruction of dens from vegetation clearing and grading that could result in injury or mortality of individuals from direct contact with equipment or entombment or as result of flushing from the den due to increased human activity, noise, and ground vibration. If individuals are flushed from a den during construction they would likely become disoriented and unable to find safe refuge, resulting in exposure, increased risk of predation, and increased risk of vehicle collisions. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys within the proposed disturbance area to identify, capture, and relocate woodrat individuals. Active nests with young inside or within 100 feet the disturbance zone will be protected by fencing. Biological monitoring will be conducted during vegetation clearing and grading activities. If San Diego desert woodrats are observed in the disturbance zone outside the breeding season, individuals will be relocated to a suitable location outside the disturbance boundary.

The combined permanent loss of suitable habitat for the San Diego desert woodrat resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 1,391 acres (21.2%) under Alternative 7 to 2,052 acres (31.2%) under Alternative 2. This would be a substantial loss of suitable habitat and will reduce the size and distribution of the San Diego woodrat population in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable habitat to support the San Diego desert woodrat in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 3,488 acres of suitable habitat for this species. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, woodrats occupying habitat in close proximity to construction zones may be disturbed by construction activities, including increased human activity, noise, and ground vibration, which may cause them to abandon the nest and increase their exposure to predation and vehicle collisions. Abandonment of an active nest likely would also result in the loss of their litter. Lighting of occupied habitat would increase predation risk from nocturnal predators. The pre-construction surveys, protection of nest with young, and biological monitoring during vegetation clearing and grading, as well as controls on lighting, will help reduce these construction-related impacts. Potential long-term effects of development include

habitat fragmentation, increased human activity, pet, stray, and feral cats and dogs, lighting, and use of rodenticides. The large open space system will provide adequate protected open space that will in part offset these impacts. Several specific mitigation measures will also be implemented to control human activities in open space areas, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting will be downcast away from open space areas. Rodenticides will be controlled through an integrated pest management (IPM) plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

All specific mitigation measures for the San Diego desert woodrat are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-96 IMPACTS TO INDIVIDUALS – SAN DIEGO DESERT WOODRAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid, minimize, or mitigate impacts to San Diego desert woodrat individuals.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two mitigation measures that will reduce impacts to San Diego desert woodrat individuals through pre-construction coordination and surveys.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-58 requires a survey within the proposed disturbance area to identify, capture, and relocate the San Diego desert woodrat 30 days prior to construction in suitable habitats. If active San Diego desert woodrat nests with young are identified within the disturbance zone or 100 feet of the disturbance zone, a fence shall be erected around the nest site to provide the San Diego desert woodrat with sufficient habitat. If San Diego desert woodrats are observed in the disturbance

zone outside the breeding season, individuals shall be relocated to a suitable location outside the disturbance boundary.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to San Diego desert woodrat individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-97 LOSS OF HABITAT – SAN DIEGO DESERT WOODRAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will mitigate the loss of suitable habitat for the San Diego desert woodrat. These mitigation measures primarily relate to habitat protection, restoration and enhancement, and management in the River Corridor SMA and High Country SMA.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 address habitat restoration in the River Corridor SMA and provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, etc.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. The River Corridor SMA includes terrestrial habitats that are used by San Diego desert woodrat and some captures on site occurred in southern willow scrub and mulefat scrub (Impact Sciences 2005). Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation; native riparian plants shall be incorporated into landscaping where feasible; roads and bridges shall be designed to discourage public access to the River Corridor SMA; and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures that will mitigate for the loss of suitable habitat for the San Diego desert woodrat; these relate to habitat restoration in the River Corridor SMA, High Country SMA, and Salt Creek area and preservation of habitat in the Salt Creek area.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, loss of habitat for San Diego desert woodrat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-98 SECONDARY IMPACTS – SAN DIEGO DESERT WOODRAT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will mitigate for potential short-term secondary effects related to construction and long-term secondary impacts due to habitat fragmentation, increased human activity, abandonment of burrows and middens, and disruption of nocturnal activities and greater vulnerability to predation by nocturnal predators (*e.g.*, owls and coyotes) as a result of nighttime lighting.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-27, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and that generally refer to habitat protection, restoration and enhancement, and management, will be implemented to mitigate for long-term habitat fragmentation effects and increased human activity.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only on developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that will reduce short-term construction-related secondary impacts, such as collapsed burrows and middens due to ground vibration, abandonment of burrows or middens, and disruptions associated with increased human activity and noise, and long-term secondary impacts related to habitat fragmentation, increased human activity, predation and harassment by pet, stray, and feral cats and dogs, and use of pesticides (including rodenticides).

BIO-52 and BIO-58, as described above, will be implemented to reduce construction-related secondary impacts to San Diego desert woodrats in close proximity to disturbance zones. These measures include pre-construction coordination (BIO-52) and pre-construction surveys and protection of nests within 100 feet of the disturbance zone boundary (BIO-58).

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, will be implemented to mitigate for impacts from habitat fragmentation and increased human activity through habitat protection, restoration and enhancement, and management.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-64 will be implemented to prevent poisoning and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to San Diego desert woodrat and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

SOUTHERN GRASSHOPPER MOUSE (CSC)

Life History

The southern grasshopper mouse (*Onychomys torridus*) occurs throughout desert habitats in the southwestern United States and much of Mexico, including western Nevada; the southern portions of California, Arizona, and New Mexico; northern Baja California; western Texas; and south to central Mexico (Hall 1981). The subspecies *O. t. ramona*, which is a California Species of Special Concern (CSC), is restricted to coastal southern California, with marginal records for Mint Canyon west of Palmdale and San Fernando in Los Angeles County, Riverside and Valle Vista in Riverside County, and Warner Pass, La Puerta Valley, Jacumba, Santee Mountains, and the mouth of the Tijuana River Valley in San Diego County (Hall 1981). The subspecies *O. t. pulcher* is more widespread and occurs to the east of *O. t. ramona* in the Mojave and Colorado deserts and as far west as the Antelope Valley in Los Angeles County (Hall 1981). In California, the CNDDB (CDFG 2007A) contains 28 records for the subspecies *O. t. ramona* from the following counties in southern California: San Diego and Riverside (11 records each), Los Angeles (two records), and San Bernardino and Imperial (one record each). The four records from Los Angeles County include Mint Canyon in the Angeles National Forest about three miles west of Agua Dulce, Pearblossom in the Mojave Desert, Tujunga Valley, and Arroyo Seco in Pasadena. The Mint Canyon record, which dates back to 1930, is located approximately 15 miles east of the Project area.

The southern grasshopper mouse rangewide is found in low arid scrub and semi-scrub vegetation (Frank and Heske 1992; McCarty 1975), and the subspecies *O. t. ramona* occurs in grasslands and sparse coastal scrub habitats. Specific habitat requirements of the southern grasshopper mouse generally are unknown, but Stapp (1997) found that the southern grasshopper mouse uses open expanses and microhabitats dominated by gopher mounds and burrows, possibly because of greater prey availability (*e.g.*, arthropods using burrows for refuge), greater mobility in open expanses, and dust bathing sites in these microhabitats.

The southern grasshopper mouse's diet consists mainly of arthropods (*e.g.*, crustaceans, insects, centipedes, millipedes, and arachnids), but may also include other insects and small rodents (Baily and Sperry 1929; Horner *et al.* 1965; McCarty 1975; Stapp 1997). The southern grasshopper mouse is primarily nocturnal and appears to be active on the surface all year round (Baily and Sperry 1929; Frank and Heske 1992; McCarty 1975).

The timing of breeding probably varies geographically and in relation to environmental conditions, but the peak breeding season is May through July (McCarty 1975). The southern grasshopper mouse exhibits postpartum estrus and can produce up to 12 litters in a year (McCarty 1975). Year-to-year survival appears to be low for the southern grasshopper mouse and juvenile mortality and/or dispersal appears to be very high. There is very little information about dispersal of the southern grasshopper mouse. Stapp (1997) reported that most juveniles

had disappeared from the study site by autumn, but no distinction was made between mortality and dispersal. Because of its high population turnover, relatively early age of sexual maturity, and senescence after the first year, the southern grasshopper mouse probably is subject to "boom and bust" population cycles and is perhaps at high risk of local extirpation under poor conditions.

Average home ranges estimated using radiotelemetry were approximately 9.1 acres for breeding males, 4.2 acres for non-breeding males, and 4.2 acres for females (Frank and Heske 1992). During the breeding season, there was extensive home-range overlap between males and between males and females, but there was little overlap in the home ranges of females (Frank and Heske 1992).

Population densities of the southern grasshopper mouse are relatively low for a rodent species. McCarty (1975) reported a density of 0.7 mice per acre in a Mojave Desert creosote scrub community and others also have reported low population densities (*e.g.*, Baily and Sperry 1929; Frank and Heske 1992). Such low population densities are consistent with the species' carnivorous habits and the distribution and availability of prey items.

There are no identified threats to the southern grasshopper mouse other than loss and fragmentation of grassland and sparse sage scrub habitats in coastal southern California, which probably are the greatest threats to local southern grasshopper mouse populations. Related threats that generally apply to native rodents are increased predation along habitat edges (Bolger *et al.* 1997) and "mesopredator release" effect where declines of coyote population numbers contribute to the increase in abundance of mesopredators, such as domestic cat, raccoon, opossum, and fox, which are the principal predators of small mammals (Crooks and Soulé 1999). In addition, pesticides that could reduce insect prey or cause secondary poisoning, as well as rodenticides that may directly affect the southern grasshopper mouse, are potential threats to this species.

Survey Results

The small mammal live-trapping study conducted by Impact Sciences (2005) did not document the southern grasshopper mouse in the Project area. The trapping study was adequate for the majority of the small rodents likely to occur in the Project area; however, a potential limitation of the study for the southern grasshopper mouse is that, where population densities are low, traps may need to be spread over a wider area to adequately sample for the species. The species also was not captured in pitfall trapping studies in 2004 and 2006 that were conducted primarily to inventory the reptiles and amphibians in the Project area (Impact Sciences 2006A). While the presence or absence of the southern grasshopper mouse on site cannot be confirmed by this study, the lack of captures indicates that the probability of the species being present is low, and that, if present, it likely occurs in very low densities. It is assumed for this analysis that the southern grasshopper mouse has the potential to occur on site at least in low densities in suitable habitat, which includes alluvial scrub, big sagebrush scrub, big sagebrush–California buckwheat,

California sagebrush scrub and associations, California sagebrush–California buckwheat, California sagebrush–undifferentiated chaparral, purple needlegrass, and California annual grassland. A total of 6,720 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 78 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.2% of these habitats on site (**Figure 4.5-125**, Alternative 2 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat). A total of 17 acres would be temporarily impacted.

Because the southern grasshopper mouse is restricted to coastal southern California and has suffered extensive habitat loss and fragmentation within its range, the permanent loss of 78 acres of suitable habitat and temporary impacts as a result of construction and/or grading activities would have a substantial direct adverse effect on this species, if present (significance criterion 1). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 2,576 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 38.3% of these habitats on site (**Figure 4.5-125**, Alternative 2 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat).

A relatively large amount and percentage of on-site habitats providing suitable habitat for the southern grasshopper mouse would be permanently removed as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. Because of the small geographic range of the southern grasshopper mouse and extensive loss and fragmentation of habitat

within its range, this loss of habitat would have a substantial adverse effect on this species, if present, by eliminating approximately 38.3% of suitable habitat, and thus substantially reducing its numbers and potential range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,654 acres (39.5%). Because of the large amount and percentage of habitat loss, the combined direct and indirect impacts to suitable habitat would have a substantial adverse effect on the southern grasshopper mouse on site, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because southern grasshopper mice are fossorial (burrowers) and probably are not mobile enough to escape impacted areas, if individuals are present, the proposed Project would result in injury or mortality of individuals occupying this habitat during vegetation clearing and/or grading activities through direct contact with construction equipment or entombment in burrows. Implementation of the SCP would not directly impact this species. Although, if present, very few individuals likely would be killed or injured because of the relatively small amount of suitable habitat directly impacted and the likely low population density, if present on site, because of the rangewide loss and fragmentation of habitat, the loss of any individuals as a result of construction and/or grading activities would have a substantial direct adverse effect on this species (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The source of indirect permanent impacts to individuals is the same as that described above for direct impacts, but the risk would be much greater due to the large amount of scrub and grassland habitats that would be impacted as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. If the species is present on site, there is high potential for injury or mortality of southern grasshopper mice during vegetation clearing and/or grading due to direct contact with equipment or entombment. The loss of any individuals would have a substantial adverse effect on this species on site through

injury and mortality and by eliminating the species from approximately 38.3% of currently occupied habitat, thus substantially reducing its number and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would have the potential to affect any southern grasshopper mice, if present, in areas adjacent to construction zones. These impacts could include collapsed burrows due to ground vibration; abandonment of burrows during the daytime resulting in exposure, and increase risk of predation and vehicle collisions; and disruptions associated with increased human activity, noise, and nighttime illumination, the latter of which may disrupt the species' nocturnal behavior and make them more vulnerable to predation by nocturnal predators, such as owls and coyotes. Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would be short term and would affect a relatively small proportion of the southern grasshopper mouse population in the Project area, if present. Implementation of the SCP would not affect this species.

This species, if present, probably occurs at a very low population density and it is unlikely that a large number of individuals would occupy habitat adjacent to construction zones. However, because of the widespread loss and fragmentation of habitat for species within its range, these impacts would have a substantial direct adverse effect on this species (significance criterion 1).

Potential long-term secondary impacts include habitat fragmentation and potential isolation of local populations of the southern grasshopper mouse resulting from build-out of the Specific Plan, VCC, and Entrada planning areas, making the species, if present, more vulnerable to extirpation. In addition, over the long term, the close proximity of urban development to suitable southern grasshopper mouse habitat could result in abandonment of burrows; disruption of nocturnal activities; greater vulnerability to predation by nocturnal predators (*e.g.*, owls and coyotes) as a result of nighttime lighting; greater vulnerability to predation by pet, stray, and feral cats and dogs as well as other mesopredators such as raccoons, foxes, skunks, and opossums (Crooks and Soulé 1999); and vulnerability to pesticides, which may reduce insect prey and cause secondary poisoning and rodenticides that may be used to control pest rodents (*e.g.*, ground squirrels in landscaped areas or golf courses). These long-term secondary impacts would permanently reduce southern grasshopper mouse populations that may occur along the urban–open space edge and contribute to the reduction of the range and distribution of the southern grasshopper mouse in the Project area (significance criteria 1 and 7).

Both short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the southern grasshopper mouse (**Figures 4.5-126** through **4.5-130**, Alternatives 3 through 7 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat):

- Alternative 3 – 82 acres (1.2%) of permanent loss and 25 acres of temporary loss;
- Alternative 4 – 74 acres (1.1%) of permanent loss and 17 acres of temporary loss;
- Alternative 5 – 96 acres (1.4%) of permanent loss and 28 acres of temporary loss;
- Alternative 6 – 109 acres (1.6%) of permanent loss and 32 acres of temporary loss; and
- Alternative 7 – 41 acres (0.6%) of permanent loss and 89 acres of temporary loss.

Compared to Alternative 2, which would result in 78 acres (1.2%) of permanent loss and 17 acres of temporary impacts, the permanent loss of habitat would not be substantially different under Alternatives 3 and 4, would be marginally different under Alternative 5, and would be somewhat greater under Alternative 6. Compared to Alternative 2, the temporary loss of habitat would be the same under Alternative 4 and would be somewhat greater under Alternatives 3, 5, and 6. The difference between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries and other changes to the Project footprint under Alternative 7 that would result in reduced permanent impacts and greater temporary impacts to suitable habitat for the southern grasshopper mouse compared to the other alternatives.

Because of the widespread loss and fragmentation of habitat for the southern grasshopper mouse within its range, and because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 generally would be similar in magnitude compared to Alternative 2, the impacts would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the southern grasshopper mouse (**Figures 4.5-126** through **4.5-130**, Alternatives 3 through 7

Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat):

- Alternative 3 – 2,408 acres (35.8%) of permanent loss;
- Alternative 4 – 2,311 acres (34.4%) of permanent loss;
- Alternative 5 – 2,232 acres (33.2%) of permanent loss;
- Alternative 6 – 1,950 acres (29.0%) of permanent loss; and
- Alternative 7 – 1,738 acres (25.9%) of permanent loss.

Compared to Alternative 2, which would result in 2,576 acres (38.3%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would result in reduced impacts to suitable habitat for the southern grasshopper mouse compared to the other alternatives.

Because of the widespread loss and fragmentation of habitat for the southern grasshopper mouse within its range, and because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to or somewhat less than the overall loss of habitat under Alternative 2, the impacts would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the southern grasshopper mouse:

- Alternative 3 – 2,490 acres (37.1%) of permanent loss;
- Alternative 4 – 2,385 acres (35.5%) of permanent loss;
- Alternative 5 – 2,328 acres (34.6%) of permanent loss;
- Alternative 6 – 2,060 acres (30.6%) of permanent loss; and
- Alternative 7 – 1,779 acres (26.5%) of permanent loss.

Compared to Alternative 2, which would result in 2,654 acres (39.5%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7. There would also be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7 and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 that would reduce impacts to suitable habitat for the southern grasshopper mouse compared to the other alternatives. Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for the southern grasshopper mouse occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial and therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual southern grasshopper mice as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than for Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Because of the widespread loss and fragmentation of habitat for the southern grasshopper mouse within its range, impacts to individual southern grasshopper mice, if present, occurring as a result of implementation of the RMDP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 if the southern grasshopper mouse occurs on site. These impacts would be similar to those presented above for Alternative 2 because each alternative would have similar short-term impacts (vibration, noise, human activity, lighting) and long-term effects due to factors such as increased human activity, habitat fragmentation, nighttime lighting, increased predation, and pesticides (including rodenticides). Both short-term and long-term secondary impacts resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to southern grasshopper mouse, if present on site: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur if burrows are disturbed during construction, including direct destruction of burrows from vegetation clearing and grading that could result in injury or mortality of individuals from direct contact with equipment or entombment or as result of flushing from the burrow due to increased human activity, noise, and ground vibration. If individuals are flushed from a burrow during construction they would likely become disoriented and unable to find safe refuge, resulting in exposure, increased risk of predation, and increased risk of vehicle collisions. In order to avoid, minimize, and mitigate these impacts, procedures for minimizing harm to or harassment of wildlife will be implemented and biological monitoring will be conducted during vegetation clearing and grading activities.

The combined permanent loss of habitat for the southern grasshopper mouse resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 1,779 acres (26.5%) under Alternative 7 to 2,654 acres (39.5%) under Alternative 2. This would be a substantial loss of suitable habitat and will reduce the size and distribution of the southern grasshopper mouse population, if present, in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable habitat to support the southern grasshopper mouse in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 2,657 acres of suitable habitat for this species. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, southern grasshopper mice, if present, occupying habitat in close proximity to construction zones may be disturbed by construction activities, including increased human activity, noise, and ground vibration, which may cause them to abandon burrows and increase their exposure to predation and vehicle collisions. Abandonment of a natal burrow containing young likely would also result in the loss of their litter. Lighting of occupied habitat would increase predation risk from nocturnal predators. Implementation of procedures to minimize impacts during construction and biological monitoring during vegetation clearing and grading will help reduce these construction-related impacts. Potential long-term effects of development include habitat fragmentation, increased human activity, pet, stray, and feral cats and dogs, lighting and use of pesticides, including rodenticides. The large open space system will provide adequate protected open space that will in part offset these impacts. Several specific mitigation measures will also be implemented to control human activities in open space areas,

including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting will be downcast away from open space areas. Pesticides, including rodenticides, will be controlled through an integrated pest management (IPM) plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

All specific mitigation measures for the southern grasshopper mouse are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-99 IMPACTS TO INDIVIDUALS – SOUTHERN GRASSHOPPER MOUSE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid, minimize, or mitigate the loss of southern grasshopper mouse.

Measures Recommended by EIS/EIR

This EIS/EIR recommends one mitigation measure related to pre-construction coordination and monitoring that will reduce impacts to southern grasshopper mouse individuals associated with construction activities.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to southern grasshopper mouse individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-100 LOSS OF HABITAT – SOUTHERN GRASSHOPPER MOUSE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will mitigate the loss of habitat for the southern grasshopper mouse. These mitigation measures primarily relate to habitat protection, restoration and enhancement, and management in the River Corridor SMA and High Country SMA.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 address habitat restoration in the River Corridor SMA and provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. The River Corridor SMA includes terrestrial habitats that are suitable for the southern grasshopper mouse, including grassland and scrub habitats, which will benefit from management. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures that will mitigate for the loss of suitable habitat for the southern grasshopper mouse that relate to habitat protection, restoration and enhancement, and/or habitat management in the River Corridor SMA, High Country SMA, and Salt Creek area.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are

provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, loss of habitat for the southern grasshopper mouse would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-101 SECONDARY IMPACTS – SOUTHERN GRASSHOPPER MOUSE

Significant for Alternatives 2, 3, 4, 5, 6, and 7

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will mitigate the short-term effect of lighting during construction and long-term secondary impacts to the southern grasshopper mouse, such as habitat fragmentation and potential isolation of local populations, abandonment of burrows, and disruption of nocturnal activities and greater vulnerability to predation by nocturnal predators (*e.g.*, owls and coyotes) as a result of nighttime lighting.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will mitigate for habitat fragmentation through habitat protection, restoration and enhancement, and management.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA and thus protect suitable habitat for the southern grasshopper mouse. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only on developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that will reduce short-term impacts related to construction activities, such as increased human activity, noise, and vibration, and long-term secondary impacts such as habitat fragmentation, predation and harassment by pet, stray, and feral cats and dogs, and the use of pesticides, including rodenticides.

BIO-52, as described above, includes procedures for reducing impacts to individuals and biological monitoring during initial vegetation clearing and grading.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, will be implemented to mitigate for impacts from habitat fragmentation and increased human activity through habitat protection, restoration and enhancement, and management.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-64 will be implemented to prevent poisoning and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides, including rodenticides and insecticides, on site prior to the issuance of building permits.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, long-term secondary impacts to the southern grasshopper mouse and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

AMERICAN BADGER (CSC)

Life History

The American badger (*Taxidea taxus*) ranges throughout the western United States; north into the western provinces of Canada; and east to Ohio, Michigan, and Ontario, Canada (Long 1972). It occurs from below sea level in Death Valley to the Arctic–Alpine Life Zone at about 3,600 meters AMSL (11,810 feet). Within California, the American badger occurs throughout the state except for the extreme northwestern coastal area (Zeiner *et al.* 1990B). The subspecies that occurs in the Project area, *T. t. berlandieri*, ranges into eastern California from about Lake Tahoe south throughout the Sierra Nevada and west to the Coast Ranges, including Baja California; east through Arizona, New Mexico, and southern Texas; and south into Mexico (Long 1972).

American badgers are generally associated with dry, open, treeless regions; prairies and grasslands; low-intensity agriculture (*e.g.*, pasture, dryland crops); drier open shrublands and forest; parklands; and cold desert areas (Long 1973; Zeiner *et al.* 1990B). American badgers are carnivores and feed on ground squirrels, cottontail rabbits, jackrabbits, small rodents, snakes, birds, insects, earthworms, eggs, and carrion (Errington 1937; Messick and Hornocker 1981; Snead and Hendrickson 1942; Zeiner *et al.* 1990B). They are fossorial (burrowing) and typically capture prey by digging them out of their burrows.

Adult American badgers are primarily nocturnal (*e.g.*, Lindzey 1978; Sargeant and Warner 1972), but juveniles appear to be active during the day, especially during dispersal from June through August (Messick and Hornocker 1981). Daily activity varies by season. American badgers often remain in their diurnal dens for days or weeks in torpor (not true hibernation) during the winter, but they may be active on warm winter days (Messick and Hornocker 1981; Wilson and Ruff 1999).

Birth of one to five offspring typically occurs in late winter and early spring (Lindzey 1978; Messick and Hornocker 1981), and young remain in the natal den for about six weeks (Wilson and Ruff 1999). Messick and Hornocker (1981) observed that most, but not all, juveniles dispersed from their natal area in southwestern Idaho. Juveniles emerged from natal dens in early May and family breakup occurred in late May and early June, with dispersal occurring at three to four months of age (June through July). Juveniles appear capable of dispersing up to 110 kilometers (68 miles). Juveniles use marginal and disturbed habitat and farmland during dispersal, which probably puts them at higher risk of mortality.

American badger home ranges are large and range from 240 hectares (593 acres) to 850 hectares (2,100 acres) (Lindzey 1978; Long 1973; Messick and Hornocker 1981; Minta 1993; Sargeant and Warner 1972). Home range is probably a function of food resource availability, social structure, and season. Aside from temporary family groups and transient mating bonds, and

despite overlapping home ranges, American badgers are mostly solitary animals (Davis 1946; Messick and Hornocker 1981; Minta 1993). Population densities of American badgers range from approximately two to six American badgers per square kilometer (*e.g.*, Messick and Hornocker 1981).

In addition to habitat loss and fragmentation, American badgers are vulnerable to vehicle collisions (especially during breeding and dispersal activities when individuals are moving longer distances) and accidental poisoning (Messick and Hornocker 1981). Other potential threats to the badger related to increasing urbanization include increased human activity and potential harassment by humans and pet, stray, and feral dogs, increased nighttime lighting which could affect their nocturnal activities, and the use of rodenticides that could result in reduction of their rodent prey base, in addition to accidental poisoning.

Survey Results

The American badger, although not common on site, has been documented three times in the Project area through systematic surveys and anecdotal observations of American badger dens and tracks: in the Specific Plan area (Impact Sciences 2005), at Potrero Creek in the Specific Plan area (Behrends 2006), and in the High Country SMA (Dudek and Associates 2006B).

The American badger is assumed to potentially occur in suitable habitat throughout the Project area because of documented occurrences on site and because of its large home ranges (Lindzey 1978; Long 1973; Messick and Hornocker 1981; Minta 1993; Sargeant and Warner 1972) and ability to disperse long distances (Messick and Hornocker 1981). Suitable habitats for the American badger on site are agriculture, alluvial scrub, big sagebrush scrub, California sagebrush scrub associations, big sagebrush–California buckwheat, California annual grassland, purple needlegrass, valley oak/grass, and river wash. A total of 9,131 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 216 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 2.4% of these habitats on site (**Figure 4.5-125**, Alternative 2 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat). A total of 123 acres would be temporarily impacted.

Drainages such as Potrero Creek that are subject to RMDP impacts are particularly likely to support badger dens. Although the American badger is highly mobile and can use a variety of upland habitats, because this species is uncommon, even a small loss of potential den habitat would be a substantial adverse effect on this species. Therefore, loss of habitat and temporary impacts as a result of construction/grading activities associated with the RMDP would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 3,780 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 41.4% of the habitat on site (**Figure 4.5-125**, Alternative 2 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat).

A relatively large amount and percentage of on-site habitats for the American badger would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from approximately 41.4% of suitable habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,995 acres (43.8%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of the American badger on site, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Adult American badgers are highly mobile and probably could escape from construction and/or grading activities of the RMDP. However, the proposed Project could result in mortality of young in a natal den and potentially the mother, which fiercely defends the natal den. Implementation of the SCP would not directly impact this species. Because individuals, particularly young, could be injured or killed during construction and/or grading activities, any loss of individuals would have a substantial adverse effect on a special-status species (significance criterion 1). If this occurred, direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is similar to that described above for direct permanent impacts to individuals in that breeding females and/or their young could be injured or killed during construction and/or grading activities. This risk is greater for the build-out of the Specific Plan, VCC, and Entrada planning areas than for the implementation of the RMDP and the SCP because of the much larger area of impact to suitable habitat. Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would have the potential to affect American badgers in areas adjacent to construction zones. These impacts could include short-term disruptions to essential behavioral activities (*e.g.*, foraging, breeding, and rearing of young) as a result of increased human activity noise, vibration, and nighttime illumination, and therefore could have a substantial adverse effect on a special-status species (significance criterion 1).

Potential long-term–development-related secondary impacts associated with use of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas include habitat fragmentation; increased risk of vehicle collisions as a result of new roads and increased traffic volumes on existing roads (*e.g.*, SR-126); nighttime illumination; increased human activity and potential harassment by humans and pet, stray, and feral dogs; and the use of rodenticides that could result in accidental poisoning and reduction of the rodent prey base for American badgers. These secondary impacts would permanently reduce the number of American badgers that may occur along the urban–open space edge, would interfere with the movement of American badgers in the Project vicinity, and would contribute to the reduction of the range and distribution of the American badger in the Project area (significance criteria 1, 4, and 7).

Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to suitable habitat for the American badger (**Figures 4.5-126** through **4.5-130**, Alternatives 3 through 7 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat):

- Alternative 3 – 195 acres (2.1%) of permanent loss and 160 acres of temporary loss;
- Alternative 4 – 186 acres (2.0%) of permanent loss and 162 acres of temporary loss;
- Alternative 5 – 223 acres (2.4%) of permanent loss and 156 acres of temporary loss;
- Alternative 6 – 209 acres (2.3%) of permanent loss and 161 acres of temporary loss; and
- Alternative 7 – 94 acres (1.0%) of permanent loss and 411 acres of temporary loss.

Compared to Alternative 2, which would result in 216 acres (2.4%) of permanent loss and 123 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 and 4 would be somewhat less overall and the permanent loss of habitat under Alternatives 5 and 6 would not be substantially different from Alternative 2. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be somewhat more overall. The difference between Alternative 7 and Alternative 2 impacts is primarily due

to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts under that alternative.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, and even the small loss of potential den habitat would be an adverse effect on this species, direct impacts to habitat resulting from implementation of the RMDP would be significant, absent mitigation for Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to suitable habitat for the American badger (**Figures 4.5-126** through **4.5-130**, Alternatives 3 through 7 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat):

- Alternative 3 – 3,569 acres (39.1%) of permanent loss;
- Alternative 4 – 3,436 acres (37.6%) of permanent loss;
- Alternative 5 – 3,350 acres (36.7%) of permanent loss;
- Alternative 6 – 2,967 acres (32.5%) of permanent loss; and
- Alternative 7 – 2,537 acres (27.8%) of permanent loss.

Compared to Alternative 2, which would result in 3,780 acres (41.4%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that reduce impacts to American badger under Alternative 7 compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the American badger occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the American badger:

- Alternative 3 – 3,764 acres (41.2%) of permanent loss;
- Alternative 4 – 3,623 acres (39.7%) of permanent loss;
- Alternative 5 – 3,573 acres (39.1%) of permanent loss;
- Alternative 6 – 3,178 acres (34.8%) of permanent loss; and
- Alternative 7 – 2,630 acres (28.8%) of permanent loss.

Compared to Alternative 2, which would result in 3,995 acres (43.8%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7. Reduced impacts would also occur because there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River (and its tributaries) and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for the American badger occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial and therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual American badgers as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than the potential for impacts to individual American badgers for Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual American badgers occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 (increased human activity, noise, vibration, and lighting) because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as increased human activity, habitat fragmentation, traffic collisions, lighting, and rodenticides. The loss or degradation of suitable habitat and impacts to individual American badgers due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to American badger: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur if natal dens are disturbed during construction, including direct destruction of dens from vegetation clearing and grading that could result in injury or mortality of individuals from direct contact with equipment or entombment or as result of behavioral disturbances due to increased human activity, noise, ground vibration, and lighting. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys within the proposed disturbance area will be conducted to identify and relocate American badgers. Natal dens will be protected by prohibiting construction within 100 feet of the disturbance zone until young are no longer dependent on the natal den. Biological monitoring will be conducted during initial vegetation clearing and grading and during periods when construction activities will occur near occupied natal dens to ensure that no impacts to the natal dens occur.

