LIST OF SECTIONS

Volume II

4.5.1 INTRODUCTION 4.5-1
4.5.1.1 Reader's Guide 4.5-1
4.5.1.1.1 Organizational Scheme 4.5-1
4.5.1.1.2 Regulatory Setting 4.5-2
4.5.1.1.3 Environmental Setting 4.5-3
4.5.1.1.3.1 Existing Conditions by Project Planning Area 4.5-3
4.5.1.1.3.2 Existing Conditions by Biological Resource 4.5-4
4.5.1.1.4 Impact Significance Criteria 4.5-6
4.5.1.1.5 Analysis of Project Impacts 4.5-8
4.5.1.1.5.1 Impacts to Vegetation Communities and Land Covers 4.5-8
4.5.1.1.5.2 Impacts to Unique Landscape Features 4.5-12
4.5.1.1.5.3 Impacts to Common Wildlife – The "Guild" Analysis 4.5-13
4.5.1.1.5.4 Impacts to Wildlife Movement and Habitat Connectivity 4.5-14
4.5.1.1.5.5 Impacts to Special-Status Species 4.5-15
4.5.1.1.5.6 Mitigation Measures 4.5-17
4.5.1.1.5.7 Summary of Significance Findings 4.5-18
4.5.1.2 Relationship of Proposed Project to Newhall Ranch Specific Plan Program EIR 4.5-18
4.5.1.3 Relationship of Proposed Project to VCC and Entrada Planning Areas 4.5-27
4.5.1.3.1 VCC Planning Area 4.5-27
4.5.1.3.2 Entrada Planning Area 4.5-28

4.5.2 REGULATORY SETTING 4.5-31
4.5.2.1 Federal Authorities and Administering Agencies 4.5-32
4.5.2.1.1 Clean Water Act of 1976 ..... 4.5-32
4.5.2.1.1.1 Section 404 Permit 4.5-32
4.5.2.1.1.2 Corps' Section 404 Permit Process. 4.5-35
4.5.2.1.1.3 NEPA Action 4.5-38
4.5.2.1.1.4 Endangered Species Act of 1973 ..... 4.5-38
4.5.2.1.1.5 USFWS Processes 4.5-39
4.5.2.1.1.6 NEPA Action 4.5-40

Page

4.5.2.2 State Authorities and Administering Agencies 4.5-40
4.5.2.2.1 California Endangered Species Act (CESA) (Fish & G. Code, § 2050 et seq.). 4.5-40
4.5.2.2.1.1 Fish and Game Code Sections 1600–1616. ..... 4.5-43
4.5.2.2.1.2 Master Streambed Alteration Process 4.5-44
4.5.2.2.1.3 CESA "Take" Authorizations. 4.5-46
4.5.2.2.1.4 CEQA Actions 4.5-47
4.5.2.3 Other Permits and Approvals 4.5-48
4.5.2.3.1 County of Los Angeles Oak Tree Ordinance (CLAOTO) 4.5-49

4.5.3 ENVIRONMENTAL SETTING AND ALTERNATIVE 1 ..... 4.5-51
4.5.3.1 Summary of Literature Review and Biological Studies Conducted in Project Area 4.5-53
4.5.3.2 Survey Methods 4.5-113
4.5.3.2.1 Vegetation Communities Mapping 4.5-113
4.5.3.2.2 Botanical Surveys 4.5-114
4.5.3.2.3 Oak Tree Surveys 4.5-121
4.5.3.2.4 Wildlife Surveys 4.5-122
4.5.3.2.4.1 General Wildlife 4.5-122
4.5.3.2.4.2 Invertebrates 4.5-123
4.5.3.2.4.3 Birds 4.5-124
4.5.3.2.4.4 Fish 4.5-127
4.5.3.2.4.5 Reptiles and Amphibians 4.5-128
4.5.3.2.4.6 Mammals 4.5-131
4.5.3.3 Existing Conditions by Project Planning Area 4.5-133
4.5.3.3.1 RMDP 4.5-133
4.5.3.3.1.1 Past and Current Land Use. 4.5-133
4.5.3.3.1.2 Vegetation Communities and Land Covers. 4.5-135
4.5.3.3.1.3 Open Space within the RMDP 4.5-144
4.5.3.3.2 VCC Planning Area 4.5-165
4.5.3.3.2.1 Past and Current Land Use 4.5-165
4.5.3.3.2.2 Vegetation Communities and Land Covers 4.5-165
4.5.3.3.2.3 Soils 4.5-166
4.5.3.3.2.4 Special Status Species 4.5-166
4.5.3.3.3 Entrada Planning Area 4.5-167
4.5.3.3.3.1 Past and Current Land Use 4.5-167
4.5.3.3.3.2 Vegetation Communities and Land Covers 4.5-167
4.5.3.3.3.3 Soils 4.5-168
4.5.3.3.3.4 Special Status Species 4.5-168

TABLE OF CONTENTS
SECTION 4.5 - BIOLOGICAL RESOURCES

Page

4.5.3.4 Existing Conditions by Biological Resource 4.5-170
4.5.3.4.1 Vegetation Communities and Land Cover Types 4.5-170
4.5.3.4.1.1 Non Native Grassland (42.000.00) 4.5-174
4.5.3.4.1.2 Native Grassland (41.000.00) 4.5-175
4.5.3.4.1.3 Coastal Scrub (32.000.00) 4.5-175
4.5.3.4.1.4 Undifferentiated Chaparral Scrubs (37.000.00) 4.5-180
4.5.3.4.1.5 Chaparral with Chamise (37.100.00) 4.5-181
4.5.3.4.1.6 Chaparral with Oak (37.400.00) 4.5-181
4.5.3.4.1.7 Other Scrubs 4.5-182
4.5.3.4.1.8 Oak Woodland and Forest (71.000.00) 4.5-182
4.5.3.4.1.9 Upland Walnut Woodland and Forest (72.000.00) 4.5-184
4.5.3.4.1.10 Marsh (52.000.00) 4.5-185
4.5.3.4.1.11 Low to High Elevation Riparian Scrub (63.000.00) 4.5-186
4.5.3.4.1.12 Riparian Forest and Woodland (61.000.00) 4.5-188
4.5.3.4.1.13 Other Riparian/Wetland Communities 4.5-191
4.5.3.4.1.14 Man Made Land Cover Types 4.5-195
4.5.3.4.2 Unique Landscape Features 4.5-197
4.5.3.4.2.1 River Corridor SMA 4.5-197
4.5.3.4.2.2 High Country SMA and Salt Creek Area 4.5-198
4.5.3.4.2.3 Middle Canyon Spring 4.5-199
4.5.3.4.3 General Wildlife 4.5-202
4.5.3.4.3.1 RMDP 4.5-202
4.5.3.4.3.2 VCC 4.5-206
4.5.3.4.3.3 Entrada 4.5-207
4.5.3.4.4 Special-Status Vegetation Communities 4.5-210
4.5.3.4.4.1 Upland Communities 4.5-210
4.5.3.4.4.2 Riparian Waters and Wetlands 4.5-212
4.5.3.4.5 Special Status Plant Species 4.5-215
4.5.3.4.5.1 San Fernando Valley Spineflower (*Chorizanthe parryi* var. *fernandina*) 4.5-219
4.5.3.4.5.2 Undescribed Everlasting (*Gnaphalium* sp. *nova*) 4.5-221
4.5.3.4.5.3 Undescribed Sunflower (*Helianthus* sp. *nova*) 4.5-222
4.5.3.4.5.4 Island Mountain Mahogany (*Cercocarpus betuloides* var. *blancheae*) 4.5-222
4.5.3.4.5.5 Late Flowered Mariposa Lily (*Calochortus weedii* var. *vestus*) 4.5-223
4.5.3.4.5.6 Mainland Cherry (*Prunus ilicifolia* ssp. *ilicifolia*) 4.5-223

4.5.3.4.5.7 Oak Trees (*Quercus* spp.) 4.5-223
4.5.3.4.5.8 Oak Leaved Nemophila (*Nemophila parviflora* var. *quercifolia*) 4.5-223
4.5.3.4.5.9 Ojai Navarretia (*Navarretia ojaiensis*) 4.5-223
4.5.3.4.5.10 Parish's Sagebrush (*Artemisia tridentata* ssp. *parishii*) 4.5-224
4.5.3.4.5.11 Peirson's Morning Glory (*Calystegia peirsonii*) 4.5-224
4.5.3.4.5.12 Plummer's Mariposa Lily (*Calochortus plummerae*) .. 4.5-225
4.5.3.4.5.13 Slender Mariposa Lily (*Calochortus clavatus* var. *gracilis*) 4.5-225
4.5.3.4.5.14 Southern California Black Walnut (*Juglans californica* var. *californica*) 4.5-226
4.5.3.4.5.15 Southwestern Spiny Rush (*Juncus acutus* ssp. *leopoldii*) 4.5-226
4.5.3.4.6 Special-Status Wildlife Species 4.5-228
4.5.3.4.6.1 Special-Status Wildlife Species Observed within the Project Area 4.5-229
4.5.3.4.7 Wildlife Habitat Connectivity and Buffers 4.5-267
4.5.3.4.7.1 Wildlife Habitat Connectivity 4.5-267

4.5.4 IMPACT SIGNIFICANCE CRITERIA 4.5-283

4.5.5 IMPACTS OF THE PROPOSED PROJECT AND ALTERNATIVES 4.5-285
4.5.5.1 Impact Analysis Approach and Methods 4.5-285
4.5.5.1.1 Direct Impacts of RMDP/SCP 4.5-287
4.5.5.1.1.1 Permanent Impacts 4.5-287
4.5.5.1.1.2 Temporary Impacts 4.5-290
4.5.5.1.2 Indirect Impacts 4.5-291
4.5.5.1.2.1 Permanent Impacts 4.5-291
4.5.5.1.3 Secondary Impacts 4.5-292
4.5.5.1.3.1 Short Term Construction Related Secondary Impacts 4.5-292
4.5.5.1.3.2 Long term Secondary Impacts Related to Implementation of the RMDP and SCP, and Build-Out of the Specific Plan, VCC, and Entrada Planning Areas 4.5-296
4.5.5.2 Impacts to Vegetation Communities, Land Covers, Unique Landscape Features, and Wildlife, Including Impact Analysis for Alternative 1 (No Action/No Project) 4.5-313
4.5.5.2.1 Summary Descriptions of the EIS/EIR Alternatives 4.5-313

4.5.5.2.1.1 Alternative 1 (No Action/No Project) 4.5-313
4.5.5.2.1.2 Alternative 2 (Proposed Project) 4.5-315
4.5.5.2.1.3 Alternative 3 (Elimination of Potrero Canyon Road Bridge and Addition of Additional Spineflower Preserves) 4.5-315
4.5.5.2.1.4 Alternative 4 (Inclusion of VCC Preserve Area and Elimination of Potrero Canyon Road Bridge) 4.5-316
4.5.5.2.1.5 Alternative 5 (Widened Tributary Channels) 4.5-316
4.5.5.2.1.6 Alternative 6 (Maximum Spineflower Expansion/Connectivity) 4.5-317
4.5.5.2.1.7 Alternative 7 (Avoidance of 100 Year Floodplains and Spineflower) 4.5-318
4.5.5.2.2 Comparative General Impacts of EIS/EIR Alternatives, Including Alternative 1 (No Action/No Project) 4.5-318
4.5.5.2.2.1 Alternative 1 (No Action/No Project) 4.5-318
4.5.5.2.2.2 Vegetation Communities and Land Covers 4.5-319
4.5.5.2.2.3 Unique Landscape Features 4.5-323
4.5.5.2.2.4 Special-Status Vegetation Communities 4.5-324
4.5.5.2.2.5 Common Wildlife 4.5-327
4.5.5.2.2.6 Special-Status Wildlife 4.5-332
4.5.5.2.2.7 Wildlife Habitat Linkages, Corridors, and Buffers 4.5-338
4.5.5.2.2.8 Special-Status Plants 4.5-341
4.5.5.2.2.9 Comparison of Alternatives 2 through 7 ..... 4.5-342
4.5.5.2.3 Impacts to Vegetation Communities and Land Covers 4.5-345
4.5.5.2.3.1 Summary Descriptions of Impacts to Vegetation Communities and Land Covers of the EIS/EIR Alternatives 4.5-347
4.5.5.2.3.2 Impacts to Vegetation Communities and Land Covers 4.5-363
4.5.5.2.3.2.1 Impacts to Vegetation Communities and Land Covers—Alternative 2 ..... 4.5-373
4.5.5.2.3.2.2 Impacts to Vegetation Communities and Land Covers—Alternatives 3 through 7 ..... 4.5-456
4.5.5.2.3.3 RMDP and SCP Components within Unique Landscape Features 4.5-477
4.5.5.2.3.4 Impacts to Common Wildlife 4.5-479
4.5.5.2.3.5 Impacts to Special Status Plant Species 4.5-547
4.5.5.2.4 Impacts to Wildlife Movement and Habitat Connectivity 4.5-561