The combined permanent loss of suitable habitat for the American badger resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,630 acres (28.8%) under Alternative 7 to 3,995 acres (43.8%) under Alternative 2. This would be a substantial loss of suitable habitat and will reduce the size and distribution of the American badger population in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable habitat to support the American badger in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 3,540 acres of suitable habitat for this species. This open space will be conserved

in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, American badgers occupying habitat in close proximity to construction zones may be disturbed by construction activities, including increased human activity, noise, ground vibration, and lighting which may alter their behavioral patterns and reduce reproductive success. Females with young may become agitated and attempt to defend the natal den. The pre-construction surveys, protection of natal dens with young, and biological monitoring during vegetation clearing and grading, as well as controls on lighting, will help reduce these construction-related impacts. Potential long-term effects of development include habitat fragmentation, increased human activity, pet, stray, and feral dogs, lighting, and use of rodenticides. The large open space system will provide adequate protected open space that will in part offset these impacts. Several specific mitigation measures will also be implemented to control human activities in open space areas, including restrictions on recreational activities and homeowner education. Pet, stray, and feral dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting will be downcast away from open space areas. Rodenticides will be controlled through an integrated pest management (IPM) plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

All specific mitigation measures for American badger are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-102 IMPACTS TO INDIVIDUALS – AMERICAN BADGER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified two mitigation measures that will avoid, minimize, or mitigate impacts to American badger individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends three additional mitigation measures to reduce impacts to American badger individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-41 requires pre-construction surveys for the American badger. If American badgers are present, occupied habitat shall be flagged and ground-disturbing activities avoided within 50 feet of the occupied den. Occupied maternity dens shall be avoided during the pup-rearing season (February 15 through July 1) and a minimum 200-foot buffer shall be established. This buffer may be reduced upon consultation with CDFG. Maternity dens shall be flagged for avoidance and identified on construction maps. A qualified biologist shall be present. If avoidance of a non-maternity den is not feasible, badgers shall be relocated by trapping or excavation before or after the pup-rearing season. A written report documenting the badger removal shall be provided to CDFG within 30 days of relocation.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to American badger individuals would be avoided and minimized to the extent feasible, and thus would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-103 LOSS OF HABITAT – AMERICAN BADGER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will mitigate the loss of habitat for the American badger. These mitigation measures primarily relate to habitat protection, restoration, and management in the River Corridor SMA and High Country SMA. Although this species primarily uses grassland, agriculture, and scrub habitats; protection, restoration, and management of habitats in these areas will reduce impacts to this species.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 address habitat restoration in the River Corridor SMA and provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. The River Corridor SMA includes terrestrial and wash habitats that are used by the American badger. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the American badger that relate to habitat restoration in the River Corridor SMA, High Country SMA, and Salt Creek area and preservation of habitat in the Salt Creek area

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to

construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

These measures will minimize and mitigate impacts to the American badger by preserving a large amount of suitable habitat in the three interconnected preserve areas: the High Country SMA, Salt Creek area, and River Corridor SMA.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for American badger would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-104 SECONDARY IMPACTS – AMERICAN BADGER

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to the American badger, including short-term construction impacts (human activity, noise, vibration, lighting) and long-term effects due to factors such as habitat fragmentation, increased traffic volumes on existing roads (*e.g.*, SR-126), lighting, and increased human activity.

SP-4.6-53 and SP-4.6-59, as described above, will be implemented to mitigate impacts from increased short-term human activity associated with construction.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will mitigate for habitat fragmentation and increased long-term human activity through protection, restoration, enhancement, and management of habitat.

SP-4.6-17, SP-4.6-20, SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.39, described below, will be implemented to protect against both potential short-term construction-related secondary impacts and long-term secondary impacts to American badger habitat associated with increased human activity and grazing.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-27 and SP-4.6-39 require removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

In addition, SP-4.6-29 through SP-4.6-32 will be implemented to mitigate for impacts related to increased human activity in the High Country SMA through limiting access to daytime use of the designated trail system, prohibiting pets (with the exception of horses on established trails), hunting, fishing, and motor or off-trail bike riding, and providing trail design guidelines to minimize impacts to native habitats.

SP-4.6-33 will be implemented to mitigate potential adverse edge effects by permitting construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 requires that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several mitigation measures that will address secondary effects such as increased human activity; potential harassment by humans and pet, stray, and feral dogs;

increased vehicle collisions; and the use of rodenticides that could result in accidental poisoning and reduction of the rodent prey base

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, refer to restoration and/or preservation of habitat in the River Corridor SMA and High Country SMA.

BIO-41, BIO-52, and BIO-58, as described above, refer to pre-construction surveys that would identify any American badger natal dens within 100 feet of construction zones and measures that will ensure that natal dens and the activities of breeding females are not affected.

In addition, BIO-63, BIO-69, and BIO-73, described below, will be implemented to mitigate for increased human activity and pet, stray, and feral dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-59 specifies that a wildlife movement corridor plan shall be prepared and implemented. The plan will include design criteria for road crossings and methods to encourage passage, such as lighting, bubblers, and vegetation planting. Road crossings will be designed to accommodate mountain lions and mule deer and will function for American badger as well. Signs shall be installed along roadways, indicating potential wildlife crossings where mountain lions and mule deer are likely to cross in order to reduce vehicle collisions for wildlife in general.

BIO-64 will be implemented to prevent secondary poisoning and requires preparation of an integrated pest management (IPM) plan controlling the use of rodenticides on site prior to the issuance of building permits.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to populations of the American badger and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

SAN DIEGO BLACK-TAILED JACKRABBIT (CSC)

Life History

The black-tailed jackrabbit (*Lepus californicus*) is widespread throughout the western United States, west from central Missouri and Arkansas, and ranges south into central Mexico (Hall 1981). It is absent only from the higher elevations of the Rocky Mountains, the Sierra Nevada, and the Cascades (Hall 1981). The subspecies San Diego black-tailed jackrabbit (*L. c. bennettii*), which is one of nine subspecies of black-tailed jackrabbit (Dunn *et al*. 1982), is confined to coastal southern California, with marginal records being Mt. Pinos in northeastern Ventura County, Arroyo Seco/Pasadena in Los Angeles County, and the San Felipe Valley and Jacumba in San Diego County (Hall 1981).

The black-tailed jackrabbit occupies many diverse habitats, but primarily is found in arid regions supporting short-grass habitats. Black-tailed jackrabbits are typically not found in high grass or dense brush where it is difficult for them to move freely, and the openness of open scrub habitat is probably preferred over dense chaparral. Black-tailed jackrabbits are common in grasslands that are overgrazed by cattle, and they are well adapted to using low-intensity agricultural habitats (Lechleitner 1959).

Black-tailed jackrabbits are considered generalist herbivores (Johnson and Anderson 1984). In semi-desert and desert rangelands in New Mexico, Nevada, and Idaho, for example, grasses and forbs are the largest components of their diet, with shrubs less important (Johnson and Anderson 1984; Hayden 1966; Wansi *et al.* 1992). However, their diet shifts between season, locations, years, and vegetation types, suggesting that jackrabbits are opportunistic foragers.

Typical dispersal distances may be relatively short, but black-tailed jackrabbits are capable of dispersing long distances. Most recorded dispersal distances are less than 0.25 mile, but a juvenile was observed to disperse 28 miles in 17 weeks (French *et al.* 1965). Most seasonal movements involve short distances and may be related to food availability (Bronson and Tiemeir 1959). Recorded home ranges of the black-tailed jackrabbit typically range from 16 to 300 hectares (49 to 346 acres) (Best 1996; French *et al.* 1965; Smith 1990).

Breeding by black-tailed jackrabbits can occur throughout the year, but shows stronger seasonality in some regions, with more northern latitudes exhibiting shorter, distinct seasons (Bronson and Tiemeir 1958; Feldhamer 1979; Wagner and Stoddart 1972). In Butte County, California, Lechleitner (1959) observed slight seasonality, and found reproductive males and young in every month of the year. Females in his study area were pregnant every month, but showed a peak pregnancy period from January to August. Young are not well-coordinated until they are two to three days old and keep close to the nest during this period (Best 1996).

The San Diego black-tailed jackrabbit is particularly sensitive to habitat fragmentation and isolation of populations. Because local populations fluctuate in relation to resources, it may disappear from a location when the size of the habitat patch declines to some critical point no longer large enough to sustain a population or the patch becomes too isolated from other occupied habitat for successful dispersal to the site. Other documented threats to jackrabbits related to urban development area vehicle collisions and pet, stray, and feral dogs (Lechleitner 1958). Inadvertent poisoning from rodenticides used to control pest rodents (*e.g.*, ground squirrels) in landscaped areas and golf courses is also a threat to the species.

Survey Results

Systematic surveys of the Project area have not been conducted, and the San Diego black-tailed jackrabbit has been only anecdotally observed. It was observed by Impact Sciences (2005) during mammal surveys; it has not been observed in several other general wildlife surveys, including those by Haglund and Baskin (2000) in the Santa Clara River corridor at I-5; by Dudek in the High Country SMA and Salt Creek area (Dudek and Associates 2006B), the VCC planning area (Dudek and Associates 2006D), and the Entrada planning area (Dudek and Associates 2006E); and by Compliance Biology (2006D) on the Castaic Mesa project site. The lack of observations of San Diego black-tailed jackrabbits indicates that this species is uncommon in the Project area. However, based on the Impact Sciences (2005) report of the subspecies in the Project area, it is assumed that the San Diego black-tailed jackrabbit potentially occurs in suitable habitat throughout the site. The lack of specification for locations in the Project area for the San Diego black-tailed jackrabbit in the Impact Sciences (2005) report is relatively unimportant because of the shifting nature of the species' habitat use of areas in relation to the abundance and distribution of resources (*e.g.*, Bronson and Tiemeir 1959; French *et al.* 1965; Johnson and Anderson 1984). For example, a high concentration of San Diego black-tailed jackrabbits in a particular area in 2004 when the Impact Sciences (2005) study was conducted may bear little relationship to San Diego black-tailed jackrabbit use of the Project area over a longer period of time or under different resource conditions.

Suitable habitat for the San Diego black-tailed jackrabbit in the Project area includes agriculture, alluvial scrub, big sagebrush scrub, California sagebrush scrub and associations, California sagebrush–black sage, California sagebrush–California buckwheat scrub, California sagebrush scrub–undifferentiated chaparral, California annual grassland, big sagebrush–California buckwheat, purple needlegrass, river wash, and valley oak/grass. A total of 9,131 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 216 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 2.4% of these habitats on site (**Figure 4.5-125**, Alternative 2 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat). A total of 123 acres would be directly temporarily impacted.

The San Diego black-tailed jackrabbit is still widespread and relatively common and forages and breeds in a broad variety of habitats that comprise more than 9,000 acres in the Project area. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 216 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,779 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 41.4% of the habitat on

site (**Figure 4.5-125**, Alternative 2 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat).

Although the San Diego black-tailed jackrabbit is still widespread and relatively common, a relatively large amount and percentage of on-site habitats for the San Diego black-tailed jackrabbit would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from approximately 41.4% of suitable habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,995 acres (43.8%). Because of the large amount and percentage of habitat loss, the combined direct and indirect permanent impacts to suitable habitat would have a substantial adverse effect on the distribution of the San Diego black-tailed jackrabbit on site, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Adult San Diego black-tailed jackrabbits are highly mobile and probably could escape from construction and/or grading activities. This species is adapted to shifting its habitat use in response to changing conditions, and adults should be relatively unaffected by construction activities. However, construction activities could result in destruction of natal sites (dens, burrows, and depressions), and mortality of young, which are not well coordinated for the first two or three days after birth and are dependent on the nest. Abandonment of the natal den by the mother could also result in the mortality of young. Implementation of the SCP would not directly impact this species. Because the black-tailed jackrabbit is uncommon on site, and individuals, particularly young, could be injured or killed during construction and/or grading activities, any loss of individuals would have a substantial adverse effect on a special-status species (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is similar to that described above for direct permanent and temporary impacts to individuals in that young could be injured or killed during construction and/or grading activities. This risk is greater for the build-out of the Specific Plan, VCC, and Entrada planning areas because of the much larger area of impact to suitable habitat. Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would have the potential to affect San Diego black-tailed jackrabbits in areas adjacent to construction zones. These impacts could include short-term disruptions to essential behavioral activities (*e.g.*, foraging, breeding, and rearing of young) as a result of increased human activity, noise, vibration, and nighttime illumination. Flushed adult females could abandon newborns, resulting in their mortality. Implementation of the SCP would not affect this species.

Potential long-term development-related secondary impacts associated with use of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas include habitat fragmentation and population isolation; increased risk of vehicle collisions as a result of new roads and increased traffic volumes on existing roads (*e.g.*, SR-126); nighttime illumination; increased human activity and potential harassment by humans and pet, stray, and feral cats and dogs; and the use of pesticides (including rodenticides), which could result in accidental poisoning. These secondary impacts would permanently reduce the number of San Diego black-tailed jackrabbits that may occur along the urban–open space edge, interfere with the movement of the species in the Project vicinity, and contribute to the reduction of the range and distribution of the species in the Project area (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the San Diego black-tailed jackrabbit (**Figures 4.5-126** through **4.5-130**, Alternatives 3 through 7 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat):

- Alternative 3 – 195 acres (2.1%) of permanent loss and 160 acres of temporary loss;
- Alternative 4 – 186 acres (2.0%) of permanent loss and 162 acres of temporary loss;
- Alternative 5 – 223 acres (2.4%) of permanent loss and 156 acres of temporary loss;
- Alternative 6 – 209 acres (2.3%) of permanent loss and 161 acres of temporary loss; and
- Alternative 7 – 94 acres (1.0%) of permanent loss and 411 acres of temporary loss.

Compared to Alternative 2, which would result in 216 acres (2.4%) of permanent loss and 123 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 and 4 would be somewhat less overall and the permanent loss of habitat under Alternatives 5 and 6 would not be substantially different. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be somewhat greater overall. The difference between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries and other changes to the Project footprint under Alternative 7 that would result in reduced permanent impacts and greater temporary impacts to suitable habitat for the San Diego black-tailed jackrabbit compared to the other alternatives.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, and because the San Diego black-tailed jackrabbit can use a variety of upland habitats in the Project area, the impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the San Diego black-tailed jackrabbit (**Figures 4.5-126** through **4.5-130**, Alternatives 3 through 7 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat):

- Alternative 3 – 3,568 acres (39.1%) of permanent loss;
- Alternative 4 – 3,436 acres (37.6%) of permanent loss;
- Alternative 5 – 3,350 acres (36.7%) of permanent loss;

- Alternative 6 – 2,967 acres (32.5%) of permanent loss; and
- Alternative 7 – 2,537 acres (27.8%) of permanent loss.

Compared to Alternative 2, which would result in 3,779 acres (41.4%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would result in reduced impacts to suitable habitat for the San Diego black-tailed jackrabbit compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large amount and percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the San Diego black-tailed jackrabbit occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the San Diego black-tailed jackrabbit:

- Alternative 3 – 3,764 acres (41.2%) of permanent loss;
- Alternative 4 – 3,623 acres (39.7%) of permanent loss;
- Alternative 5 – 3,573 acres (39.1%) of permanent loss;
- Alternative 6 – 3,176 acres (34.8%) of permanent loss; and
- Alternative 7 – 2,630 acres (28.8%) of permanent loss.

Compared to Alternative 2, which would result in 3,995 acres (43.8%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7. There would also be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7 and there would be additional pullbacks from the Santa Clara

River and its tributaries and other Project footprint reductions under Alternative 7 that would reduce impacts to suitable habitat for the San Diego black-tailed jackrabbit compared to the other alternatives.

Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for the San Diego black-tailed jackrabbit occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial and therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual San Diego black-tailed jackrabbits as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. The main risk to San Diego black-tailed jackrabbit individuals is mortality of newborns at natal sites (dens, burrows, or depressions) either as a result of direct destruction of the den or abandonment by the mother. Therefore, impacts to individual San Diego black-tailed jackrabbits occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction-related impacts (increased human activity, noise, vibration, lighting) and long-term effects due to factors such as increased human activity, increased incidence of traffic collisions, lighting, and rodenticides. Therefore, the loss or degradation of suitable habitat and the impacts to individual San Diego black-tailed jackrabbits due to short-term and long-term secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to the San Diego black-tailed jackrabbit: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur if natal dens are disturbed during construction, including direct destruction of dens from vegetation clearing and grading that could result in injury or mortality of young from direct contact with equipment or as a result of behavioral disturbances due to increased human activity, noise, ground vibration, and lighting. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys within the proposed disturbance area will be conducted to identify and relocate San Diego black-tailed jackrabbits. Biological monitoring will be conducted during initial vegetation clearing and grading.

The combined permanent loss of suitable habitat for the San Diego black-tailed jackrabbit resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from **2,630** acres (**28.8**%) under Alternative 7 to 3,995 acres (43.8%) under Alternative 2. This would be a substantial loss of suitable habitat and will reduce the size and distribution of the San Diego black-tailed jackrabbit population in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable habitat to support the San Diego black-tailed jackrabbit in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 3,540 acres of suitable habitat for this species. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With respect to secondary effects, San Diego black-tailed jackrabbits occupying habitat in close proximity to construction zones may be disturbed by construction activities, including increased human activity, noise, ground vibration, and lighting, which may alter their behavioral patterns and reduce reproductive success. Females with young may abandon the natal den, resulting in mortality of the young. The pre-construction surveys and biological monitoring during vegetation clearing and grading, as well as controls on lighting, will help reduce these construction-related impacts. Potential long-term effects of development include habitat fragmentation; increased human activity; pet, stray, and feral cats and dogs; lighting; and use of rodenticides. The large open space system will provide adequate protected open space that will in part offset these impacts. Several specific mitigation measures will also be implemented to control human activities in open space areas, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting will be downcast away from open space areas.

Rodenticides will be controlled through an integrated pest management (IPM) plan. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

All specific mitigation measures for the San Diego black-tailed jackrabbit are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-105 IMPACTS TO INDIVIDUALS – SAN DIEGO BLACK-TAILED JACKRABBIT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified two mitigation measures that will avoid, minimize, or mitigate impacts to San Diego black-tailed jackrabbit individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to San Diego black-tailed jackrabbit individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with the contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-58 requires a survey within the proposed disturbance area to identify, flush, capture, and relocate San Diego black-tailed jackrabbits 30 days prior to construction in suitable habitats. If San Diego black-tailed jackrabbits are present, non-breeding rabbits would be flushed from areas to be disturbed. Dens, depressions, nests, or burrows occupied by pups shall be flagged, and

ground-disturbing activities shall be avoided within a minimum of 200 feet during the pup rearing season (February 15 through July 1). This buffer may be reduced based on the location of the den upon consultation with CDFG. Occupied maternity dens, depressions, nests, or burrows shall be flagged for avoidance and a biological monitor shall be present during construction. If unattended young are discovered, they shall be relocated to suitable habitat by a qualified biologist. The applicant shall document all San Diego black-tailed jackrabbit identified, flushed, avoided, or moved and provide a written report to CDFG within 72 hours. Capture and relocation of animals shall only be conducted by biologists with the proper scientific collection and handling permits.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to San Diego black-tailed jackrabbit individuals will be avoided and minimized to the extent feasible, and thus would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-106 LOSS OF HABITAT – SAN DIEGO BLACK-TAILED JACKRABBIT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will mitigate the loss of habitat for the San Diego black-tailed jackrabbit. These mitigation measures primarily relate to habitat protection, restoration, and management in the River Corridor SMA and High Country SMA. Although this species primarily uses grassland, agriculture, and scrub habitats, protection, restoration, and management of habitats in these areas will reduce impacts to this species.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 address habitat restoration in the River Corridor SMA and provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. The River Corridor SMA includes terrestrial and wash habitats that are used by the San Diego black-tailed jackrabbit. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes,

other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the San Diego black-tailed jackrabbit that relate to habitat restoration in the River Corridor SMA, High Country SMA, and Salt Creek area and preservation of habitat in the Salt Creek area.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

These measures will minimize and mitigate impacts to the San Diego black-tailed jackrabbit by preserving a large amount of suitable habitat in the three interconnected preserve areas: the High Country SMA, Salt Creek area, and River Corridor SMA.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for San Diego black-tailed jackrabbit would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-107 SECONDARY IMPACTS – SAN DIEGO BLACK-TAILED JACKRABBIT

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to the San Diego black-tailed jackrabbit, including short-term construction-related impacts (human activity, noise, vibration, lighting) and long-term effects due to factors such as habitat fragmentation, increased traffic volumes on existing roads (*e.g.*, SR-126), nighttime lighting, increased human activity, and rodenticides.

SP-4.6-53 and SP-4.6-59, as described above, will be implemented to mitigate impacts from increased short-term human activity associated with construction.

SP-4.6-1 through SP-4.6-16, SP-4.6-18, SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will mitigate for habitat fragmentation and increased long-term human activity through protection, restoration and enhancement, and management of habitat.

SP-4.6-17, SP-4.6-20, SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.39 will be implemented to protect against both potential short-term construction-related secondary impacts and long-term secondary impacts to San Diego black-tailed jackrabbit habitat associated with grazing and increased human activity.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-27 and SP-4.6-39 require removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

In addition, SP-4.6-29 through SP-4.6-32 will be implemented to mitigate for impacts related increased human activity in the High Country SMA through limiting access to daytime use of the designated trail system; prohibiting pets (with the exception of horses on established trails), hunting, fishing, and motor or off-trail bike riding; and providing trail design guidelines to minimize impacts to native habitats.

SP-4.6-33 will be implemented to mitigate potential adverse edge effects by permitting construction of buildings and other structures only on developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 requires that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that will address secondary effects, such as increased human activity; potential harassment by humans and pet, stray, and feral dogs; increased incidence of vehicle collisions; and the use of pesticides (including rodenticides), which could result in accidental poisoning.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, refer to restoration and/or preservation of habitat in the River Corridor SMA and High Country SMA.

BIO-52 and BIO-58, as described above, refer to pre-construction coordination and surveys that will avoid and minimize impacts to San Diego black-tailed jackrabbit.

In addition, BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-59 specifies that a wildlife movement corridor plan shall be prepared and implemented. The plan will include design criteria for road crossings and methods to encourage passage, such as lighting, bubblers, and vegetation planting. Road crossings will be designed to accommodate mountain lions and mule deer and will function for San Diego black-tailed jackrabbit as well. Signs shall be installed along roadways, indicating potential wildlife crossings where mountain lions and mule deer are likely to cross in order to reduce vehicle collisions for wildlife in general.

BIO-64 will be implemented to prevent poisoning and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to any populations of the San Diego black-tailed jackrabbit and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

MONARCH BUTTERFLY (WINTERING SITES) (CALIFORNIA SPECIAL ANIMAL)

Life History

The monarch butterfly (*Danaus plexippus*) follows a pattern of seasonal migration. The summer grounds of the species are found in New England, the Great Lakes region, and the northern Rocky Mountains; these areas are occupied from May through late August to mid-September (Urquhart 1987). The New England and Great Lakes populations migrate southwest to wintering grounds in the Sierra Madre mountain range of Mexico. The Rocky Mountains population migrates southwest to wintering grounds along the California coast.

The species' distribution is controlled by the distribution of its larval host plant (*i.e.*, various milkweeds, genus *Asclepias*). Eggs are deposited and hatch on the underside of leaves of the milkweed plant. Upon hatching, the larva will feed upon the fine hairs on the leaves of the plant and stay on the same plant throughout its molting stages. After molting, the larva will leave the milkweed and construct its chrysalis elsewhere. However, once an adult monarch butterfly emerges from the chrysalis, it will soon return to a milkweed plant for foraging and shelter (Urquhart 1987).

Monarch butterfly wintering sites are considered special status by CDFG. Wintering sites in California are associated with wind-protected groves of large trees (primarily eucalyptus or pine) with nectar and water sources nearby, generally near the coast. A few California sites (*e.g.*, Pacific Grove and Natural Bridges) support concentrated numbers of overwintering adults, but adults often winter as scattered individuals or in small clusters (Emmel and Emmel 1973). No wintering sites are known from the Santa Clarita Valley.

Sexually mature monarch butterflies mate along their northern migratory route (while returning to their summer grounds) and deposit eggs on milkweed plants. Adults die shortly after mating and laying eggs, leaving the completion of the northern migration to their offspring.

Existing and potential overwintering sites along the southern California coast supporting large eucalyptus and/or pine trees are important for the long-term survival of western United States monarch populations (Compliance Biology 2004A). When monarch butterflies are concentrated in wintering areas, the colony is particularly vulnerable to threats. In addition to the direct loss of tree groves used as wintering sites, wintering monarch butterflies are vulnerable to several effects related to construction activities and urbanization. Excessive fugitive dust, noise, and ground vibrations associated with construction activities near wintering grounds could disrupt wintering behavior and result in the abandonment of winter roost sites. Additionally, tree groves used as wintering sites could be subject to a higher fire risk from nearby development or to adverse affects from increased light and glare.

Survey Results

Focused surveys for monarch butterflies and their wintering sites have not been conducted on the RMDP site. However, focused surveys for San Emigdio blue butterfly were conducted throughout the RMDP site and the Entrada planning area in April and May 2004 and in Salt Creek Canyon (which is within the High Country SMA) and Potrero Canyon (which is in the Specific Plan area of the RMDP site) in April and May 2005 (Compliance Biology 2004A, 2004B, 2004C, 2005). These surveys included conducting an inventory of all butterfly species observed.

Individual monarch butterflies were observed during these surveys as well as during various other wildlife and plant surveys that have been conducted. However, due to the site's distance from the coast, it is unlikely that the Project area would be used by large numbers of overwintering adults (Compliance Biology 2004A). Milkweed plants present on the Project site may be used as oviposition sites by passing females while returning to summer grounds. Both California milkweed (*Asclepias californica*) and narrow-leaf milkweed (*Asclepias fascicularis*) have been observed on site. Because milkweed plants occur as an occasional component of various upland vegetation communities on site, potential habitat acreage was not calculated for this species.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Due to the Project area's distance from the coast, it is unlikely that it would be used by a large number of overwintering adults (Compliance Biology 2004A). Therefore, the occurrence of monarch butterflies in the Project area is expected to be limited to individual butterflies passing across the site during migration.

Vegetation clearing could result in the loss of milkweed plants, the host plants for monarch butterfly eggs or larvae. Milkweeds are widespread and are not considered

special status by CDFG. No wintering sites are expected to occur on the Project site. In addition, monarch butterfly populations in California appear to be stable (Compliance Biology 2004A). This impact would not result in a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species on site or rangewide (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

Due to the Project site's distance from the coast, it is unlikely that it would be used by a large number of overwintering adults (Compliance Biology 2004A). Therefore, the occurrence of monarch butterflies on the Project site is expected to be limited to individual butterflies passing across the site during migration.

The status of the monarch butterfly as a California Special Animal is associated with wintering sites (CDFG 2008C); wintering sites are not expected to occur on the Project site. As milkweeds are widespread and monarch butterfly populations appear to be stable (Compliance Biology 2004A), occurrences of the species host plant are not considered special status. Therefore, this impact would not result in a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species on site or rangewide (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas could result in the loss of milkweed plants, the host plants for monarch butterfly eggs or larvae. Milkweeds are widespread and are not considered special status by CDFG. No wintering sites are expected to occur on the Project site. In addition, monarch butterfly populations in California appear to be stable (Compliance Biology 2004A). This impact would not result in a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide;

threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species on site or rangewide (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Monarch butterflies are highly mobile, and it is not expected that construction activities associated with the implementation of the RMDP and the SCP would result in the loss of any adults of the species. However, female adult monarch butterflies could deposit eggs on milkweed plants on the Project site during their northern migration. These eggs and larvae would be susceptible to loss or harm during vegetation clearing.

Due to the Project site's distance from the coast, it is unlikely that it would be used by a large number of overwintering adults (Compliance Biology 2004A). Therefore, construction activities associated with the implementation of the RMDP and the SCP would not be expected to result in the loss of individual monarch butterflies at a wintering site. However, milkweed plants on the Project site could be removed during vegetation clearing, which could result in the loss of eggs and larvae. This impact would not have a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species on site or rangewide (significance criteria 1, 4, and 7). The loss of individual monarch butterflies occurring as a result of implementation of the RMDP and the SCP under Alternative 2 therefore would be adverse but not significant.

Indirect Permanent Impacts

As discussed above, monarch butterflies are highly mobile, and it is not expected that construction activities associated with the implementation of the build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of any adults of the species, or loss of a wintering site. However, female adult monarch butterflies could deposit eggs on milkweed plants on the Project site during their northern migration. These eggs and larvae would be susceptible to loss or harm during vegetation clearing. Milkweed plants on the Project site could be removed during vegetation clearing, which could result in the loss of eggs and larvae. This impact would not have a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of

the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species on site or rangewide (significance criteria 1, 4, and 7). The loss of individual monarch butterflies occurring as a result of implementation of the build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternative 2 therefore would be adverse but not significant.

Secondary Impacts

Due to the Project site's distance from the coast, it is unlikely that it would be used by a large number of overwintering adults (Compliance Biology 2004A). As wintering sites are not expected to occur, no secondary impacts to these sensitive habitats associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas are anticipated. Short-term impacts associated with the implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas, such as fugitive dust, could interfere with larval development on milkweeds. However, monarch butterfly populations are known to be stable statewide and larval host plant habitat is not considered to be special status by CDFG, given the widespread distribution of suitable plants. Because the occurrence of monarch butterflies on the Project site is expected to be limited to individual butterflies passing across the site during migration, long-term impacts associated with the proposed development are not anticipated to affect this species.

Short-term and long-term secondary impacts would not have a substantial adverse effect on the species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species on site or rangewide (significance criteria 1 and 7). Secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

The potential for loss of habitat for monarch butterfly as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Therefore, the loss of habitat for monarch butterfly occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Impacts to Individuals

The potential for loss of individual monarch butterflies as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Therefore, the loss of individual monarch butterflies occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Secondary Impacts

Secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activity effects, such as fugitive dust, which could interfere with larval development on milkweeds. Because the occurrence of monarch butterflies on the Project site is expected to be limited to individual butterflies passing across the site during migration, long-term impacts associated with the proposed development alternatives are not anticipated to affect this species. Therefore, the loss or degradation of suitable habitat and the loss of individual monarch butterflies due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Mitigation Strategy and Summary

This species would not be subject to significant direct, indirect, or secondary impacts from the proposed Project. Although no mitigation is required, the monarch butterfly will benefit from previously incorporated Mitigation Measures SP-4.6-53 and SP-4.6-59, which state that, at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

SAN EMIGDIO BLUE BUTTERFLY (CALIFORNIA SPECIAL ANIMAL)

Life History

The San Emigdio blue butterfly (*Plebulina emigdionis*) is restricted to southern California in lower Sonoran and riparian habitats from the Owens Valley south to the Mojave River, and west to northern Ventura and Los Angeles Counties. The primary location where this species has been collected is along the Mojave River near Victorville, but isolated colonies have been reported in Bouquet and Mint canyons near Castaic, in canyons along the north side of the San Gabriel Mountains near the desert's edge, and in arid areas south of Mount Abel near San Emigdio Mesa (Emmel and Emmel 1973; Murphy 1990). This butterfly can be locally abundant in association with its primary host plant, four-wing saltbush (*Atriplex canescens*), but has also been observed in association with quail brush (*A. lentiformis*) (Compliance Biology 2004C, 2005).

Although its primary host plant is widespread throughout the western United States, the distribution of the San Emigdio blue butterfly is much more localized, suggesting that other factors may determine habitat suitability (Murphy 1990). For example, habitat suitability may, at least in part, be attributed to a suspected symbiotic relationship with at least one ant species, *Formica pilicornis* (Ballmer and Pratt 1991). These ants presumably extract droplets containing glucose and amino acids from the nectary glands of San Emigdio blue butterfly larvae and provide the butterfly larvae protection from predators.

San Emigdio blue butterfly adults are active from late April to early September. The species can have up to three broods per year, with the first brood generally occurring in late April to May, the second brood in late June to early July, and the third brood in August to early September (Emmel and Emmel 1973). Adults are generally observed perching on their host plant or other plants in the immediate vicinity, and nectaring on nearby flowers.

The San Emigdio blue butterfly has a limited distribution and often occurs in small, isolated colonies. These characteristics make colonies vulnerable to direct and indirect habitat disturbance, given the limited extent of occupied habitat and limited potential for recolonization. Many colonies in the Mojave Desert and Owens Valley are isolated from anthropogenic disturbances, but other colonies found closer to growing urban areas may be situated near major roads, railroad tracks, and other developments, which may contribute to further decline (Compliance Biology 2005).

Survey Results

Focused surveys for San Emigdio blue butterfly were conducted throughout the Specific Plan and Entrada planning areas in April and May 2004 and in Salt Creek Canyon (which is within the High Country SMA) and Potrero Canyon (which is in the Specific Plan area) in April and

May 2005 (Compliance Biology 2004A, 2004B, 2004C, 2005). The primary objectives of the surveys were to determine the presence or absence of San Emigdio blue butterfly, to identify the locations of any colonies present, and to identify all areas containing potentially suitable habitat (*i.e.*, adequately sized clusters of the host plant). A general butterfly inventory was also conducted. Collectively, the surveys included all areas of potentially suitable habitat in the Specific Plan and Entrada planning areas as well as a small portion of the High Country SMA.

During the 2004 surveys, San Emigdio blue butterfly was documented within the Specific Plan area in the west-central edge of Potrero Canyon (**Figure 4.5-132**, Potrero Canyon San Emigdio Blue Butterfly, and **Figure 4.5-6**, RMDP/SCP—Special-Status Wildlife Species Occurrences) (Compliance Biology 2004C). During the 2005 surveys, five adult San Emigdio blue butterflies were again observed at this location. One San Emigdio blue butterfly was also observed in the High Country SMA at the northwestern edge of Salt Creek Canyon during the 2005 surveys (**Figure 4.5-6**) (Compliance Biology 2005).

The butterfly surveys described above identified patches of quail brush that were observed within San Martinez Grande Canyon on the north side of SR-126 in 2004 and within Salt Creek Canyon in the High Country SMA in 2005.

Focused surveys for San Emigdio blue butterfly have not been conducted within the VCC planning area. Both four-wing saltbush and quail brush have been observed within the VCC planning area, but their occurrence was restricted to individual plants or small clusters of plants (Miller 2007). However, because neither a focused habitat evaluation nor focused surveys for San Emigdio blue butterfly have been conducted within the VCC planning area, the potential for the species to occur there cannot be ruled out.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Colonies of San Emigdio blue butterfly are dependent on the presence of the host plants and, potentially, other environmental factors (*e.g.*, the presence of the ant *Formica pilicornis*). While the species' primary host plant is four-wing saltbush, it occurs in association with quail brush on the Project site. Vegetation clearing associated with construction of RMDP facilities would result in the removal of quail brush plants associated with the colony that occurs outside the Potrero Preserve Area and fence construction could result in the removal of quail brush plants around the Potrero Preserve Area in accordance with the SCP (**Figure 4.5-133**, Alternative 2 Impacts to Potrero Canyon San Emigdio Blue Butterfly). The extent of quail brush within or immediately adjacent to Salt Creek Canyon wash could expand and potentially provide suitable habitat for the San Emigdio blue butterfly in future years. While Salt Creek Canyon is within the High Country SMA and will be protected in perpetuity by a conservation easement, some bank stabilization would occur along portions of Salt Creek Canyon wash through implementation of the RMDP that could result in the loss of potential habitat.

Given that only one San Emigdio blue butterfly colony is known to occur on the site, the loss of habitat at the one known colony on site would have a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of a native wildlife nursery site; substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species on site or rangewide (significance criteria 1, 4, and 7). The loss would be mitigated in part through replacement of quail brush within the colony at a 1.5:1 ratio. That portion of the San Emigdio blue butterfly habitat within the Potrero Preserve Area and the adjacent Open Area, and the potential habitat in Salt Creek Canyon, would be monitored and managed as described below. Even with replacement, preservation, and management as proposed, direct permanent and temporary impacts (Loss of Habitat) would be significant and unavoidable.

Indirect Permanent Impacts

Vegetation clearing associated with build-out of the Specific Plan area would result in the removal of quail brush plants associated with the colony that occurs outside the Potrero Preserve Area (**Figure 4.5-133**, Alternative 2 Impacts to Potrero Canyon San Emigdio Blue Butterfly). The remainder of the San Emigdio blue butterfly colony not impacted by the RMDP or Specific Plan area build-out is located within a designated Open Area

and partially within the proposed Potrero Preserve Area. Patches of quail brush of adequate size to support San Emigdio blue butterfly were identified in San Martinez Grande Canyon in areas that would be impacted, but no butterflies were observed at these locations during the 2004 surveys. No other patches of quail brush of adequate size to support San Emigdio blue butterfly were identified during these surveys (Compliance Biology 2004A, 2004B, 2004C).

Quail brush plants would be removed from portions of the Project site, but these areas were not found to support the San Emigdio blue butterfly (Compliance Biology 2004A, 2004B, 2004C, 2005). Additionally, areas of potentially suitable habitat would be preserved in the Salt Creek area within the High Country SMA. Given that only one San Emigdio blue butterfly colony is known to occur on the site, the loss of habitat at the one known colony on site could have a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of a native wildlife nursery site; substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species on site or rangewide (significance criteria 1, 4, and 7). The loss would be mitigated in part through replacement of quail brush within the colony at a 1.5:1 ratio. That portion of the San Emigdio blue butterfly habitat within the Potrero Preserve Area and the adjacent Open Area, and the potential habitat in Salt Creek Canyon, would be monitored and managed as described below. Even with replacement, preservation and management as proposed, direct permanent and temporary impacts (Loss of Habitat) would be significant and unavoidable.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas could result in the loss of quail brush plants, the host plants for San Emigdio blue butterfly eggs or larvae. Given that only one San Emigdio blue butterfly colony is known to occur on the site, the loss of habitat at the one known colony on site could have a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of a native wildlife nursery site; substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species on site or rangewide (significance criteria 1, 4, and 7). The loss would be mitigated in part through replacement of quail brush within the colony at a 1:5:1 ratio. That portion of the San Emigdio blue butterfly habitat within the Potrero Preserve Area and the adjacent Open Area, and the potential habitat in Salt Creek Canyon, would be monitored and managed

as described below. Even with replacement, preservation and management as proposed, the combined direct and indirect permanent impacts (Loss of Habitat) would be significant and unavoidable.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Construction and vegetation clearing activities associated with the implementation of the RMDP and the SCP would result in the loss of San Emigdio blue butterfly adults, eggs, or larvae occurring on quail brush plants (**Figure 4.5-133**, Alternative 2 Impacts to Potrero Canyon San Emigdio Blue Butterfly). Given that only one San Emigdio blue butterfly colony is known to occur on the site, the potential direct loss of eggs and larvae could have a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of a native wildlife nursery site; substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species on site or rangewide (significance criteria 1, 4, and 7). The loss would be mitigated in part through limiting the removal of quail brush plants from the San Emigdio blue butterfly colony in Potrero Canyon to periods when eggs and larvae are not present, and through replacement of quail brush within the colony at a 1:5:1 ratio. That portion of the San Emigdio blue butterfly habitat within the Potrero Preserve Area and the adjacent Open Area, and the potential habitat in Salt Creek Canyon, would be monitored and managed as described below. Even with avoidance, replacement, preservation, and management as proposed, the loss of individual San Emidgio blue butterflies occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternative 2 would be significant and unavoidable, absent further mitigation.

Indirect Permanent Impacts

Construction and vegetation clearing activities associated with the implementation of the build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of San Emigdio blue butterfly adults, eggs, or larvae occurring on quail brush plants (**Figure 4.5-133**, Alternative 2 Impacts to Potrero Canyon San Emigdio Blue Butterfly). Given that only one San Emigdio blue butterfly colony is known to occur on the site, the potential indirect loss of eggs and larvae could have a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of a native wildlife nursery site; substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number

or restrict the range of the species on site or rangewide (significance criteria 1, 4, and 7). The loss would be mitigated in part through limiting the removal of quail brush plants from the San Emigdio blue butterfly colony in Potrero Canyon to periods when eggs and larvae are not present, and through replacement of quail brush within the colony at a 1:5:1 ratio. That portion of the San Emigdio blue butterfly habitat within the Potrero Preserve Area and the adjacent Open Area, and the potential habitat in Salt Creek Canyon, would be monitored and managed as described below. Even with avoidance, replacement, preservation, and management as proposed, the loss of individual San Emidgio blue butterflies occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternative 2 would be significant and unavoidable.

Secondary Impacts

Secondary impacts to the San Emigdio blue butterfly colony could result from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas. Short-term construction-related secondary impacts include vegetation clearing, trampling, exposure to fugitive dust, contact with polluted runoff, and changes in hydrology. Long-term secondary impacts include intrusion by non-native species, human disturbance, increased fire frequency, isolation of the San Emigdio blue butterfly colony, and use of the proposed road. Therefore, secondary impacts associated with the proposed Project could have a substantial adverse effect on the species; interfere substantially with the movement of the species or impede the use of a native wildlife nursery site; substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species on site or rangewide (significance criteria 1, 4, and 7). These secondary impacts would be mitigated in part through avoidance measures and management and monitoring of Open Space areas, the spineflower Potrero Preserve, and the High Country SMA. Even with avoidance, preservation and management as proposed, secondary impacts of Alternative 2 associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would be significant and unavoidable.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

The loss of habitat for San Emigdio blue butterfly as a result of implementation of the RMDP under Alternatives 3 through 7 would be somewhat less compared to Alternative 2. These differences are primarily due to the avoidance of impacts to the Potrero Canyon drainage compared to Alternative 2 (**Figures 4.5-134** through **4.5-138,** Alternatives 3

through 7 Impacts to Potrero Canyon San Emigdio Blue Butterfly). These differences are related to the construction of grade control structures and the placement of buried bank stabilization within and adjacent to lower Potrero Canyon Creek, which would be limited to the eastern edge of the butterfly colony. Alternatives 3 and 4 only remove butterfly habitat as a result of the construction of grade control structures. Alternatives 5, 6, and 7 have habitat impacts due to buried bank stabilization as well. Vegetation clearing associated with construction of RMDP facilities and fence construction around the Potrero Preserve Area in accordance with the SCP would result in the removal of quail brush plants associated with the colony that occurs outside the spineflower preserve boundary, but these impacts would be reduced compared to Alternative 2.

Therefore, the direct loss of habitat for San Emigdio blue butterfly occurring as a result of implementation of the RMDP and the SCP and Specific Plan build-out under Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

The loss of habitat for San Emigdio blue butterfly as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 6 would be somewhat less compared to Alternative 2. These differences are primarily due to the successively reduced footprints of Alternatives 3 through 7 (**Figures 4.5-134** through **4.5-138,** Alternatives 3 through 7 Impacts to Potrero Canyon San Emigdio Blue Butterfly). Under Alternatives 5 and 6, vegetation clearing associated with Specific Plan build-out would result in the removal of quail brush plants associated with the colony that occurs outside the spineflower preserve boundary, but these combined direct and indirect impacts would be reduced compared to Alternative 2. Under Alternatives 3, 4, and 7, build-out of the Specific Plan would not result in indirect loss of habitat for San Emigdio blue butterfly.

Therefore, the indirect loss of habitat for San Emigdio blue butterfly occurring as a result of implementation of the RMDP and the SCP and Specific Plan build-out under Alternatives 5 and 6 would be significant, absent mitigation. Under Alternatives 3, 4, and 7, Specific Plan build out would not result in the loss of habitat and therefore no impacts are expected to occur.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas would result in the loss of habitat for San Emigdio blue butterfly under Alternatives 3 through 7. These impacts would be reduced compared to Alternative 2. These differences are related to the construction of grade control structures and the placement of

buried bank stabilization within and adjacent to lower Potrero Canyon Creek, which would be limited to the eastern edge of the butterfly colony. Alternatives 3 and 4 only remove butterfly habitat as a result of the construction of grade control structures. Alternatives 5, 6, and 7 have habitat impacts due to buried bank stabilization as well. The combined direct and indirect permanent loss of habitat for San Emigdio blue butterfly occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Impacts to Individuals

The potential for loss of individual San Emigdio blue butterflies as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be somewhat less compared to Alternative 2. These differences are primarily due to the avoidance of impacts to the Potrero Canyon drainage compared to Alternative 2 (**Figures 4.5-134** through **4.5-138**, Alternatives 3 through 7 Impacts to Potrero Canyon San Emigdio Blue Butterfly). Construction and vegetation clearing activities would result in the loss of San Emigdio blue butterfly adults, eggs, or larvae occurring on quail brush plants, but these impacts would be reduced compared to Alternative 2.

Therefore, the loss of individual San Emigdio blue butterflies occurring as a result of implementation of the RMDP and the SCP, or build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be somewhat less compared to Alternative 2 due to the pullback of development from Potrero Canyon, although each alternative has similar short-term construction activity-related effects, such as vegetation clearing, trampling, exposure to fugitive dust, contact with polluted runoff, and changes in hydrology. Long-term secondary impacts include intrusion by non-native species, human disturbance, increased fire frequency, isolation of the San Emigdio blue butterfly colony, and use of the proposed road in Potrero Canyon (Alternatives 2, 5, and 6 only). Therefore, the loss or degradation of suitable habitat and the loss of individual San Emigdio blue butterflies due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to San Emigdio blue butterfly: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

The San Emigdio blue butterfly colony and associated habitat in Potrero Canyon will largely be preserved within the Potrero Preserve Area and the adjacent Open Area. The portion of the San Emigdio blue butterfly colony not impacted by the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only) and Entrada, is located within the Potrero Preserve Area and the adjacent Open Area. These areas would not be developed. However, vegetation removal from the colony could be required for construction of RMDP facilities RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only) and Entrada, and fence construction related to implementation of the SCP. Vegetation removal from the colony will only be permitted when eggs and larvae of the San Emigdio blue butterfly are not present. Any required removal of quail brush from the colony will be replaced at a 1:5:1 ratio. Additionally, Salt Creek Canyon is located within the High Country SMA; potentially suitable San Emigdio blue butterfly habitat occurs in this location. Further, the River Corridor SMA and High Country SMA will be protected and will continue to provide potentially suitable habitat for the San Emigdio blue butterfly. Additionally, 1,518 acres in the Salt Creek area will be protected and will continue to provide potentially suitable habitat for the San Emigdio blue butterfly.

Short-term secondary impacts, such as hydrologic and biogeochemical alterations, contact with pollutants, and exposure to fugitive dust will be avoided and minimized by providing erosion control plans, dust control plans, an overall Project SWPPP, and other BMPs. Long-term secondary impacts associated with intrusion by non-native species and human disturbance will be addressed by monitoring and management of the spineflower preserve; review of landscaping plans and inspection of plants proposed for planting near the preserve; restricting access to the spineflower preserve; and preparation of a landscaping plan composed of native or non-native, non-invasive plant species. While several of these mitigation measures apply directly to the spineflower preserve, by virtue of its adjacent location, the portion of the San Emigdio blue butterfly colony occurring outside the preserve boundary will also benefit from the measures. Secondary impacts associated with isolation of the San Emigdio blue butterfly colony will be further reduced by the preservation and management of the High Country SMA, River Corridor SMA, and Salt Creek area. These areas provide potentially suitable habitat for the San Emigdio blue butterfly and potential dispersal and movement routes to the north, south, east, and west. Secondary impacts associated with use of the proposed road will be addressed by the monitoring of the Potrero Canyon San Emigdio blue butterfly colony and the implementation of habitat creation/restoration measures should the population decline.

All specific mitigation measures for the San Emigdio blue butterfly are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-108 IMPACTS TO INDIVIDUALS – SAN EMIGDIO BLUE BUTTERFLY

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid, minimize, or mitigate the loss of San Emigdio blue butterfly individuals.

Measures Recommended by EIS/EIR

This EIS/EIR recommends one mitigation measure to reduce the loss of San Emigdio blue butterfly individuals.

BIO-65 limits the removal of quail brush plants from the San Emigdio blue butterfly habitat in Potrero Canyon to periods when eggs and larvae are not present.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to San Emigdio blue butterfly individuals under Alternative 2 will remain significant. Implementation of Alternative 2 creates significant unavoidable impacts.

After mitigation, impacts associated with the loss of San Emigdio blue butterfly individuals would be adverse but not significant for Alternatives 3, 4, 5, 6, and 7 because these alternatives would minimize impacts to the colony in Potrero Canyon.

IMPACT 4.5-109 LOSS OF HABITAT – SAN EMIGDIO BLUE BUTTERFLY

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that would mitigate the loss of habitat for the San Emigdio blue butterfly.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area mentioned below, these areas will form a large, interconnected open space system that provide potentially suitable habitat for the San Emigdio blue butterfly and potential dispersal and movement routes to the north, south, east, and west (**Figure 4.5-3**).

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the San Emigdio blue butterfly.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. In combination with the River Corridor SMA mentioned above, these areas will form a large, interconnected open space system that provide potentially suitable habitat for the San Emigdio blue butterfly and potential dispersal and movement routes to the north, south, east, and west.

BIO-66 requires that any quail brush plants removed from the San Emigdio blue butterfly habitat in Potrero Canyon be replaced at a minimum 1.5:1 ratio and planted contiguous to the existing colony quail brush plants.

BIO-67 states that prior to any construction activities occurring within 200 feet of the San Emigdio blue butterfly colony in Potrero Canyon, the boundaries of the colony shall be clearly marked with flagging. This will mitigate potential encroachment into the colony.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, loss of habitat for the San Emigdio blue butterfly under Alternative 2 will not be less than significant. Other potentially feasible mitigation measures might include minimizing impacts to the colony in Potrero Canyon, by implementation of Alternatives 3 through 7. Implementation of Alternative 2 creates significant unavoidable impacts, absent further mitigation.

After mitigation, impacts associated with the loss of habitat for the San Emigdio blue butterfly would be adverse but not significant for Alternatives 3, 4, 5, 6, and 7.

IMPACT 4.5-110 SECONDARY IMPACTS – SAN EMIGDIO BLUE BUTTERFLY

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that would mitigate for secondary impacts for the San Emigdio blue butterfly.

In order to mitigate impacts from exposure to fugitive dust, contact with polluted runoff, and changes in hydrology, the Newhall Ranch Specific Plan Program EIR identified SP-4.6-55 and

SP-4.6-58, which require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

In order to mitigate impacts from increased fire frequency, the Newhall Ranch Specific Plan Program EIR identified SP-4.6-33, SP-4.6-49 through SP-4.6-52, and SP-4.6-67, which require the creation and maintenance of fuel modification zones and buffer zones along the boundaries of the High Country SMA, Open Areas, and spineflower preserves.

In order to mitigate impacts from isolation of the colony and vehicle collisions, the Newhall Ranch Specific Plan Program EIR identified SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42, which are summarized above.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate secondary impacts to the San Emigdio blue butterfly from intrusion by non-native species, human disturbance, exposure to fugitive dust, contact with polluted runoff, hydrologic changes, increased fire risk, isolation of the colony, and operation of the proposed road.

In order to mitigate impacts from exposure to fugitive dust, contact with polluted runoff, and changes in hydrology, this EIS/EIR identifies the following mitigation measures.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

BIO-71 requires dust control measures for development areas to prevent dust from impacting vegetation communities and special-status plant and aquatic wildlife species. Dust control plans shall comply with SCAQMD Rule 403 (SCAQMD 2005) and chemical dust suppression shall not be used within 100 feet of known special-status plant communities.

In order to mitigate impacts from non-native plant and wildlife species, this EIS/EIR identifies BIO-72, which specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

In order to mitigate impacts from construction-related activities, this EIS/EIR identifies BIO-52, which states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractors describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

In addition, the following mitigation measures will be implemented:

BIO-24 specifies that the applicant's preserve manager(s) and/or natural lands management organization(s) (NLMO(s)) shall manage the spineflower preserves. The proposed preserve manager(s)/NLMO(s) shall be approved by the County and CDFG.

BIO-34 requires plant palettes proposed for use within 100 feet of a spineflower preserve to be reviewed by the spineflower preserve manager or qualified biologist to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants to be installed within 200 feet of the spineflower preserve shall be inspected by the spineflower preserve manager or qualified biologist for the presence of disease, weeds, and pests, including Argentine ants.

BIO-35 through BIO-37 provide guidelines for the installation of permanent fencing and signage for the spineflower preserves. All portions of the spineflower preserves shall be closed with the exception of pre-identified existing dirt roads and utility easements. Fencing shall be installed along the outside edge of the spineflower preserve and buffer areas, although specific areas adequately protected by steep terrain (1.5:1 or steeper) and/or dense vegetation may not require fencing but will require signage. Outdoor all-weather signs (12 by 16 inches) shall be posted on spineflower preserve access gates and adjacent to road crossings as well as along spineflower preserve fencing at 800-foot intervals.

In order to mitigate impacts from use of the proposed road, the EIS/EIR identifies BIO-79, which requires monitoring of the Potrero Canyon San Emigdio blue butterfly colony for five years after the completion of Potrero Canyon Road to evaluate whether operation of the road may be contributing to a population decline. Should it be determined that a population decline is occurring, a habitat creation plan shall be prepared that details the location and methods for habitat creation, success criteria, and measures to stabilize San Emigdio blue butterfly populations should habitat creation not succeed.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to San Emigdio blue butterfly under Alternative 2 will not be less than significant. Other potentially feasible mitigation measures might include minimizing impacts to the colony in Potrero Canyon, by implementation of Alternatives 3 through 7. Implementation of Alternative 2 creates significant unavoidable impacts, absent further mitigation.

After mitigation, short-term and long-term secondary impacts to San Emigdio blue butterfly would be adverse but not significant for Alternatives 3, 4, 5, 6, and 7.

COASTAL WESTERN WHIPTAIL (CALIFORNIA SPECIAL ANIMAL)

Life History

A moderate amount of information is known about the full species western whiptail (*Aspidoscelis tigris*), while less information is available about the subspecies coastal western whiptail (*A. t. stejnegeri*).[1] Therefore, much of the following discussion is based on the life history of the western whiptail, with expected similarities occurring in behaviors and habitat associations with the coastal western whiptail subspecies. The coastal western whiptail is found in coastal southern California, mostly west of the Peninsular Ranges and south of the Transverse Ranges; north into Ventura County; and south into Baja California, Mexico (Lowe *et al.* 1970; Stebbins 2003). The full species western whiptail ranges from north-central Oregon and southern Idaho; south through California and Nevada to Baja California, Mexico; and east into Utah and Arizona. The western whiptail is found at elevations from below sea level to around 2,130 meters (7,000 feet) AMSL (Stebbins 2003). In California the western whiptail is considered to be widely distributed but uncommon, except in desert regions where it is abundant in suitable habitat (Zeiner *et al.* 1988).

The western whiptail is found in a variety of habitats, primarily in areas where plants are sparse and where there are open areas for running. According to Stebbins (2003), the species ranges from deserts to montane pine forests where it prefers warmer and drier areas. The species is also found in woodland and streamside growth, and avoids dense grassland and thick shrub growth. The species is commonly found on the eastern and western slopes of the San Gabriel Mountains in all habitats except yellow pine forest (Schoenherr 1976). Schoenherr (1976) also indicates that the western whiptail probably occurs in oak woodlands.

The western whiptail is a diurnal, actively foraging lizard (Anderson 1993). Its prey include termites; scorpions; solfugids; cockroaches; antlion larvae; and various insect eggs, larvae, and pupae (Anderson 1993). Its daily activity period involves nearly continuous movement associated with foraging, with activity peaks in the morning and afternoon. Seasonal activity appears to vary with location. Pequegnat (1951), for example, observed that the most active periods for the western whiptail in the Santa Ana Mountains in Orange County occurred during early and late summer, and they were seldom detected during late June, July, and early August. Schoenherr (1976) observed that western whiptails in the San Gabriel Mountains first emerged during April and May, increased their activity until June, remained abundant and active all summer, and then reduced activity in September, with activity ceasing altogether in October.

[1] The full species *Aspidoscelis tigris* was formerly *Cnemidophorus tigris*, and the subspecies *A.t. stejnegeri* was formerly *C.t. multiscutatus*. The scientific name change is based on Reeder *et al.* (2002) and was subsequently adopted by CDFG for the Special Animals List (CDFG 2008C). Pre-2002 studies of the western whiptail used the old genus name *Cnemidophorus.*

In temperate zone populations, the reproductive season generally begins in May, but it occurs earlier in desert regions (Anderson and Karazov 1988). Western whiptails lay their eggs in the soil or underground (NatureServe 2007). Mean clutch size of the western whiptail varies from 2.1 to 4.0 (Garland 1993). Female body size is the major factor determining clutch and egg size. The length of the reproductive season appears to influence clutch frequency and is likely influenced by rainfall, temperature, reproductive resources, microenvironmental conditions for egg development, and adequate resources for hatchlings. Western whiptails may have two or three clutches per season in the southern part of their range (NatureServe 2007). Western whiptails probably are sexually mature at the end of their first year in the southern part of their range and in 20 to 23 months in the northern part of their range (NatureServe 2007).

Anderson (1993) reported home ranges in California of 2.5 acres (1.0 hectare) for males and 0.8 acre (0.3 hectare) for females. Individual home ranges overlap but are not defended (NatureServe 2007). There is no information available regarding dispersal, but the relatively large observed homes range for the species in California suggest that the western whiptail probably is mobile and capable of dispersing fairly long distances. However, it should be assumed that unsuitable habitat and physical barriers, such as wide roads, are limitations to dispersal.

Although the coastal western whiptail is still common and widespread within it range, habitat fragmentation and isolation of populations resulting from urban development constitute a long-term threat to this species because, like other small reptiles, the coastal western whiptail probably has limited ability to move through unsuitable habitat and across physical obstacles such as wide roads. Other potential threats related to urban development include an increase in the abundance of diurnal urban-related predators such as pet, stray, and feral cats and dogs (the whiptail's almost constant surface activity makes them highly detectable and particularly vulnerable to predators), habitat degradation (*e.g.*, trampling of vegetation and introduction of exotic species), increased roadkill, off-road vehicles, cattle grazing, and frequent fires that may cause long-term habitat transitions from shrublands (scrubs and chaparrals) to annual grassland (although fires that help maintain open areas probably are beneficial to this species).

Survey Results

Coastal western whiptails were observed in the High Country SMA (Dudek and Associates 2006B) and off site in Castaic Mesa (Compliance Biology 2006) during general wildlife surveys and habitat evaluations. Coastal western whiptails were not observed in the Specific Plan area during surveys for reptiles using pitfall traps conducted in 2004 and 2006 (Impact Sciences 2006A).

While coastal western whiptails were not trapped or otherwise observed during the pitfall trap surveys, the subspecies was identified as having potential to occur in the Project area (Impact Sciences 2006A). Because of observations in the High Country SMA and nearby locations

(Compliance Biology 2006; Dudek and Associates 2006B), the presence of suitable habitat, observance that the Project area is within the range of the subspecies as described by Stebbins (2003), and the fact that the entire Project area was not surveyed by Impact Sciences (2006A) at a level of detail necessary to determine presence or absence of a particular reptile species, the coastal western whiptail is assumed to be present in the Project area. Coastal western whiptails are assumed to be present in the following plant communities in the Project area: alluvial scrub, arrow weed scrub, big sagebrush scrub, coastal scrub alliances and associations, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, California annual grassland, big sagebrush–California buckwheat, California walnut woodland, coast live oak woodland, Mexican elderberry, *Eriodictyon* scrub, mixed oak woodland and forest, purple needlegrass, river wash, valley oak woodland, and valley oak/grass. A total of 10,734 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 140 acres of suitable habitat would be permanently lost through implementation of the RMDP, representing 1.3% of suitable habitat on site (**Figure 4.5-72,** Alternative 2 Impacts to General Wildlife Habitats). A total of 61 acres would be temporarily impacted. Activities associated with implementation of the SCP (*e.g.*, fence construction) could also result in a small loss of potential habitat for the coastal western whiptail, although this impact has not been quantified.

Although the coastal western whiptail is still a wide-ranging species, it has suffered habitat loss and fragmentation throughout much of its range. Therefore, the loss of habitat that would occur as a result of construction and/or grading activities would have a substantial adverse effect on coastal western whiptail (significance criterion 1). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 3,144 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 29.3% of suitable habitat on site (**Figure 4.5-72,** Alternative 2 Impacts to General Wildlife Habitats).

Although the coastal western whiptail is still a wide-ranging species, a relatively large amount and percentage of on-site habitat for the coastal western whiptail would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of coastal western whiptail on site by eliminating it from 29.3% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,283 acres (30.6%). Because of the large amount and percentage of habitat loss, the combined direct and indirect impacts to suitable habitat would have a substantial adverse effect on the distribution of the coastal western whiptail on site, thus substantially reducing its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Coastal western whiptails are mobile over short distances. However, those large-scale construction and/or grading activities associated with the RMDP causing permanent and temporary impacts likely would result in injury or mortality of individuals as a result of direct contact with or crushing by construction equipment used for vegetation clearing and grading. In addition, hibernating individuals could be injured or killed during construction and/or grading activities conducted during colder months by entombment or direct contact with grading equipment. Activities associated with implementation of the SCP (*e.g.*, fence construction) could also result in impacts to coastal western whiptail individuals if fence construction occurred during colder months when whiptails are hibernating. Coastal western whiptail probably is capable of escaping potential impacts from fence construction when it is active on the ground surface in the warmer months because ground disturbances would be much more localized.

Because of the loss and fragmentation of habitat throughout much of this species' range, impacts to coastal western whiptails that would occur as a result of construction and/or grading activities would have a substantial adverse effect on this species (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals, but over a much larger area. There is a potential for substantial mortality of coastal western whiptails during vegetation clearing, grading, and other construction-related activities. This potential loss of individuals would have a substantial adverse effect on coastal western whiptail on site by eliminating it from 29.3% of potentially occupied habitat, thus substantially reducing its number and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

In the short term, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would have the potential to affect coastal western whiptails in areas adjacent to construction zones. These impacts include construction-related dust, which could affect its prey; the inadvertent disturbance of habitat and loss of individual lizards in areas outside of the development footprint; and other disruptions associated with increased human activity. Although construction activities associated with RMDP facilities would be short term, would be phased over time, and would affect a relatively small proportion of potential habitat in the Project area, because of the general loss and fragmentation of habitat throughout its range, the construction activities would have a substantial adverse effect on the coastal western whiptail (significance criterion 1). Short-term secondary impacts would be significant, absent mitigation.

Long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas could also include habitat fragmentation and isolation of some local populations of coastal western whiptail, making the species more vulnerable to extirpation. In addition, over the long term, the close proximity of urban development to suitable coastal western whiptail habitat could result in disruption of essential behavioral activities (*e.g.*, foraging, reproduction) and greater vulnerability to several potential secondary impacts, including human-caused habitat degradation (*e.g.*, trampling of vegetation, introduction of invasive species, such as Argentine ants and off-road vehicles); harassment and collection; predation by pet, stray, and feral cats and dogs; increased incidence of roadkill; and use of pesticides, which may reduce its prey or cause secondary poisoning. These secondary impacts would permanently reduce coastal western whiptail populations along the urban–open space edge and would contribute to the reduction of

the range and distribution of the coastal western whiptail in the Project area (significance criteria 1 and 7). Long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the coastal western whiptail (**Figures 4.5-73** through **4.5-77,** Impacts to General Wildlife Habitats):

- Alternative 3 – 138 acres (1.3%) of permanent loss and 74 acres of temporary loss;
- Alternative 4 – 133 acres (1.2%) of permanent loss and 61 acres of temporary loss;
- Alternative 5 – 157 acres (1.5%) of permanent loss and 79 acres of temporary loss;
- Alternative 6 – 169 acres (1.6%) of permanent loss and 79 acres of temporary loss; and
- Alternative 7 – 73 acres (0.7%) of permanent loss and 151 acres of temporary loss.

Compared to Alternative 2, which would result in 140 acres (1.3%) of permanent loss and 61 acres of temporary impacts, the combined direct permanent and temporary loss of habitat under Alternative 3 would not be substantially different; under Alternatives 5, 6, and 7 it would be marginally to somewhat greater, and the combined direct permanent and temporary loss of habitat would be marginally less under Alternative 4. The difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and greater temporary impacts under that alternative.

The overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be similar in magnitude compared to Alternative 2 (ranging from 1.2% for Alternative 4 to 1.6% for Alternative 6, compared to 1.3% for Alternative 2), and somewhat less under Alternative 7. Because of habitat loss and fragmentation throughout this species' range, these impacts for Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the coastal western whiptail (**Figures 4.5-73** through **4.5-77,** Impacts to General Wildlife Habitats):

- Alternative 3 – 2,937 acres (27.4%) of permanent loss;
- Alternative 4 – 2,815 acres (26.2%) of permanent loss;
- Alternative 5 – 2,736 acres (25.5%) of permanent loss;
- Alternative 6 – 2,420 acres (22.5%) of permanent loss; and
- Alternative 7 – 2,127 acres (19.8%) of permanent loss.

Compared to Alternative 2, which would result in 3,144 acres (29.3%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that would reduce impacts to coastal western whiptail suitable habitat under Alternative 7 compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the coastal western whiptail occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the coastal western whiptail:

- Alternative 3 – 3,075 acres (28.6%) of permanent loss;
- Alternative 4 – 2,948 acres (27.5%) of permanent loss;
- Alternative 5 – 2,893 acres (27.0%) of permanent loss;

- Alternative 6 – 2,589 acres (24.1%) of permanent loss; and
- Alternative 7 – 2,199 acres (20.5%) of permanent loss.

Compared to Alternative 2, which would result in 3,283 acres (30.6%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the coastal western whiptail occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential impacts to individual coastal western whiptails to occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual coastal western whiptails occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as construction-related dust; human-caused habitat degradation; invasive species such as Argentine ants; harassment and collection; predation by pet, stray, and feral cats and dogs; increased incidence of roadkill; and use of pesticides. Short-term and long-term secondary impacts to coastal western whiptail resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to coastal western whiptail: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment, entombment of hibernating individuals, and increased exposure of individuals left without protective cover. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys within the proposed disturbance area will be conducted by a qualified biologist in possession of a scientific collecting permit to capture and relocate coastal western whiptails. General procedures to avoid and minimize impacts to coastal western whiptails during construction will be implemented and a qualified biologist would be present during construction in order to relocate any identified remaining individuals, further reducing impacts to the species.

The combined permanent loss of suitable habitat for the coastal western whiptail resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,199 acres (20.5%) under Alternative 7 to 3,283 acres (30.6%) under Alternative 2. This would be substantial loss of suitable habitat and will reduce the size and distribution of the coastal western whiptail population in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable habitat to support the coastal western whiptail in the Project vicinity. Implementation of these mitigation measures will result in protection, restoration and enhancement, and management of approximately 5,687 acres of suitable habitat for this species. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**). Restoration and enhancement of habitat used by the coastal western whiptail in these areas will improve habitat quality for the species and reduce impacts cause by the Project..

With respect to secondary effects, coastal western whiptails occupying habitat in close proximity to construction zones may be disturbed by construction activities, including increased human activity, noise, ground vibration, and dust. Biological monitoring during vegetation clearing and grading, as well as dust suppression measures, will help reduce these construction-related impacts. Potential long-term effects of development include habitat fragmentation; increased human activity, including habitat degradation; invasive species such as Argentine ant; pet, stray, and cats and feral dogs; vehicle collisions; and use of pesticides. The large open space system will provide adequate protected open space that will in part offset these impacts, especially habitat fragmentation and vehicle collisions. Several specific mitigation measures will also be

implemented to control human activities in open space areas, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. Pesticides will be controlled through an integrated pest management (IPM) plan. Argentine ant invasions of upland habitats in the open space system will be monitored and controlled to the extent feasible. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

All specific mitigation measures for coastal western whiptail are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-111 IMPACTS TO INDIVIDUALS – COASTAL WESTERN WHIPTAIL

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified two mitigation measures that will avoid, minimize, or mitigate the loss of coastal western whiptail individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to reduce impacts to coastal western whiptail individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-54 requires surveys to capture and relocate coast horned lizard, silvery legless lizard, coastal western whiptail, rosy boa, San Bernardino ringneck snake, and coast patch-nosed snake individuals 30 days prior to construction activities in suitable habitats.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to coastal western whiptail individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-112 LOSS OF HABITAT – COASTAL WESTERN WHIPTAIL

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the coastal western whiptail through protection, restoration and enhancement, and management of habitat. Although this species primarily uses scrub and chaparral habitats, protection, restoration and enhancement, and management of habitat in the River Corridor SMA will reduce impacts to this species.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. The River Corridor SMA includes terrestrial habitats that are used by coastal western whiptail, and these areas would benefit from restoration activities. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the coastal western whiptail through protection, restoration and enhancement, and management of habitat.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

The mitigation required by the Newhall Ranch Specific Plan Program EIR and the mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will conserve habitat for the coastal western whiptail in the Project vicinity. A total of 5,687 acres of potential habitat will be protected and managed, in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**). Therefore, after mitigation, the loss of habitat for the coastal western whiptail would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-113 SECONDARY IMPACTS – COASTAL WESTERN WHIPTAIL

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to the coastal western whiptail, including short-term construction activities and long-term effects due to factors such as human-caused habitat degradation**,** harassment and collection, and increased incidence of roadkill.

SP-4.6-53 and SP-4.6-59, as described above, will be implemented to mitigate impacts from increased short-term human activity associated with construction.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will be implemented to mitigate impacts from increased long-term human activity through protection, restoration and enhancement, and management of habitat.

SP-4.6-17, SP-4.6-20, SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-39 will be implemented to protect against both potential short-term construction-related secondary impacts and long-term secondary impacts to habitat and/or coastal western whiptail individuals associated with increased human activity and grazing.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian

and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-27 and SP-4.6-39 require removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-1 through SP-4.6-16, SP-4.6-17, SP-4.6-18, SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will be implemented to mitigate for impacts due to habitat fragmentation and potential isolation of populations.

In addition, SP-4.6-29 through SP-4.6-32 will be implemented to mitigate for impacts related to increased human activity in the High Country SMA through limiting access to daytime use of the designated trail system; prohibiting pets (with the exception of horses on established trails); prohibiting hunting, fishing, and motor or off-trail bike riding; and providing trail design guidelines to minimize impacts to native habitats.

SP-4.6-33 will be implemented to mitigate potential adverse edge effects by permitting construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures that address secondary effects such as construction-related dust; increased human activity; invasive species such as Argentine ant; predation by pet, stray, and feral cats and dogs; and pesticides, which may reduce prey or cause secondary poisoning.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, will be implemented to mitigate for impacts from increased human activity through habitat protection, restoration and enhancement, and management.

BIO-63, BIO-69, and BIO-73 also will be implemented to mitigate impacts related to increases in human activity:

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-64 requires preparation of an IPM plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-72, BIO-85, and BIO-87 will be implemented to reduce and control Argentine ants in open space areas.

BIO-72 specifies that container plants for use within 100 feet of the open space areas shall be inspected for pests, including Argentine ants. Plant palettes also will include non-invasive species that do not require high irrigation rates, which will help keep moisture levels low at the open space-urban interface. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to coastal western whiptail and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

ROSY BOA (CALIFORNIA SPECIAL ANIMAL)

Life History

The rosy boa (*Charina trivirgata*) occurs from southern California and southwestern Arizona; south throughout Baja California, Mexico and northwestern mainland Mexico; avoiding the lowest deserts, which are mainly in agricultural production, or open dunes (Stebbins 2003; Yingling 1982; Zeiner *et al.* 1988). The rosy boa in California ranges from Los Angeles, eastern Kern, and southern Inyo counties, and south through San Bernardino, Riverside, Orange, and Diego counties (Spiteri 1988; Stebbins 2003; Zeiner *et al.* 1988). The species occurs at elevations from sea level to 1,370 meters (5,000 feet) AMSL in the Peninsular and Transverse mountain ranges. Within its range in southern California, the rosy boa is absent only from the southeastern corner of California around the Salton Sea and the western and southern portions of Imperial County (Zeiner *et al.* 1988).

The rosy boa inhabits rocky shrubland and desert habitats, and is attracted to oases and streams, but does not require permanent water (Stebbins 2003). In coastal areas, the rosy boa occurs in rocky chaparral-covered hillsides and canyons, while in the desert it occurs on scrub flats with good cover (Zeiner *et al.* 1988). Holland and Goodman (1998) add that the species is known in a variety of desert and semi-desert habitats, and that it may occur in oak woodlands intergrading with scrub or chaparral habitats but is absent from grasslands. A majority of the specimens found on the Marine Corps Base, Camp Pendleton (San Diego County, California) were in coastal sage scrub, chaparral, or mixed habitats, but the species was also found in riparian areas (Holland and Goodman 1998). Yingling (1982) observed that the rosy boa occurs in chaparral and desert-edge foothills and, within these habitats, it appears to prefer moderate to dense vegetative cover with rocks. Holland and Goodman (1998) state that rock outcrops are commonly found in habitats used by the rosy boa and, according to Zeiner *et al.* (1988), the species has been found under rocks, in boulder piles, and along rock outcrops and vertical canyon walls. Additionally, woodrat (*Neotoma* sp.) nests are often used as refugia (Holland and Goodman 1998). The species is known to be a good climber (Stebbins 2003).

Rosy boas are primarily nocturnal but may be active at dusk and rarely in the daytime (Stebbins 2003). However, Holland and Goodman (1998) maintain that the species can be diurnally or nocturnally active, though diurnal excursions are often conducted during overcast days. Rosy boas are active between April and September (Holland and Goodman 1998). The rosy boa may aestivate in the hottest months and hibernate in the coolest months of the year, remaining inactive in burrows or under surface debris (NatureServe 2007).

There is little information on the foraging habits or prey species for the rosy boa. Holland and Goodman (1998) and Stebbins (2003) indicate that this species preys upon small mammals (including pocket mice (*Chaetodipus* and *Perognathus* spp.) and young woodrats), reptiles,

amphibians, and birds. Zeiner *et al.* (1988) notes that the species is known to eat lizards in captivity and may do so in the wild.

Little is known regarding rosy boa reproduction. Female rosy boas generally give birth to three to 14 young from October through November, and the young are live-born (Stebbins 2003). Available information regarding dispersal by the species is also limited. The only information available in the literature is a statement by Zeiner *et al.* (1988) that the rosy boa probably does not migrate.

The spatial behavior and movement ecology of the coastal rosy boa (*C. t. roseofusca*), which is the same subspecies that occurs in the Project vicinity, was studied using radiotelemetry by Diffendorfer *et al.* (2005) at four sites in San Diego and Riverside counties for up to four years. Movement (measured as estimated distance moved per day) was characterized by frequent short-distance movements and rare long-distance movement events that primarily occurred in the spring. Short-distance movements per day were predominantly less than 10 meters (33 feet) per day. Home ranges were relatively small, with a largest recorded home range of 1.5 hectares (3.7 acres) after four years of cumulative data. Home ranges expanded during the warmer months and were stable or smaller during the colder months. Males and females exhibited similar movement patterns, and there was a high level of spatial overlap among individuals and lack of territoriality (*i.e.*, defended home ranges).

Although the rosy boa is not considered to be very threatened on a rangewide basis due to large amounts of relatively inaccessible habitat (NatureServe 2007), it may be threatened with local extirpation in coastal regions of southern California resulting from development-related habitat fragmentation and isolation of populations. The extent of this potential threat is unknown as little information is available on dispersal by the species, although, as noted above, adults do not move very far (Diffendorfer *et al.* 2005). The species is noted to search black top roads for prey (Stebbins 2003), making it vulnerable to road mortality. As a primarily nocturnal species, increased lighting would make the species more vulnerable to predation from nocturnal predators such as raccoon, skunk, opossum, fox, coyotes, and owls. An increase in the abundance of pet, stray, and feral cats and dogs would also make the species more vulnerable to predation. Other potential threats related to urban development include the use of rodenticides near open space, which could result in fewer mammal burrows that provide refugia and a reduced prey base, collecting of snakes (the rosy boa is popular in the pet trade (NatureServe 2007)), and habitat degradation (*e.g.*, trampling of vegetation and introduction of exotic species).

Survey Results

A habitat assessment and surveys for reptiles were conducted on portions of the Specific Plan area in 2004 and 2006 (Impact Sciences 2006A). Rosy boas were not trapped or otherwise observed during the surveys. However, based on the presence of suitable habitat and microhabitat resources in the Project area, that the Project area is within the range of the species,

and that the Project area has not been surveyed in its entirety or at a level of detail necessary to determine presence or absence of a particular reptile species, rosy boa has been identified as having high potential to occur in the Project area (Dudek and Associates 2006B). Therefore, the rosy boa is considered potentially present within the following on-site plant communities: alluvial scrub, big sagebrush scrub, coastal scrub alliances and associations, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, big sagebrush–California buckwheat, *Eriodictyon* scrub, and river wash. A total of 6,908 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 102 acres of suitable habitat would be permanently lost through implementation of the RMDP, representing 1.5% of suitable habitat on site (**Figure 4.5-102,** Alternative 2 Impacts to Scrub and Chaparral Wildlife Habitat). A total of 47 acres would be temporarily impacted. Activities associated with implementation of the SCP (*e.g.*, fence construction) could also result in a small loss of potential habitat for the species, although this impact has not been quantified.

Although the rosy boa is still a wide-ranging species, it is becoming increasingly uncommon as result of habitat loss and fragmentation throughout its range, and also likely because of collecting. The loss of habitat that would occur as a result of construction and/or grading activities would have a substantial adverse effect on this species (significance criterion 1). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 2,006 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 29.0% of suitable

habitat on site (**Figure 4.5-102,** Alternative 2 Impacts to Scrub and Chaparral Wildlife Habitat).

Although the rosy boa is still a wide-ranging species, a relatively large amount and percentage of on-site habitat for the rosy boa would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of this species on site by eliminating it from 29.0% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,107 acres (30.5%). Because of the large amount and percentage of habitat loss, the combined direct and indirect impacts to suitable habitat would have a substantial adverse effect on the distribution of the rosy boa on site, thus substantially reducing its range on site (significance criteria 1 and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Rosy boas are not very mobile, and those large-scale construction and/or grading activities associated with the RMDP causing permanent and temporary impacts likely would result in injury or mortality of individuals as a result of direct contact with or crushing by construction equipment used for vegetation clearing and grading. In addition, hibernating individuals could be injured or killed during construction and/or grading activities conducted during colder months. Activities associated with implementation of the SCP (*e.g.*, fence construction) could also result in injury or mortality of rosy boa individuals if fence construction occurred during colder months when individuals are hibernating. This species probably is capable of escaping impacts from fence construction when it is active on the ground surface in the warmer months because ground disturbances would be much more localized.

Because this species is becoming increasingly uncommon in its range, impacts that would occur as a result of construction and/or grading activities would have a substantial adverse effect on this species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals, but over a much larger area. There is a potential for substantial mortality of rosy boas during vegetation clearing, grading, and other construction-related activities. This potential loss of individuals would have a substantial adverse effect on this species on site by eliminating it from 29.0% of potentially occupied habitat, thus substantially reducing its number and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas could include disruptions associated with increased human activity, noise, and nighttime illumination; the latter of which may disrupt the natural activity cycle of this diurnal species, making it more vulnerable to predation by nocturnal predators such as owls and coyotes. Although potential secondary impacts of the construction activities would be short-term and would be phased over time, this species is becoming increasingly uncommon throughout its range. Therefore, construction activities would have a substantial adverse effect on this species (significance criterion 1). Short-term secondary impacts would be significant, absent mitigation.

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in habitat fragmentation and isolation of some local populations of the rosy boa, making the species more vulnerable to extirpation. In addition, over the long term, the close proximity of urban development to suitable rosy boa habitat could result in disruption of essential behavioral activities (*e.g.*, foraging and reproduction) and greater vulnerability to several potential secondary impacts, including human-caused habitat degradation (*e.g.*, trampling of vegetation and introduction of invasive species, such as Argentine ant) and harassment and collection; predation by pet, stray, and feral cats and dogs as well as other mesopredators; increased predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; increased incidence of roadkill; and introduction of rodenticides that may be used to control prey species (*e.g.*, small rodents), resulting in both the loss of burrows used for refuge and a reduction in the prey base. These secondary impacts would permanently reduce rosy boa populations along the urban–open space edge and would contribute to the reduction of the range and distribution of the rosy boa in the Project area (significance criteria 1 and 7). Long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the rosy boa (**Figures 4.5-103** through **4.5-107,** Alternatives 3 through 7 Impacts to Scrub and Chaparral Wildlife Habitat):

- Alternative 3 – 95 acres (1.4%) of permanent loss and 54 acres of temporary loss;
- Alternative 4 – 97 acres (1.4%) of permanent loss and 45 acres of temporary loss;
- Alternative 5 – 100 acres (1.4%) of permanent loss and 59 acres of temporary loss;
- Alternative 6 – 84 acres (1.2%) of permanent loss and 56 acres of temporary loss; and
- Alternative 7 – 47 acres (0.7%) of permanent loss and 76 acres of temporary loss.

Compared to Alternative 2, which would result in 102 acres (1.5%) of permanent loss and 47 acres of temporary impacts, the combined direct permanent and temporary loss of habitat under Alternatives 3, 4, and 5 would not be substantially different; the combined direct permanent and temporary loss of habitat would be marginally lower under Alternative 6 and somewhat lower under Alternative 7. The larger difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and greater temporary impacts under that alternative.

The overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be similar in magnitude compared to Alternative 2, and would be substantially less under Alternative 7. Because the rosy boa is becoming increasingly uncommon, direct impacts for Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to suitable habitat for the rosy boa (**Figures 4.5-103** through **4.5-107,** Alternatives 3 through 7 Impacts to Scrub and Chaparral Wildlife Habitat):

- Alternative 3 – 1,895 acres (27.4%) of permanent loss;
- Alternative 4 – 1,830 acres (26.5%) of permanent loss;
- Alternative 5 – 1,780 acres (25.8%) of permanent loss;
- Alternative 6 – 1,525 acres (22.1%) of permanent loss; and
- Alternative 7 – 1,355 acres (19.6%) of permanent loss.

Compared to Alternative 2, which would result in 2,006 acres (29.0%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and/or Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that would reduce impacts to rosy boa suitable habitat under Alternative 7 compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the rosy boa occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the rosy boa:

- Alternative 3 – 1,989 acres (28.8%) of permanent loss;
- Alternative 4 – 1,927 acres (27.9%) of permanent loss;
- Alternative 5 – 1,879 acres (27.2%) of permanent loss;
- Alternative 6 – 1,609 acres (23.3%) of permanent loss; and
- Alternative 7 – 1,402 acres (20.3%) of permanent loss.

Compared to Alternative 2, which would result in 2,107 acres (30.5%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect

impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and/or Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the rosy boa occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual rosy boas as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to rosy boas occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as human-caused habitat degradation and harassment and collection; predation by pet, stray, and feral cats and dogs as well as other mesopredators; invasive species such as Argentine ant; increased predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; increased incidence of roadkill; and introduction of rodenticides that may be used to control prey species (*e.g.*, small rodents), resulting in a reduction in the prey base for the species. Short-term and long-term secondary impacts to rosy boa resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to rosy boa: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment, entombment of individuals in burrows, and increased exposure of individuals left without protective cover. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys within the proposed disturbance area will be conducted by a qualified biologist in possession of a Scientific Collecting Permit to capture and relocate rosy boas. General procedures to avoid and minimize impacts to rosy boas during construction will be implemented, and a qualified biologist will be present during construction in order to relocate any identified remaining individuals, further reducing impacts to the species.

The combined permanent loss of suitable habitat for the rosy boa resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 1,402 acres (20.3%) under Alternative 7 to 2,107 acres (30.5%) under Alternative 2. This would be a substantial loss of suitable habitat and would reduce the size and distribution of the rosy boa population, if present, in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable habitat to support the rosy boa in the Project vicinity. Implementation of these mitigation measures will result in protection, restoration and enhancement, and management of approximately 3,724 acres of suitable habitat for this species. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**). Restoration and enhancement of habitat used by the rosy boa in these areas will improve habitat quality for the species by providing additional cover and habitat for prey species and will reduce impacts caused by the Project.

With respect to secondary effects, rosy boas occupying habitat in close proximity to construction zones may be disturbed by construction activities, including increased human activity, noise, ground vibration, and lighting. Biological monitoring during vegetation clearing and grading, as well as dust suppression measures, will help reduce these construction-related impacts. Potential long-term effects of development include habitat fragmentation; increased human activity, including habitat degradation and collection; invasive species, such as Argentine ant; pet, stray, and cats and feral dogs; vehicle collisions; and use of rodenticides. The large open space system will provide adequate protected open space that will in part offset these impacts, especially habitat fragmentation and vehicle collisions. Several specific mitigation measures will also be implemented to control human activities in open space areas, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. Rodenticides will be controlled through an integrated pest management (IPM) plan. Argentine ant invasions of upland habitats in the open space system will be monitored and controlled to the extent feasible.

Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

All specific mitigation measures for rosy boa are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-114 IMPACTS TO INDIVIDUALS – ROSY BOA

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified two mitigation measures that will avoid, minimize, or mitigate the impacts to rosy boa individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to reduce impacts to rosy boa individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-54 requires surveys to capture and relocate coast horned lizard, silvery legless lizard, coastal western whiptail, rosy boa, San Bernardino ringneck snake, and coast patch-nosed snake individuals 30 days prior to construction activities in suitable habitats.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to rosy boa individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-115 LOSS OF HABITAT – ROSY BOA

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the rosy boa through protection, restoration and enhancement, and management of habitat. Although this species primarily uses scrub and chaparral habitats, protection, restoration and enhancement, and management of habitat in the River Corridor SMA will reduce impacts to this species.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. The River Corridor SMA includes terrestrial habitats that may used by rosy boa, and these areas would benefit from restoration activities. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities

for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the rosy boa through protection, restoration and enhancement, and management of habitat.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

The mitigation required by the Newhall Ranch Specific Plan Program EIR and the mitigation measures recommended by this EIS/EIR will result in a large, managed open space system that will conserve habitat for the rosy boa in the Project vicinity. A total of 3,724 acres of potential habitat for the rosy boa will be protected and managed, in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**). Therefore, after mitigation, the loss of habitat for the rosy boa would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-116 SECONDARY IMPACTS – ROSY BOA

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to the rosy boa, including short-term construction activities and long-term effects due to factors such as human-caused habitat degradation**;** habitat fragmentation; lighting; and harassment and collection.

SP-4.6-53 and SP-4.6-59, as described above, will be implemented to mitigate impacts from increased short-term human activity associated with construction.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will be implemented to mitigate impacts from increased long-term human activity through protection, restoration and enhancement, and management of habitat.

SP-4.6-17, SP-4.6-20, SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-39 will be implemented to protect against both potential short-term construction-related secondary impacts and long-term secondary impacts to habitat and/or rosy boa individuals associated with increased human activity and grazing.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-27 and SP-4.6-39 require removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-1 through SP-4.6-16, SP-4.6-17, SP-4.6-18, SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will be implemented to mitigate for impacts due to habitat fragmentation and potential isolation of populations.

In addition, SP-4.6-29 through SP-4.6-32 will be implemented to mitigate for impacts related to increased human activity in the High Country SMA through limiting access to daytime use of the designated trail system; prohibiting pets (with the exception of horses on established trails); prohibiting hunting, fishing, and motor or off-trail bike riding; and providing trail design guidelines to minimize impacts to native habitats.

SP-4.6-33 will be implemented to mitigate potential adverse edge effects by permitting construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 will be implemented to mitigate for potential lighting impacts by requiring that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures that address specific potential edge effects, including harassment by humans; predation by pet, stray, and feral cats and dogs; invasion by Argentine ants; and use of rodenticides.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, will be implemented to mitigate for impacts from increased human activity through habitat protection and restoration and enhancement.

In addition, BIO-63, BIO-64, BIO-69, and BIO-73 will be implemented to mitigate impacts related to increases in human activity:

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 requires preparation of an integrated pest management (IPM) plan that addresses the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-72, BIO-85, and BIO-87 will be implemented to reduce and control Argentine ants in open space areas.

BIO-72 specifies that container plants for use within 100 feet of the open space areas shall be inspected for pests, including Argentine ants. Plant palettes also will include non-invasive species that do not require high irrigation rates, which will help keep moisture levels low at the open space–urban interface. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the rosy boa and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

SAN BERNARDINO RINGNECK SNAKE (CALIFORNIA SPECIAL ANIMAL)

Life History

A fair amount of information is available for the full species ringneck snake (*Diadophis punctatus*), while less information is available for the subspecies San Bernardino ringneck snake (*D. p. modestus*). Therefore, much of the following discussion is based on the life history of the full species ringneck snake, with expected similarities occurring in behaviors and habitat associations with the San Bernardino ringneck snake subspecies.

The ringneck snake is widely distributed in North America, with 13 currently recognized subspecies occurring from southern Washington and Idaho to northern Baja California, Mexico and from the Atlantic Coast to the Pacific Coast (Hinojosa 1996; Pinou *et al.* 1995; Stebbins 2003; Stoltz 1993). The ringneck snake is widespread in California and is absent only from large portions of the Central Valley, high mountains, desert, and areas east of the Sierra–Cascade crest (Zeiner *et al.* 1988). Currently there are six recognized subspecies in California occurring at elevations ranging from sea level to 2,150 meters (7,050 feet) AMSL (Zeiner *et al.* 1988). The San Bernardino ringneck snake subspecies is found along the southern California coast from the Santa Barbara area south to northern San Diego County, and inland into the San Bernardino Mountains. It should be noted, however, that the genus *Diadophis* is in need of taxonomic study, and that the six recognized subspecies in California are nearly genetically indistinguishable (NatureServe 2007).

The ringneck snake is found in moist habitats, including woodlands, hardwood and conifer forest, grassland, sage scrub, chaparral, croplands/hedgerows, and gardens (NatureServe 2007; Stebbins 2003). In arid regions, the ringneck snake occurs in forests, woodlands, sage scrub, chaparral, and riparian corridors (Stebbins 2003). At the Marine Corps Base, Camp Pendleton, in San Diego County, California, the species is found in most habitats, including coastal sage scrub, chaparral, oak woodland, riparian areas, and grassland (Holland and Goodman 1998). During a 26-year-long study in Kansas, Fitch (1975) found that; while ringneck snakes used a wide variety of habitats, terrain, and vegetation; their primary habitat requirements included soil that is slightly damp but not wet or soggy; abundant shelter in the form of a surface mat of dead vegetation and/or loose objects such as flat rocks, boards, or trash; and screening shrubs or trees with open canopies sparse enough to permit abundant sunshine to reach the ground. Zeiner *et al.* (1988) state that ringneck snakes are most common in open, relatively rocky areas within valley–foothill, mixed chaparral, and annual grassland habitats. Holland and Goodman (1998) observed the species to be more common in grasslands and more scarce in riparian areas where sandy soils are extensive or not bordered by areas with heavier soils. While ringneck snakes utilize a wide variety of habitats, they are usually found on the ground under bark, beneath and inside rotting logs, and under stones and boards (Stebbins 2003).

The ringneck snake appears to have geographic variation in its preferred prey species. In some regions, earthworms appear to be the primary food source (Myers 1965; Fitch 1975), and in other regions salamanders (Barbour 1950; Stebbins 1954; Basey 1976; Zeiner *et al.* 1988) or lizards (Gehlbach 1974) are the primary food source. Other known prey items include insects (Holland and Goodman 1998) and other arthropods (Tennant 1984); treefrogs; skinks; legless lizards (Stebbins 1954); and small snakes such as the two-striped garter snake (Gehlbach 1974; Zeiner *et al.* 1988; Goodman and Tate 1998). Zeiner *et al.* (1988) state that the range of the ringneck snake in California overlaps with that of various species of slender salamander, suggesting that the ringneck snake's distribution may be limited by this food source.

During the day in the spring and summer, ringneck snakes are typically found under surface objects (Holland and Goodman 1998; Zeiner *et al.* 1988), with crepuscular (dawn and dusk) and some nocturnal activity observed during the summer (Holland and Goodman 1998; Zeiner *et al.* 1988). Ringneck snakes may aestivate during the heat of summer and are generally inactive and hibernate during the winter (NatureServe 2007).

Ringneck snakes are sexually mature in two to three years (NatureServe 2007). Females typically become sexually active after their third hibernation season and males become sexually active after their second hibernation season (Fitch 1975). Sexes are often found together at suitable shelter areas (Fitch 1975), and it is thought that ringneck snakes use olfactory cues to follow other individuals to these shelter areas (Dundee and Miller 1968). Mating presumably occurs in March and April, with egg-laying generally occurring in June and July (Perkins 1938; Fitch 1975; Stebbins 2003; Holland and Goodman 1998). Fitch (1975) found that ringneck snakes in Kansas ovulate in the latter half of May, with the eggs laid in late June or early July. Some egg laying, however, may occur as early as April (Nussbaum *et al.* 1983). Nussbaum *et al.* (1983) found that eggs are laid from April to July depending on local conditions. Eggs are laid from late May through August in Florida, and double clutches may be laid in the south (NatureServe 2007). Eggs are generally deposited in loose aerated soil, in stabilized talus, or in rotting logs (Nussbaum *et al.* 1983), with communal nesting common (Holland and Goodman 1998; NatureServe 2007). Clutch sizes range from one to 18 eggs. Incubation of eggs may take between 42 to 56 days (Clark *et al.* 1997; NatureServe 2007; Perkins 1938). Hatching has been reported from August to October (Nussbaum *et al.* 1983), but Fitch (1975) reports that most hatching occurs in August.

Ringneck snakes may exhibit site tenacity, establishing a long-term home range, but there is no evidence of territorial defense (Zeiner *et al.* 1988). Fitch (1975) found that after a number of years, ringneck snakes could still be located within 10 meters (33 feet) of their initial capture point, indicating strong site tenacity. Some ranges for ringneck snakes in Kansas tended to be elongate, with maximum axes of 140 meters (460 feet) (Fitch 1975). The distance between recaptures in this study averaged 80 meters (262 feet), with a range of 0 to 1,700 meters (0 to 5,577 feet). In areas with large seasonal temperature fluctuations, there appears to be some

seasonal movement between habitats, with average movements between summer habitats and hibernacula of about 120 meters (394 feet) (Fitch 1975; Parker and Brown 1974). In montane locations in California, it is possible that this shift also occurs (Zeiner *et al.* 1988), but in areas where the temperature shift is not great, the species likely does not shift between habitats.

Ringneck snakes appear to be clumped in distribution, often occurring together in suitable cover (Hammerson 1982; Blanchard 1942). Population density in Kansas was estimated at 1,266 individuals per hectare (range of 719 to 1,849 per hectare) (Fitch 1975), but densities are expected to vary considerably depending on local habitat conditions, available resources, and other factors.

Survey Results

A habitat assessment and surveys for reptiles were conducted on portions of the Specific Plan area in 2004 and 2006 (Impact Sciences 2006A). San Bernardino ringneck snakes were not trapped or otherwise observed during the surveys. However, based on the presence of abundant suitable habitat and microhabitat resources in the Project area, the fact that the Project area is within the range of the subspecies, and the fact that the Project area has not been surveyed in its entirety or at a level of detail necessary to determine presence or absence of a particular reptile species, San Bernardino ringneck snake has been identified as having high potential to occur in the Project area (Dudek and Associates 2006B). Therefore, the San Bernardino ringneck snake is considered potentially present within the following on-site plant communities: alluvial scrub, big sagebrush scrub, coastal scrub alliances and associations, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, California annual grassland, big sagebrush–California buckwheat, California walnut woodland, coast live oak woodland, Mexican elderberry, mulefat scrub, southern willow scrub, southern cottonwood–willow riparian, *Eriodictyon* scrub, mixed oak woodland, purple needlegrass, river wash, southern coast live oak riparian forest, shrub tamarisk, valley oak woodland, and valley oak/grass. A total of 11,236 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 191 acres of suitable habitat would be permanently lost through implementation of the RMDP, representing 1.7% of suitable habitat on site (**Figure 4.5-72,** Alternative 2 Impacts to General Wildlife Habitats). A total of 111 acres would be temporarily impacted. Activities associated with implementation of the SCP (*e.g.*, fence construction) could also result in a small loss of potential habitat for San Bernardino ringneck snake, although this impact has not been quantified.