Page

4.5.5.2.4.1 Habitat Connectivity and Wildlife Movement Background Information by Guild 4.5-562
4.5.5.2.4.2 Impacts to Wildlife Landscape Habitat Linkages 4.5-573
4.5.5.2.4.3 Impacts to Wildlife Corridors 4.5-579
4.5.5.2.4.4 Wildlife Crossings 4.5-593
4.5.5.3 Impacts to Special-Status Species 4.5-597
Arroyo Toad (FE, CSC) *4.5-605*
California Red-Legged Frog (FT, CSC) *4.5-633*
Southern Steelhead (FE) *4.5-653*
Unarmored Threespine Stickleback (FE, CE, CFP) *4.5-671*
American Peregrine Falcon (BCC, CE, CFP) *4.5-695*
California Condor (FE, CE, CFP) *4.5-705*
Golden Eagle (Nesting and Wintering) (BCC, WL, CFP) *4.5-717*
White Tailed Kite (Nesting) (CFP) *4.5-735*
Least Bell's Vireo (Nesting) (FE, CE) *4.5-755*
Willow Flycatcher (Nesting) (CE)/Southwestern Willow Flycatcher (Nesting) 4.5- (FE, CE) *4.5-787*
Western Yellow Billed Cuckoo (Nesting) (FC, BCC, CE) *4.5-809*
Coastal California Gnatcatcher (FT, CSC) *4.5-827*
Ringtail Cat (CFP) *4.5-845*

Volume III

Undescribed Snail Species (No Current Status) *4.5-861*
Coast Horned Lizard (CSC) *4.5-875*
Coast Patch-Nosed Snake (CSC) *4.5-890*
Silvery Legless Lizard (CSC) *4.5-904*
South Coast Garter Snake (CSC) *4.5-919*
Southwestern Pond Turtle (CSC) *4.5-938*
Two-Striped Garter Snake (CSC) *4.5-962*
Western Spadefoot Toad (CSC) *4.5-982*
Arroyo Chub (CSC) *4.5-1001*
Santa Ana Sucker (CSC) *4.5-1021*
Loggerhead Shrike (BCC, CSC) *4.5-1042*
Long Eared Owl (Nesting) (CSC) *4.5-1057*
Northern Harrier (Nesting) (CSC) *4.5-1075*
Short-Eared Owl (Nesting) (USBC, CSC) *4.5-1095*
Western Burrowing Owl (Burrow Sites and Some Wintering Sites) (BCC, CSC) *4.5-1105*
Summer Tanager (Nesting) (CSC) *4.5-1120*

Tricolored Blackbird (Nesting Colony) (BCC, CSC) 4.5-1129
Vermilion Flycatcher (Nesting) (CSC) 4.5-1149
Yellow-Breasted Chat (Nesting) (CSC) 4.5-1158
Yellow Headed Blackbird (Nesting) (CSC)..... 4.5-1174
Yellow Warbler (Nesting) (CSC) 4.5-1184
Grasshopper Sparrow (Nesting) (CSC)..... 4.5-1200
Pallid Bat (CSC) 4.5-1210
Pocketed Free-Tailed Bat (CSC) 4.5-1224
Townsend's Big-Eared Bat (CSC)..... 4.5-1237
Western Mastiff Bat (CSC)..... 4.5-1251
Western Red Bat (CSC)..... 4.5-1264
San Diego Desert Woodrat (CSC) 4.5-1277
Southern Grasshopper Mouse (CSC)..... 4.5-1290
American Badger (CSC) 4.5-1304
San Diego Black-Tailed Jackrabbit (CSC)..... 4.5-1318
Monarch Butterfly (Wintering Sites) (California Special Animal)..... 4.5-1333
San Emigdio Blue Butterfly (California Special Animal)..... 4.5-1339
Coastal Western Whiptail (California Special Animal)..... 4.5-1353
Rosy Boa (California Special Animal)..... 4.5-1368
San Bernardino Ringneck Snake (California Special Animal)..... 4.5-1383
Cooper's Hawk (Nesting) (WL)..... 4.5-1399
Ferruginous Hawk (Wintering) (BCC, WL)..... 4.5-1417
Merlin (Wintering) (WL)..... 4.5-1426
Prairie Falcon (Nesting) (BCC, WL)..... 4.5-1435
Sharp Shinned Hawk (Nesting) (WL)..... 4.5-1444
Turkey Vulture (CDFG Trust Resource)..... 4.5-1453
Black-Crowned Night-Heron (Rookery) (California Special Animal) 4.5-1468
Nuttall's Woodpecker (Nesting) (California Special Animal) 4.5-1478
California Horned Lark (WL)..... 4.5-1493
Allen's Hummingbird (Nesting) (California special animal)..... 4.5-1507
Bell's Sage Sparrow (Nesting) (BCC, WL) 4.5-1523
Black Chinned Sparrow (Nesting) (BCC, California Special Animal)..... 4.5-1538
Costa's Hummingbird (Nesting) (California Special Animal)..... 4.5-1547
Rufous Hummingbird (Nesting) (BCC, California Special Animal)..... 4.5-1562
Southern California Rufous-Crowned Sparrow (WL) 4.5-1571
Chipping Sparrow (Nesting) (California Special Animal) 4.5-1585
Hermit Warbler (Nesting) (CDFG Trust Resource)..... 4.5-1600
Lawrence's Goldfinch (Nesting) (BCC, California Special Animal)..... 4.5-1608
Oak Titmouse (Nesting) (California Special Animal)..... 4.5-1627

Fringed Myotis (California Special Animal) *4.5-1642*
Long-Legged Myotis (California Special Animal) *4.5-1655*
Western Small-Footed Myotis (California Special Animal) *4.5-1669*
Yuma Myotis (California Special Animal) *4.5-1683*
American Black Bear (CDFG Trust Resource) *4.5-1696*
Mountain Lion (Specially Protected Mammal) *4.5-1706*
Mule Deer (CDFG Trust Resource) *4.5-1722*
San Fernando Valley Spineflower (FC, CE, CNPS List 1B.1) *4.5-1731*
Undescribed Everlasting (No Current Status) *4.5-1763*
Undescribed Sunflower (No Current Status) *4.5-1778*
Island Mountain-Mahogany (CNPS List 4.3/S3.3) *4.5-1790*
Late-Flowered Mariposa Lily (CNPS List 1B.2/s2.2) *4.5-1803*
Mainland Cherry (Locally Regulated) *4.5-1809*
Oak Trees (Locally Regulated) *4.5-1826*
Oak-Leaved Nemophila (CNPS List 4.3/S3.3) *4.5-1850*
Ojai Navarretia (CNPS List 1B.1/S2) *4.5-1863*
Parish's Sagebrush (Locally Regulated) *4.5-1869*
Peirson's Morning-Glory (CNPS List 4.2/S3.2) *4.5-1885*
Plummer's Mariposa Lily (CNPS List 1B.2/S3.2) *4.5-1899*
Slender Mariposa Lily (CNPS List 1B.2/S1.1?) *4.5-1905*
Southern California Black Walnut (CNPS List 4.2/S3.2) *4.5-1925*
Southwestern Spiny Rush (CNPS List 4.2/S3.2) *4.5-1942*

4.5.6 MITIGATION MEASURES 4.5-1949
4.5.6.1 Mitigation Measures Already Required by the Adopted Specific Plan 4.5-1949
4.5.6.2 Additional Mitigation Measures Proposed by this EIS/EIR 4.5-1975

4.5.7 SUMMARY OF SIGNIFICANCE FINDINGS 4.5-2029

4.5.8 SIGNIFICANT UNAVOIDABLE IMPACTS 4.5-2049

4.5.9 LITERATURE CITED 4.5-2051

LIST OF TABLES

4.5-1	Acreage of Each Approved Land Use in the Specific Plan Area	4.5-19
4.5-2	Newhall Ranch Specific Plan Program EIR Impacts to Biological Resources Caused by Implementation of the Specific Plan and WRP	4.5-20
4.5-3	Acreage of Each Approved Land Use in VCC Planning Area	4.5-28
4.5-4	Impacts to Biological Resources Caused By VCC Implementation	4.5-28
4.5-5	Acreage of Each Projected Land Use in Entrada Planning Area	4.5-29
4.5-6	Biological Surveys Conducted in the Project Area and Immediate Vicinity – 1988 to Present	4.5-55
4.5-7	Special-Status Plant Species Observed within the Project Area	4.5-70
4.5-8	Special-Status Plant Species Not Expected to Occur within the Project Area	4.5-78
4.5-9	Special-Status Wildlife Species Observed on Site	4.5-85
4.5-10	Special-Status Wildlife Species with Potential to Occur on Site	4.5-102
4.5-11	Special-Status Wildlife Species Not Expected to Occur or Rarely Occurring on Site	4.5-107
4.5-12	Special-Status Plant Species Potentially Occurring at Newhall Ranch	4.5-116
4.5-13	River Corridor SMA Vegetation Communities/Land Cover	4.5-150
4.5-14	High Country SMA Vegetation Communities/Land Cover	4.5-156
4.5-15	Salt Creek Area Vegetation Communities/Land Cover	4.5-160
4.5-16	Open Area (Preserved Portion) Vegetation Communities/Land Cover	4.5-163
4.5-17	Existing Vegetation Communities, Floristic Alliances and Associations, and Land Cover Types in Project Area	4.5-171
4.5-18	Special Status Plant Species Documented on the Project Site	4.5-217
4.5-19	San Fernando Valley Spineflower Population and Area Occupied	4.5-220
4.5-20	Population Data for the Undescribed Everlasting That Occurs within VCC and the Specific Plan Area	4.5-221
4.5-21	Slender Mariposa Lily Summary of Occurrence Data	4.5-225
4.5-22	Crossing Structure Type and Size: Recommendations for Different Species	4.5-275
4.5-23	Key Components of Alternatives	4.5-314
4.5-24	Comparison of RMDP Infrastructure Impacts and Spineflower Preserves for Alternatives 2 through 7	4.5-343
4.5-25	Direct Permanent and Temporary Loss of General Vegetation and Land Cover Types for Alternatives 2 through 7 Resulting from Implementation of RMDP and SCP	4.5-348

Page

LIST OF TABLES (continued)

4.5-26 Indirect Permanent Loss of General Vegetation and Land Cover Types for Alternatives 2 through 7 Resulting from Build-Out of Specific Plan, VCC, and Entrada Areas 4.5-349
4.5-27 Impacts of the Proposed Project to Vegetation Communities and Land Covers 4.5-365
4.5-28 Applicable Mitigation Measures for Direct Impacts to Riparian Vegetation Communities 4.5-382
4.5-29 Applicable Mitigation Measures for Secondary Impacts to Riparian Vegetation Communities 4.5-392
4.5-30 Applicable Mitigation Measures for Direct Impacts to California Annual Grassland, Agriculture, and Disturbed Land 4.5-400
4.5-31 Applicable Mitigation Measures for Secondary Impacts to California Annual Grassland, Agriculture, and Disturbed Land 4.5-406
4.5-32 Applicable Mitigation Measures for Direct Impacts to Oak Woodland Vegetation Communities 4.5-440
4.5-33 Applicable Mitigation Measures for Secondary Impacts to Purple Needlegrass 4.5-451
4.5-34 RMDP Components and Related Facilities within the River Corridor SMA by Alternative 4.5-477
4.5-35 Special Status Species Occurring or with Potential to Occur on the Project Site, Organized by Guild 4.5-480
4.5-36 Applicable Mitigation Measures for Impacts to the Insect Guild 4.5-486
4.5-37 Applicable Mitigation Measures for Impacts to the Reptile – Low Mobility Guild 4.5-492
4.5-38 Applicable Mitigation Measures for Impacts to the Reptile and Amphibian – Semi Aquatic Guild 4.5-498
4.5-39 Applicable Mitigation Measures for Impacts to the Fish Guild 4.5-502
4.5-40 Applicable Mitigation Measures for Impacts to the Bird – Raptor Guild 4.5-506
4.5-41 Applicable Mitigation Measures for Impacts to the Bird – Riparian Guild 4.5-512
4.5-42 Applicable Mitigation Measures for Impacts to the Bird – Upland Grassland Guild 4.5-516
4.5-43 Applicable Mitigation Measures for Impacts to the Bird – Upland Scrub and Chaparral Guild 4.5-521
4.5-44 Applicable Mitigation Measures for Impacts to the Bird – Upland Woodland Guild 4.5-526
4.5-45 Applicable Mitigation Measures for Impacts to the Bat Guild 4.5-531

LIST OF TABLES (continued)

4.5-46 Applicable Mitigation Measures for Impacts to the Mammal – Low Mobility Guild 4.5-536
4.5-47 Applicable Mitigation Measures for Impacts to the Mammal – Moderate Mobility Guild 4.5-541
4.5-48 Applicable Mitigation Measures for Impacts to the Mammal – High Mobility Guild 4.5-545
4.5-49 Permanent Direct Loss of Cumulative Area for SFVS Due to Implementation of the SCP for Alternatives 2 through 7 (Acres) 4.5-548
4.5-50 Direct Loss (within Both the Permanent and Temporary Footprints) of Special Status Plant Species for Alternatives 2 through 7 (Number of Individuals) 4.5-549
4.5-51 Permanent and Temporary Loss of Suitable Habitat (or Cumulative Occupied Area where Noted) for Special Status Plant Species for Alternatives 2 through 7 (Acres) 4.5-549
4.5-52 Cross Walk between Consolidated and Original Wildlife Guilds 4.5-562
4.5-53 Summary of Proposed Road Crossing Culverts/Bridges in Constrained Wildlife Corridors 4.5-582
4.5-54 Special-Status Species Organized by Status and Guild 4.5-600
4.5-55 Estimate of Least Bell's Vireo Territories by County 4.5-756
4.5-56 Most Recent Comprehensive Estimates of Least Bell's Vireos at 11 Population Units 4.5-757
4.5-57 SFVS Population and Area Occupied 4.5-1734
4.5-58 Direct Impacts of the Proposed SCP to SFVS Cumulative Occupied Area 4.5-1736
4.5-59 SFVS Buffer Widths, Proposed SCP 4.5-1737
4.5-60 Occurrence Data for the Undescribed Everlasting that Occurs within the Specific Plan and VCC Planning Areas 4.5-1766
4.5-61 Species Distribution for Oak Trees within the GPS Inventory Areas (Heritage Oaks) 4.5-1830
4.5-62 Slender Mariposa Lily Individuals Observed 4.5-1907
4.5-63 Slender Mariposa Lily Cumulative Occupied Area Observed 4.5-1907
4.5-64 Impacts to Slender Mariposa Lily Cumulative Occupied Area by Alternative 4.5-1909
4.5-65 Impacts to Slender Mariposa Lily Individuals by Alternative 4.5-1909
4.5-66 Slender Mariposa Lily Individuals within 300 Feet of Development by Alternative 4.5-1911