Although the San Bernardino ringneck snake is still a wide-ranging species, loss and fragmentation of habitat due to urban development likely has reduced populations of this species. The loss of habitat that would occur as a result of construction and/or grading activities would have a substantial adverse effect on San Bernardino ringneck snake (significance criterion 1). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 3,154 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 28.1% of suitable habitat on site (**Figure 4.5-72,** Alternative 2 Impacts to General Wildlife Habitats).

A relatively large amount and percentage of on-site habitat for the San Bernardino ringneck snake would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This loss of habitat would have a substantial adverse effect on the distribution of San Bernardino ringneck snake on site by eliminating it from 28.1% of currently occupied habitat, thus substantially reducing its numbers and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,345 acres (29.8%). Because of the large amount and percentage of habitat loss, the combined direct and indirect impacts to suitable habitat would have a substantial adverse effect on the distribution of the San Bernardino ringneck snake on site, thus substantially reducing its range on site (significance criteria 1

and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

San Bernardino ringneck snakes are relatively mobile over short distances. However, large-scale construction and/or grading activities associated with the RMDP causing permanent and temporary impacts likely would result in injury or mortality of individuals. In addition, hibernating individuals could be injured or killed during construction and/or grading activities conducted during colder months. Activities associated with implementation of the SCP (*e.g.*, fence construction) could also result in impacts to San Bernardino ringneck snake individuals if fence construction occurred during colder months when individuals are hibernating. San Bernardino ringneck snake probably is capable of escaping potential impacts from fence construction when it is active on the ground surface in the warmer months.

Because this species has suffered loss and fragmentation of habitat throughout its range, impacts to San Bernardino ringneck snakes that would occur as a result of construction and/or grading activities would have a substantial adverse effect (Impacts to Individuals) and would be significant, absent mitigation.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent impacts to individuals, but over a much larger area. There is a potential for substantial mortality of San Bernardino ringneck snakes during vegetation clearing, grading, and other construction-related activities. This potential loss of individuals would have a substantial adverse effect on San Bernardino ringneck snake on site by eliminating it from 28.1% of potentially occupied habitat, thus substantially reducing its number and restricting its range on site (significance criteria 1 and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas could include disruptions associated with construction-related dust (which may affect its prey), increased human activity, noise, and nighttime illumination; the latter of which may disrupt the natural activity cycle of this diurnal subspecies, making it more vulnerable to predation by nocturnal predators, such as owls and

coyotes. Although construction activities will be short term and phased over time, because of the loss and fragmentation of habitat for this species throughout its range, construction activities would have a substantial adverse effect on San Bernardino ringneck snake (significance criterion 1). Short-term secondary impacts would be significant, absent mitigation.

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in habitat fragmentation and isolation of some local populations of the San Bernardino ringneck snake, making the subspecies more vulnerable to extirpation. In addition, over the long term, the close proximity of urban development to suitable San Bernardino ringneck snake habitat could result in disruption of essential behavioral activities (*e.g.*, foraging and reproduction) and greater vulnerability to several potential secondary impacts, including human-caused habitat degradation (*e.g.*, trampling of vegetation and introduction of invasive species, such as Argentine ant) and harassment and collection; predation by pet, stray, and feral cats and dogs as well as other mesopredators; increased predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; increased incidence of roadkill; and introduction of rodenticides that may be used to control prey species (*e.g.*, small rodents), resulting in both the loss of burrows used for refuge and a reduction in the prey base. These secondary impacts would permanently reduce San Bernardino ringneck snake populations along the urban–open space edge and would contribute to the reduction of the range and distribution of the San Bernardino ringneck snake in the Project area (significance criteria 1 and 7). Long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the San Bernardino ringneck snake (**Figures 4.5-73** through **4.5-77,** Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 176 acres (1.6%) of permanent loss and 123 acres of temporary loss;
- Alternative 4 – 172 acres (1.5%) of permanent loss and 107 acres of temporary loss;
- Alternative 5 – 202 acres (1.8%) of permanent loss and 133 acres of temporary loss;

- Alternative 6 – 202 acres (1.8%) of permanent loss and 127 acres of temporary loss; and
- Alternative 7 – 81 acres (0.7%) of permanent loss and 179 acres of temporary loss.

Compared to Alternative 2, which would result in 191 acres (1.7%) of permanent loss and 111 acres of temporary impacts, the combined direct permanent and temporary loss of habitat under Alternative 3 would not be substantially different, and the combined direct permanent and temporary loss of habitat would be marginally to somewhat lower under Alternatives 4 and 7 and marginally to somewhat higher under Alternatives 5 and 6. Alternative 7 would have the least amount of permanent impacts and greatest amount of temporary impacts, although the combined total impact would still be the lowest of all the alternatives. The difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and greater temporary impacts under that alternative.

The overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be similar in magnitude compared to Alternative 2 (ranging from 1.5% for Alternative 4 to 1.8% for Alternatives 5 and 6, compared to 1.7% for Alternative 2); it would be substantially less under Alternative 7 (0.7%). Because the San Bernardino ringneck snake has suffered from loss and fragmentation of habitat, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to suitable habitat for the San Bernardino ringneck snake (**Figures 4.5-73** through **4.5-77,** Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 2,945 acres (26.2%) of permanent loss;
- Alternative 4 – 2,820 acres (25.1%) of permanent loss;
- Alternative 5 – 2,738 acres (24.4%) of permanent loss;
- Alternative 6 – 2,419 acres (21.5%) of permanent loss; and
- Alternative 7 – 2,126 acres (18.9%) of permanent loss.

Compared to Alternative 2, which would result in 3,154 acres (28.1%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be

constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and/or Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that would reduce impacts to San Bernardino ringneck snake suitable habitat under Alternative 7 compared to the other alternatives.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the relatively large percentage of habitat lost on site. The indirect permanent loss of suitable habitat for the San Bernardino ringneck snake occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the San Bernardino ringneck snake:

- Alternative 3 – 3,121 acres (27.8%) of permanent loss;
- Alternative 4 – 2,992 acres (26.6%) of permanent loss;
- Alternative 5 – 2,939 acres (26.2%) of permanent loss;
- Alternative 6 – 2,620 acres (23.3%) of permanent loss; and
- Alternative 7 – 2,207 acres (19.6%) of permanent loss.

Compared to Alternative 2, which would result in 3,345 acres (29.8%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. These reduced impacts would occur because VCC would not be constructed under Alternatives 4 through 7, there would be successive reductions in the Specific Plan and/or Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 compared to Alternatives 2 through 6. The combined direct and indirect permanent loss of suitable habitat for the San Bernardino ringneck snake occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual San Bernardino ringneck snakes as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Impacts to individual San Bernardino ringneck snakes occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to factors such as construction-related dust; human-caused habitat degradation and harassment and collection; predation by pet, stray, and feral cats and dogs as well as other mesopredators; increased predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; increased incidence of roadkill; invasive species such as Argentine ant; and introduction of rodenticides that may be used to control prey species (*e.g.*, small rodents), resulting in both the loss of burrows used for refuge and a reduction in the prey base. Short-term and long-term secondary impacts to San Bernardino ringneck snake resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 therefore would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to San Bernardino ringneck snake: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals could occur during construction as a result of vegetation clearing and grading, including injury and mortality due to direct contact with construction equipment, entombment of aestivating or hibernating individuals, and increased exposure of individuals left without protective cover. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys within the proposed disturbance area will be conducted by a qualified biologist in possession of a scientific collecting permit to capture and relocate San Bernardino ringneck snakes. General procedures to avoid and minimize impacts to ringneck snakes during construction will be implemented, and a qualified

biologist will be present during construction in order to relocate any identified remaining individuals, further reducing impacts to the species.

The combined permanent loss of suitable habitat for the San Bernardino ringneck snake resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 2,207 acres (19.6%) under Alternative 7 to 3,154 acres (28.1%) under Alternative 2. This would be a substantial loss of suitable habitat and will reduce the size and distribution of the San Bernardino ringneck snake population in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable habitat to support the San Bernardino ringneck snake in the Project vicinity. Implementation of these mitigation measures will result in protection, restoration and enhancement, and management of approximately 6,047 acres of suitable habitat for this species. This open space will be conserved in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**). Restoration and enhancement of habitat used by the San Bernardino ringneck snake in these areas will improve habitat quality for the species.

With respect to secondary effects, San Bernardino ringneck snakes occupying habitat in close proximity to construction zones may be disturbed by construction activities, including increased human activity, noise, ground vibration, and dust. Biological monitoring during vegetation clearing and grading, as well as dust suppression measures, will help reduce these construction-related impacts. Potential long-term effects of development include habitat fragmentation; increased human activity, including habitat degradation and collection; invasive species such as Argentine ant; pet, stray, and cats and feral dogs; vehicle collisions; and use of pesticides. The large open space system will provide adequate protected open space that will in part offset these impacts, especially habitat fragmentation and vehicle collisions. Several specific mitigation measures will also be implemented to control human activities in open space areas, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in, or adjacent to, open space areas. Pesticides will be controlled through an integrated pest management (IPM) plan. Argentine ant invasions of upland habitats in the open space system will be monitored and controlled to extent feasible. Implementation of these measures will allow this species to persist on site after development in the large amount of permanent open space that will be protected and managed.

All specific mitigation measures for San Bernardino ringneck snake are listed below and are described fully in **Subsection 4.5.6,** Mitigation Measures.

IMPACT 4.5-117 IMPACTS TO INDIVIDUALS – SAN BERNARDINO RINGNECK SNAKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified two mitigation measures that will avoid, minimize, or mitigate impacts to San Bernardino ringneck snake individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to reduce impacts to San Bernardino ringneck snake individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-54 requires surveys to capture and relocate coast horned lizard, silvery legless lizard, coastal western whiptail, rosy boa, coast patch-nosed snake, and San Bernardino ringneck snake individuals 30 days prior to construction activities in suitable habitats.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to San Bernardino ringneck snake individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-118 LOSS OF HABITAT – SAN BERNARDINO RINGNECK SNAKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the San Bernardino ringneck snake through protection, restoration and enhancement, and management of habitat. This subspecies primarily uses scrub and chaparral habitats but also uses riparian habitats. Therefore, protection, restoration and enhancement, and management of habitat in the River Corridor SMA will reduce impacts to this species.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

SP-4.6-27 requires removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the San Bernardino ringneck snake through protection, restoration and enhancement, and management of habitat.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the San Bernardino ringneck snake would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-119 SECONDARY IMPACTS – SAN BERNARDINO RINGNECK SNAKE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for secondary impacts to the San Bernardino ringneck snake, including short-term construction activities and long-term effects due to factors such as human-caused habitat degradation**,** habitat fragmentation, lighting, and harassment and collection.

SP-4.6-53 and SP-4.6-59, as described above, will be implemented to mitigate impacts from increased short-term human activity associated with construction.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will be implemented to mitigate impacts from increased long-term human activity through protection, restoration and enhancement, and management of habitat.

SP-4.6-17, SP-4.6-20, SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-39 will be implemented to protect against both potential short-term construction-related secondary impacts and long-term secondary impacts to habitat and/or San Bernardino ringneck snake individuals associated with increased human activity and grazing.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats.

SP-4.6-20, SP-4.6-34, and SP-4.6-35 require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-27 and SP-4.6-39 require removal of grazing from the High Country SMA except for those grazing activities associated with long-term resource management programs. All enhancement activities for riparian habitat within the High Country SMA shall be governed by the same provisions set forth for enhancement in the River Corridor SMA.

SP-4.6-1 through SP-4.6-16, SP-4.6-17, SP-4.6-18, SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above, will be implemented to mitigate for impacts due to habitat fragmentation and potential isolation of populations.

In addition, SP-4.6-29 through SP-4.6-32 will be implemented to mitigate for impacts related to increased human activity in the High Country SMA through limiting access to daytime use of the designated trail system; prohibiting pets (with the exception of horses on established trails);

prohibiting hunting, fishing, and motor or off-trail bike riding; and providing trail design guidelines to minimize impacts to native habitats.

SP-4.6-33 will be implemented to mitigate potential adverse edge effects by permitting construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 will be implemented to mitigate for potential lighting impacts by requiring that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures that address secondary effects such as construction-related dust; harassment by humans; Argentine ants; predation by pet, stray, and feral cats and dogs; and use of pesticides.

BIO-1 through BIO-16 and BIO-19 through BIO-21, as described above, will be implemented to mitigate for impacts from increased human activity through habitat protection, restoration and enhancement, and management.

In addition, BIO-63, BIO-64, BIO-69, and BIO-73 will be implemented to mitigate impacts related to increases in human activity:

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 requires preparation of an integrated pest management (IPM) plan that addresses the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits for the initial tract map.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-72, BIO-85, and BIO-87 will be implemented to reduce and control Argentine ants in open space areas.

BIO-72 specifies that container plants for use within 100 feet of the open space areas shall be inspected for pests, including Argentine ants. Plant palettes also will include non-invasive species that do not require high irrigation rates, which will help keep moisture levels low at the open space-urban interface. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the San Bernardino ringneck snake and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

COOPER'S HAWK (NESTING) (WL)

Life History

The Cooper's hawk (*Accipiter cooperii*) is a diurnally active species that breeds from British Columbia eastward to Nova Scotia and southward to northern Mexico and Florida. This species' winter range extends from British Columbia eastward to New England and southward primarily to Honduras (AOU 1998). In California, the Cooper's hawk is a breeding resident throughout most woodlands of the state and is present year round except for the Colorado River and desert areas where the species no longer breeds. The species also occurs in California as a spring and fall migrant and as a winter resident (Garrett and Dunn 1981). The Cooper's hawk ranges from sea level to above 2,700 meters (9,000 feet) AMSL (Zeiner *et al.* 1990A).

Cooper's hawk is found in areas with dense stands of live oak, riparian, or other forest habitats near water (Zeiner *et al.* 1990A). They frequent landscapes where wooded areas occur in patches and grooves and often use patchy woodlands and edges with snags for perching (Beebe 1974). The Cooper's hawk nests in extensive forests, woodlots, and occasionally in isolated trees in more open areas (Price 1941; Call 1978; Reynolds *et al.* 1982; Moore and Henny 1983; Wiggers and Kritz 1991; Stewart 1975; Asay 1987). Canopy cover is an important aspect for nesting because it provides greater protection from extreme weather and predation, whereas understory cover does not appear to be an important feature in nest selection (Bosakowski *et al.* 1992). During spring and fall, migrating individuals preferred deciduous forests rather than open or human-occupied areas (Goodrich 2005). Winter habitat use is similar to that of the breeding season (Millsap 1981).

During breeding and non-breeding season, the Cooper's hawk feeds predominantly on avian prey, sometimes taking mammals (Terres 1980). Mammals constitute a higher proportion of the hawk's diet in the western United States than elsewhere (Bosakowski *et al.* 1992). Other prey groups included in their diet are reptiles, amphibians, insects, and fish (Rosenfield 1988). The Cooper's hawk typically forages near open water or riparian vegetation and catches its prey in the air, on ground, and in vegetation. It is common for the hawk to fly with its prey to a nearby water source in order to drown it (Terres 1980).

The Cooper's hawk breeds from March through August, with peak breeding occurring May through July. The species breeds primarily in riparian areas and oak woodlands and is most common in montane canyons (Garrett and Dunn 1981; Hamilton and Willick 1996). Nests usually occur in second-growth conifer stands or in deciduous riparian areas, usually near streams or open water (Zeiner *et al.* 1990A). It is common in the western United States to find Cooper's hawk nests in stands of cottonwoods along stream courses, especially where the tree stands are fairly large (Call 1978). Nesting areas and breeding locations are typically reused over multiple years.

Clutch size consists of four to five eggs that have an incubation time of 35 to 36 days; during the incubation period, the male provides food to the female while the female tends to and defends the nest (Brown and Amadon 1968). The young birds usually depart the nest at 30 to 34 days but continue to be brought food for up to seven weeks after leaving the nest. The young may remain together near the nest for another five to six weeks (County of Riverside 2008).

Primary threats to Cooper's hawks include habitat destruction, primarily lowland riparian areas, and human disturbance at nest sites (Remsen 1978; Boal and Mannan 1998). Because of increased urbanization and development within preferred habitat of Cooper's hawk, there has been a decline in the population of this species in California (Remsen 1978). The most common nesting fatalities are due to predation by raccoons and ravens, both urban-adapted species, and great horned owls (Schriver 1969; Rosenfield 1988). Boal and Mannan (1998) found that 70% of adult Cooper's hawk deaths were a result of collisions with man-made objects in urban areas. Another documented threat to the species is the use of pesticides. DDT and other chlorinated hydrocarbon pesticides have been used worldwide to control crop pests and disease-carrying insects since the 1940s. Long-term DDT exposure and accumulation resulted in eggshell thinning and loss of young in many raptor species, resulting in serious declines in reproductive success (Terres 1980; Henny and Wight 1972). Pesticides may also affect prey abundance, including small mammals, amphibians, and reptiles, and may also cause secondary poisoning. Several other potential human- or development-related factors may affect Cooper's hawks. Construction-related impacts include dust, noise and ground vibration, increased human activity in close proximity to nesting and foraging areas, and lighting, which may alter behavior, induce physiological stress, and increase predation risk. Long-term effects related to development include increased human activity, noise, and lighting.

Survey Results

Avian biological inventories have been conducted for multiple years along the Santa Clara River within suitable habitat for the Cooper's hawk. Surveys for upland bird species have been conducted throughout the Project area and in nearby areas between 1995 and 2008.

The Cooper's hawk has been regularly observed within riparian and oak woodland habitats over multiple years during the bird surveys conducted from 1988 through 2006 along the Santa Clara River within the riparian scrub and woodland habitat (Guthrie 1988, 1989, 1990, 1991A, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2005A, 2005B, 2006A, 2006C; Bloom Biological 2007A, 2008; Dudek and Associates 2006B; Compliance Biology 2006D; Labinger *et al.* 1995, 1996, 1997B; Labinger and Greaves 1999A). This species is known to be a year-round resident within the Project area (Bloom Biological 2007A, 2008).

The Project area provides both foraging and nesting habitat for the species. California walnut woodland, coast live oak woodland, mixed oak woodland, southern coast live oak riparian forest, southern cottonwood–willow riparian, southern willow scrub, valley oak woodland, and valley oak/grass are suitable nesting and foraging habitats for the Cooper's hawk. There is a total of 1,940 acres of suitable nesting/foraging habitat within the Project area. Additional suitable foraging habitat in the Project area for the Cooper's hawk, necessary for the development of broods, includes big sagebrush scrub, coastal scrub alliances and associations, *Eriodictyon* scrub, and Mexican elderberry. There is a total of 4,441 acres of additional suitable foraging habitat within the Project area. The combined suitable nesting and foraging habitat in the Project area is 6,381 acres.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 104 acres of suitable nesting and/or foraging habitat would be permanently lost through implementation of the RMDP and the SCP, representing 1.6% of these habitats on site (**Figure 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass and Walnut Woodland Wildlife Habitat). Of these impacts, 48 acres are nesting and foraging habitat (*i.e.*, habitat suitable for both nesting and foraging, including California walnut woodland, coast live oak woodland, mixed oak woodland, southern coast live oak riparian forest, southern cottonwood–willow riparian, southern willow scrub, valley oak woodland, and valley oak/grass), representing 2.5% of this habitat on site. The remaining 56 acres of impact are foraging habitat only (*i.e.*, habitat suitable only for foraging, including big sagebrush scrub, coastal scrubs and associations, *Eriodictyon* scrub, and Mexican elderberry), representing 1.3% of this habitat on site. A total of 53 acres of suitable nesting and/or foraging habitat would be temporarily impacted, of which 46 acres are nesting and foraging habitat and 7.5 acres are foraging habitat only.

The Cooper's hawk is still relatively widespread and common throughout its range. However, this species is a breeding raptor on site, and raptors in general are uncommon

and receive special protection from CDFG. Therefore, the loss of raptor nesting habitat would be considered a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 1,640 acres of suitable nesting and/or foraging habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 25.7% of these habitats on site (**Figure 4.5-114**, Alternative 2 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass and Walnut Woodland Wildlife Habitat). Of these impacts, 93 acres are nesting and foraging habitat, representing 4.8% of this habitat on site. The remaining 1,547 acres of impact are foraging habitat only, representing 34.8% of this habitat on site.

The Cooper's hawk is still relatively widespread and common throughout its range. However, this species is a breeding raptor on site, and raptors receive special protection from CDFG. Therefore, the loss of raptor nesting would be considered a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable nesting and/or foraging habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 1,744 acres (27.3%). Of these impacts, 141 acres are nesting and foraging habitat, representing 7.3% of this habitat on site. The remaining 1,603 acres of impact are foraging habitat only, representing 36.1% of this habitat on site.

The combined loss of 27.3% of nesting and/or foraging habitat, including 7.3% of foraging and nesting habitat and 36.1% of foraging habitat only, would be a substantial habitat loss on site. This impact would be considered a substantial adverse effect on the

habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

As Cooper's hawks are highly mobile, it is unlikely that RMDP-related construction/grading activities would result in direct injury or mortality of adult birds. However, this species has been observed nesting within the RMDP area west of Grapevine Mesa in the undisturbed dry canyon woodlands (Guthrie 2000B) and adjacent to the Project site in the Entrada planning area north of the Santa Clara River (Bloom Biological 2007A). Absent mitigation, construction and/or grading activities associated with the proposed RMDP could adversely affect foraging and nesting Cooper's hawks. Foraging individuals may avoid construction areas, and if construction occurred during the breeding season, active nests could be disturbed or destroyed, and eggs and/or young could be destroyed, injured, or killed. Impacts on foraging behavior by adults during the rearing period could also affect the health of young, potentially resulting in reduced survivorship and reproductive success. Also, construction activities could cause females to abandon nests, resulting in the loss of the nest due to predators or exposure. These would be significant impacts (significance criteria 1 and 7), absent mitigation. Implementation of the SCP would not directly impact this species.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent and temporary impacts to individuals. Because the species nests and forages on site in habitat that would be directly affected, build-out of the Specific Plan, VCC, and Entrada planning areas could adversely affect nesting Cooper's hawks. This would be a significant impact (significance criteria 1 and 7), absent mitigation.

Secondary Impacts

Short-term, construction-related impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas could potentially affect Cooper's hawks nesting or foraging in areas adjacent to construction zones. These impacts include construction-related fugitive dust, nesting and foraging disturbance from increased

human activity, noise and ground vibration, and nighttime illumination, which could modify essential behaviors of individuals, increase physiological stress, potentially increase their risk of predation, and potentially cause nest abandonment. Attraction of ravens to construction areas could also increase the risk of nest predation.

Potential long-term secondary effects resulting from RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas adjacent to nesting and foraging habitat include nighttime lighting; increased human activity; increased noise; harassment and predation by pet, feral, and stray cats and dogs, other mesopredators (particularly raccoons and opossums), and ravens; the use of pesticides, which could result in the loss of prey and secondary poisoning; and increased incidence of collisions with vehicles and man-made structures.

Both short-term and long-term secondary impacts would have a substantial adverse effect on this species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable nesting and/or foraging habitat for Cooper's hawk (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 87 acres (1.4%) permanent loss and 55 acres of temporary loss of nesting and/or foraging habitat, including
  - 35 acres (1.8%) of permanent loss and 45 acres of temporary loss of nesting and foraging habitat
  - 52 acres (1.2%) of permanent loss and 10 acres of temporary loss of foraging habitat only;
- Alternative 4 – 87 acres (1.4%) permanent loss and 50 acres of temporary loss of nesting and/or foraging habitat, including
  - 35 acres (1.8%) of permanent loss and 43 acres of temporary loss of nesting and foraging habitat

  - 52 acres (1.2%) of permanent loss and 7.1 acres of temporary loss of foraging habitat only;
- Alternative 5 – 101 acres (1.6%) permanent loss and 61 acres of temporary loss of nesting and/or foraging habitat, including
  - 44 acres (2.3%) of permanent loss and 48 acres of temporary loss of nesting and foraging habitat
  - 57 acres (1.3%) of permanent loss and 13 acres of temporary loss of foraging habitat only;
- Alternative 6 – 81 acres (1.3%) permanent loss and 58 acres of temporary loss of nesting and/or foraging habitat, including
  - 36 acres (1.9%) of permanent loss and 44 acres of temporary loss of nesting and foraging habitat
  - 45 acres (1.0%) of permanent loss and 14 acres of temporary loss of foraging habitat only; and
- Alternative 7 – 35 acres (0.5%) permanent loss and 71 acres of temporary loss of nesting and/or foraging habitat, including
  - 14 acres (0.7%) of permanent loss and 37 acres of temporary loss of nesting and foraging habitat
  - 21 acres (0.5%) of permanent loss and 34 acres of temporary loss of foraging habitat only.

Compared to Alternative 2 for nesting and/or foraging habitat, which would result in 104 acres (1.6%) of permanent loss and 53 acres of temporary impacts, Alternatives 3 through 7 would have reduced permanent impacts and similar to somewhat higher temporary impacts. This general pattern is similar for permanent impacts to nesting and foraging habitat for Alternatives 3 through 7, with fewer impacts than Alternative 2, which would result in 48 acres (2.5%) of permanent loss. For temporary impacts, Alternatives 3 through 6 would have not substantially different to marginally different impacts compared to Alternative 2, which would result in 46 acres of temporary loss, and Alternative 7 would have somewhat reduced impacts. Compared to Alternative 2 for permanent loss of foraging habitat only, which would result in 56 acres (1.3%) of permanent loss, Alternatives 3 through 6 would not have similar to somewhat different impacts and Alternative 7 would have substantially reduced impacts. Compared to Alternative 2 for temporary impacts to foraging habitat only, which would result in 7.5 acres of temporary loss, Alternatives 3 through 6 would not be substantially different, and Alternative 7 would be substantially higher.

The relatively greater difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and relatively more temporary impacts.

The overall permanent loss of nesting and/or foraging habitat resulting from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be less than or similar in magnitude compared to Alternative 2. However, because nesting habitat would be lost under all of the alternatives, this impact would be considered a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species. The direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for Cooper's hawk (**Figures 4.5-115** through **4.5-119**, Alternatives 3 through 7 Impacts to Scrub, Chaparral, Riparian, Oak Woodland, Oak/Grass and Walnut Woodland Wildlife Habitat):

- Alternative 3 – 1,528 acres (23.9%) permanent loss of nesting and/or foraging habitat, including
  - 73 acres (3.8%) of permanent loss of nesting and foraging habitat
  - 1,455 acres (32.8%) of permanent loss of foraging habitat only;
- Alternative 4 – 1,481 acres (23.2%) permanent loss of nesting and/or foraging habitat, including
  - 68 acres (3.5%) of permanent loss of nesting and foraging habitat
  - 1,413 acres (31.8%) of permanent loss of foraging habitat only;
- Alternative 5 – 1,432 acres (22.4%) permanent loss of nesting and/or foraging habitat, including
  - 69 acres (3.6%) of permanent loss of nesting and foraging habitat
  - 1,363 acres (30.7%) of permanent loss of foraging habitat only;
- Alternative 6 – 1,157 acres (18.1%) permanent loss of nesting and/or foraging habitat, including

  - 42 acres (2.2%) of permanent loss of nesting and foraging habitat
  - 1,115 acres (25.1%) of permanent loss of foraging habitat only; and
- Alternative 7 – 1,071 acres (16.8%) permanent loss of nesting and/or foraging habitat, including
  - 45 acres (2.3%) of permanent loss of nesting and foraging habitat
  - 1,026 acres (23.1%) of permanent loss of foraging habitat only.

Compared to Alternative 2 for nesting and/or foraging habitat, which would result in 1,640 acres (25.7%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. This general pattern is similar for permanent impacts to nesting and foraging habitat. Compared to Alternative 2, which would result in 93 acres (4.8%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Compared to Alternative 2 for permanent loss of foraging habitat only, which would result in 1,547 acres (34.8%) of permanent loss, Alternatives 3 through 6 would have reduced impacts. Overall for nesting and/or foraging habitat, Alternatives 4 through 7 would have fewer impacts than Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, and each would have successively fewer impacts due to other differences in the Project footprints. Alternative 7 would have the least amount of impact due to pullbacks from the Santa Clara River and its tributaries.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, all would result in impacts to nesting and foraging habitat and substantial impacts to foraging habitat only. These impacts would have a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species. Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for Cooper's hawk:

- Alternative 3 – 1,615 acres (25.3%) permanent loss of nesting and/or foraging habitat, including

  - 108 acres (5.6%) of permanent loss of nesting and foraging habitat
  - 1,507 acres (33.9%) of permanent loss of foraging habitat only;
- Alternative 4 – 1,568 acres (24.6%) permanent loss of nesting and/or foraging habitat, including
  - 103 acres (5.3%) of permanent loss of nesting and foraging habitat
  - 1,465 acres (33.0%) of permanent loss of foraging habitat only;
- Alternative 5 – 1,533 acres (24.0%) permanent loss of nesting and/or foraging habitat, including
  - 113 acres (5.8%) of permanent loss of nesting and foraging habitat
  - 1,420 acres (32.0%) of permanent loss of foraging habitat only;
- Alternative 6 – 1,238 acres (19.4%) permanent loss of nesting and/or foraging habitat, including
  - 78 acres (4.0%) of permanent loss of nesting and foraging habitat
  - 1,160 acres (26.1%) of permanent loss of foraging habitat only; and
- Alternative 7 – 1,106 acres (17.3%) permanent loss of nesting and/or foraging habitat, including
  - 59 acres (3.0%) of permanent loss of nesting and foraging habitat
  - 1,047acres (23.6%) of permanent loss of foraging habitat only.

Compared to Alternative 2 for nesting and/or foraging habitat, which would result in 1,744 acres (27.3%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. This general pattern is similar for permanent impacts to nesting and foraging habitat. Compared to Alternative 2, which would result in 141 acres (7.3%) of permanent loss, Alternatives 3 through 7 would have reduced impacts. Compared to Alternative 2 for the combined direct and indirect permanent loss of foraging habitat only, which would result in 1,602 acres (36.1%) of permanent loss, Alternatives 3 through 6 would have reduced impacts. Overall for nesting and/or foraging habitat, Alternatives 4 through 7 would have fewer combined direct and indirect impacts than Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, and each would have successively fewer impacts due to other differences in the Project footprints. Alternative 7 would have the least amount of impact due to pullbacks from the Santa Clara River and its tributaries and other differences in the Project footprint.

Although Alternatives 3 through 7 would have reduced combined direct and indirect permanent impacts compared to Alternative 2, all would result in impacts to nesting and

foraging habitat and substantial impacts to foraging habitat only. These combined direct and indirect permanent impacts would have a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species. Combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to Cooper's hawk individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Suitable nesting and foraging habitat is present on site and, absent mitigation, construction/grading activities could result in disruption of foraging activities and destruction of nests and eggs and/or injury or mortality of young where Cooper's hawks are nesting, resulting in reduced survivorship and reduced reproductive success. Impacts to Cooper's hawk individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative would have similar construction activities and long-term effects.

Short-term effects include construction-related noise, ground vibration, lighting, and disturbance from human activity that could disrupt foraging behavior and natal care and cause nest abandonment. Urban development could result in long-term secondary impacts, such as increased human activity; noise; nighttime lighting; harassment by pet, stray, and feral cats and dogs; secondary poisoning and loss of prey from use of pesticides; and increased incidence of collisions with vehicles and man-made structures.

These short-term and long-term secondary impacts therefore may interfere with the movement of this species on site, impede the use of nursery sites, or substantially reduce the number of this species or cause the species to drop below self-sustaining levels. Short-term and long-term secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to the Cooper's hawk: (1) impacts to individuals; (2) loss of suitable foraging and nesting habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Nesting and foraging by this species has been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. While adults are highly mobile and likely able to escape direct injury or mortality from relatively slow-moving construction equipment, individuals could be displaced from suitable foraging habitat by construction activities. Impacts to individuals also could occur if vegetation clearing and construction/grading activities occur during the breeding season, potentially resulting in the destruction of the nests and loss of eggs and/or young. Construction activities may also alter foraging behavior, reducing the health of young, or cause abandonment of nests due to human activity, noise, and ground vibration. Lighting could alter nesting behavior, induce physiological stress, or increase predation risk by nocturnal mesopredators. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 500 feet of any active nest until young have fledged. In addition, a qualified biologist will be present during vegetation clearing and grading activities.