Page

LIST OF TABLES (continued)

4.5-67 Slender Mariposa Lily Cumulative Occupied Area within 300 Feet of Development by Alternative 4.5-1911
4.5-68 CDFG Jurisdictional Permanent Impacts Mitigation Ratios 4.5-1976
4.5-69 Potential Plant Species for Vegetation Community Restoration in the River Corridor SMA and Tributaries 4.5-1978
4.5-70 Additional BIO-22c Oak Tree Replacement Ratios 4.5-1991
4.5-71 Optimal Woodland Densities and Acorn Planting Quantities, by Oak Woodland Type 4.5-1992
4.5-72 Summary of Significance Findings for Impacts to Vegetation Communities and Unique Landscape Features 4.5-2031
4.5-73 Summary of Significance Findings for Impacts to Common Wildlife 4.5-2032
4.5-74 Summary of Significance Findings for Impacts to Wildlife Habitat Linkages, Wildlife Corridors, and Wildlife Crossings 4.5-2033
4.5-75 Summary of Significance Findings for Special Status Species 4.5-2035

4.5.1 INTRODUCTION

4.5.1.1 Reader's Guide

The Biological Resources section of the EIS/EIR is comprehensive, complex, and covers a wide range of important scientific issues—from Project impacts to special-status plants to the adequate width of a wildlife crossing. By necessity, this section contains technical information and vocabulary, and sometimes this can pose a challenge to the lay reader. Therefore, to ensure that this section functions properly as a public disclosure document, a "Reader's Guide" has been prepared that describes the contents of the various biology subsections, explains their importance to the overall Project impacts analysis, and identifies where in the document one can locate specific data or discussions.

4.5.1.1.1 Organizational Scheme

The Biological Resources section is organized much like the other sections of the EIS/EIR. For example, all discussions are broken down into the Project's three main areas: the Newhall Ranch Specific Plan (Specific Plan) and the VCC and Entrada planning areas. The RMDP and the SCP are provided in **Appendix 1.0**. For each of these areas, this section provides individualized assessments of existing biological conditions, anticipated Project impacts, and proposed mitigation measures. Also, like the other sections, the Biological Resources section begins by explaining the relationship between the proposed Project and the Newhall Ranch Specific Plan Program EIR, which was certified by the County of Los Angeles on May 27, 2003, and addressed many of the same geographical areas and resource impacts evaluated in this EIS/EIR. The section then describes the relationship between the proposed RMDP and the SCP on one hand, and the Newhall Ranch Specific Plan, VCC, and Entrada developments on the other. These discussions are meant to orient the reader and provide both an historical and a geographical context for the biological analyses to follow.

Before describing the biological conditions at the Project area, however, this section: (1) explains the various federal, state, and local regulations that govern the proposed Project and drive the biological impacts analysis; (2) identifies the various permits and approvals the applicant must obtain to move forward with the proposed Project and alternatives; (3) provides a summary of the scientific literature that was reviewed during the preparation of the biological analysis; and (4) describes the survey methodology used to assess biological resources affected by the proposed Project and alternatives. Again, this prefatory information provides valuable background information and helps to frame the more detailed and technical discussions that come later.

4.5.1.1.2 Regulatory Setting

The regulatory setting consists of those federal, state, and local statutes and regulations that govern development of the proposed Project and alternatives. In this section of the EIS/EIR, the discussion focuses on those legal rules that affect biological resources. These include the following:

- The federal Clean Water Act (CWA) section 404, which governs whether and under what conditions construction projects—or debris from such projects—may lawfully intrude into the waters of the United States, including wetlands.
- The California Fish and Game Code section 1600, *et seq.*, which regulates streambed alteration in California and protects the state's rivers and streams, as well as the riparian habitats they support.
- The federal Endangered Species Act (ESA), which regulates impacts to threatened and endangered plants, animals, and insects. The federal ESA requires, among other things, that federal permitting agencies, such as the U.S. Army Corps of Engineers (Corps), consult with the U.S. Fish and Wildlife Service (USFWS) to determine whether the project under review would jeopardize the survival of any federally protected species.
- The California Fish and Game Code section 2080, which regulates impacts to state-listed species.
- The California Fish and Game Code sections 3511, 4700, 5056, and 5515, which address what are known as "fully protected" species. Under the California Fish and Game Code, it is illegal to "take" (*i.e.*, to kill) any "fully protected" species.
- The National Environmental Policy Act (NEPA), which requires that federal permitting agencies—such as the U.S. Army Corps of Engineers here—assess a proposed project for its potential impacts to the human environment.
- The California Environmental Quality Act (CEQA), which, like NEPA, requires that the lead approving agency—in this case, the California Department of Fish and Game (CDFG)—analyze the environmental impacts of the project under review.

These statutes and regulations, either directly or indirectly, dictate the type and rigor of the impacts analysis set forth in this section of the EIS/EIR. They impose on federal, state, and local agencies the duty to study impacts to biological resources and to ensure they have been mitigated to the extent feasible before granting federal and state permits.

4.5.1.1.3 Environmental Setting

To prepare a proper impacts analysis, the effects of the proposed Project and alternatives must be tested against a baseline. Under NEPA and CEQA, that baseline is known as the "Environmental Setting," which consists of the existing physical conditions within the impact area of a project. With large, complex projects, such as the RMDP and the SCP, the lead agency must conduct significant research to establish a project's existing conditions. This research takes two forms: (1) a review of the relevant scientific literature; and (2) surveys of the vegetation communities, plants, and wildlife on the project area. This latter effort typically requires biologists to walk large portions of the property, taking careful notes of the various plant and animal species they observe. These notes, often referred to as "field data," form the bedrock of the existing conditions discussion.

4.5.1.1.3.1 *Existing Conditions by Project Planning Area*

As indicated above, the Project area is divided into three planning areas—the Specific Plan, VCC, and Entrada. While these planning areas share many topographic features and biological resources, they are nevertheless unique. It is important to understand the resources that each one supports, as those resources often differ from one planning area to the next. Knowing what these resources are and where they are located will assist the reader in evaluating the impacts that will occur in each planning area should CDFG and the Corps approve the proposed Project.

Note that within each planning area discussion, the existing conditions are broken down into four basic categories: (1) past and current land use; (2) vegetation communities and land covers; (3) soils; and (4) special-status species. For purposes of conducting a biological resources impact study, these four topics largely define the environmental baseline:

- *"Past and current land use"* simply describes the manner in which human activities have affected the planning area and identifies those past and present projects or commercial operations that have influenced the existing environment.
- *"Vegetation communities and land covers"* describes in detail the flora within each planning area and identifies where key vegetation and land cover types are located on site.
- *"Soils"* describes the various soil types that exist in each planning area. Soil type often dictates what can grow or reside, and what can be constructed, at a given location.
- *"Special-status species"* describes those plants and animals (including invertebrates) on site that have special federal, state, or local designations due to their rarity, ecological importance, and/or their susceptibility to potential extinction. In most cases, project-

related impacts to special-status species must be avoided or minimized to the extent feasible. Note that the EIS/EIR makes a special point of identifying where occurrences of San Fernando Valley spineflower are located, as these will, in some cases, form part of the proposed Project's spineflower preserve.

Within the RMDP discussion—which is by far the longest—the EIS/EIR includes sub-discussions on the River Corridor Special Management Area/Significant Ecological Area (SMA/SEA) 23, the High Country SMA/SEA 20, the Salt Creek area, and Open Area. These four areas have special importance, as they are largely undisturbed and support a wide range of special-status plant and animal life. For this reason, the EIS/EIR provides a focused inventory of the special-status species and vegetation communities, and associated soils that exist in these four areas.

Unlike the Specific Plan, the VCC and Entrada planning areas include no SMAs. They do, however, include lands that support San Fernando Valley spineflower and may be included in the proposed Project's spineflower preserve.

4.5.1.1.3.2 *Existing Conditions by Biological Resource*

The geographic limits of many biological resources do not coincide with the boundaries of the Project planning areas. For this reason, a planning-area-by-planning-area assessment of existing biological conditions may not describe clearly the overall, Project-wide conditions of particular resources, such as oak trees and arroyo toads, a federally listed endangered species known from the Santa Clara River. To address this potential problem, the EIS/EIR includes a separate discussion of each key biological resource on site.

This discussion is broken down into the following seven sub-topics:

- *Vegetation communities.* As indicated above, vegetation communities are plant matrices where the various species exist interdependently but are usually dominated by one to a few particular species. For example, although coastal scrub communities support a wide array of plants, two of the most dominant species on site are California sagebrush and California buckwheat.
- *Unique landscape features.* For purposes of the proposed Project, the "unique landscape features" consist of the River Corridor SMA/SEA 23, the High Country SMA/ SEA 20, the Salt Creek area, and Middle Canyon Spring. These areas are of special ecological significance due to their riparian resources and, in the case of the High Country SMA/SEA 20 and Salt Creek area, their upland habitat, all of which support a diverse collection of special-status plant and wildlife species.

- *General wildlife*. As the name suggests, general wildlife consists of those birds, fish, invertebrates, mammals, reptiles, and amphibians that exist within the Project area but have no special status or protective designation.
- *Special-status vegetation communities*. Some vegetation communities on site are rare or provide habitat for special-status species. For these reasons, they require special protection. For example, the purple needlegrass community is the only vegetation community on the Project site that is dominated by native grasses. The other grasslands on site are dominated by invasive, non-native species, such as bromes and wild oats.
- *Special-status plants*. Individual plant species that have been designated as rare, threatened, or endangered by CDFG or USFWS qualify as special-status plants. The special-status plant category also includes "candidate species" (plants proposed for listing), "species of concern" (plants of importance to local regulatory agencies), and plants considered sensitive by the other organizations that have expertise in plants indigenous to the area, such as the California Native Plant Society (CNPS). Note that there are 15 special-status plants in the Project area. Among these is the state-listed endangered San Fernando Valley spineflower.
- *Special-status wildlife*. This category includes those birds, mammals, invertebrates, fish, reptiles, and amphibians that CDFG and/or USFWS have designated as rare, threatened, or endangered. It also includes "candidate species," "Species of Special Concern," "Special Animals," and "Watch List" species, as designated by CDFG. In addition, this wildlife category contains a special grouping of animals, known as "Fully Protected" species. Under California Fish and Game Code sections 3511, 4700, 5056, and 5515, Fully Protected species may not be "taken" under any circumstances. According to recent surveys, five Fully Protected species reside in or use the Project area at least occasionally (or have the potential to do so)—the golden eagle, the American peregrine falcon, the white-tailed kite, the ringtail cat, and the unarmored threespine stickleback. The Project area also supports one "Specially Protected Mammal," the mountain lion.
- *Wildlife habitat connections and buffers*. To survive and reproduce, wildlife species must be able to move safely between key habitat areas. For this reason, habitat connectivity is critical to the overall health and functionality of the ecosystems on site. This subsection of the EIS/EIR will address three different kinds of habitat connections—landscape-level habitat linkages, local wildlife corridors, and local wildlife crossings—and will also address buffer zones, which serve a slightly different function. *Linkages* are relatively large open space areas that: (1) contain "live-in" natural habitat; and (2) connect two larger adjacent habitat areas. *Corridors*, by contrast, are narrower and more linear, and allow species to traverse between two habitat areas; however, they typically do not provide "live-in" habitat. *Wildlife crossings* usually are manmade structures that permit

animals to traverse obstacles, such as paved roads, that fragment larger habitat areas. *Buffers* are habitat areas—either preserved or created—that separate the urban development edge from a valued biological resource, thus blunting the impacts of the former on the latter.

Each of these seven biological resource categories plays a role in the ecological functions of the Project area; and each has the potential to be affected by the proposed Project. When viewed together, they form the "existing conditions" baseline for identifying and evaluating potential impacts to biological resources.

4.5.1.1.4 Impact Significance Criteria

All analytical sections of this EIS/EIR—from Air Quality to Traffic—include a list of criteria that, when applied to the particular impact at hand, will help the decision maker and the public determine whether the impact is significant and thus requires mitigation. The Biological Resources section is no different, except that its significance criteria are specially tailored to biological concerns.

Specifically, the Corps and CDFG will apply the following seven significance criteria to the biological resource impacts identified in this section:

The proposed Project and alternatives would create a significant impact if they:

1. *Cause a substantial effect, via habitat modification, on special-status species or violate state or federal conservation laws.* This criterion is important because a project's impacts to habitat are sometimes severe enough to interrupt the necessary behaviors and activities of wildlife. Such activities include foraging, finding or building shelter, reproduction, and migration. This criterion also addresses impacts that may violate regulations and statutes specifically designed to protect plants and animals, such as the federal Migratory Bird Treaty Act and California Fish and Game Code section 3503.

2. *Cause a substantial effect on riparian habitat or special-status vegetation communities.* This criterion is important because riparian habitat (*i.e.,* habitat near rivers and streams) and special-status vegetation communities are relatively rare, provide important ecological values, and support an unusually diverse range of wildlife species. For this reason, they warrant special protection.

3. *Cause substantial effect on federally protected wetlands.* Wetlands—even more than riparian habitats—are increasingly rare. Moreover, they provide vital

resources to a host of special-status plants and animals. As a result, project-related impacts to wetlands, even if small, will usually be considered significant.

4. *Substantially interfere with movement of native or migrant species or wildlife corridors or substantially interfere with wildlife use of nursery sites.* As indicated above, many wildlife species need to move within or between habitat areas, as such movement enables the animals to hunt, forage, locate shelter when necessary, find mates for reproduction, and disperse. Therefore, it is imperative that the proposed Project and alternatives not interfere unduly with wildlife corridors. Nursery sites—those unique locations where animals give birth and raise their young (such as rookeries for birds)—are critical to the reproductive success of the species in question. For this reason, these sites are given special protection.

5. *Conflict with local policies that protect biological resources.* In addition to state and federal rules protecting certain species and types of habitat, most local agencies—such as Los Angeles County—have their own policies designed to preserve the integrity of biological resources within their respective jurisdictions. It is important that the proposed Project and alternatives comply with these policies; where they do not, a significant impact may result.

6. *Cause scouring of any riverbed, resulting in loss of aquatic, wetland, or riparian habitats.* The proposed Project and alternatives have the potential to increase the amount of water that enters local and regional waterways. If the increase is substantial enough, the heightened water flows may scour the affected streams and riverbeds, effectively destroying aquatic, wetland, and even riparian habitats. This criterion addresses whether and to what extent the proposed Project and alternatives would have significant scouring effects.

7. *Substantially reduce the habitat of fish or wildlife species, or cause the populations of such species to drop below self-sustaining levels; threaten to eliminate a plant or animal community; or substantially reduce or restrict the range of a rare, threatened, endangered, or special-status species.* This criterion overlaps somewhat with criteria 1 through 3, but it also addresses other issues, such as reductions in population levels and the elimination of an entire plant or animal community, which can happen when a species' entire range is contained within a project site.

4.5.1.1.5 Analysis of Project Impacts

The heart of any EIS/EIR is the analysis of the project's impacts to existing environmental conditions. With respect to the Biological Resources section, this analysis focuses on five impact categories: (1) Project impacts to vegetation communities and land covers; (2) Project impacts to unique landscapes; (3) Project impacts to general wildlife (*i.e.,* non-special status), as organized by guild; (4) Project impacts to wildlife connectivity; and (5) Project impacts to special-status plants and wildlife.

For purposes of the impact analysis, Alternative 2 is the proposed Project. Therefore, the assessment of Project effects is based on the particular components and design features of Alternative 2. This does not mean, however, that the impacts of Alternatives 3 through 7 are disregarded. On the contrary, they are fully discussed and evaluated both independently and in relation to the Alternative 2 impacts, providing the reader with a comparative analysis, as required under NEPA and CEQA. Note that this comparative analysis takes place with respect to all four categories listed above.

To gain a better understanding of the types of impacts assessed in this section, a brief description of those impacts is provided below:

4.5.1.1.5.1 *Impacts to Vegetation Communities and Land Covers*

The Project area lies within the Santa Clara River Watershed (SCRW), which is largely undeveloped. As a result, the Project area supports a wide variety of vegetation communities and land covers, most of which would be affected by the proposed Project and alternatives to some extent. These vegetation communities and land covers include the following:

- Riparian communities. Riparian communities consist of the various plants, shrubs, and trees located near, and dependent on, recurrent sources of water, such as a stream, wetland, or pond. Because the Project area is located within the SCRW, it contains a wide array of riparian vegetation communities, from sand and gravel bars dominated by willow saplings and cattails to river banks dominated by mature cottonwood trees with full understories of smaller trees and shrubs. Riparian communities in the Project area are highly sensitive and of significant biological value, as they support a variety of special-status plants and animals. These include the federally listed arroyo toad, the federally listed California red-legged frog, the federally listed least Bell's vireo, the federally listed Santa Ana sucker, the federally listed southwestern willow flycatcher/state-listed willow flycatcher (only the southwestern subspecies is federally listed), as well as two California Fully Protected Species—the white-tailed kite and the unarmored threespine stickleback (also federally listed as endangered). (The Fully

Protected ringtail cat, which uses riparian communities, has not been documented in the Project area, but is considered to have some potential to occur due to the presence of suitable habitat.)

- California annual grasslands, Agriculture, Disturbed land, and Developed land. California annual grassland and these manmade land covers are characterized by some form of human disturbance or activity. For example, the California annual grasslands in the Project area tend to be characterized by a mixture of weedy, introduced grasses, such as bromes, wild oats, and Russian thistle. These species typically emerge following grazing, fires, discing, and other forms of mechanical disturbance. Agricultural activities also comprise a significant portion of the Project area. In addition, some of the Project area already has been disturbed or developed for industrial or urban purposes. These land covers, however, are not completely devoid of biological value. California annual grasslands support a number of special-status plants, including the San Fernando Valley spineflower, the Peirson's morning-glory, and the slender mariposa lily. Grasslands and agricultural areas also provide important foraging habitat for raptors (birds of prey), such as the golden eagle, white-tailed kite, and American kestrel.
- Coastal scrub communities. Coastal scrub communities on site are characterized by a variety of soft, low, aromatic shrubs that are adapted to drought conditions, such as California sagebrush and California buckwheat. These communities typically develop on south-facing slopes and other locations that receive little rainfall. Coastal scrub exists within large areas of the Specific Plan and within the VCC and Entrada planning areas. They provide habitat for a wide variety of special-status species, including the golden eagle, southern California rufous-crowned sparrow, coast horned lizard, and mountain lion. They also provide dispersal habitat for the federally listed coastal California gnatcatcher.
- Chaparral communities. Chaparral communities are drought- and fire-adapted communities of broad-leafed shrubs that often form dense, impenetrable stands. They develop primarily on north-facing slopes and in canyons. Common chaparral species include chamise, hoaryleaf ceanothus, scrub oak, laurel sumac, and black sage. There is actually very little chaparral within the Project area. These communities are limited to a few small locations within the southern portion of the Entrada planning area. Chaparral provides habitat for a number of special-status plants, such as the Peirson's morning-glory and the island mountain mahogany, as well as for a wide array of special-status wildlife, including the rosy boa, loggerhead shrike, and mountain lion.
- Oak woodland communities. Oak woodland on site actually consists of four different communities—coast live oak woodland, mixed oak woodland, valley oak/grass, and valley oak woodland. Each of these communities supports a variety of special-status

birds, such as white-tailed kite, oak titmouse, and Nuttall's woodpecker, and special-status reptiles, such as San Bernardino ringneck snake. They also provide general cover for larger mammals, such as mountain lions.

- Purple needlegrass. Purple needlegrass is rare in southern California and, even where found, it is usually mixed with a variety of non-native grasses and forbs. For purposes of this EIS/EIR, purple needlegrass is defined as needlegrass that is composed of at least 10% native grasses. There is less than one acre of purple needlegrass in the Project area, and it is located in the High Country SMA/SEA 20 in the south-central portion of the Specific Plan.
- California walnut woodland. As its name suggests, California walnut woodland is dominated by native walnut trees. This vegetation community is considered sensitive by CDFG and provides habitat for raptors, such as the merlin and sharp-shinned hawk, and for special-status reptiles, such as the San Bernardino ringneck snake and the coastal western whiptail. There are only about 27 acres of California walnut woodland in the Project area, and it is located in the High Country SMA/SEA 20 and the Salt Creek area.

With respect to each of these vegetation communities and land covers, the Biological Resources section analyzes three different kinds of Project-related impacts—*direct* impacts (those caused by the direct implementation of the RMDP and the SCP), *indirect* impacts (those occurring within the development "footprint" of the Specific Plan, VCC, and Entrada planning areas), and *secondary* impacts (those caused by implementation of the RMDP, the SCP, Specific Plan, VCC, and Entrada projects but occurring outside the actual development envelopes or Project footprint). These effects are further broken down into *temporary* impacts (which are due to construction activities for the RMDP and the SCP only) and *permanent* impacts (which are inherent to the Project itself and would remain after the Project is completed).

Impacts to vegetation communities and land covers are expressed in terms of acres temporarily disturbed or permanently lost, with permanent impacts also expressed as the percentage of the total habitat currently on site. For example, the RMDP part of the proposed Project would have *direct* permanent impacts to 28 acres of chaparral communities, of which there are approximately 2,146 acres in the Specific Plan/RMDP site. Thus, the RMDP portion of the Project would cause the loss of 1.3% of the chaparral on site.

Each impact to vegetation communities is then tested against the applicable significance criteria to determine: (1) whether the impact is "significant" as that term is used in NEPA and CEQA; and (2) whether and to what extent the impact must be mitigated. If an impact is deemed "adverse but not significant," or "less than significant," then no mitigation is required and the analysis ends there. The phrase "adverse but not significant" is most commonly used in the

analysis and generally refers to situations where there is a measureable impact (*e.g.*, loss of quantified acreage of habitat), but which does not rise to the level of "significant." The phrase "less than significant" is usually used in the context where, prior to mitigation, there would be no measurable residual impact. For example, southern steelhead is not expected to spawn or rear young on site due to lack of suitable habitat, but a vagrant may rarely occur. For this species, loss of habitat is considered to be less than significant because, although it could occur, it is not a measureable or predictable impact. If an impact is deemed "significant, absent mitigation," the EIS/EIR then provides a mitigation strategy designed specifically to address the impact under review and reduce its severity. The mitigation strategy is composed of various measures, which, if implemented, will either avoid the impact or reduce its effect on the vegetation community in question.

The final part of the analysis is determining whether the impact, once mitigated, would remain "significant" or be reduced to "adverse but not significant," "less than significant" (with the same distinction as described above), or "not significant because no impact would occur," if complete avoidance is possible. Under CEQA, any impact that remains significant even after mitigation (*i.e.*, significant and unavoidable) will require special findings by the lead agency (in this case, CDFG) if it approves the proposed Project. Specifically, CDFG would have to adopt a Statement of Overriding Considerations indicating that the Project brings certain social, economic, environmental, and/or technological benefits that outweigh its significant and unavoidable impacts to the environment. The primary purpose of the mitigation strategy, however, is to adopt all feasible mitigation measures to reduce impacts to less-than-significant levels.

The following example illustrates the analytical sequence described above:

The proposed Project is expected to result in the permanent loss (both direct and indirect) of 116 of the 1,189 acres of riparian communities on site. Given the biological importance of riparian habitat, this would be a significant impact, absent mitigation. To reduce this impact to a level that is less than significant, the EIS/EIR recommends 20 mitigation measures, including habitat restoration/enhancement, mitigation banking, and riparian vegetation and oak tree replacement. These mitigation measures are designed to restore the functions and services provided by the riparian vegetation communities lost as a result of development. The EIS/EIR thus concludes that the proposed Project's direct and indirect impacts to riparian communities, once mitigated, will be "adverse but not significant." The term "adverse" is included because even with mitigation, some residual impacts would occur.

This same analytical approach is applied to California annual grasslands, agriculture, disturbed and developed lands; coastal scrub; chaparral; oak woodlands; purple needlegrass; and California walnut woodlands.

4.5.1.1.5.2 *Impacts to Unique Landscape Features*

The EIS/EIR identifies "unique landscape features" that are within the Project area and may be affected either by implementation of the RMDP or build-out of the Specific Plan, VCC, or Entrada planning areas. These are: (1) the River Corridor SMA/SEA 23; (2) the High Country SMA/SEA 20; (3) the Salt Creek area; and (4) Middle Canyon Spring. Each of these unique landscape features (except Middle Canyon Spring) is subject to a conservation and public access easement running in favor of the County of Los Angeles. These areas have been singled out for protection and enhancement due to the high level of biodiversity that exists within each. The River Corridor SMA/SEA 23, for example, which extends the length of the Project area along the Santa Clara River, supports a wide range of native species and habitats, many of which are special status and/or declining in the region. The High Country SMA/SEA 20 also supports native species and habitat, although they tend to be upland communities rather than riparian. The Salt Creek area, on the other hand, provides an important riparian travel corridor for wildlife. Middle Canyon Spring likewise provides riparian habitat and, in addition, supports the undescribed snail and undescribed sunflower, two unique species.

Impacts to the River Corridor SMA. Given that the RMDP, by design, would involve the construction of hydrological improvements at various points along the Santa Clara River, it would necessarily have impacts to the River Corridor SMA/SEA 23. Specifically, the RMDP would cause temporary and permanent loss of habitat for special-status species that utilize riparian and wetland areas within the River Corridor SMA/SEA 23. Build-out of the Specific Plan area would likewise result in the loss of riparian habitat within the SMA. The EIS/EIR discusses these impacts in detail, and also describes project secondary or "edge" effects on the River Corridor SMA/SEA 23. Note, however, that these impacts will be addressed through a comprehensive mitigation strategy, also described in the EIS/EIR.