The combined permanent loss of suitable nesting and foraging habitat for the Cooper's hawk resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 1,106 acres (17.3%) under Alternative 7 to 1,744 acres (27.3%) under Alternative 2. This would be a substantial loss of suitable habitat for this species and would alter its use of the Project area for foraging, and potentially nesting. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a permanent open space system that will provide suitable habitat to support both foraging and breeding by the Cooper's hawk in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 3,612 acres of the suitable habitat for this species in the River Corridor SMA, High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With regard to secondary effects, foraging and nesting activities by the Cooper's hawk could be adversely affected in the short term by increased human activity, noise, ground vibration, dust, and lighting. These secondary effects may cause adults to vacate foraging areas and abandon nests due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to predators and exposure. These short-term construction-related secondary impacts will be minimized by conducting pre-construction surveys within 500 feet of disturbance zones and by retaining a qualified biologist during all vegetation clearing and grading activities. Long-

term development-related impacts include increased noise; lighting; increased human activity; pesticides, which may cause direct and secondary poisoning and loss of prey; predation and harassment by pet, stray, and feral cats and dogs, other mesopredators, and ravens; and increased collisions with vehicles and man-made structures. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of 3,612 acres of suitable nesting and foraging habitat in the River Corridor SMA, High Country SMA, and Salt Creek area will provide Cooper's hawks with relatively undisturbed habitat for foraging and nesting. Lighting restrictions along the perimeter of natural areas will help reduce predation of nest sites by predators and reduce behavioral disturbances and physiological stress. Limited recreational usage and access restrictions within the High Country SMA, control of pet, stray, and feral cats and dogs in or near open space areas, trail signage, and homeowner education regarding special-status resources in preserved natural habitat areas will help protect Cooper's hawks by allowing them to nest and forage without disturbance. Controls on pesticides will reduce the chance of direct and secondary poisoning, loss of prey, and loss of burrow sites. Provision of a large, relatively undisturbed open space system providing nesting and foraging habitat away from development areas will also help mitigate for increased collisions with vehicles and manmade structures.

IMPACT 4.5-120 IMPACTS TO INDIVIDUALS – COOPER'S HAWK

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of Cooper's hawk individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to Cooper's hawk individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance

of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to Cooper's hawk individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-121 LOSS OF HABITAT – COOPER'S HAWK

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for Cooper's hawk through habitat protection, restoration and enhancement, and management.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and a 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**). The River Corridor SMA will preserve and enhance at least 380 acres of suitable nesting and/or foraging habitat for Cooper's hawk**.** The High Country SMA will preserve and enhance 2,199 acres of suitable nesting and/or foraging habitat for Cooper's hawk.

SP-4.6-26a requires that mitigation requirements for riparian vegetation in the High Country SMA be the same as required for the River Corridor SMA and oak tree replacement occur as described in SP-4.6-48. SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA, including the following: replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for Cooper's hawk through habitat protection, restoration and enhancement, and management.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site, which provides foraging habitat for Cooper’s hawk. The preservation of this vegetation

type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-22 states that the Oak Resource Management Plan shall incorporate the findings of the Draft Newhall Ranch Mitigation Feasibility Report (Dudek 2007A) and areas identified as being suitable for oak woodland enhancement and creation shall be used for mitigation.

BIO-42 requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities (County of Los Angeles 1988). Fencing shall extend to the root protection zone.

BIO-55 requires that maps of suitable riparian habitat be updated for special-status avian species, and the creation or enhancement of habitat shall be similar to the habitat removed.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the Cooper's hawk would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-122 SECONDARY IMPACTS – COOPER'S HAWK

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on Cooper's hawk associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as increased human activity, nighttime lighting, and potentially increased incidence of collisions with vehicles and manmade structures. Mitigation measures to minimize inadvertent impacts to habitat outside construction zones will also be implemented.

SP-4.6-1 through SP-4.6-16, SP-4.6-18 and SP-4.6-19, SP-4.6-21 through SP-4.6-26, SP-4.6-36 through SP-4.6-42, and SP-4.6-63, as described above and which generally refer to habitat protection, restoration and enhancement, and management, will be implemented to mitigate for

the effects of increased human activity and the increase in incidence of vehicle collisions. This open space area will also help mitigate for increased incidence of collisions with vehicles and man-made structures by providing a large undisturbed area to support nesting and foraging.

Several mitigation measures will control human activities in the River Corridor SMA and High Country SMA. SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

To avoid inadvertent impacts to habitat during construction, SP-4.6-20, SP-4.6-34, and SP-4.6-35 will be implemented. These mitigation measures require that all grading perimeters within the River Corridor SMA and High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor SMA and High Country SMA.

SP-4.6-33 addresses edge effects along open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to Cooper's hawk, including short-term construction-related dust, noise, ground vibration, and increased human activity, as well as long-term effects such as increased human activity; harassment by pet, stray, and feral cats and dogs; secondary poisoning and loss of prey due to the use of pesticides; and increased incidence of collisions with vehicles and man-made structures.

BIO-52 and BIO-56, as described above, will mitigate the effects of construction noise and increased human activity by identifying nest sites and providing for buffers between nests and construction activities.

BIO-1 through BIO-16 and BIO-19 through BIO-22, as described above, will mitigate for increased human activity and collisions in the Project area through habitat protection, restoration and enhancement, and management.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-64 will be implemented to prevent poisoning and loss of prey from pesticides and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to Cooper's hawk would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

FERRUGINOUS HAWK (WINTERING) (BCC, WL)

Life History

The ferruginous hawk (*Buteo regalis*) occurs throughout western North America from southernmost Canada between the Great Plains and Rocky Mountains, south to northern Arizona and New Mexico. This species breeds from southeast Alberta and extreme southwest Manitoba south to the northwest corner of Texas, west to the Great Basin, Columbia River Basin regions of eastern Oregon and southeast Washington. It was more recently discovered breeding in California (Small 1994). The ferruginous hawk most commonly winters from southern California, Colorado, Arizona, and New Mexico to northern Texas. Northern populations are completely migratory, while birds from southern breeding locations appear to migrate short distances or to be sedentary (Bechard and Schmutz 1995). The ferruginous hawk is an uncommon winter resident and migrant at lower elevations and open grasslands in the Modoc Plateau, Central Valley, and Coast Ranges of California (Polite and Pratt 1999).

The ferruginous hawk forages in open grasslands, agriculture (primarily grazing lands), sagebrush flats, desert scrub, and fringes of pinyon–juniper habitats (Polite and Pratt 1999). Birds seem to show a strong preference for elevated nest sites (boulders, creek banks, knolls, low cliffs, buttes, trees, large shrubs, utility structures, and haystacks), but will nest on nearly level ground when elevated sites are absent and when located far from human activities (Bechard and Schmutz 1995). Their winter range consists of open terrain from grassland to desert. West of the Rocky Mountains, grassland and arid areas of California, Arizona, and New Mexico are used heavily where prairie dogs, lagomorphs (rabbits and hares), ground squirrels, or pocket gophers are abundant. Amphibians, reptiles, and birds are occasionally taken. Hunting occurs from early morning to late afternoon and follows one of four types of pursuits: still hunting, short-distance strikes, aerial hunting, and hovering (Bechard and Schmutz 1995; NatureServe 2008).

Nest-building generally occurs in March in southern to mid-latitudes and birds occur on breeding areas from late February through early October (NatureServe 2008). In California, it has been reported that this species prefers native grassland and shrubland habitats over cropland, and areas with no perches for their nest sites (Janes 1985). Clutch size for this species is usually two to four with an incubation period of about 32 to 33 days. Young fledge in 35 to 50 days (Natureserve 2008).

The major threat to this species is the loss of breeding and wintering habitat. Local declines of ferruginous hawk have been noted (*e.g.*, Woffinden and Murphy 1989), but a widespread decline was not evident as of the early 1990s (57 FR 37507–37513; Olendorff 1993). Olendorff (1993) attributed population declines to the effects of cultivation, grazing, poisoning, and controlling small mammals, mining, and fire in nesting habitats, with cultivation being the most serious source of impact. Impacts from collisions with stationary or moving structures or objects,

pesticides and other contaminants, and shooting and trapping are not considered significant for this species.

Survey Results

The Project area is outside the ferruginous hawk's breeding range and it is not expected to nest on site. It was not observed in the numerous spring avian surveys conducted between 1988 and 2008. Because the spring surveys would have been unlikely to detect this species, a focused winter bird survey was conducted in 2008 by Bloom Biological, Inc. (2008) during the time period this species would be expected to occur on site if it was using the Project area as winter foraging habitat. During this study, ferruginous hawks were observed almost every day in eastern alfalfa fields, Wolcott agricultural fields, Potrero Canyon, and other agriculture fields along the Santa Clara River. The species was the most common winter raptor observed on site during the study and it was estimated that seven to 12 individuals were using the Project area.

Suitable winter foraging habitat for the ferruginous hawk within the Project area includes agriculture (*e.g.*, grazed, fallow/disked, alfalfa, but not intensive row crops; California annual grassland; purple needlegrass; disturbed land (excluding dense, weedy areas); and open scrub habitats, including alluvial scrub, arrow weed scrub, big sagebrush scrub, and coastal scrub alliances and associations (excluding dense California sagebrush scrub–undifferentiated chaparral and coyote brush scrub). A total of 9,417 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 266 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 2.8% of these habitats on site (**Figure 4.5-125**, Alternative 2 Impacts to Scrub, California Annual Grassland,

Oak/Grass, Agriculture, and River Wash Wildlife Habitat). A total of 103 acres would be temporarily impacted.

The ferruginous hawk is a wide-ranging species that only occurs on site as a winter visitor. On site, this species frequently uses Potrero Canyon where there would be substantial permanent RMDP impacts. Although the permanent loss of 266 acres and temporary impacts to habitat in Potrero Canyon and elsewhere resulting from implementation of the RMDP would be relatively small in the context of the more than 9,400 acres of suitable foraging habitat in the Project area, impacts in Potrero Canyon would adversely affect foraging in this area which is frequently used by the ferruginous hawk. Therefore, these permanent and temporary impacts would have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

A total of 4,529 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 48.1% of these habitats on site (**Figure 4.5-125**, Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat). A substantial portion of this habitat loss (1,581 acres; 34.9%) would occur in the agricultural areas adjacent to the Santa Clara River where the ferruginous hawk was regularly observed during the winter in 2008 (Bloom Biological 2008).

Although the ferruginous hawk is a wide-ranging species that occurs on site only as a winter visitor, the permanent loss of 4,529 acres (48.1%) of winter foraging habitat that would occur as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; and substantially reduce the number or restrict the range of the species (significance criteria 1 and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 4,795 acres (50.9%). As with indirect permanent

impacts alone, this combined direct and indirect permanent loss of winter foraging habitat would have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; and substantially reduce the number or restrict the range of the species (significance criteria 1 and 7). Combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The ferruginous hawk is a mobile species that forages on site during the winter and it is highly unlikely that construction activities associated with implementation of the RMDP would result in injury or mortality of individual adult birds. Foraging individuals would likely avoid areas under construction due to the lack of prey and construction activities. The ferruginous hawk does not breed on site so nests with eggs or young would not be affected. Implementation of the SCP would not directly impact this species. Because only foraging activity potentially would be altered and because substantial alternative foraging areas would be available during construction, direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

The ferruginous hawk is a mobile species and it is highly unlikely that build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of individual adult birds. Foraging individuals would likely avoid areas under construction due to the lack of prey and construction activities. The ferruginous hawk does not breed on site so nests with eggs or young would not be affected. Because only foraging activity potentially would be altered and because substantial alternative foraging areas would be available during construction, indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, fugitive dust, and general human activity. These effects may deter ferruginous hawks from foraging in areas near construction activities. Construction activities may also reduce the abundance of their prey in areas near these activities.

Potential long-term secondary impacts associated with urban development include increased human activity; use of rodenticides in areas adjacent to development that could cause secondary poisoning and reduce prey abundance; and potential harassment and predation by pet, stray, and

feral cats and dogs. These secondary impacts may deter ferruginous hawks from foraging in some undeveloped areas in close proximity to urban development.

Because the ferruginous hawk is a wide-ranging species that uses the site as winter foraging habitat and because of the limited time period (construction-related effects) and limited area over which long-term secondary effects may occur, these short-term and long-term secondary impacts would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the ferruginous hawk (**Figures 4.5-126** through **4.5-130**, Alternatives 3 through 7 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat):

- Alternative 3 – 246 acres (2.6%) of permanent loss and 147 acres of temporary loss;
- Alternative 4 – 227 acres (2.4%) of permanent loss and 153 acres of temporary loss;
- Alternative 5 – 288 acres (3.1%) of permanent loss and 133 acres of temporary loss;
- Alternative 6 – 278 acres (3.0%) of permanent loss and 149 acres of temporary loss; and
- Alternative 7 – 133 acres (1.4%) of permanent loss and 475 acres of temporary loss.

Compared to Alternative 2, which would result in 266 acres (2.8%) of permanent habitat loss and 103 acres of temporary impacts, the permanent loss of habitat would be marginally to somewhat reduced under Alternatives 3 and 4, marginally to somewhat higher under Alternatives 5 and 6, and substantially reduced under Alternative 7. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be somewhat higher and would be substantially higher under Alternative 7. The difference for direct permanent and temporary impacts under Alternative 7 compared to the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

The overall permanent loss of habitat from implementation of the RMDP and the SCP under Alternatives 3, 4, and 7 would be marginally to substantially reduced and would be marginally to somewhat higher under Alternatives 5 and 6 compared to Alternative 2, and temporary impacts would be somewhat higher to substantially higher. However, under each of the Alternatives, impacts would occur in Potrero Canyon, thus adversely affecting foraging activities in this area. Therefore, these direct impacts to habitat would be significant absent mitigation under Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the ferruginous hawk ((**Figures 4.5-126** through **4.5-130**, Alternatives 3 through 7 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat**)**:

- Alternative 3 – 4,313 acres (45.8%) of permanent loss;
- Alternative 4 – 4,137 acres (43.9%) of permanent loss;
- Alternative 5 – 4,033 acres (42.8%) of permanent loss;
- Alternative 6 – 3,573 acres (37.9%) of permanent loss; and
- Alternative 7 – 3,053 acres (32.4%) of permanent loss.

Compared to Alternative 2, which would result in 4,529 acres (48.1%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would have substantially reduced impacts compared to Alternative 3 because VCC would not be constructed under these alternatives and there would be successive reductions under Alternatives 4 through 7 due to other differences in the Project footprints. Alternative 7 would have the least amount of impact because of the pullback from the Santa Clara River and its tributaries, as well as avoidance of some agricultural areas adjacent to the River, but the permanent loss of 3,053 acres (32.4%) of foraging habitat under Alternative 7, including 830 acres of agriculture, would still be a substantial loss.

Although the overall loss of habitat resulting from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than under Alternative 2, these impacts would be still be substantially adverse and therefore significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and

Entrada planning areas would result in the following impacts to suitable habitat for the ferruginous hawk:

- Alternative 3 – 4,559 acres (48.4%) of permanent loss;
- Alternative 4 – 4,364 acres (46.3%) of permanent loss;
- Alternative 5 – 4,322 acres (45.9%) of permanent loss;
- Alternative 6 – 3,851 acres (40.9%) of permanent loss; and
- Alternative 7 – 3,186 acres (33.8%) of permanent loss.

Compared to Alternative 2, which would result in 4,795 acres (50.9%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons described above for indirect permanent impacts. Although the combined direct and indirect permanent loss of suitable habitat for the ferruginous hawk occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than under Alternative 2, these impacts would still be substantially adverse and therefore significant, absent mitigation.

Impacts to Individuals

The potential for impacts to ferruginous hawk individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2. Adult birds would likely avoid impacts during construction activities by avoiding or leaving construction areas. Further, because the species does not nest on site, nests with eggs and young would not be affected. Because only foraging activity may be altered during construction and because substantial alternative habitat would be available, impacts to ferruginous hawk individuals occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7. These potential short-term and long-term secondary impacts would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term impacts include construction-related noise and dust, increased human activity, and potential reduction of prey in areas near construction areas. Potential long-term secondary

impacts associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas include increased human activity; use of rodenticides; and harassment and predation by pet, stray, and feral cats and dogs, as described above for Alternative 2.

Because the ferruginous hawk is a wide-ranging species that uses the site as winter foraging habitat and because of the limited time period (construction-related effects) and limited area over which long-term secondary effects may occur, these short-term and long-term secondary impacts would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Short-term and long-term secondary impacts would be adverse but not significant for Alternatives 3 through 7.

Mitigation Strategy and Summary

The Project would result in one significant impact to the ferruginous hawk: loss of suitable foraging habitat.

The combined permanent loss of suitable foraging habitat for the ferruginous hawk resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 3,186 acres (33.8%) under Alternative 7 to 4,795 acres (50.9%) under Alternative 2. This would be a substantial loss of suitable foraging habitat for this species and would alter its use of the Project area for winter foraging. As mitigation for this impact, the combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a permanent open space system that will provide suitable habitat to support winter foraging by the ferruginous hawk in the Project vicinity. Implementation of these mitigation measures will result in protection and management of a minimum of approximately 3,000 acres of the suitable habitat for this species in the River Corridor SMA, High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

IMPACT 4.5-123 LOSS OF HABITAT – FERRUGINOUS HAWK

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the ferruginous hawk through habitat protection in the River Corridor SMA and High Country SMA where the species is most likely forage in the Project area after build-out.

SP-4.6-21 through SP-4.6-25 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and High Country SMA, as well as guidelines for ownership, management, and public access. The River Corridor SMA and High Country SMA combined will protect and manage a minimum of about 2,040 acres of suitable foraging habitat for the ferruginous hawk.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the ferruginous hawk through habitat protection, restoration and enhancement, and management in the Salt Creek area, where the species may forage during the winter.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. This area includes about 955 acres of suitable foraging habitat for the ferruginous hawk.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of foraging habitat for the ferruginous hawk would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

MERLIN (WINTERING) (WL)

Life History

The merlin (*Falco columbarius*) is a small falcon that occurs in North America, Europe, Asia, and the Middle East. In North America, the merlin breeds from Alaska eastward through most of Canada to Newfoundland and Maine, and south to Washington. Between 1995 and 2004, the species expanded its breeding range to include northern New York and northern New England (Sodhi *et al.* 2005). The species winters in most of its breeding range and southward to northern South America (AOU 1998; Sodhi *et al.* 2005). The Caribbean Islands are also a key wintering area (Clark and Wheeler 1987).

The merlin is an uncommon to rare winter visitor in California from September to May and is not known to breed in the state (Garrett and Dunn 1981; Zeiner *et al.* 1990A). Merlins may occur in most of the western half of the state below 1,500 meters (3,900 feet) AMSL, including the Mojave Desert to the east and the Channel Islands to the west. According to Remsen (1978), wintering birds are concentrated along the coast and in the Central Valley but numbers have declined markedly in California in recent decades.

The merlin uses a wide variety of semi-open to open habitats during breeding and wintering (Garrett and Dunn 1981; Sodhi *et al.* 2005). Foraging birds occur along coastlines and in grasslands, savannahs, open woodlands, lakes, wetlands, edges, and communities in early successional stages. In southern California, merlins are rarely found in heavily wooded areas or over open deserts. Habitats used can range from agricultural fields and annual grasslands to ponderosa pine and montane hardwood–conifer woodlands (Zeiner *et al.* 1990A). Merlins often use areas with undulating topography (County of Riverside 2008). Individuals in urban populations perch on buildings, utility poles, and tall trees (Oliphant 1974; Servheen 1985; Warkentin *et al.* 1990). Tree stands used for cover and nesting are frequently close to bodies of water and adjacent to open space areas for foraging.

The merlin feeds primarily on small birds usually weighing less than 50 grams (0.11 pound). It also feeds on small mammals, reptiles, and insects (Sodhi *et al.* 2005). Merlins usually attack from a perch with a wide view. Most prey are captured mid-air, but some are caught on the ground or while perching. Hunting mostly takes place in the early morning or late afternoon (Dekker 1988; Sodhi *et al.* 2005).

Use of organochlorine pesticides, especially DDT and its metabolite DDE, caused declines in the merlin population between about 1950 and 1980 due to eggshell thinning. These compounds accumulated in merlins that fed on contaminated prey, interfering with their calcium metabolism. Currently, loss of suitable habitat may be the major factor affecting merlins in North America (Cade 1982; Oliphant 1985), although this species can use urban areas for nesting. Nesting merlins appear to be fairly resilient to human disturbance if they are not directly threatened

(Sodhi *et al.* 2005). There is some evidence that direct disturbance of nest trees (*e.g.*, by climbing) early during incubation can cause nest abandonment (Oliphant 1974), but a subsequent study of the same population did not document this behavior (Sodhi *et al.* 2005). Frequent nest site visits and radio-tagging do not appear to affect reproductive success or survival of this species (Grier and Fyfe 1987; Sodhi *et al.* 1991).

Survey Results

The Project area provides suitable foraging habitat for migrant and wintering merlins. Avian surveys have been conducted in the riparian areas of the Santa Clara River and Castaic Creek from 1988 through 2008. Focused surveys for wintering raptors in 2007 included four observations of wintering or migrating merlins between March 4 and March 23 (Bloom Biological, Inc. 2007A). This survey covered all habitats within the Santa Clara River floodplain and approximately 0.5 mile on each side of the River along a stretch of 25 miles and its major tributaries in and around the Project area. Bloom Biological, Inc. (2008) expanded the survey area to include upland areas as well as the Santa Clara River from November 2007 through February 2008 and observed five or six individuals hunting over agricultural fields along the Santa Clara River and in Potrero Canyon between December 21 and January 2.

Merlins were not observed during bird surveys in any other year between 1988 and 2007. These other surveys for upland and riparian bird species were generally conducted in the spring to mid-summer (April through June) throughout the Project area. Therefore, the lack of observations of merlins during these surveys is not indicative of their status on site because occasional winter migrants would not have been observed during spring or summer surveys.

Based on the Bloom Biological, Inc. (2007A, 2008) observations, the merlin is considered to occur throughout the site during winter in suitable foraging habitat, including agriculture, disturbed land, California annual grassland, purple needlegrass, woodlands (California walnut woodland, coast live oak woodland, mixed oak woodland, valley oak woodland), valley oak/grass, and riparian communities (alluvial scrub, arrow weed scrub, herbaceous wetland, Mexican elderberry, mulefat scrub, river wash, southern willow scrub, southern coast live oak riparian forest, southern cottonwood–willow riparian). A total of 7,679 acres of suitable wintering and migration foraging habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use

practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 302 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 3.9% of these habitats on site (**Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat, and **Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat). A total of 192 acres would be temporarily impacted.

The merlin is still a wide-ranging species, is only expected to occur on site as a winter migrant, and forages in a wide variety of habitats. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging habitat in the High Country SMA, Salt Creek area, and River Corridor SMA would be available for this species at any given time. Therefore, the permanent loss of 302 acres of foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,225 acres of suitable habitat would be permanently loss through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 42.0% of suitable habitats on site (**Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat, and **Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat).

While a relatively large amount and percentage of suitable foraging habitat for the merlin would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada

planning areas, this habitat is only used by wintering and migrant individuals during the winter months. Wintering and migrating merlins are not restricted to any one migration route or wintering habitat area and use a variety of habitats throughout the state. They are somewhat nomadic during the non-breeding period in the southern portion of the state. In addition, approximately 3,181 acres of foraging habitat would remain in the River Corridor SMA, High Country SMA, and Salt Creek area. For these reasons, this loss of foraging habitat would not have a substantial adverse effect on this species; interfere with the movement of the species between important habitat areas or impede the use of native wildlife nursery sites (nests); cause the species to drop below self-sustaining levels on site or range-wide; threaten to eliminate the species on site or range-wide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,527 acres (45.9%). For the reasons provided above for indirect permanent impacts, this loss of habitat would not have a substantial adverse effect on wintering and migrant individuals (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because these birds are highly mobile, it is unlikely that RMDP-related construction activities would result in injury or mortality of adult birds of this species. Foraging birds may avoid active construction areas, thus altering their foraging behavior on site. Vegetation clearing and grading would not result in destruction of young or eggs of this species because it does not nest on site. Implementation of the SCP would not directly impact this species. Because only foraging behavior in construction areas would be affected and because there would be substantial alternative foraging habitat available, RMDP-related construction/grading activities would not have a substantial direct adverse effect on this species; interfere with the movement of the species between important habitat areas or impede the use of native wildlife nursery sites (nests); have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent and temporary impacts to individuals. Wintering and migrating adults are highly mobile and would not be directly affected by construction activities. Only foraging activities in construction areas would be affected, and substantial alternative foraging habitat would be available. Therefore, indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

In the short term, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas occurring during the winter have the potential to affect foraging by merlins in areas adjacent to construction zones. These short-term secondary impacts could include exposure to noise, fugitive dust, and increased human activity.

Potential long-term development-related secondary impacts along the open space–urban development edge include increased human activity; potential harassment by humans and pet, stray, and feral cats and dogs, and other mesopredators; and loss of prey and secondary poisoning from pesticides, such as insecticides and rodenticides.

Because the merlin only occurs on site during the winter and approximately 3,181 acres of foraging habitat would remain in the River Corridor SMA, High Country SMA, and Salt Creek area, these potential secondary impacts would not have a substantial adverse effect on this species; interfere substantially with the movement of the species between important habitat areas or impede the use of native wildlife nursery sites (nests); cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the merlin (**Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat, and **Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 266 acres (3.5%) of permanent loss and 237 acres of temporary loss;
- Alternative 4 – 251 acres (3.3%) of permanent loss and 238 acres of temporary loss;
- Alternative 5 – 314 acres (4.1%) of permanent loss and 228 acres of temporary loss;
- Alternative 6 – 307 acres (4.0%) of permanent loss and 232 acres of temporary loss; and
- Alternative 7 – 133 acres (1.7%) of permanent loss and 528 acres of temporary loss.

Compared to Alternative 2, which would result in 302 acres (3.9%) of permanent habitat loss and 192 acres of temporary impacts, the permanent loss of habitat would be somewhat reduced under Alternatives 3 and 4, not substantially different under Alternatives 5 and 6, and would be substantially reduced under Alternative 7. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be somewhat higher and would be substantially increased under Alternative 7. The difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in fewer permanent impacts and greater temporary impacts.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the merlin (**Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat, and **Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat):

- Alternative 3 – 3,073 acres (40.0%) of permanent loss;
- Alternative 4 – 2,920 acres (38.0%) of permanent loss;
- Alternative 5 – 2,862 acres (37.3%) of permanent loss;
- Alternative 6 – 2,607 acres (34.0%) of permanent loss; and
- Alternative 7 – 2,144 acres (27.9%) of permanent loss.

Compared to Alternative 2, which would result in 3,225 acres (42.0%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7.

The overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, but still substantial. However, because the merlin only uses the Project area for wintering and during migration, the approximately 3,181 acres of foraging habitat that would remain in the River Corridor SMA, High Country SMA, and Salt Creek area would be adequate for these individuals. For these reasons, indirect permanent impacts (Loss of Habitat) would be adverse but not significant for Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the merlin:

- Alternative 3 – 3,339 acres (43.5%) of permanent loss;
- Alternative 4 – 3,171 acres (41.3%) of permanent loss;
- Alternative 5 – 3,176 acres (41.4%) of permanent loss;
- Alternative 6 – 2,914 acres (37.9%) of permanent loss; and
- Alternative 7 – 2,277 acres (29.7%) of permanent loss.

Compared to Alternative 2, which would result in 3,527 acres (45.9%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect permanent impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, there would also be successive reductions in the Specific Plan and Entrada planning areas under these alternatives, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7.

Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for the merlin occurring as a result of implementation of the

RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial. However, as described above for indirect permanent impacts, the 3,181 acres of foraging habitat that would remain in the River Corridor SMA, High Country SMA, and Salt Creek area would be adequate for wintering and migrant merlins. Therefore, the combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant under Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to merlin individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2. Because adult merlins are highly mobile and the species does not nest on site, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3), and Entrada planning areas would not result in injury or mortality of individuals. Foraging merlins, however, would probably avoid active construction areas, but substantial alternative foraging habitat would be available. Therefore, impacts to individuals would be adverse but not significant under Alternatives 3 through 7.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term impacts include construction-related noise and increased human activity. These effects are more likely to occur during build-out of the Specific Plan, VCC, and Entrada planning areas than during implementation of the RMDP and the SCP because of the much larger area of impact.

Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include increased human activity, increased harassment and predation, and loss of prey and secondary poisoning, as described above for Alternative 2.

Because approximately 3,181 acres of foraging habitat would remain in the River Corridor SMA, High Country SMA, and Salt Creek area, which would be adequate to support wintering and migrant merlins, short-term and long-term secondary impacts would be adverse but not significant.

Mitigation Strategy and Summary

No mitigation is required for impacts to the merlin because all impacts were determined to be adverse but not significant. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA, High Country SMA and Salt Creek area—areas that will form a large, contiguous open space system containing approximately 3,086 acres of foraging habitat for this species. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, lighting, fugitive dust, and increased human activity during construction because individuals will have access to foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; dust; and pesticides will also be mitigated through a variety of measures.

PRAIRIE FALCON (NESTING) (BCC, WL)

Life History

The prairie falcon (*Falco mexicanus*) has a broad geographic range and occurs in most of the western and central United States, southwestern portions of Canada, and Mexico. Its breeding and summer range extends north to south-central British Columbia, south Alberta, and southernmost Saskatchewan. It breeds east to the Badlands and plains of North Dakota; western Nebraska; east-central Colorado; south to Sonora, Mexico; and west to Washington, Oregon, and California (Steenhof 1998). The species winters east to Minnesota, Iowa, Missouri, Oklahoma, and Texas, and occasionally in Illinois, Wisconsin, Indiana, and Michigan. Its wintering range extends west to Vancouver, British Columbia, Washington, Oregon, California, and Baja California, and south to central Mexico (Steenhof 1998). Prairie falcons are a permanent resident throughout California except in the northwest and in mountain areas (Remsen 1978). The total population of prairie falcon in California is relatively low compared to other portions of the species' range (Remsen 1978).

Prairie falcons inhabit open habitats in North America, including arid plains and steppe habitats. In the western states they prefer chaparral, desert grasslands, and creosote bush habitats. Nesting areas are on cliffs or bluffs near these open habitats. During the spring and fall migration, as well as overwintering, prairie falcons use primarily the same open scrub and grassland habitats for foraging purposes (Steenhof 1998).

Prairie falcons primarily feed on ground squirrels throughout their range, especially when numbers of squirrels increase in the spring and summer months in correspondence with falcon nesting and brood rearing. When their ground squirrel availability is limited, prairie falcons will prey on open habitat birds, most commonly horned larks (*Eremophila alpestris*) and western meadowlark (*Sturnella neglecta*), and also supplement their diet with lizards and insects (Steenhof 1998). They forage in areas with low vegetation, typically capturing prey near the ground, but are capable of taking birds in the air.

The prairie falcon begins breeding in early spring and eggs can be laid into late spring. They primarily nest on sheltered ledges of cliffs and embankments at heights of 10 to more than 100 meters (33 to 328 feet) (Roppe *et al.* 1989; Steenhof 1998). They usually lay four or five eggs that have an incubation time of 29 to 30 days and nestlings fledge 29 to 47 days after hatching (Steenhof 1998). The young begin to disperse at 65 days, traveling only a short distance from the nest site (Steenhof 1998).

The prairie falcon is not a true migrant, particularly in California, but more of a nomadic wanderer during the non-breeding months in response to prey availability. The prairie falcon is not territorial in the winter. In California, the average defended territory includes a 300- to 400-meter (984 to 1,312 feet) radius around the nest and 100 meters (328 feet) above the nest.

Identified threats to prairie falcons related to development and agriculture include human disturbance, such off-road vehicle use, rock climbing, and hiking near nesting areas; grazing; invasive exotic plants; energy development where disturbance is excessive; electrocution from power lines; collisions with wires, structures, and ground and air vehicles; drowning in stock tanks; and pesticides, such as DDE, which cause eggshell thinning (Nature Conservancy 2001). Use of rodenticides could reduce prey and result in secondary poisoning. Altered fire regimes may also affect foraging behavior by this species, which could be adverse or beneficial (DeLong and Steenhof 2004). Prairie falcons typically select unburned areas with a heterogeneous matrix of native shrub and grassland, but fire suppression may be adverse. Periodic natural fire regimes in fire-dependent communities may actually be beneficial (Tesky 1994).

Survey Results

Suitable foraging habitat for the prairie falcon is present throughout the Project area and individuals have been occasionally observed on site. Guthrie observed two prairie falcon individuals during surveys during spring/summer avian surveys: one individual was detected in April 2000 in Potrero Canyon and Long Canyon areas, and the other was observed in July 2001 along Castaic Creek between the confluence with the Santa Clara River and I-5 (Guthrie 2000D; Guthrie 2001A). Dudek and Associates observed one individual in the Salt Creek watershed in late November 2005 (2006B) and an incidental sighting occurred in late August 2007 over Salt Creek within the High Country SMA (Trow 2007). Bloom Biological, Inc. (2007A) observed one individual flying northward over the confluence of Salt Creek and the Santa Clara River in April 2007. In December 2007 and January 2008, at least two individuals were observed on several occasions in Potrero Canyon; and two other individuals were observed along the Santa Clara River on other occasions (Bloom Biological, Inc. 2008). These scattered, but consistent, observations indicate that the prairie falcon uses the Project area regularly.

Limited suitable nesting habitat (*i.e.*, cliff ledges and rock outcrops) is present in the High Country SMA, but nesting by the prairie falcon has not been documented on site in this area (Dudek and Associates 2006B). Additionally, Bloom Biological, Inc. (2008) noted that there were no known nests in the area. Because nesting has not been documented on site, the relatively few observations of prairie falcons over multiple survey years, and the ability of prairie falcons to travel long distances to forage in relation to prey availability, these observations are likely nomadic or regionally resident foraging individuals. For this reason, this analysis assumes that the prairie falcon's use of the Project area is limited to foraging. Furthermore, if the species were to nest on site, nesting would occur in the High Country SMA and not in areas planned for development.

Suitable foraging habitat in the Project area includes agriculture, disturbed land, California annual grassland, purple needlegrass, and valley oak/grass habitats. A total of 5,579 acres of suitable foraging habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 212 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 3.8% of these habitats on site (**Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat). A total of 94 acres would be temporarily impacted.

The prairie falcon is still a wide-ranging species that infrequently forages in the Project area. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging habitat in the High Country SMA, Salt Creek area, and River Corridor SMA would be available for this species at any given time. Therefore, the permanent loss of 212 acres of foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 3,100 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 55.6% of these habitats on site (**Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat).

The prairie falcon is a wide-ranging species that infrequently occurs on site. The infrequent observations of the prairie falcon on site indicate that the Project area is not critically important for this species and that it probably uses the site opportunistically for foraging. The lack of evidence of nesting indicates that the site is not important for supporting nesting pairs and their offspring. In addition, more than 1,400 acres of foraging habitat would remain in the River Corridor SMA, High Country SMA, and Salt Creek area. The permanent loss of 3,100 acres (55.6%) of foraging habitat as a result of build-out of the Specific Plan, VCC, and Entrada planning areas, while adverse, would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 3,312 acres (59.4%). For the reasons cited above for indirect permanent impacts, the loss of this foraging habitat from the combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because these birds are highly mobile, it is unlikely that RMDP-related construction activities would result in injury or mortality of adult birds of this species. Foraging birds may avoid active construction areas, thus altering their foraging behavior on site. Vegetation clearing and grading would not result in destruction of young or eggs of this species because it does not nest on site. Implementation of the SCP would not directly impact this species. Because only foraging behavior in construction areas would be affected and because there would be substantial alternative foraging habitat available, RMDP-related construction/grading activities would not have a substantial direct adverse

effect on this species; interfere with the movement of the species between important habitat areas or impede the use of native wildlife nursery sites (nests); have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent and temporary impacts to individuals. Wintering and migrating adults are highly mobile and would not be directly affected by construction activities. Only foraging activities in construction areas would be affected, and substantial alternative foraging habitat would be available. Therefore, indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

Short-term secondary effects of construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include construction-related noise, fugitive dust, and general human activity. These effects may deter prairie falcons from foraging in areas near construction activities. Construction activities may also reduce the abundance of their prey in areas near construction activities.

Potential long-term secondary impacts associated with urban development include increased human activity; use of pesticides in areas adjacent to development that could cause secondary poisoning and reduce prey abundance; and potential harassment and predation by pet, stray, and feral cats and dogs. These secondary impacts may deter prairie falcons from foraging in some undeveloped areas in close proximity to urban development.

Because the prairie falcon is a wide-ranging species that occasionally occurs on site and because of the limited time period (for construction-related effects) and limited area over which long-term secondary effects may occur, these short-term and long-term secondary impacts would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the prairie falcon (**Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 197 acres (3.5%) of permanent loss and 132 acres of temporary loss;
- Alternative 4 – 179 acres (3.2%) of permanent loss and 142 acres of temporary loss;
- Alternative 5 – 234 acres (4.2%) of permanent loss and 118 acres of temporary loss;
- Alternative 6 – 240 acres (4.3%) of permanent loss and 132 acres of temporary loss; and
- Alternative 7 – 112 acres (2.0%) of permanent loss and 438 acres of temporary loss.

Compared to Alternative 2, which would result in 212 acres (3.8%) of permanent habitat loss and 94 acres of temporary impacts, the permanent loss of habitat would be somewhat reduced under Alternatives 3 and 4, would be somewhat higher under Alternatives 5 and 6, and would be substantially reduced under Alternative 7. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be somewhat higher and would be substantially higher under Alternative 7. The difference for permanent and temporary impacts under Alternative 7 compared to the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries.

Because the overall permanent and temporary loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the prairie falcon (**Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 2,966 acres (53.2%) of permanent loss;
- Alternative 4 – 2,832 acres (50.8%) of permanent loss;
- Alternative 5 – 2,778 acres (49.8%) of permanent loss;
- Alternative 6 – 2,558 acres (45.8%) of permanent loss; and
- Alternative 7 – 2,099 acres (37.6%) of permanent loss.

Compared to Alternative 2, which would result in 3,100 acres (55.6%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would have somewhat reduced impacts compared to Alternative 3 because VCC would not be constructed under these alternatives and there would be successive reductions under these alternatives due to other differences in the Project footprints. Alternative 7 would have the least amount of impact because of the pullback from the Santa Clara River and its tributaries and avoidance of some agricultural areas adjacent to the River.

The prairie falcon is a wide-ranging species that infrequently occurs on site. The infrequent observations of the prairie falcon on site indicate that the Project area is not critically important for this species and that it probably uses the site opportunistically for foraging. The lack of evidence of nesting indicates that the site is not important for supporting nesting pairs and their offspring. Although reduced compared to Alternative 2, the combined direct and indirect permanent loss of suitable habitat for the prairie falcon occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would still be substantial. However, as described above for indirect permanent impacts, the more than 1,400 acres of foraging habitat that would remain in the River Corridor SMA, High Country SMA, and Salt Creek area would be adequate for foraging prairie falcons. Therefore, the combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the prairie falcon:

- Alternative 3 – 3,163 acres (56.7%) of permanent loss;
- Alternative 4 – 3,012 acres (54.0%) of permanent loss;
- Alternative 5 – 3,012 acres (54.0%) of permanent loss;

- Alternative 6 – 2,797 acres (50.1%) of permanent loss; and
- Alternative 7 – 22,211 acres (39.6%) of permanent loss.

Compared to Alternative 2, which would result in 3,312 acres (59.4%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons described above for indirect permanent impacts. Although reduced compared to Alternative 2, this loss of habitat under Alternatives 3 through 7 would still be substantial. However, more than 1,400 acres of foraging habitat would remain in the River Corridor SMA, High Country SMA, and Salt Creek area. As with Alternative 2, and for the reasons cited for indirect permanent impacts, the combined direct and indirect permanent loss of suitable habitat for the prairie falcon occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Impacts to Individuals

The potential for impacts to prairie falcon individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2. Because adult prairie falcons are highly mobile and the species does not nest on site, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3), and Entrada planning areas would not result in injury or mortality of individuals. Foraging prairie falcons, however, would probably avoid active construction areas, but substantial alternative foraging habitat would be available. Therefore, impacts to individuals would be adverse but not significant under Alternatives 3 through 7.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term impacts include construction-related noise and dust, increased human activity, and potential reduction of prey in areas near construction areas. Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas include increased human activity; use of pesticides; and harassment and predation by pet, stray, and feral cats and dogs, as described above for Alternative 2.

Because the prairie falcon is a wide-ranging species that occasionally occurs on site, and because of the limited time period (for construction-related effects) and limited area over which long-term secondary effects may occur, these short-term and long-term secondary impacts would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Short-term and long-term secondary impacts would be adverse but not significant for Alternatives 3 through 7.

Mitigation Strategy and Summary

No mitigation is required for impacts to the prairie falcon because all impacts were determined to be adverse but not significant. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA, High Country SMA and Salt Creek area—areas that will form a large, contiguous open space system containing more than 1,400 acres of foraging habitat for this species. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, fugitive dust, and increased human activity during construction because individuals will have access to foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction and controls on lighting. Long-term effects, such as increased human activity; pet, stray, and feral cats and dogs; dust; and pesticides will also be mitigated through a variety of measures.

SHARP-SHINNED HAWK (NESTING) (WL)

Life History

The sharp-shinned hawk (*Accipiter striatus*) has a broad geographic range, occurring over much of the United States, including Alaska, and throughout Canada and Mexico (Bildstein and Meyer 2000). The sharp-shinned hawk breeds from Alaska southward throughout much of Canada, the northern lower 48 states, the Rocky Mountains and mountains of the far west, parts of the Gulf Coast states, and the highlands of Mexico (Terres 1980). In southern California, it is a fairly common migrant and winter resident. The sharp-shinned hawk potentially breeds south to the Coast Ranges to about 35° latitude and within scattered locations in the Transverse and Peninsular ranges, but sparingly in mid-elevation habitats (Zeiner *et al.* 1990A).

Sharp-shinned hawks primarily occur in riparian forest and woodlands (NatureServe 2007), including ponderosa pine, black oak, riparian deciduous, mixed conifer, and Jeffrey pine habitats (Joy *et al.* 1984; Zeiner *et al.* 1990A; NatureServe 2007). The sharp-shinned hawk is highly migratory and winters from the lower 48 states to Panama and various Caribbean islands (AOU 1998). It nests in most forest types but shows a preference for young stands of dense boreal forest (Wiggers and Kritz 1991; Zeiner *et al.* 1990A). During spring and fall migration, sharp-shinned hawks use similar riparian and forest and woodland habitats, but also old fields, abandoned agricultural lots, chaparral, and mixed hardwood (Zeiner *et al.* 1990A; NatureServe 2007).

Sharp-shinned hawks feed mostly on small birds, but adults also take small mammals during the incubation and fledgling stages of reproduction (Joy *et al.* 1984). Sharp-shinned hawks hunt in forested areas throughout the tree canopy, along hedgerows, the edge of woodlands, brushy pastures, fields, and shorelines where migrating shorebirds and songbirds are found (Bildstein and Meyer 2000). During the winter they also forage in more open space and feedlots or bird feeders where prey are abundant (Bildstein and Meyer 2000).

Sharp-shinned hawks breed from early April through July (Bildstein and Meyer 2000; Zeiner *et al.* 1990A). Nests are typically constructed in densely forested areas in the lower part of the canopy, with an average distance of about 2.5 miles between nest sites (Zeiner *et al.* 1990A). While conifers are preferred for nests, deciduous trees are used in areas where conifers are sparse or absent (Bildstein and Meyer 2000; Wiggers and Kritz 1991). Clutch size is usually four or five and incubation lasts 30 to 32 days (Zeiner *et al.* 1990A; NatureServe 2007). The female incubates the eggs, while the male provides food for the female during incubation. The young first fly about 23 days after hatching (Brown and Amadon 1968). Breeding territories are commonly reused; however, occupation of previously used nests is rare (Bildstein and Meyer 2000).

Sharp-shinned hawk populations had experienced a steady decline from the early 1950s through the early 1960s but had stabilized by the mid-1960s and increased to near early 1950s levels by the late 1960s (Remsen 1978). However, due to the smaller population in California, there has been little research on threats and causes for decline (Bildstein and Meyer 2000). In addition to direct loss of habitat, sharp-shinned hawks probably are vulnerable to several effects related to urbanization and agriculture. Sharp-shinned hawks are affected by exposure to pesticides, and populations probably declined due to these effects (Henny 1987; Reynolds 1989). Use of pesticides may reduce their prey or cause secondary poisoning. Other identified causes of injury and mortality include collisions with cars and collisions with windows near bird feeders.

Survey Results

Sharp-shinned hawks have been observed several times during the course of the spring/summer avian surveys conducted along the Santa Clara River corridor. Two adults were observed on separate occasions in 1995 and again in 1997 and 1999 (Guthrie 1995B; Guthrie 1997A; Guthrie 1999B). One individual was observed in March 2007 by Bloom Biological, Inc. (2007A), and individuals were observed hunting along agriculture fields along the Santa Clara River during the winter of 2007 to 2008 by Bloom Biological, Inc. (2008). Based on these regular observations, the sharp-shinned hawk is considered to be a regular migrant, and possibly a winter visitor, in the Project area. The Project area is not considered to provide nesting habitat for the species. No sharp-shinned hawk nests or territories have been observed or have ever been known to occur in the Project area or in the region. For this reason, this analysis is limited to impacts to suitable foraging habitat that is used by migrant, and possibly wintering, sharp-shinned hawks.

Suitable foraging habitat in the Project area includes agriculture, disturbed land, grasslands (California annual grassland, purple needlegrass), scrubs (coastal scrub alliances and associations, *Eriodictyon* scrub), chaparrals (undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral), woodlands (California walnut woodland, coast live oak woodland, mixed oak woodland, valley oak woodland), valley oak/grass, riparian habitats (alluvial scrub, big sagebrush scrub, arrow weed scrub, southern coast live oak riparian forest, southern cottonwood–willow riparian, southern willow scrub, Mexican elderberry, mulefat scrub, and river wash), bulrush–cattail wetland, and herbaceous wetland. A total of 14,254 acres of suitable foraging habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use

practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 382 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 2.7% of suitable habitat on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats). A total of 201 acres would be temporarily impacted.

The sharp-shinned hawk is still a wide-ranging species, is only expected to occur on site as a winter visitor or migrant, and forages in a wide variety of habitats. The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging habitat in the High Country SMA, Salt Creek area, and River Corridor SMA would be available for this species at any given time. Therefore, the permanent loss of 382 acres of foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 5,195 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 36.4% of these habitats on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats).

The sharp-shinned hawk is still a wide-ranging species and only occurs on site as a migrant or winter visitor. In addition, approximately 6,570 acres of foraging habitat would remain in the River Corridor SMA, High Country SMA, and Salt Creek area. For these reasons, this permanent loss of habitat as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this

species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 5,578 acres (39.1%).

Because the sharp-shinned hawk is still a wide-ranging species and only occurs on site as a migrant or winter visitor, this combined direct and indirect permanent loss of habitat would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because these birds are highly mobile, it is unlikely that RMDP-related construction activities would result in injury or mortality of adult birds of this species. Foraging birds may avoid active construction areas, thus altering their foraging behavior on site. Vegetation clearing and grading would not result in destruction of young or eggs of this species because it does not nest on site. Implementation of the SCP would not directly impact this species. Because only foraging behavior in construction areas would be affected and because there would be substantial alternative foraging habitat available, RMDP-related construction/grading activities would not have a substantial direct adverse effect on this species; interfere with the movement of the species between important habitat areas or impede the use of native wildlife nursery sites (nests); have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is the same as described above for direct permanent and temporary impacts to individuals. Wintering and migrating adults are highly mobile and would not be directly affected by construction activities. Only foraging activities in construction areas would be affected, and substantial alternative foraging habitat would be available. Therefore, indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would be short term and potential secondary effects, such as fugitive dust, ground vibration, noise, nighttime illumination, and increased human activity, would affect a small proportion of sharp-shinned hawks migrating through the Project area.

Similarly, potential long-term development-related secondary effects resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas, such as nighttime illumination; noise; increased human activity; predation by pet, stray, and feral cats and dogs and other mesopredators; and pesticides would affect very few individuals migrating through of wintering in the Project area. Furthermore, there would be adequate foraging habitat for migrant and wintering individuals well away from development edges; approximately 6,570 acres of suitable foraging habitat would be protected in the River Corridor SMA, High Country SMA, and Salt Creek area.

These potential short-term and long-term secondary impacts would not have a substantial adverse effect on this species; cause the species to drop below self-sustaining levels on site or rangewide; interfere with the movement of the species between important habitat areas; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable habitat for the sharp-shinned hawk (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 342 acres (2.4%) of permanent loss and 249 acres of temporary loss;
- Alternative 4 – 328 acres (2.3%) of permanent loss and 246 acres of temporary loss;
- Alternative 5 – 396 acres (2.8%) of permanent loss and 242 acres of temporary loss;
- Alternative 6 – 375 acres (2.6%) of permanent loss and 248 acres of temporary loss; and
- Alternative 7 – 175 acres (1.2%) of permanent loss and 571 acres of temporary loss.

Compared to Alternative 2, which would result in 382 acres (2.7%) of permanent habitat loss and 201 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 and 4 would be somewhat reduced, would not be substantially different under Alternatives 5 and 6, and would be substantially reduced under Alternative 7. Compared to Alternative 2, the temporary loss of habitat under Alternatives 3 through 6 would be somewhat increased, and would be substantially increased under Alternative 7. The difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in substantially fewer permanent impacts and substantially greater temporary impacts.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude compared to Alternative 2, these impacts from Alternatives 3 through 7 would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the sharp-shinned hawk (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 4,983 acres (34.6%) of permanent loss;
- Alternative 4 – 4,734 acres (33.2%) of permanent loss;
- Alternative 5 – 4,628 acres (32.5%) of permanent loss;
- Alternative 6 – 4,125 acres (28.9%) of permanent loss; and
- Alternative 7 – 3,493 acres (24.5%) of permanent loss.

Compared to Alternative 2, which would result in 5,195 acres (36.4%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would have fewer impacts than Alternative 3 because VCC would not be constructed under these alternatives, and there would be successive reductions under Alternatives 4 through 7 due to other reductions in the Project footprints. In addition, more than 6,570 acres of foraging habitat would remain in the River Corridor SMA, High Country SMA, and Salt Creek area.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than under Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the sharp-shinned hawk:

- Alternative 3 – 5,281 acres (37.0%) of permanent loss;
- Alternative 4 – 5,062 acres (35.5%) of permanent loss;
- Alternative 5 – 5,204 acres (35.2%) of permanent loss;
- Alternative 6 – 4,499 acres (31.6%) of permanent loss; and
- Alternative 7 – 3,668 acres (25.7%) of permanent loss.

Compared to Alternative 2, which would result in 5,578 acres (39.1%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts, with Alternatives 4 through 7 having fewer impacts compared to Alternative 3 because VCC would not be constructed under these alternatives. Also, there would be successive reductions in impacts under Alternatives 4 through 7 due to other reductions in the Project footprints. In addition, more than 6,570 acres of foraging habitat would remain in the River Corridor SMA, High Country SMA, and Salt Creek area. Because the combined direct and indirect permanent loss of suitable habitat occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than under Alternative 2, these impacts would be adverse but not significant.

Impacts to Individuals

The potential for impacts to sharp-shinned hawk individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada

planning areas under Alternatives 3 through 7 would be similar to Alternative 2. Because adult sharp-shinned hawks are highly mobile and the species does not nest on site, construction activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3), and Entrada planning areas would not result in injury or mortality of individuals. Foraging sharp-shinned hawks, however, would probably avoid active construction areas, but substantial alternative foraging habitat would be available. Therefore, impacts to individuals would be adverse but not significant under Alternatives 3 through 7.

Secondary Impacts

Potential short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development.

Short-term impacts include construction-related dust, noise, ground vibration, and nighttime illumination. These effects are more likely to occur during build-out of the Specific Plan, VCC, and Entrada planning areas than during implementation of the RMDP and the SCP because of the much larger area of impact associated with build-out of the Specific Plan, VCC, and Entrada planning areas.

Potential long-term secondary impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas include increased human activity and increased predation, as described above for Alternative 2.

Because the sharp-shinned hawk is a migrant and possibly a winter visitor, and because there would be adequate suitable habitat well away from development edges, these potential short-term and long-term secondary effects would not have a substantial adverse effect on the species or contribute to the reduction of its range and distribution. These secondary impacts would be adverse but not significant.

Mitigation Strategy and Summary

No mitigation is required for impacts to the sharp-shinned hawk because all impacts were determined to be adverse but not significant. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA, High Country SMA and Salt Creek area—areas that will form a large, contiguous open space system containing approximately 6,575 acres of foraging habitat for this species. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, fugitive dust, and increased human activity

during construction because individuals will have access to foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction, and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; dust; and pesticides will also be mitigated through a variety of measures.

TURKEY VULTURE (CDFG TRUST RESOURCE)

Life History

The turkey vulture (*Cathartes aura*) is widespread throughout North and South America. It is found in most parts of the United States with the exception of the Great Plains and high elevations in the Sierra Nevada mountains. In the east, it breeds from Illinois northeast toward Maine and in portions of southern Quebec; in the west, it breeds from Texas to British Colombia and in portions of Minnesota, North and South Dakota, Colorado, and Kansas (Kirk and Mossman 1998). In California, it is common during the breeding season, and is a year-long resident west of the Sierra Nevada Mountains, especially in coastal areas. Summer and year-long ranges also include the southeastern United States; portions of Texas, Mexico and Central America, and South America; and some islands in the Caribbean (Kirk and Mossman 1998).

Turkey vultures use a variety of habitats while foraging on both wild and domestic carrion. They prefer open stages of most habitats. In the western United States, they tend to occur regularly in areas of hilly pastured rangeland, nonintensive agriculture, and areas with rock outcrops suitable for nesting, although they are not generally found in high-elevation mountain areas (Kirk and Mossman 1998; Zeiner *et al.* 1990A). However, the species prefers hilly areas that provide deflective updrafts for flight and generally avoids extensive areas of row-crop farmland (Kirk and Mossman 1998).

In addition to general habitat loss, turkey vultures are vulnerable to several threats directly related to human activities. As scavengers, turkey vultures can suffer lead poisoning from ingestion of lead bullet fragments in carrion (Kirk and Mossman 1998), and they are especially sensitive to lead poisoning during late fall and winter months, when lead poisoning is most likely to occur from hunted game animals (Kirk and Mossman 1998). They may also be affected by other contaminants, such as mercury when fish are eaten (Kirk and Mossman 1998), or from primary and secondary poisoning as a result of insecticide use (Kirk and Mossman 1998). After 1946, the use of DDT thinned eggshells and may have affected the species enough to compromise populations regionally (Kirk and Mossman 1998). Turkey vultures sometimes feed on roadkill, and vehicle collisions are fairly common (Kirk and Mossman 1998). Collisions with aircraft also pose a serious threat to turkey vultures due to their size, widespread geographic distribution, and occurrence at the same altitudes as many aircraft (Kirk and Mossman 1998). Because of the turkey vulture's large size, entanglement with powerlines and electrocution is also a potential cause of accidental injury or mortality.

Survey Results

No focused surveys have been conducted for the turkey vulture. However, this species has been incidentally observed on site over multiple years during bird surveys conducted from 1988

through 2007 along the Santa Clara River within the riparian and upland habitat. There are no mapped locations for any of these observations from 1988 through 2007.

Bloom Biological, Inc. (2007A) surveyed for raptor nests during February through June in 2007, including turkey vulture nests, and no turkey vulture nests were observed.

Foraging habitat for this species is very broad and includes all shrublands (alluvial scrub, arrow weed scrub, big sagebrush scrub, coastal scrub alliances and associations, and *Eriodictyon* scrub), grasslands (California annual grassland, purple needlegrass, valley oak/grass), agriculture, and disturbed land. A total of 10,027 acres of suitable foraging habitat is present in the Project area.

Nesting habitat is more specific than foraging habitat, and this species would only nest in areas that contain microhabitats of rocky outcrops, boulders, crevices, and possibly standing or fallen snags, the latter of which would be found in the more upland woodland habitats on site (coast live oak woodland, mixed oak woodland, valley oak woodland, and valley oak/grass). A total of 1,468 acres of suitable nesting habitat is present in the Project area; however, the microhabitats that this species could utilize for nesting on site within this larger area have not been quantified. If such sites exist on site, they probably are present in the upper portions of the High Country SMA and Salt Creek area where no development would occur.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 9.3 acres of suitable nesting habitat would be permanently lost through implementation of the RMDP and the SCP, representing 0.6% of these habitats on site (**Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat). A total of 1.4 acres of suitable nesting habitat would be temporarily impacted. A total of 269 acres of suitable foraging habitat would be permanently lost through implementation of the RMDP and the SCP, representing 2.7% of these habitats

on site (**Figure 4.5-125**, Alternative 2 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat). A total of 104 acres of suitable foraging habitat would be temporarily impacted.

Turkey vultures have never been observed nesting within or immediately adjacent to the Santa Clara River corridor and are not expected to nest within the corridor (inclusive of the RMDP site). The construction of RMDP facilities would be phased over a long period of time and thousands of acres of suitable foraging and potential nesting habitat in the High Country SMA, Salt Creek area, and River Corridor SMA would be available for this species at any given time. Therefore, the permanent loss of 9.3 acres of nesting habitat and 269 acres of foraging habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available foraging and nesting habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not cause a substantial adverse effect on this species either directly or *via* habitat modifications; interfere with its movement on site; or substantially reduce the number of this species or cause the species to drop below self-sustaining levels (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 85 acres of suitable nesting habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 5.8% of these habitats on site (**Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat). A total of 4,644 acres of suitable foraging habitat would be permanently lost through implementation of the RMDP and the SCP, representing 46.3% of these habitats on site (**Figure 4.5-125**, Alternative 2 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat).

This species has the potential to nest in some of the rocky outcrops, crevices, or snags within woodlands or canyons on the Project site. However, these microhabitats do not occur extensively across the Project site and have to been quantified. Because much of the suitable nest microhabitat, particularly rocky outcrops, cliff faces, and ledges, occur within the High Country SMA and Salt Creek area, which will not be developed, it is unlikely that a substantial amount of suitable nesting habitat would be impacted. With regard to the loss of foraging habitat for the turkey vulture, this species is an opportunistic carrion scavenger and forages in suitable habitat throughout its broad range. The loss of 46.3% of its foraging habitat in the Project area with build-out of the Specific Plan, VCC, and Entrada planning areas, while adverse, would not have a substantial adverse effect on this species either directly or *via* habitat modifications; interfere with

the movement of this species on site; or substantially reduce the number of this species or cause the species to drop below self-sustaining levels (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect loss of suitable nesting habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 95 acres (6.5%). The combined direct and indirect loss of suitable foraging habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 4,913 acres (49.0%). Because of the limited potential for the turkey vulture to nest in the Project area and because of its use of a broad variety of foraging habitat (*i.e.*, wherever carrion is available), the loss of 49.0% of foraging habitat, while adverse, would not substantially affect this wide-ranging species, the build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species either directly or *via* habitat modifications; interfere with the movement of this species on site; or substantially reduce the number of this species or cause the species to drop below self-sustaining levels (significance criteria 1, 4, and 7). Combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The RMDP primarily impacts the River corridor and associated drainages, which are unlikely to support turkey vulture nests. Because turkey vultures generally prefer more open habitat, especially in hilly areas where they can take advantage of deflective updrafts, the relatively flat and dense riparian woodlands associated with the RMDP are not considered high-quality nesting habitat. In addition, over the course of almost 20 years of avian surveys conducted along the Santa Clara River, no turkey vultures have ever been observed nesting within the RMDP site. Consequently, this species is not expected to nest within the RMDP site.

As these birds are highly mobile, it is unlikely that RMDP-related construction activities would result in direct injury or mortality of adult birds, although there is some risk of collision with fast-moving construction equipment or vehicles if individuals attempt to scavenge carrion in construction areas. If nesting occurred, construction and/or grading activities associated with the proposed RMDP could result in destruction of young or eggs in active nests of this species if such activities occurred during the nesting season, or nests could be abandoned if nesting adults are disturbed. Implementation of the SCP would not directly impact this species. If nests were disturbed, implementation of the

RMDP would have a substantial direct adverse effect on this species; interfere substantially with the movement of the species between important habitat areas or impede the use of native nursery sites (nests); have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

Similar to the direct permanent and temporary impacts resulting from the implementation of the RMDP, build-out of the Specific Plan, VCC, and Entrada planning areas is unlikely to result in injury or mortality of individual adult birds, although there is some risk of collision with fast-moving construction equipment or vehicles if individuals attempt to scavenge carrion in construction areas. While there have been no recorded observations of turkey vultures nesting within the build-out area, suitable nesting habitat does occur and construction/grading activities could result in destruction of nests, eggs, or young, or nests could be abandoned if nesting adults are disturbed, if such activities occurred in areas where turkey vultures are nesting (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term, construction-related impacts associated with RMDP and SCP implementation and build-out of the Specific Plan, VCC, and Entrada planning areas could affect this species' foraging and roosting activities in areas adjacent to construction zones. These impacts include construction-related noise, lighting, and disturbance from human activity that could cause nest abandonment or affect foraging behavior.

While short-term secondary impacts associated with the implementation of the RMDP and the SCP would not cause a substantial adverse effect because turkey vultures have never been observed nesting within or immediately adjacent to the Santa Clara River corridor, and are not expected to nest within the corridor, build-out of the Specific Plan, VCC, and Entrada planning areas would occur over a much larger area and would have greater potential to affect this species during construction.

Build-out of the Specific Plan, VCC, and Entrada planning areas also would result in urbanization of lands adjacent to suitable turkey vulture nesting and foraging habitat within the Project area. Urban development could result in long-term secondary impacts such as harassment from humans and pets, secondary poisoning from use of pesticides, lead poisoning

from ingestion of carrion shot with lead ammunition, entanglement with powerlines and electrocution, and increased incidence of vehicle collisions. Because turkey vultures generally avoid nesting in urbanized areas, the development of residential and commercial areas would decrease or restrict the suitable nesting areas on site or birds may abandon nests. This species feeds on carcasses, including roadkill, and the build-out of roads may increase the frequency of vehicle collisions for this species. The use of pesticides in landscaped areas, parks, or common areas may result in secondary poisoning and/or reduce prey for this species.

These short-term and long-term secondary impacts therefore may interfere with the movement of this species on site, impede the use of nursery sites, or substantially reduce the number of this species or cause the species to drop below self-sustaining levels (significance criteria 4 and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable nesting and foraging habitat for the turkey vulture (**Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat, and **Figures 4.5-126** through **4.5-130**, Alternatives 3 through 7 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat):

- Alternative 3
  - 9.5 acres (0.6%) of permanent loss and 1.4 acres of temporary loss of nesting habitat
  - 248 acres (2.5%) of permanent loss and 147 acres of temporary loss of foraging habitat;
- Alternative 4
  - 8.9 acres (0.6%) of permanent loss and 1.4 acres of temporary loss of nesting habitat
  - 230 acres (2.3%) of permanent loss and 153 acres of temporary loss of foraging habitat;
- Alternative 5
  - 13 acres (0.9%) of permanent loss and 1.4 acres of temporary loss of nesting habitat

  - 290 acres (2.9%) of permanent loss and 134 acres of temporary loss of foraging habitat;
- Alternative 6
  - 18 acres (11.3%) of permanent loss and 1.3 acres of temporary loss of nesting habitat
  - 284 acres (2.8%) of permanent loss and 150 acres of temporary loss of foraging habitat; and
- Alternative 7
  - 5.6 acres (0.4%) of permanent loss and 13 acres of temporary loss of nesting habitat
  - 135 acres (1.4%) of permanent loss and 4478 acres of temporary loss of foraging habitat.