Impacts to the High Country SMA/Salt Creek Area. Implementation of the RMDP and the SCP would result in construction-related impacts to the High Country SMA/SEA 20 and Salt Creek area. Such impacts would result in loss of habitat used by special-status species, including southwestern pond turtle, Cooper's hawk, coast horned lizard, and others. Build-out of the Specific Plan area would have indirect impacts to the High Country SMA/Salt Creek area as well, although these would be relatively limited due to the lack of development within the High Country SMA/SEA 20 and Salt Creek area.

Most of the impacts would occur along the edge that these unique landscape features share with the proposed subdivisions. As with Project-related impacts to the River Corridor SMA, the impacts to the High Country SMA/SEA 20 and Salt Creek area will be mitigated through a combination of habitat restoration, creation, enhancement, and preservation.

Impacts to Middle Canyon Spring. The RMDP and the SCP have the potential to cause direct impacts to Middle Canyon Spring. In addition, as Middle Canyon Spring is the only location where the undescribed sunflower and undescribed snail are expected to occur, it is possible that the RMDP and the SCP would adversely affect these species as well. Build-out of the Specific Plan could also affect Middle Canyon in the form of habitat loss. However, this impact is not likely to disturb the undescribed sunflower or undescribed snail, as neither species occurs in the areas potentially affected by the RMDP or Specific Plan projects. Mitigation measures similar to those recommended for the impacts to the River Corridor SMA/SEA 23 and High Country SMA/SEA 20 and Salt Creek area also have been recommended to reduce Project-related impacts to Middle Canyon Spring.

4.5.1.1.5.3 *Impacts to Common Wildlife – The "Guild" Analysis*

After discussing impacts to vegetation communities and unique landscape features, the EIS/EIR shifts its focus and evaluates project effects on "Common Wildlife," a term that encompasses those insects and animals that reside in or use the Project area but do not qualify as "special-status" species, as defined in section in **Subsection 4.5.3.4.5**, **Subsection 4.5.3.4.6**, and listed in **Subsection 4.5.3.1** of this EIS/EIR. Because common wildlife species have no formal conservation status, they have been grouped into "guilds," which correspond to their common wildlife classification and, in some cases, to the habitat they use and their relative mobility. Thus, for example, in addition to the *Insect* guild, the *Fish* guild, and the *Aquatic Mollusk* guild, there is also a *Bird – Upland Woodland* guild, and a *Mammal – Low Mobility* guild, among others.

The purpose of the Common Wildlife impact analysis is to determine the extent to which the various components of the proposed Project and alternatives would affect these common animal species, that, nonetheless, probably provide important biological functions in the overall ecosystem (*e.g.*, as predators or prey). Most NEPA and CEQA documents, including this one, tend to focus their analyses on species with special conservation designations, such as federally listed or state-listed plants and animals. While this is a rational approach to evaluating a project's biological impacts, it tends to ignore those more common species, which, despite having no protective designation, nevertheless likely play key roles in the overall ecosystem of the Project

area. To give those species the consideration they deserve, this EIS/EIR evaluates how they might be affected by the proposed Project and alternatives.

Again, however, due to the large number of common wildlife species in the Project area, this analysis is done on a guild level, not on a species level. In addition, impacts to guilds are expressed in terms of habitat loss, not in terms of harm to or loss of individual animals.

Finally, as with all other impacts discussions, the analysis of common wildlife impacts starts with Alternative 2 and then addresses Alternatives 3 through 7. Mitigation for each impact, by alternative, is provided at the back of the analysis.

4.5.1.1.5.4 *Impacts to Wildlife Movement and Habitat Connectivity*

While some wildlife species are able to reproduce, find food and shelter, and rear their young in a single, confined space, most species need some freedom of movement to successfully complete all aspects of their life histories. For this reason, it is important to preserve wildlife movement corridors, including connections between habitats. The EIS/EIR divides its analysis of project-related impacts to wildlife movement into four elements:

- Background information on the specific wildlife movement needs of each wildlife guild.
- Impacts to landscape-scale habitat linkages, resulting first from Alternative 2 and then from Alternatives 3 through 7. Note that landscape-scale habitat linkages constitute the largest type of wildlife connection. They not only provide live-in habitat for many species, they provide adequate cover for such large animals as mountain lions and mule deer.
- Impacts to wildlife corridors, resulting first from Alternative 2 and then from Alternatives 3 through 7. Typically, wildlife corridors are not as wide as landscape-scale habitat linkages and for that reason provide live-in habitat for fewer (and generally smaller) species. These corridors, however, do serve a critical wildlife movement function, as they connect core habitat areas and allow animals to travel in relative safety between them.
- Impacts to wildlife crossings, resulting first from Alternative 2 and then from Alternatives 3 through 7. Unlike habitat linkages and wildlife corridors, wildlife crossings usually provide no live-in habitat, are relatively short, and serve primarily as means for wildlife to avoid or bypass obstacles that otherwise fragment habitat. An example of a wildlife crossing is a road underpass.

As explained in the EIS/EIR, implementation of the RMDP and the SCP, under Alternative 2, would require construction of three large-span bridges as well as bank protection within the Santa Clara River corridor. These structures would affect existing landscape-scale habitat linkages, but would not appreciably diminish their ability to function. Once mitigated and protected with conservation easements, the River Corridor SMA/SEA 23, the High Country SMA/SEA 20, and the Salt Creek area will be able to serve the large-scale mobility needs of the wildlife species on site. A third linkage, known as the Castaic/Halsey corridor, also would remain intact and provide connectivity between the Santa Clara River and upland habitats to the northeast of the Project area, extending to Castaic Lake and the Angeles National Forest.

The proposed Project and alternatives also would have impacts to local habitat connectivity and wildlife movement. Specifically, planned development may constrain existing wildlife corridors or cause some of them to become dead-ends. The EIS/EIR evaluates the 15 wildlife corridors on site and determines which ones would be adversely affected by the proposed Project and alternatives. Where the proposed Project or alternatives would eliminate or significantly constrain a particular corridor, mitigation measures are recommended.

With respect to wildlife crossings, these would not be inhibited by implementation of the RMDP or any other aspect of the proposed Project or alternatives, although some changes in wildlife behavior are expected as a result of secondary impacts, such as traffic noise and lighting. These impacts, however, are not anticipated to be significant. For this reason, no mitigation measures have been recommended for impacts to wildlife crossings.

One final note on wildlife movement: Due to the importance of habitat connectivity, in all its various forms, this section relies upon a study, sometimes referred to as the "Conceptual Regional Open Space Connectivity Report" (Penrod *et al.* 2006), to identify which linkages, corridors, and crossings are of greatest value to existing wildlife. The findings and recommendations of this report are discussed in the EIS/EIR, and the Penrod *et al.* habitat linkage design is incorporated into the mitigation measures.

4.5.1.1.5.5 *Impacts to Special-Status Species*

Together, CDFG, the Corps, and the applicant have identified 91 plant and wildlife species that qualify as "special-status" species, as that term is defined in this EIS/EIR. This does not mean, however, that all 91 species are equally sensitive or have the same conservation designation or require the same level of protection. In fact, the 91 "special-status" species fall along a sensitivity continuum.

At the extreme or "most sensitive" end of this continuum are species that are: (1) listed as endangered or threatened under the federal ESA; (2) listed as endangered or threatened under

CESA; and (3) listed as California Fully Protected. Impacts to such species are tightly controlled by federal and state law, and may require incidental "take" permits following consultation with USFWS and CDFG. In the case of Fully Protected species, impacts rising to the level of "take" are statutorily prohibited. Listed species include the arroyo toad, the southwestern willow flycatcher/willow flycatcher, and the least Bell's vireo, among others. Fully protected species known to occur on site, or with the potential to occur on site, include the unarmored threespine stickleback, ringtail cat, white-tailed kite, golden eagle, and American peregrine falcon.

Next in line on the sensitivity continuum would be species currently under consideration for listing under either the federal ESA or CESA. These species, known as "candidate" species, are often treated as if they have already been approved for listing. For this reason, impacts to candidate species are reviewed with a high level of scrutiny. The only federal candidate species observed in the Project area are the western yellow-billed cuckoo and the San Fernando Valley spineflower, both of which are already state-listed species. No state candidate species exist on site.

Occupying the middle position on the sensitivity scale are animals that CDFG has identified as "Species of Special Concern." CDFG applies this designation to species which, while not warranting placement, or which have not been fully analyzed for placement on the endangered species list, are either rare or declining in numbers within their home range. Such species include, among others, the western spadefoot toad, the southwestern pond turtle, the short-eared owl, and the arroyo chub.

Next down the line are "Specially Protected Mammals" such as the mountain lion, and "Trust Resources" such as the mule deer and black bear. These animals, while neither rare nor documented to be experiencing significant population declines, are nevertheless emblematic of the California wilderness and play important roles in the regional ecosystems they inhabit.

At the low end of the sensitivity continuum are those species placed on CDFG's "Watch List" or identified by CDFG as "Special Animals." These species usually still are relatively common and have widespread ranges, but are being tracked by CDFG because their habitats may be under pressure from conversion and development or they may be vulnerable to anthropogenic threats. Such species include, among others, the rufous hummingbird, the prairie falcon, and the coastal western whiptail.

Plant species, other than those listed under the federal ESA or CESA, are given sensitivity rankings based on criteria developed by CNPS.

Sensitivity and protective status are not the only things that distinguish the 91 special-status species evaluated in this EIS/EIR. The manner in which the species use the Project area also

differs among the species, and sometimes dramatically. For example, some birds, such as the southern California rufous-crowned sparrow spend their entire life cycle at the Project site, while others, such as the federally threatened coastal California gnatcatcher do not nest at the site or use it for any purpose other than dispersal. These distinctions can have a profound influence on the species-by-species impact analysis. If, for example, a listed species rarely uses the Project area even though suitable habitat exists on site to support it, impacts to that species are not likely to be significant, as the proposed Project and alternatives are not going to substantially disrupt its life cycle or harm individuals. On the other hand, if the proposed Project or the alternatives are expected to disturb a significant portion of the habitat used by, say, a "Special Animal," and if that Special Animal relies on that habitat for a substantial part of its life cycle, the impact likely would be deemed significant, absent mitigation. So while the protective designation and relative sensitivity of the species is important when determining impact significance, it is not the only factor. The manner and extent to which a given species uses the affected habitat also bear on the significance conclusion.

For each of the 91 special-status species, the EIS/EIR addresses direct, indirect, and secondary impacts. In addition, the direct and indirect impact analyses are further broken down into: (1) impacts to habitat used by the species and (2) impacts to individuals of the species. As with the other aspects of the biological analysis, the assessment of impacts to special-status species treats Alternative 2 as the proposed alternative and then compares its impacts with those of Alternatives 3 through 7. Thus, for example, the EIS/EIR indicates that, under Alternative 2, the Project would result in the permanent loss of 140 acres of suitable habitat for the coast horned lizard, while the other five alternatives would affect 138 acres (Alternative 3), 133 acres (Alternative 4), 157 acres (Alternative 5), 173 acres (Alternative 6), and 76 acres (Alternative 7), respectively. This summary for each alternative allows the reader to compare the various alternatives on an impact-by-impact basis.

4.5.1.1.5.6 *Mitigation Measures*

Under both NEPA and CEQA, any impact identified as "significant" must be feasibly mitigated to the extent feasible. In most cases, significant impacts can actually be mitigated to "less-than-significant" levels (also termed "adverse but not significant" in this EIS/EIR if residual impacts would occur). The biological analysis identifies a host of Project-related significant impacts, from loss of riparian vegetation to secondary effects on least Bell's vireo, a federally listed bird species. To address these impacts, the EIS/EIR recommends more than 160 mitigation measures. Some of these measures—identified by the abbreviation "SP"—were originally developed as part of the Newhall Ranch Specific Plan Program EIR but could not be implemented until an actual project was proposed for construction. In addition to the SP mitigation measures, the Biological Resources section includes new mitigation measures designed specifically to address the impacts

of the RMDP and the SCP, as well as those associated with build-out of the Specific Plan, VCC, and Entrada planning areas. These mitigation measures are identified by the abbreviation "BIO."

The reader will notice that some of the mitigation measures—especially those that create large habitat preserves—apply to a substantial number of biology impacts, including impacts to habitat, impacts to individuals, and secondary impacts, such as lighting and noise. This is by design. One of the basic tenets of conservation biology is that the best way to protect special-status and common species and fragile ecosystems is to create or preserve large areas of minimally fragmented habitat that contain a wide array of vegetation and support a diverse range of wildlife. For example, lighting impacts to a species can be reduced in part by providing a large protected area for the species that is not influenced by lighting.

However, not all impacts can be addressed adequately through the creation of habitat preserves. Some impacts are very specific in their effects. For example, build-out of the Entrada planning area is expected to disturb an existing bat roost. To offset this impact, the EIS/EIR recommends that the roost be replaced at a suitable location sufficiently removed from human interference. With the example of lighting, an additional mitigation measure to reduce lighting effects is to require that all lighting adjacent to open space areas be downcast or away from habitat to minimize the lighting impact along the open space–urban interface.

This mitigation approach—adding specific measures to generally applicable measures—runs consistently throughout the Biological Resources section. In fact, virtually every significant impact is addressed by a combination of both general and specific mitigation measures. Each such measure is described briefly after the impact it is designed to offset. A comprehensive description of each of the approximately 169 mitigation measures is provided at the end of the Biological Resources section.

4.5.1.1.5.7 *Summary of Significance Findings*

To assist the reader in locating a particular biology resource or impact, **Subsection 4.5.7**, Summary of Significance Findings, summarizes the impacts (and proposed mitigation where appropriate) for each affected vegetation community and land cover, each unique landscape feature, each common wildlife guild, each wildlife corridor, and each of the 91 special-status species.

4.5.1.2 Relationship of Proposed Project to Newhall Ranch Specific Plan Program EIR

The Specific Plan contains approximately 11,999 acres. The acreages of the land uses within the approved Specific Plan are listed in **Table 4.5-1**. The Specific Plan includes residential

development (and associated school sites, parks, and other facilities); mixed-use development (*e.g.*, commercial, residential, office); commercial development; business park uses; visitor-serving development; community facilities (*e.g.*, fire stations, library, water reclamation plant); and arterial roads and bridges on 3,763 acres. The 8,236 acres of open space includes the River Corridor SMA/SEA 23, High Country SMA/SEA 20, Open Area, and spineflower preserve (Dudek 2008D).

Table 4.5-1
Acreage of Each Approved Land Use in the Specific Plan Area

Approved Land Use	Acres
Open space	8,236[1]
Residential/commercial/non-residential/other development	3,763
Total	**11,999**

Notes:
[1] Open space refers to natural (preserved) and manufactured open space, and includes the Specific Plan's High Country SMA, the River Corridor SMA, Open Area, spineflower preserve, and other specified open space areas (primarily located within the Specific Plan's Estate Residential designation). Approximately 1,900 of the 3,420 acres of Open Area will be preserved as natural vegetation communities and existing land covers. Open space does not include the Salt Creek area, adjacent to the Specific Plan boundary, comprising about 1,517 acres. If the Salt Creek area were included, the total open space area would be approximately 9,753 acres (8,236 + 1,517 = 9,753).
Source: RMDP (Dudek 2008D).

This section provides a standalone assessment of the potentially significant impacts to biological resources associated with the proposed Project and alternatives; however, the previously certified Newhall Ranch environmental documentation provides important information and analysis for the RMDP and the SCP components of the proposed Project. Implementation of these Project components would require federal and state permitting, consultation, and agreements that are needed to facilitate development of the approved land uses within the Specific Plan area. Further, if approved, the proposed Project would establish comprehensive spineflower preserves within the Specific Plan area, also facilitating development of the approved Specific Plan. Due to this relationship, the Newhall Ranch environmental documentation, findings, and mitigation, as they relate to biological resources, are summarized below to provide context for the proposed Project.

Section 4.6 of the Newhall Ranch Revised Draft EIR (County of Los Angeles 1999) identified and analyzed the existing biological resources, potential impacts, and mitigation measures for the entire Specific Plan area. In addition, Section 5.0 of the Newhall Ranch Revised Draft EIR (County of Los Angeles 1999) identified and analyzed the potential impacts to biological resources and mitigation measures associated with construction and operation of the approved Water Reclamation Plant (WRP), which would treat the wastewater generated by the Specific

Plan. Thereafter, additional environmental analysis was conducted for the Specific Plan. Specifically, the Newhall Ranch Revised Additional Analysis, Section 2.3, Floodplain Modifications (County of Los Angeles 2003A) was prepared to further assess the biological effects of the Specific Plan caused by changes to the hydrology and hydraulics of the Santa Clara River. This additional analysis also examined in greater depth the Salt Creek corridor and Specific Plan consistency with Los Angeles County (County) General Plan policies pertaining to Significant Ecological Areas (SEAs). (See Newhall Ranch Revised Additional Analysis, Sections 2.2 and 2.4 (County of Los Angeles 2003A).)

Based on the Newhall Ranch environmental documentation, the Specific Plan was determined to result in significant impacts to sensitive biological resources. Thus, the Newhall Ranch environmental documentation required implementation of the Specific Plan's Resource Management Plan and several program-level mitigation measures, which the County determined reduced some but not all of the Specific Plan's impacts to identified sensitive biological resources.[1] **Table 4.5-2** summarizes the Specific Plan's impacts to biological resources, the applicable mitigation measures (SP-4.6-1 through SP-4.6-80; SP-5.0-30 through SP-5.0-32), and the County's significance findings after adopting the mitigation contained in the Newhall Ranch certified environmental documentation. Consistent with State CEQA Guidelines section 15093, the County's Board of Supervisors found that the Specific Plan offered acceptable overriding economic, legal, social, and other public benefits that outweighed the identified significant unavoidable impacts.

Table 4.5-2
Newhall Ranch Specific Plan Program EIR
Impacts to Biological Resources Caused by Implementation of the Specific Plan and WRP

Impact Description	Mitigation Measures	Conclusion After Mitigation
Loss of Habitat – As approved, implementation of the Specific Plan would result in the loss of 1,820 of the 5,183 acres of coastal scrub, 202 of the 1,213 acres of chaparral, and 1,480 of the 1,896 acres of non-native grassland habitat present on the site (when combined, 42% of these vegetation types would be lost).[a]	See measures listed below for impacts to special-status animal species and sensitive habitats.	Significant

[1] References to mitigation measures included in the Newhall Ranch Specific Plan Program EIR are preceded by "SP" in this EIS/EIR, to distinguish them from other mitigation measures discussed herein.

Table 4.5-2
Newhall Ranch Specific Plan Program EIR
Impacts to Biological Resources Caused by Implementation of the Specific Plan and WRP

Impact Description	Mitigation Measures	Conclusion After Mitigation
General Wildlife Impacts – Based on the amount of habitat lost (5,132 acres), the impact potential of implementation of the Newhall Ranch Specific Plan on the diminishment of habitat for wildlife or plants is considered significant.	See measures listed below for impacts to special-status wildlife species.	Significant
The impact potential of implementation of the Newhall Ranch Specific Plan on the movement of resident wildlife species is considered significant due to the reduction in open land available for wildlife movement between the River and upland areas.	See measures listed below for impacts to special-status wildlife species and habitats.	Significant
It is acknowledged that any loss of plant species listed as rare, threatened, or endangered is considered a significant impact. Those include the following:		
slender-horned spineflower (*Dodecahema leptoceras*) (significant if present)	Mitigation Measures SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-53	Not Significant
California Orcutt grass (*Orcuttia californica*)	Mitigation Measures SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-53	Not Significant
Lyon's pentachaeta (*Pentachaeta lyonii*)	Mitigation Measures SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-53	Not Significant
Nevin's barberry (*Mahonia nevinii*)	Mitigation Measures SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-53	Not Significant
thread-leaved brodiaea (*Brodiaea filifolia*)	Mitigation Measures SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-53	Not Significant
Santa Susana tarweed (*Hemizonia minthornii*)	Mitigation Measures SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-53	Not Significant
Braunton's milk-vetch (*Astragalus brauntonii*)	Mitigation Measures SP-4.6-27, SP-4.6-34, SP-4.6-35, and SP-4.6-53	Not Significant
San Fernando Valley spineflower (*Chorizanthe parryi* var. *fernandina*) (significant in Additional Analysis)	Mitigation Measures SP-4.6-53, SP-4.6-59, and SP-4.6-65–SP-4.6-80	Not Significant
short-joint beavertail cactus (*Opuntia basilaris* var. *brachyclada*) (significant in Additional Analysis)[b]	Mitigation Measures SP-4.6-27, SP-4.6-34, SP-4.6-35, SP-4.6-53, and SP-4.6-59	Not Significant

Table 4.5-2
Newhall Ranch Specific Plan Program EIR
Impacts to Biological Resources Caused by Implementation of the Specific Plan and WRP

Impact Description	Mitigation Measures	Conclusion After Mitigation
Calochortus sp. (potentially significant in Additional Analysis depending upon actual species present)	Mitigation Measures SP-4.6-27, SP-4.6-34, SP-4.6-35, SP-4.6-53, and SP-4.6-59	Not Significant
Dudleya sp. (potentially significant depending upon actual species present)[b]	Mitigation Measures SP-4.6-27, SP-4.6-34, SP-4.6-35, SP-4.6-53, and SP-4.6-59	Not Significant
Based on this analysis of indirect impacts to spineflower and other special-status plants, seven indirect impacts/edge effects are considered significant in connection with the proposed development of Newhall Ranch.	Mitigation Measures SP-4.6-53, SP-4.6-59, and SP-4.6-65–SP-4.6-80	Not Significant
Project construction and operation may have potential significant impacts to a number of special-status wildlife species through loss of habitat and/or decrease in water quality if impacts are unmitigated. Species include the following:		
Santa Ana sucker (*Catostomus santaanae*)	Mitigation Measures SP-4.6-44, SP-4.6-53, SP-4.6-55, SP-4.6-57, and SP-4.6-58	Not Significant
unarmored threespine stickleback (*Gasterosteus aculeatus williamsoni*)	Mitigation Measures SP-4.6-53, SP-4.6-54, SP-4.6-55, SP-4.6-57, SP-4.6-58, and SP-4.6-59	Not Significant
arroyo chub (*Gila orcutti*)	Mitigation Measures SP-4.6-44, SP-4.6-53, SP-4.6-55, SP-4.6-57, and SP-4.6-58	Not Significant
arroyo toad (*Bufo californicus*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
western spadefoot toad (*Spea hammondii*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-56, and SP-4.6-55	Not Significant
silvery legless lizard (*Anniella pulchra pulchra*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant
southwestern pond turtle (*Actinemys marmorata pallida*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-56, and SP-4.6-55	Not Significant

Table 4.5-2
Newhall Ranch Specific Plan Program EIR
Impacts to Biological Resources Caused by Implementation of the Specific Plan and WRP

Impact Description	Mitigation Measures	Conclusion After Mitigation
rosy boa (*Charina trivirgata*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant
San Bernardino ringneck snake (*Diadophis punctatus modestus*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant
two-striped garter snake (*Thamnophis hammondii*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-56, and SP-4.6-55	Not Significant
coast [California] horned lizard (*Phrynosoma coronatum*)[c]	Mitigation Measures SP-4.6-27–SP-4.6-43, SP-4.6-53, SP-4.6-56, and SP-4.6-55	Significant
coast [San Diego] horned lizard (*Phrynosoma coronatum*)[c]	Mitigation Measures SP-4.6-27–SP-4.6-43, SP-4.6-53, SP-4.6-56, and SP-4.6-55	Significant
coast patch-nosed snake (*Salvadora hexalepis virgultea*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant
least Bell's vireo (*Vireo bellii pusillus*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-56, and SP-4.6-59	Not Significant
southwestern willow flycatcher (*Empidonax traillii extimus*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-56, and SP-4.6-59	Not Significant
northern harrier (*Circus cyaneus*)	Mitigation Measures SP-4.6-27-SP-4.6-43, and SP-4.6-53	Significant
Cooper's hawk (*Accipiter cooperii*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
vermilion flycatcher (*Pyrocephalus rubinus*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant

Table 4.5-2
Newhall Ranch Specific Plan Program EIR
Impacts to Biological Resources Caused by Implementation of the Specific Plan and WRP

Impact Description	Mitigation Measures	Conclusion After Mitigation
yellow warbler (*Dendroica petechia brewsteri*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
summer tanager (*Piranga rubra*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
southern California rufous-crowned sparrow (*Aimophila ruficeps canescens*)	Mitigation Measures SP-4.6-27–SP-4.6-43, SP-4.6-53, SP-4.6-56, and SP-4.6-55	Significant
tricolored blackbird (*Agelaius tricolor*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-56, and SP-4.6-55	Significant
great blue heron (*Ardea herodias*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
great egret (*Ardea alba*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
snowy egret (*Egretta thula*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55 and SP-4.6-56	Not Significant
black-crowned night heron (*Nycticorax nycticorax*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
white-tailed kite (*Elanus leucurus*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant
Swainson's hawk (*Buteo swainsoni*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant
mountain plover (*Charadrius montanus*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant

Table 4.5-2
Newhall Ranch Specific Plan Program EIR
Impacts to Biological Resources Caused by Implementation of the Specific Plan and WRP

Impact Description	Mitigation Measures	Conclusion After Mitigation
western least bittern (*Ixobrychus exilis hesperis*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
fulvous whistling duck (*Dendrocygna bicolor*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
Bell's sage sparrow (*Amphispiza belli belli*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant
ferruginous hawk (*Buteo regalis*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant
western burrowing owl (*Athene cunicularia hypugaea*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant
sharp-shinned hawk (*Accipiter striatus*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant
golden eagle (*Aquila chrysaetos*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant
pallid bat (*Antrozous pallidus*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
pocketed free-tailed bat (*Nyctinomops femorosaccus*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
Townsend's big-eared bat (*Corynorhinus townsendii*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
western mastiff bat (*Eumops perotis californicus*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
mountain lion (*Puma concolor*)	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-53	Significant

Table 4.5-2
Newhall Ranch Specific Plan Program EIR
Impacts to Biological Resources Caused by Implementation of the Specific Plan and WRP

Impact Description	Mitigation Measures	Conclusion After Mitigation
San Diego black-tailed jackrabbit (*Lepus californicus bennettii*)	Mitigation Measures SP-4.6-27–SP-4.6-43, SP-4.6-53, SP-4.6-56, and SP-4.6-55	Significant
San Diego desert woodrat (*Neotoma lepida intermedia*)	Mitigation Measures SP-4.6-27–SP-4.6-43, SP-4.6-53, SP-4.6-56, and SP-4.6-55	Significant
Yuma myotis (*Myotis yumanensis*)	Mitigation Measures SP-4.6-1–SP-4.6-26, SP-4.6-53, SP-4.6-55, and SP-4.6-56	Not Significant
Development of the Specific Plan would result in impacts to sensitive habitats including the following:		
Coastal sage scrub	Mitigation Measures SP-4.6-27–SP-4.6-43	Significant
Valley oak woodland and valley oak/grass	Mitigation Measures SP-4.6-27–SP-4.6-43	Significant
Elderberry scrub	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-60	Not Significant
Mainland cherry forest	Mitigation Measures SP-4.6-27–SP-4.6-43, and SP-4.6-61	Not Significant
Southern willow scrub	Mitigation Measures SP-4.6-1–SP-4.6-26	Not Significant
Southern cottonwood–willow riparian forest and southern willow riparian woodland	Mitigation Measures SP-4.6-1–SP-4.6-26	Not Significant
Valley freshwater marsh and ponds	Mitigation Measures SP-4.6-1–SP-4.6-26	Not Significant
Wetlands	Mitigation Measures SP-4.6-1–SP-4.6-26	Not Significant
High Country SMA (SEA 20)	Mitigation Measures SP-4.6-1–SP-4.6-26	Not Significant
River Corridor SMA (SEA 23)	Mitigation Measures SP-4.6-26a–SP-4.6-52	Not Significant

Table 4.5-2
Newhall Ranch Specific Plan Program EIR
Impacts to Biological Resources Caused by Implementation of the Specific Plan and WRP

Impact Description	Mitigation Measures	Conclusion After Mitigation
Indirect Impacts – Implementation of the Newhall Ranch Specific Plan has the potential to indirectly impact adjacent natural areas and special-status biological resources that occur proximate to the site. This would occur as a result of increased use of the Santa Clara River and upland areas by humans and domestic animals, increased use of adjacent natural areas by animals typical of an urban environment, and the potential effects of light, glare, sediment, and urban pollutant runoff, unless mitigated.	Mitigation Measures SP-4.6-18, SP-4.6-19, and SP-4.6-56	Significant
Cumulative Biological Impacts	None Proposed/Required	Significant

Notes:
[a] The vegetation classification system used for the Specific Plan and WRP environmental documentation was based on the Holland system (1986). The system used in this EIS/EIR is the "List of California Terrestrial Natural Communities Recognized by the California Natural Diversity Database" (CDFG 2003, updated in October 2007 (CDFG 2007D))
[b] It has since been confirmed that these taxa do not occur on the Newhall Ranch Specific Plan site.
[c] CDFG 2008 Special Animals list (CDFG 2008B) treats the former "California" horned lizard as the coast horned lizard and the former "San Diego" horned lizard as the coast horned lizard (*blainvillei* population). *P.c. blainvillei* and *P.c. frontale* are no longer treated by CDFG as separate subspecies.

4.5.1.3 Relationship of Proposed Project to VCC and Entrada Planning Areas

4.5.1.3.1 VCC Planning Area

The SCP component of the proposed Project, if approved, would facilitate development in the VCC planning area. The VCC is reliant on the SCP and associated take authorizations, and would not be developed without the take authorizations due to grading constraints. The VCC planning area is the remaining undeveloped portion of the VCC commercial/industrial complex currently under development by the applicant. The VCC was the subject of an EIR certified by Los Angeles County in April 1990 (SCH No. 1987-123005). The applicant recently has submitted to Los Angeles County the last tentative parcel map (TPM No. 18108) needed to complete build-out of the remaining undeveloped portion of the VCC planning area. The County will require preparation of an EIR in conjunction with the parcel map and related Project approvals; however, the County has not yet issued a Notice of Preparation (NOP) of the EIR or released the EIR. **Table 4.5-3** summarizes the approved acreages for the VCC planning area. **Table 4.5-4** summarizes the VCC's biological resources impacts, the applicable mitigation measures, and the significance findings after mitigation from the previously certified VCC EIR (April 1990).

Table 4.5-3
Acreage of Each Approved Land Use in VCC Planning Area

Approved Land Use	Acres
Open space	154
Commercial	73
Industrial	92
Public facilities	15
Total	**334**

Table 4.5-4
Impacts to Biological Resources Caused By VCC Implementation

VCC Impact Description	VCC Mitigation Measures	Finding After Mitigation
Project Impacts to Biological Resources: Development of the VCC Project would remove half of the existing vegetation on the site and up to 51 of 79 oak trees; Castaic Creek will be channelized, temporarily removing riparian habitat; during grading and construction, siltation of the downstream, protected habitat could occur.	Mitigation measures call for replacement and maintenance of oak trees; revegetating graded areas with drought tolerant, fire resistant native and non-native species; compliance with a section 404 Permit issued on December 11, 1990; installation of soft bottom channels; implementation of a vegetation restoration plan; observation of a qualified biologist during channel work; require industrial users to provide on-site containment systems; and parking lots required to contain storm drainage system.	Not significant
Cumulative Impacts to Biological Resources: No other filed development plans on adjoining parcels were pending. Other projects would be required to consult with CDFG and USFWS to ensure that suitable habitat for special-status species is maintained.	No further mitigation recommended.	Not significant

Source: VCC EIR (County of Los Angeles 1990).

4.5.1.3.2 Entrada Planning Area

The applicant is seeking approval from Los Angeles County for planned residential and nonresidential development within the Entrada planning area. The SCP component of the proposed Project would designate an area within Entrada as a spineflower preserve. If approved, the SCP component would include take authorization of spineflower populations in Entrada that

are located outside of the designated spineflower preserve area. Thus, the planned residential and nonresidential development within portions of the Entrada planning area is reliant on the SCP and associated take authorizations, and those portions would not be developed without the take authorizations. The applicant has submitted to Los Angeles County Entrada development applications, which cover the portion of the Entrada planning area facilitated by the SCP component of the proposed Project. However, as of this writing, the County has not yet issued an NOP of an EIR or released an EIR for Entrada. As a result, there is no underlying local environmental documentation for the Entrada planning area at this time. The acreages of the proposed Entrada land uses are listed in **Table 4.5-5**. It is projected that approximately 138 acres of land would be preserved as open space. The remaining 252 acres are proposed for residential, commercial, and public facility uses.

Table 4.5-5
Acreage of Each Projected Land Use in Entrada Planning Area

Projected Land Use	Acres
Open space	138

INTENTIONALLY LEFT BLANK

4.5.2 REGULATORY SETTING

As described above in **Section 2.3**, Requested Project Approvals, the applicant is requesting that the Corps issue a section 404 Permit under the federal Clean Water Act (33 U.S.C. §§ 1251–1387) and that CDFG issue a Master Streambed Alteration Agreement pursuant to Fish and Game Code section 1600 *et seq*., and two Incidental Take Permits under CESA issued by CDFG pursuant to Fish and Game Code section 2081, subdivisions (b) and (c). The requested Project approvals would facilitate the future development of the Specific Plan and portions of the Entrada and VCC planning areas. The requested Project approvals would also:

- Streamline the permitting process if there is a need for ongoing authorizations for individual projects or components through the issuance of a single section 404 Permit and a Master Streambed Alteration Agreement, rather than case-by-case permitting;
- Include in the permitting process mitigation requirements for listed and unlisted species, and incidental take authorizations for species currently listed under CESA;
- Standardize the mitigation applicable for Corps and CDFG regulated activities;
- Authorize all regulated activities to be carried out by parties other than the applicant, subject to the terms and conditions of the federal and state permits; and
- Authorize the Los Angeles County Department of Public Works (DPW) to carry out flood control maintenance activities, subject to the terms and conditions of the federal and state permits.

Although the Corps acknowledges the applicant's requested Project approvals as described above, it can only issue a section 404 Permit that: (1) authorizes activities that meet the requirements under the section 404(b)(1) guidelines and are not contrary to the public interest; (2) provides assurances that the authorized discharges into waters of the United States would be completed in accordance with the permit conditions and applicable laws and regulations; and (3) provides the Corps with the necessary flexibility and administrative remedies to address changed environmental conditions, modifications in laws and regulations, and compliance problems.

The Corps is also evaluating the RMDP component of the proposed Project for compliance with section 404(b)(1) guidelines. The Corps will use the results of the environmental impact analysis in this EIS/EIR and input from the public and commenting agencies in reaching a decision on whether to issue the section 404 Permit and, if so, what types of conditions are necessary. Thus, no decision has been made to issue a section 404 Permit for the RMDP component of the proposed Project at this time.

CDFG also acknowledges the applicant's requested Project approvals and its desire to obtain a Master Streambed Alteration Agreement, and the two Incidental Take Permits under CESA. CDFG would execute the requested master agreement and issue the requested permits provided they meet CDFG's requirements to protect and conserve fish and wildlife resources of the state under Fish and Game Code section 1600 *et seq*.; to protect and conserve threatened, endangered, and candidate species under CESA; to avoid take of fully protected species under Fish and Game Code sections 3511, 4700, 5050, and 5155; and to otherwise comply with CDFG's trustee obligations for fish and wildlife resources as provided in various provisions of the Fish and Game Code, including sections 1802, 3503, 3503.5, and 3513. Under CEQA, CDFG must avoid, or substantially reduce, to the extent feasible, all significant direct and indirect environmental impacts resulting from approval and implementation of the proposed Project.

4.5.2.1 Federal Authorities and Administering Agencies

4.5.2.1.1 Clean Water Act of 1976

4.5.2.1.1.1 *Section 404 Permit*

Section 404 of the Clean Water Act (CWA) authorizes the Secretary of the Army, acting through the Corps, to issue permits regulating the discharge of dredged or fill materials into the "navigable waters at specified disposal sites." CWA section 502 further defines "navigable waters" as "waters of the United States, including territorial seas." "Waters of the United States" are broadly defined in the Code of Federal Regulations, title 33, section 328.3, subdivision (a)1 to include navigable waters, perennial and intermittent streams, lakes, rivers, ponds, as well as wetlands, marshes, and wet meadows. Specifically, section 328.3(a) defines "waters of the United States" as follows:

1) All waters which are currently used, or were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to the ebb and flow of the tide;
2) All interstate waters, including interstate wetlands;
3) All other waters such as intrastate lakes, rivers, streams (including intermittent streams), mudflats, sandflats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural

1 This regulation, 33 C.F.R., section 328.3, and the definitions contained therein, have been the subject of recent litigation. In addition, the U.S. Supreme Court has recently limited the scope and extent of the Corps' jurisdiction over "navigable waters" and "waters of the United States" under the CWA. See, *e.g.*, *Solid Waste Agency of Northern Cook Cty.* v. *U.S. Army Corps of Engineers*, 531 U.S. 159 (2001) ("SWANCC"); *Rapanos* v. *United States*, 126 S.Ct. 2208 (2006). Despite the impact of these recent decisions, the definitions continue to provide guidance to the extent that they establish an outer limit for the extent of the Corps' jurisdiction over "waters of the United States," and, therefore, are referenced here for that purpose.

ponds, the use, degradation, or destruction of which could affect interstate or foreign commerce including any such waters:

i. Which are or could be used by interstate or foreign travelers for recreational or other purposes;

ii. From which fish or shellfish are or could be taken and sold in interstate or foreign commerce; or

iii. Which are or could be used for industrial purpose by industries in interstate commerce;

4) All impoundments of waters otherwise defined as waters of the United States under the definition;

5) Tributaries of waters identified in paragraphs (a)(1) through (4) of this section;

6) The territorial seas; and

7) Wetlands adjacent to waters (other than waters that are themselves wetlands) identified in paragraphs (a)(1) through (6) of this section.

Waste treatment systems, including treatment ponds or lagoons designed to meet the requirements of CWA (other than cooling ponds as defined in 40 C.F.R. 123.11(m) which also meet the criteria of this definition) are not waters of the United States.

8) Waters of the United States do not include prior converted cropland. Notwithstanding the determination of an area's status as prior converted cropland by any other federal agency, for the purposes of CWA, the final authority regarding CWA jurisdiction remains with the EPA.

The lateral limits of the Corps' section 404 jurisdiction in non-tidal waters are defined by the "ordinary high-water mark" (OHWM), unless adjacent wetlands are present. The OHWM is a line on the shore or edge of a channel established by the fluctuations of water and indicated by physical characteristics such as a clear, natural line impressed upon the bank, shelving, changes in the character of soil, destruction of vegetation, or presence of debris (33 C.F.R. § 328.3, subd.(e)). As such, waters are recognized in the field by the presence of a defined watercourse with appropriate physical and topographic features. If wetlands occur within, or adjacent to, waters of the United States, the lateral limits of the Corps' jurisdiction will extend beyond the OHWM to the outer edge of the wetlands. The upstream limit of jurisdiction in the absence of adjacent wetlands is the point beyond which the OHWM is no longer perceptible (33 C.F.R. § 328.4; see also 51 FR 41217).

The CWA section 404(b)(1) Guidelines govern the issuance of permits authorizing the placement of fill material into waters of the United States, and state that (40 C.F.R. § 230.10, subd.(a)):

> … no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impacts on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences.

Under the section 404(b)(1) Guidelines, the applicant must demonstrate avoidance or minimization of impacts to waters of the United States to the maximum extent practicable. Under the above requirements, the Corps can only issue a section 404 Permit for the "least environmentally damaging practicable alternative" (LEDPA). In addition, the Corps is prohibited from issuing a permit that is contrary to the public interest (33 C.F.R. § 320.4).

Section 401 of the CWA requires an applicant requesting a federal permit (including a section 404 Permit) for an activity that may result in any discharge into navigable waters to provide state certification that the proposed activity will not violate state and federal water quality standards.

In addition to the above regulations on discharges of dredged or fill material into waters of the United States, CWA section 404 extends additional protection to certain rare and/or sensitive aquatic habitats. These are termed "special aquatic sites," and include six categories: sanctuaries and refuges, wetlands, mudflats, vegetated shallows, coral reefs, and riffle/pool complexes (40 C.F.R. § 230.40–45).

For proposed discharges into these special aquatic sites, the section 404(b)(1) Guidelines require consideration of whether the activity associated with the proposed discharge is dependent on access or proximity to or siting within a special aquatic site to fulfill its basic project purpose. If an activity is determined not to be water dependent, the section 404(b)(1) Guidelines establish the following two presumptions (40 C.F.R. § 230.10, subd.(a)(3)) that the applicant is required to rebut in addition to satisfying the alternatives analysis requirements:

- That practicable alternatives not involving discharges of fill material into special aquatic sites are presumed to be available; and,
- That all practicable alternatives to the proposed discharge not involving a discharge into a special aquatic site are presumed to have less adverse impacts on the aquatic ecosystem.

For nonwater-dependent projects, the applicant must rebut these presumptions in order to demonstrate compliance with the section 404(b)(1) Guidelines.

Of the six categories of special aquatic sites, only wetlands are at issue with respect to the proposed Project. The CWA defines wetlands as (33 C.F.R. § 328.3, subd. (b)):

> [T]hose areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances

do support, a prevalence of vegetation typically adapted for life in saturated soil conditions.

The Corps has developed a field technique to identify wetlands, which is often referred to as the "three-parameter technique" (Corps 1987). This method involves a procedure to identify the three requisite characteristics of a section 404 jurisdictional wetland:

- Hydrophytic vegetation: more than 50% of dominant plants are adapted to anaerobic soil conditions;
- Hydric soils: soils classified as hydric or that exhibit characteristics of a reducing soil environment; and
- Wetland hydrology: inundation or soil saturation during at least 5% of the growing season (in southern California, this is equal to 18 days).

The Corps' wetlands delineation manual (Corps 1987) describes an approach to identify field indicators of the above characteristics. In general, all three characteristics must be evident by field indicators, and their presence must be determined independent of the other characteristics. Positive identification of wetlands based on the presence of fewer than three characteristics can only occur when one or more parameters is absent due to normal seasonal variation in environmental conditions ("Problem Areas"), or due to recent human activities ("Atypical Situations"). Delineation of wetlands using the Corps' 1987 manual requires a systematic field investigation of soil, plants, and hydrology using formal data forms.

4.5.2.1.1.2 *Corps' Section 404 Permit Process.*

The section 404 Permit process for the proposed Project began with the issuance of the Corps' Public Notice (announcing the receipt of a section 404 Permit application) and scoping meetings for the EIS/EIR. Based upon the information in this EIS/EIR, public comments, and input from various agencies, the Corps will conduct a permit evaluation considering the probable project and cumulative impacts of the proposed Project on the public interest. The decision will reflect the national concern for both protection and utilization of important aquatic resources and the applicable legal requirements. The benefit that may reasonably be expected to accrue from the proposed actions will be balanced against their reasonably foreseeable detriments.

In summary, the Corps will:

- Determine if the proposed actions are consistent with section 404(b)(1) Guidelines;
- Consult with the USFWS to determine if the proposed actions would adversely affect threatened and endangered species or their critical habitat under the provisions of Endangered Species Act section 7 (16 U.S.C. § 1531 *et seq.*);

- Coordinate with the National Oceanic and Atmospheric Administration (NOAA) Fisheries Service to ensure that the proposed actions would not affect southern steelhead or its critical habitat under the provisions of Endangered Species Act section 7 (16 U.S.C. § 1531 *et seq.*);
- Coordinate with the State Historic Preservation Officer to ensure compliance with National Historic Preservation Act section 106; and
- Consider all agency and public comments on the Public Notice and the EIS/EIR in the permit decision.

A section 404 Permit would not be valid until the applicant receives a section 401 water quality certification or waiver from the RWQCB. The water quality certification, denial, or waiver generally occurs concurrently with the Corps' permit decision. The Corps anticipates that any permit issued for the proposed actions would likely be a provisional permit until completion of the state process because the RWQCB cannot take action on a request for certification or waiver for the proposed section 404 Permit without compliance with CEQA (*i.e.*, certification of a Final EIR and adoption of CEQA findings by CDFG).

The permit process proposed by the Corps consists of two major steps: (1) an evaluation of the proposed Project followed by a decision; and (2) individual project verifications during the life of the permit. The key steps are as follows:

- Upon completion of the NEPA review, section 7 consultation, permit evaluation, and agency coordination, the Corps would issue a provisional permit, which would become an individual section 404 Permit after all regulatory authorizations are obtained, for the life of the Project.
- Upon CDFG's certification of the Final EIS/EIR and adoption of CEQA findings, the RWQCB would issue a waiver or section 401 water quality certification. The latter would become a condition of the Corps' section 404 Permit.
- The applicant would need to submit a request for verification of authorization to the Corps for each proposed project element described in the Final EIS/EIR. Project elements can only be implemented when the Corps has issued a written verification to the applicant.

  Project Modification. If the applicant modifies a project element significantly from that described in the Final EIS/EIR, a request to modify the section 404 Permit would be submitted to the Corps with an explanation for the modification and description of the following items: (1) new impacts associated with the modification and their significance; (2) changes in the overall environmental impacts due to the modification of an individual project element; and (3) conformance with the environmental protection elements of the

Final EIS/EIR and section 404 Permit conditions. Significant deviation from the Final EIS/EIR may also trigger the need for a Supplemental EIS/EIR if new significant or substantially more severe environmental impacts could occur.

Third-Party Use of Permit. Parties other than the applicant could seek authorization for section 404 activities that are included in the section 404 Permit by submitting a sub-notification letter to the Corps. The request must include a statement that the party will abide by the conditions of the section 404 Permit and any subsequent modifications to that permit.

Annual Reports. The applicant would be required to submit an Annual Permit Status Letter Report to the Corps by April 1 of each year. For this Project, the applicant has also proposed to submit an Annual Mitigation Status Report and Mitigation Accounting Form to the Corps and CDFG by April 1 of each year. Under the provisions of the section 404 Permit program (33 C.F.R. § 325.7), the Corps has the authority to reevaluate the circumstances and conditions of the section 404 Permit, and may initiate action to modify, suspend, or revoke the permit as may be made necessary by considerations of the public interest.

Maintenance. Prior to any maintenance activities, the DPW or other management entity would submit a Maintenance Notification to the Corps, CDFG, and the RWQCB. The Maintenance Notification would be submitted to the Corps 30 calendar days prior to the planned activities. The Corps would be required to respond within the 30-day period, notifying the DPW or other management entity that: (1) the maintenance activities can proceed as planned because they are consistent with the Final EIS/EIR and the conditions of the section 404 Permit; or (2) the activities cannot proceed as planned.

For maintenance activities that are not included in the section 404 Permit, the DPW would be required to submit a new permit modification application to the Corps. The Corps would have the discretion to modify the section 404 Permit and its conditions to include the new proposed projects, or to issue a separate nationwide or individual permit, as appropriate.

If the DPW or other management entity modifies a maintenance activity from the Final EIS/EIR, a request to modify the section 404 Permit would be submitted to the Corps with an explanation of the modification and descriptions of the following items: (1) new impacts associated with the modification; (2) changes in the overall environmental impacts due to the modification of an individual project; and (3) conformance with the environmental protection elements of the Final EIS/EIR and section 404 Permit conditions. The Corps would review the requested modifications, and would have the discretion to modify the section 404 Permit and its conditions to include the new

maintenance activity after review by the appropriate resource and regulatory agencies, or to issue a separate nationwide or individual permit, as appropriate.

4.5.2.1.1.3 *NEPA Action*

The Corps is the lead agency under NEPA guidelines responsible for review of the environmental impacts of the proposed Project. In that capacity, the Corps must assess, and is analyzing in this EIS/EIR, the potential for significant direct, indirect, and cumulative impacts on the environment that may result from approval and implementation of the proposed RMDP and SCP components of the proposed Project, and issuance of the requested section 404 Permit. The Corps' responsibilities include the evaluation of a range of reasonable alternatives to the proposed Project and the identification of feasible mitigation measures to minimize identified adverse effects of the proposed Project.

4.5.2.1.1.4 *Endangered Species Act of 1973*

The federal ESA (16 U.S.C. § 1531 *et seq*.) and the implementing regulations (50 C.F.R. § 17.1 *et seq*.) include provisions for the protection and management of federally listed threatened or endangered plants and animals and their designated critical habitats. Generally, the USFWS regulates upland and freshwater species and the NOAA Fisheries Service oversees provisions for protection of anadromous, marine, and estuarine species. ESA section 4 requires USFWS and/or NOAA Fisheries Service to make determinations on whether any species should be listed as an endangered or threatened species and to designate critical habitat for endangered and threatened species (16 U.S.C. § 1533). ESA section 3 defines critical habitat for endangered and threaten species as follows (16 U.S.C. § 1532):

(i) the specific areas within the geographical area occupied by the species, at the time it is listed in accordance with the provisions of § 1533 of this title, on which are found those physical or biological features (I) essential to the conservation of the species and (II) which may require special management considerations or protection; and

(ii) specific areas outside the geographic area occupied by the species at the time it is listed in accordance with the provisions of § 1533 of this title, upon a determination by the Secretary that such areas are essential for the conservation of the species.

ESA section 4 also requires the preparation of recovery plans for the conservation and survival of an endangered or threatened species, unless such a plan would not promote the conservation of the species. Recovery plans include a description of site-specific management actions necessary to achieve the goal(s) for conservation and survival of the species; objective

measurable criteria which, if met, would result in a determination of removing the species from the endangered or threatened species list; and estimates of the time required and cost to carry out the measures needed to achieve the plan's goal(s) and to achieve the immediate steps to the goal(s) (16 U.S.C. § 1533).

ESA section 7 requires federal agencies to consult with USFWS and/or NOAA Fisheries Service and obtain a Biological Opinion prior to carrying out any federal program or agency action that may adversely affect threatened or endangered species. The section 7 consultation and Biological Opinion process includes an evaluation of whether a project is likely to jeopardize the continued existence of any endangered or threatened species or result in the "destruction or adverse modification" of critical habitat, and requires the inclusion of reasonable and prudent measures in the implementation of a project or agency action in order to minimize any impact (16 U.S.C. § 1536).

With regard to the proposed Project, the Corps would comply with these requirements through consultation with USFWS and NOAA Fisheries Service. In fact, in December 2007, the Corps initiated the required consultation, and requested the biological opinion of the USFWS on impacts to five federally listed species (least Bell's vireo, unarmored threespine stickleback, arroyo toad, southwestern willow flycatcher, and California condor). In addition, the Corps will confer with and request a biological opinion from USFWS regarding the proposed Project's impacts to two additional federally listed threatened species (California red-legged frog and coastal California gnatcatcher). This is because suitable habitat for the California red-legged frog exists within the Project area, because non-breeding (likely dispersing) California gnatcatchers have been observed on two occasions in the Project area, and because the two species are known to inhabit areas in the vicinity of the Project area. As a result, the potential exists for these two additional species to establish populations on site in the future and for the proposed Project to adversely affect these two species.

4.5.2.1.1.5 *USFWS Processes*

For federally listed species, the USFWS would review the Biological Assessment submitted by the Corps. Within 135 days, the USFWS will determine whether the project activities would jeopardize a federally listed species and issue either a Biological Opinion or Jeopardy Decision.

Should a new species become federally listed that is known to occur, or at least has moderate potential to occur, within the Project area, the applicant would coordinate with the Corps and the USFWS to determine whether surveys for that species are necessary. If the USFWS and the Corps determine that the Project activities would affect the newly-listed species, it is anticipated that the USFWS would amend the Biological Opinion.

In addition, the USFWS would review the applicant's proposed Candidate Conservation Agreement and associated SCP. Once the Candidate Conservation Agreement is deemed complete by the USFWS and upon completion of the Final EIS/EIR by the Corps, the SCP would be made a part of the Candidate Conservation Agreement signed by both the applicant and USFWS.

4.5.2.1.1.6 *NEPA Action*

The USFWS would utilize this EIS/EIR in evaluating whether to approve the requested Candidate Conservation Agreement, which will be made a part of the SCP component of the proposed Project. In that capacity, USFWS must assess the potential for significant direct, indirect, and cumulative impacts on the environment that may result from approval and implementation of the proposed Candidate Conservation Agreement. The USFWS would also consider the range of reasonable alternatives