For nesting habitat, Alternatives 3 and 4 would have similar permanent and temporary impacts compared to Alternative 2, which would result in 9.3 acres (0.6%) of permanent loss of nesting habitat and 1.4 acres of temporary impacts. Alternatives 5 and 6 would have greater permanent impacts and similar temporary impacts. Alternative 7 would have fewer permanent impacts but somewhat greater temporary impacts. The difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and relatively more temporary impacts.

For foraging habitat, Alternatives 3 and 4 would result in fewer permanent impacts and greater temporary impacts compared to Alternative 2, which would result in 269 acres (2.7%) of permanent loss of foraging habitat and 104 acres of temporary impacts. Alternatives 5 and 6 would have greater permanent and temporary impacts to foraging habitat. Alternative 7 would have substantially fewer permanent impacts to foraging habitat, but substantially greater temporary impacts. The difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and relatively more temporary impacts.

Because the overall permanent loss of nesting and foraging habitat resulting from implementation of the RMDP and the SCP under Alternatives 3 through 6 would be similar in magnitude compared to Alternative 2, and the greater total impact under Alternative 7 is mainly due to temporary impacts, impacts to nesting and foraging habitat for the turkey vulture would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the turkey vulture (**Figures 4.5-109** through **4.5-113**, Alternatives 3 through 7 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat, and **Figures 4.5-126** through **4.5-130**, Alternatives 3 through 7 Impacts to Scrub, California Annual Grassland, Oak/Grass, Agriculture, and River Wash Wildlife Habitat):

- Alternative 3 – 66 acres (4.5%) of permanent loss of nesting habitat and 4,419 acres (44.1%) of permanent loss of foraging habitat;
- Alternative 4 – 65 acres (4.4%) of permanent loss of nesting habitat and 4,243 acres (42.4%) of permanent loss of foraging habitat;
- Alternative 5 – 66 acres (4.5%) of permanent loss of nesting habitat and 4,140 acres (41.3%) of permanent loss of foraging habitat;
- Alternative 6 – 41 acres (2.8%) of permanent loss of nesting habitat and 3,673 acres (36.6%) of permanent loss of foraging habitat; and
- Alternative 7 – 44 acres (3.0%) of permanent loss of nesting habitat and 3,123 acres (31.1%) of permanent loss of foraging habitat.

For nesting habitat, Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, which would result in 85 acres (5.8%) of permanent loss of nesting habitat. Because impacts to nesting habitat for the turkey vulture would be less under Alternatives 3 through 7 compared to Alternative 2, this impact would be adverse but not significant.

Alternatives 3 through 7 would also result in fewer permanent impacts to foraging habitat compared to Alternative 2, which would result in 4,644 acres (46.3%) of permanent loss of foraging habitat. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed, and these alternatives would have successively fewer impacts due to reductions in the Project footprint. The substantial difference between Alternative 7 and the other alternatives is primarily due to the pullback of the Project footprint from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts. Although Alternatives 3 through 7 would result in the permanent loss of 31.1% to 44.1% of foraging habitat on site for the turkey vulture, for the reasons cited above for Alternative 2, this impact would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the turkey vulture:

- Alternative 3 – 76 acres (5.2%) of permanent loss of nesting habitat and 4,667 acres (46.5%) of permanent loss of foraging habitat;
- Alternative 4 – 74 acres (5.0%) of permanent loss of nesting habitat and 4,473 acres (44.6%) of permanent loss of foraging habitat;
- Alternative 5 – 79 acres (5.4%) of permanent loss of nesting habitat and 4,430 acres (44.2%) of permanent loss of foraging habitat;
- Alternative 6 – 59 acres (4.0%) of permanent loss of nesting habitat and 3,957 acres (39.5%) of permanent loss of foraging habitat; and
- Alternative 7 – 50 acres (3.4%) of permanent loss of nesting habitat and 3,257 acres (32.5%) of permanent loss of foraging habitat.

For nesting habitat, compared to Alternative 2, which would result in 95 acres (6.5%) of combined direct and indirect permanent loss, Alternatives 3 through 7 would have reduced impacts. Alternatives 3, 4, and 5 would have similar impacts, and Alternatives 6 and 7 would have further reduced impacts. Because Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, impacts to nesting habitat for the turkey vulture would be adverse but not significant under these alternatives.

For foraging habitat, compared to Alternative 2, which would result in 4,913 acres (49.0%) of combined direct and indirect permanent loss, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above for the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed, there would also be successive reductions in the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7. For the same reasons as cited above for Alternative 2, the combined direct and indirect permanent loss of 32.5% to 46.5% of foraging habitat on site for the turkey vulture would be adverse but not significant.

Impacts to Individuals

The potential for impacts to turkey vulture individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. There is some potential for collisions with fast-moving construction equipment or vehicles if turkey vultures attempt to scavenge carrion in construction areas, but this impact is considered unlikely to occur. While there have been no recorded observations of turkey vultures nesting within the build-out area, suitable nesting habitat does occur and construction/grading activities could result in destruction of nests, eggs, or young or abandonment of nests if such activities occurred in areas where turkey vultures are nesting. Such impacts to nesting turkey vulture individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative would have similar construction activities and long-term effects.

Short-term effects include construction-related noise, lighting, and disturbance from human activity that could cause nest abandonment and disrupt foraging behavior. These effects are more likely to occur during build-out of the Specific Plan, VCC, and Entrada planning areas than implementation of the RMDP and the SCP because of the much larger area of impact.

Urban development could result in long-term secondary impacts, such as harassment from humans and pets, secondary poisoning from use of pesticides, ingestion of lead from scavenged animal carcasses, entanglement with powerlines and electrocution, and increased incidence of vehicle collisions, as described above for Alternative 2.

These short-term and long-term secondary impacts therefore may interfere with the movement of this species on site, impede the use of nursery sites, or substantially reduce the number of this species or cause the species to drop below self-sustaining levels. Secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in two types of significant impacts to turkey vulture: (1) direct and indirect impacts to individuals; and (2) secondary impacts to individuals.

Although nesting by turkey vultures has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas, suitable nesting habitat (oak woodlands and oak/grass) is present on site and it is assumed for the purpose of this analysis that nesting could occur. Impacts to individuals could occur if active nests were disturbed during construction, including destruction of nests and loss of eggs and/or fledglings, or abandonment of nests as a result of human activity and noise. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 500 feet of any active nest until young have fledged. It is also possible that individuals could be injured or killed by fast-moving equipment or vehicles if they attempted to scavenge carrion in construction areas, but this impact is considered to be unlikely or rare, and therefore would be adverse but not significant.

With regard to secondary effects, any nesting activities by the turkey vulture could be adversely affected in the short term by increased human activity and noise if construction occurred during the nesting season. Nighttime lighting may cause adults to abandon nests due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to nocturnal predators. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 500 feet and by retaining a qualified biologist during all grading and construction activities. Long-term development-related impacts include an increased potential for entanglement with power lines poles, resulting in physical injury or death from electrocution. Reproductive success also could be affected by increased noise; lighting; pesticides, which may cause secondary poisoning and loss of prey; lead poisoning due to ingestion of carrion that had been shot; human disturbances of nest sites; and pet, stray, and feral cats and dogs. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of nesting and/or foraging habitat in the High Country SMA and Salt Creek area will provide turkey vultures with relatively undisturbed habitat for foraging and potentially nesting, especially in the remote portions of the High Country SMA. Lighting restrictions along the perimeter of natural areas will help reduce impacts to potential nest sites. Limited recreational usage and access restrictions within the High Country SMA, control of pet, stray, and feral cats and dogs in or near open space areas, trail signage, and homeowner education regarding special-status resources in preserved natural habitat areas will help protect turkey vultures during foraging activities and at potential nest sites. Controls on pesticides (including rodenticides) will prevent accidental poisoning and potential loss of prey. Installation of new or relocation of existing power lines in the High Country SMA and Salt Creek area will be coordinated with CDFG and structures will be designed in accordance with Avian Power Line Interaction Committee (APLIC 2006) guidelines and operated with anti-perching devices to help reduce turkey vulture collisions and electrocutions.

The specific mitigation measures for the turkey vulture are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-124 IMPACTS TO INDIVIDUALS – TURKEY VULTURE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of turkey vulture individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce impacts to turkey vulture individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. If active nests are found, the nests shall be buffered from clearing and construction in the vicinity.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to turkey vulture individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-125 SECONDARY IMPACTS – TURKEY VULTURE

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on the turkey vulture associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as human activity and pets, increased incidence of vehicle collisions, inadvertent impacts to habitat during construction, and nighttime lighting. These mitigation measures include measures that will preserve, restore and enhance, and manage suitable nesting and foraging habitat in the High Country SMA that will provide a large open space area away from development for the turkey vulture.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce the effects of increased human activity, pets, and increased incidence of vehicle collisions in the Project area (**Figure 4.5-3**). The High Country SMA will protect at least 2,189 acres of suitable foraging habitat and 867 acres of suitable nesting habitat for the turkey vulture.

SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area. Replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Several mitigation measures will control human activities in the High Country SMA. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA. The prohibition of hunting will help protect turkey vultures from lead poisoning due to ingesting contaminated carrion.

SP-4.6-33 addresses edge effects along the open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-34 and SP-4.6-35 require that all grading perimeters within the High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to biological resources outside the grading area in the High Country SMA.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to the turkey vulture, including short-term construction-related noise and increased human activity, as well as long-term increased human activity; greater vulnerability to harassment by pet, stray, and feral cats and dogs; entanglement with power lines and electrocution; and secondary poisoning and loss of prey from use of pesticides.

BIO-52 and BIO-56, as described above, will mitigate the effects of noise by identifying nest sites and providing for buffers between nests and construction activities.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. The Salt Creek area includes at least 1,068 acres of foraging habitat and 380 nesting habitat for the turkey vulture.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated. Along with BIO-29, this measure will help offset the effects of increased human activity in the area by providing high quality habitat for prey such as mule deer, as well as a variety of smaller prey.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-63 and BIO-69 will also be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-64 will be implemented to prevent poisoning and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides and insecticides) on site prior to the issuance of building permits.

BIO-81 and BIO-82 will be implemented to mitigate for the impacts from powerlines as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas.

BIO-81 requires the installation/relocation of utility poles in the High Country SMA and Salt Creek area to be coordinated with CDFG.

BIO-82 specifies anti-perching devices to deter turkey vultures and other raptors from perching on all surfaces of new utility towers. Towers shall be kept clean of debris, such as cable, trash, and construction materials.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the turkey vulture would be adverse but not significant for Alternatives 2, 3, 4, 5 6, and 7.

BLACK-CROWNED NIGHT-HERON (ROOKERY) (CALIFORNIA SPECIAL ANIMAL)

Life History

The black-crowned night-heron (*Nycticorax nycticorax*) is a widespread species, breeding on every continent except Australia and Antarctica (County of Riverside 2008). It breeds in the western hemisphere from British Columbia eastward to Nova Scotia, southward locally through the Americas to southern South America, and winters locally from Washington to New England southward throughout the remainder of the breeding range (AOU 1998). Its distribution generally is determined by the suitable wetland habitat for feeding. In California, the black-crowned night-heron is a fairly common, year-round resident in lowlands and foothills throughout most of the state, including the Salton Sea and Colorado River areas, and very common locally in large nesting colonies (Zeiner *et al.* 1990A). In southern California, the species generally occurs locally throughout the region as a year-round resident, except for in mountainous and desert areas (Garrett and Dunn 1981). Rookeries (nesting colonies) for this species are scarce within southern California. This species is a local migrant, dispersing widely from breeding colonies after nesting (County of Riverside 2008). Much of the breeding population from northwestern and northeastern California probably moves southward and is absent from those areas in midwinter.

The black-crowned night-heron's habitat requirements are varied, including all types of wetland areas, including fresh, brackish, and salt water ecosystems and even using man-made ditches, canals, reservoirs, and wet agricultural fields (County of Riverside 2008). It is restricted to more aquatic wetlands such as marshes, ponds, reservoirs, and estuaries for foraging and also occurs along the margins of lacustrine, large riverine, and fresh and saline emergent habitats (Garrett and Dunn 1981; County of Riverside 2008). Nests and roosts are associated with dense-foliaged trees and dense emergent wetlands (Zeiner *et al.* 1990A). During spring and fall migration, the black-crowned night-heron uses wetlands associated with the coasts and river drainages (County of Riverside 2008). Winter habitat includes freshwater marshes and swamps in tropical areas (County of Riverside 2008).

The black-crowned night-heron feeds on annelid worms, insects, crustaceans, amphibians, and fish, with fish being the dominant food source (County of Riverside 2008). The species prefers shallow, weedy pond margins, creeks, and marshes for foraging habitat and feeds mainly from evening to early morning, but feeds during the day during the breeding season (Williams 1979; County of Riverside 2008). The black-crowned night-heron breeds from February to July throughout most of California, but April to August in northeastern California (Cogswell 1977). It uses more forested riparian areas for nesting (Garrett and Dunn 1988) and nests are located in dense-foliaged trees; dense, fresh, or brackish emergent wetlands; or dense shrubbery or vine tangles, usually near aquatic or emergent feeding areas. Nests are built of twigs and/or marsh

plants (Zeiner *et al.* 1990A). The species is nocturnally active and disperses widely from breeding colonies after nesting (County of Riverside 2008). Custer and Osborn (1978) found that, in North Carolina, black-crowned night-herons foraged up to five miles from their nesting area. Black-crowned night-heron pairs defend both feeding and nesting territories and may chase other species from foraging areas or crows near nesting areas (Noble *et al.* 1938; Teal 1965). Many year-old black-crowned night-herons return to the vicinity of their natal colony, but others may end up thousands of miles from their natal area. Juvenile birds disperse widely in all directions after nesting but make relatively restricted movements thereafter (County of Riverside 2008; Erwin *et al.* 1996).

Development- and human-related threats to black-crowned night-heron include disturbance at breeding colonies, drainage of wetlands, and land development (Gross 1923; County of Riverside 2008). Human disturbance of nesting colonies may result in nest abandonment, predation of eggs, and reduced late-season nesting (County of Riverside 2008). Nest predators include crows and ravens, both of which are attracted to construction areas, urban development, and agriculture. Environmental contaminants and disease may also affect this species, as evidenced by recent, massive die-offs of water-associated species at the Salton Sea (County of Riverside 2008). DDT and other pesticides are thought to have caused local reproductive failure and population declines, but convincing documentation is lacking and sparse census data from the early 20th century makes trend analysis difficult (County of Riverside 2008). As with other wetland and riparian species, black-crowned night-herons may be sensitive to several other human- or development-related impacts. Construction-related dust, noise and ground vibration, nighttime lighting, diminished water quality, and altered hydrology are all factors that could affect black-crowned night-herons in the short term. Noise; lighting; diminished water quality and altered hydrology (*e.g.*, groundwater pumping and dewatering); pesticides that could reduce prey or cause secondary poisoning; and predation by pet, stray, and feral cats and dogs and other mesopredators are all factors that could adversely affect black-crowned night-heron over the long term.

Survey Results

Surveys for riparian species have been conducted for multiple years along the Santa Clara River in suitable habitat for the black-crowned night-heron. These surveys were conducted by Guthrie from 1988 through 2007 within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C); within portions of the Santa Clara River by Labinger and Greaves in 1994, 1996, 1997 and 1998 (Labinger *et al.* 1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A); within Castaic Creek, Salt Creek, High Country SMA, and portions of the Santa Clara River adjacent to the Project site by Dudek

in 2006 (Dudek and Associates 2006B, 2006D, 2006E); and within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line by Bloom in 2007 and 2008 (Bloom Biological 2007A, 2008).

The black-crowned night-heron has been regularly observed over multiple years during bird surveys conducted from 1988 through 2007 along the Santa Clara River within the riparian scrub and woodland habitat in the RMDP Project area (Guthrie 1993A, 1993B, 1994B, 1995B, 1996B, 1998A, 1999C, 2000C, 2001B, 2002A, 2003B, 2004H, 2005B, 2006A; Labinger *et al.* 1995, 1996; Bloom Biological 2007A, 2008), in the VCC planning area (Guthrie 1988, 1992, 1994A, 1995A, 1996A, 1997A, 1998B, 1999A, 2000E), off site in the Castaic Junction area (Guthrie 1988, 1989, 1993A, 1994A, 1995A, 1997A, 1998A, 1999A, 2000C, 2001A, 2003A, 2004I, 2005A, 2006C), and in the San Francisquito Creek area (Guthrie 2006A, 2006C).

Individuals have been observed early in the year and are thought to be wintering individuals or migrants. Although the riparian bird surveys were not focused on the black-crowned night-heron, roosts or rookeries would have been readily detected if present. None have been detected during the surveys within or adjacent to the Project area.

Although no roosts or rookeries for the black-crowned night-heron have been documented during the many surveys on site, the Project area supports suitable foraging and potentially supports nesting habitat for the species, and, thus, this EIS/EIR analyzes the impact of the Project on this habitat. Potential nesting and foraging habitat for this species on site includes bulrush–cattail wetland, coastal and valley freshwater marsh, and mulefat scrub. In addition, southern coast live oak riparian forest, southern cottonwood–willow riparian, and southern willow scrub are potential nesting habitats for this species. Because potential nesting habitat is inclusive of all suitable foraging habitat, this analysis refers to nesting and foraging habitat. A total of 520 acres of potential nesting habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 56 acres of potential nesting habitat, which also includes all suitable foraging habitat, would be permanently lost through implementation of the RMDP and the SCP, representing 10.7% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). A total of 53 acres would be temporarily impacted.

The black-crowned night-heron is very widespread and a relatively low-status species in California, and no roosts or rookeries have been documented in the Project area. Its potential to nest on site is considered to be low. Loss of habitat, however, could alter foraging behavior by winter visitors and migrants. However, because this species is widespread and its sensitivity status is related to nesting areas (rookeries), loss of foraging habitat would not be a substantial adverse effect on this species. Furthermore, the construction of RMDP facilities would be phased over a long period of time and hundreds of acres of suitable riparian habitat in the River Corridor SMA and associated tributaries would be available for this species at any given time. Therefore, the permanent loss of 56 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 15 acres of potential nesting habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 2.8% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat).

The black-crowned night-heron is very widespread and a relatively low-status species in California, and its potential to nest on site is considered to be low. Loss of habitat, however, would alter foraging behavior by winter visitors and migrants. However,

because this species is widespread and its sensitivity status is related to nesting areas (rookeries), loss of foraging habitat would not be a substantial adverse effect on this species. Therefore, permanent loss of 2.8% of nesting habitat as a result of construction/grading activities would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of potential nesting habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 70 acres (13.5%). Because the black-crowned night-heron is a widespread and a relatively low-status species in California, no roosts or rookeries have been documented on site, and only foraging habitat would be lost, the combined permanent loss of 70 acres of nesting habitat as a result of construction/grading activities would not have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

There are no black-crowned night-heron roosts or rookeries documented on site and this low-status species is highly mobile, so it is unlikely that the proposed Project would result in the mortality of adults, young, and/or eggs due to destruction of nests if construction and/or grading activities occurred during the nesting season of this species. The only anticipated impacts of the Project to individuals would be alteration of foraging behavior by winter visitors and migrants due to construction activities and loss of habitat, as analyzed above. Implementation of the SCP would not directly impact this species. Because of the relatively small permanent loss and temporary impacts to habitat, because no roosts or rookeries are documented on site, and because adults are very mobile, there would be a very low probability of injury or mortality of black-crowned night-herons using this habitat as a result of construction/grading activities. The proposed Project

would not have a substantial direct adverse effect on this species; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be adverse but not significant.

Indirect Permanent Impacts

The potential for indirect permanent impacts to individuals is similar to that described above for direct permanent impacts to individuals, but is relatively less because less potential nesting habitat would be affected. It is highly unlikely that the proposed Project would result in mortality of adults, young, and/or eggs caused by the destruction of nests if construction and/or grading activities occurred during the nesting season of this species. The only anticipated impacts of the Project on individuals would be alteration of foraging behavior by winter visitors and migrants due to construction activities and loss of habitat, as analyzed above. The proposed Project would not have a substantial adverse effect on this species; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

In the short term, noise, dust, and nighttime illumination from the construction-related activities in and around the Santa Clara River corridor could disrupt behavioral activities, including foraging, of wintering individuals and migrants. Nesting activities would not be disrupted because no rookeries have been documented on site and the potential for nesting to occur on site is considered to be very low. Short-term secondary impacts to foraging behavior would not be substantially adverse, however, because the black-crowned night-heron is capable of foraging elsewhere in the River corridor during construction. Similarly, long-term secondary effects on foraging by wintering and migrant individuals, resulting from implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas (*e.g.*, increased human activity and pets) would not be substantially adverse because adequate foraging habitat will be available for this species in the River corridor. In addition, numerous mitigation measures, as described fully in **Subsection 4.5.6**, Mitigation Measures, will be implemented to control for potential impacts related to construction-generated dust, noise, and ground vibration; nighttime lighting; diminished water quality and altered hydrology; pesticides; increased human activity; and predation by pet, stray, and feral cats and dogs and other mesopredators. For these reasons, potential short-term and long-term secondary impacts as a result of the construction of RMDP

facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial adverse effect on this species; interfere with the movement of the species between important habitat areas; cause the species' population to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to potential nesting habitat for the black-crowned night-heron (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 40 acres (7.6%) of permanent loss and 54 acres of temporary loss;
- Alternative 4 – 41 acres (7.9%) of permanent loss and 50 acres of temporary loss;
- Alternative 5 – 47 acres (9.0%) of permanent loss and 57 acres of temporary loss;
- Alternative 6 – 34 acres (6.6%) of permanent loss and 52 acres of temporary loss; and
- Alternative 7 – 8.6 acres (1.7%) of permanent loss and 35 acres of temporary loss.

Compared to Alternative 2, which would result in 56 acres (10.7%) of permanent habitat loss and 53 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 through 7 would be substantially less. Compared to Alternative 2, the temporary loss of habitat would not be substantially different under Alternative 3, marginally to somewhat less under Alternatives 4 and 6, somewhat more under Alternative 5, and substantially less under Alternative 7. The difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under this alternative, which would result in fewer direct permanent and temporary impacts.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to potential nesting habitat for the black-crowned night-heron (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 12 acres (2.2%) of permanent loss;
- Alternative 4 – 8.7 acres (1.7%) of permanent loss;
- Alternative 5 – 5.5 acres (1.1%) of permanent loss;
- Alternative 6 – 2.6 acres (0.5%) of permanent loss; and
- Alternative 7 – 1.3 acres (0.2%) of permanent loss.

Compared to Alternative 2, which would result in 15 acres (2.8%) of permanent loss of potential nesting habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7.

Because the overall loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be less than Alternative 2, these impacts would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to potential nesting habitat for the black-crowned night-heron:

- Alternative 3 – 51 acres (9.8%) of permanent loss;
- Alternative 4 – 50 acres (9.5%) of permanent loss;
- Alternative 5 – 52 acres (10.0%) of permanent loss;
- Alternative 6 – 37 acres (7.1%) of permanent loss; and
- Alternative 7 – 9.9 acres (1.9%) of permanent loss.

Compared to Alternative 2, which would result in 70 acres (13.5%) of combined direct and indirect permanent loss of nesting habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons described above for the discussions of direct and indirect impacts. Alternatives 6 and 7 would have reduced impacts compared to Alternatives 2, 3, 4 and 5 due to additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternatives 6 and 7 compared to Alternatives 2, 3, 4, and 5. The combined direct and indirect permanent loss of potential nesting habitat for the black-crowned night-heron occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be adverse but not significant.

Impacts to Individuals

The potential for impacts to individuals of the black-crowned night-heron as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would be the same under Alternatives 3 through 7 as compared to Alternative 2. Because rookeries have not been documented on site and because adults are highly mobile, injury or mortality of individuals resulting from construction activities is highly unlikely. The only anticipated impact is alteration of foraging by winter visitors and migrants as a result of construction activities and loss of suitable habitat. Because this species is widespread and does not nest on site, impacts to individuals of the black-crowned night-heron occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would be adverse but not significant for Alternatives 3 through 7.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term construction activities and long-term effects due to urban development. Some wintering and migrant individuals may be displaced from foraging habitat, but this impact would not be substantially adverse because this species is widespread and adequate alternative foraging habitat will be available in the River corridor. In addition, numerous mitigation measures, as described fully in **Subsection 4.5.6**, Mitigation Measures, will be implemented to control for potential impacts related to construction-generated dust, noise, and ground vibration; nighttime lighting; diminished water quality and altered hydrology; pesticides; increased human activity; and predation by pet, stray, and feral cats and dogs and other mesopredators. Short-term and long-term secondary impacts would be adverse but not significant for Alternatives 3 through 7.

Mitigation Strategy and Summary

No mitigation is required for impacts to the black-crowned night-heron because all impacts were determined to be adverse but not significant. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of approximately 370 acres of suitable riparian habitat in the River Corridor SMA, as well as drainages in the Salt Creek area and High Country SMA that contain riparian habitats. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, lighting, and increased human activity during construction because individuals will have access to foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; and pesticides will also be mitigated through a variety of measures.

NUTTALL'S WOODPECKER (NESTING) (CALIFORNIA SPECIAL ANIMAL)

Life History

Nuttall's woodpecker (*Picoides nuttallii*) is a permanent resident in California with a range extending from northern California southward to northwestern Baja California, and generally west of deserts and the Sierra divide. Nuttall's woodpecker occurs from Siskiyou, Shasta, and northwestern Lassen counties; southward into the foothills of eastern Trinity and southeastern Mendocino counties to the Pacific Coast at Sonoma County and south to Los Angeles, Riverside, and San Bernardino counties. In southern California, Nuttall's woodpecker occurs in riparian habitats into deserts and along the eastern mountain slopes in eastern San Diego County (Garrett and Dunn 1981; Small 1994). Isolated populations east of the Sierra Nevada mountains are present along the Owens River in Inyo County. In northwestern Baja California, Nuttall's woodpecker occurs below 1,250 meters (4,101 feet) AMSL, south to La Encantada and Rancho Rosarito (Lowther 2000).

Nuttall's woodpecker primarily occurs in upland oak woodlands, to a lesser extent in riparian woodlands, and rarely occurs in conifer forests. It has been described as a species characteristic of, if not confined to, oak woodlands in California (Lowther 2000). However, its habitat preference shifts from upland oak woodlands to riparian habitat as it ranges southward in its distribution and oaks decrease in abundance (Lowther 2000). In northern California, Nuttall's woodpecker occurs in hills dominated by coast live oak and valley oaks and willow and sycamore in riparian habitats (Jenkins 1979). In Kern County, California, it occurs from 1,100 to 1,700 meters (3,609 to 5,577 feet) AMSL in elevation in blue oak, valley oak, California black oak, interior live oak, and canyon live oak woodlands (Block 1991). In northwestern Baja California, Nuttall's woodpecker occurs in desert riparian areas containing cottonwoods and willows (Zeiner *et al.* 1990A).

Nuttall's woodpecker feeds mostly on adult and larval insects, primarily beetles, which make up as much as 80% of their diet. A smaller portion of its diet is composed of berries, poison-oak seeds, nuts, fruits, and sap (Zeiner *et al.* 1990A). It forages mostly in low elevation oak and riparian deciduous habitats, gleaning prey from trunks, branches, twigs, and foliage (Jenkins 1979), but occasionally attempts aerial capture of insects, as well as feeding on the ground (Zeiner *et al.* 1990A).

Nuttall's woodpecker breeds from late March to early July, with a peak in April to early June (Zeiner *et al.* 1990A). It forms monogamous pairs and appears to use the same territory year round (Lowther 2000). It uses snags and dead limbs in soft wood for nest excavations, with the tree cavity and foliage providing cover. The nesting cavities are 0.6 to 18 meters (2 to 60 feet) above the ground and occur primarily in riparian habitat located in dead and occasionally live trunks or limbs of willow, sycamore, cottonwood, or alder (Zeiner *et al.* 1990A; Miller and Bock 1972).

Although a year-round resident in California, Nuttall's woodpeckers may move upslope out of the foothills and canyons of higher mountain ranges after breeding (Small 1994). Miller and Bock (1972) found the home range for Nuttall's woodpecker to be 0.8 kilometer (0.5 mile) in a riparian strip in Monterey County.

Nuttall's woodpecker populations appear to be stable at this time, and this species is common and somewhat tolerant of human activity (Lowther 2000). Threats to Nuttall's woodpecker include loss of preferred habitat due to flood control, urbanization, and agriculture. Raccoons, which are adapted to urban environments, prey on young and eggs (Zeiner *et al.* 1990A). It is presumed that pet, stray, and feral cats would also prey on Nuttall's woodpecker. Other development- and human-related impacts expected to affect this species include construction-related dust; noise and ground vibration; nighttime lighting; and pesticides, which may reduce prey or cause secondary poisoning. Invasive species in riparian areas such as giant reed and tamarisk also would be expected to adversely affect nesting and foraging habitat for this species, and Argentine ants may prey on nestlings.

Survey Results

Avian surveys have been conducted over multiple years along the Santa Clara River within suitable habitat for the Nuttall's woodpecker, including by Guthrie from 1988 through 2006 within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C); within portions of the Santa Clara River by Labinger *et al.*, in 1994, 1996, 1997 (1995, 1996, 1997A, 1997B); and by Labinger and Greaves in 1998 (1999A) within Castaic Creek, Salt Creek, High Country SMA; within portions of the Santa Clara River adjacent to the Project site by Dudek and Associates (2006B, 2006D, 2006E); and within Castaic Creek and the Santa Clara River from the I-5 bridge to Las Brisas Bridge west of the Ventura County line by Bloom Biological, Inc. in 2007 and 2008 (Bloom Biological 2007A, 2008).

Nuttall's woodpecker has been observed nearly every year along the Santa Clara River since surveys began in 1988. Bloom Biological, Inc. (2007A, 2008), for example, found Nuttall's woodpecker to be common in cottonwood and willow riparian habitat along the Santa Clara River and Castaic Creek, as well as in coast live oak woodland in canyons and adjoining uplands. As a resident species, Nuttall's woodpecker would likely nest in riparian habitat located in dead and occasionally live trunks or limbs of willow, sycamore, cottonwood, or alder (Zeiner *et al.* 1990A; Miller and Bock 1972). Additional observations occur along the Santa Clara River east of Castaic Creek, in the VCC planning area, at South Fork, in the Entrada planning area, and west of Airport Mesa (Bloom Biological 2007A).

Suitable nesting habitat for Nuttall's woodpecker in the Project area includes oak woodlands (coast live oak woodland, mixed oak woodland and forest, and valley oak woodland), valley oak/grass, mulefat scrub, southern coast live oak riparian forest, southern cottonwood–willow riparian, and southern willow scrub. A total of 1,985 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 64 acres of suitable habitat would be permanently lost through implementation of the RMDP and the SCP, representing 3.2% of these habitats on site (**Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat). A total of 54 acres would be temporarily impacted.

The Nuttall's woodpecker is still a common and wide-ranging species, populations seem to be stable, and it uses a variety of riparian and woodland habitats. The construction of RMDP facilities would be phased over a long period of time and more than 1,600 acres of suitable riparian and woodland habitat in the River Corridor SMA, High Country SMA, and Salt Creek area would be available for this species at any given time. Therefore, the permanent loss of 64 acres of habitat and temporary impacts that would occur as a result of construction and/or grading activities would not substantially reduce the available habitat for this species during construction of RMDP facilities. At the completion of temporary disturbances, these areas would be restored. Therefore, these permanent and temporary impacts would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict

the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 100 acres of suitable habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 5.0% of these habitats on site (**Figure 4.5-108**, Alternative 2 Impacts to Riparian, Oak Woodland, and Oak/Grass Wildlife Habitat).

Because Nuttall's woodpecker is still a common and wide-ranging species, populations appear to be stable, and more than 1,600 acres of habitat would be preserved for this species, the loss of 100 acres habitat as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species rangewide; interfere with the movement of the species between important habitat areas; cause the species to drop below self-sustaining levels rangewide; threaten to eliminate the species rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts
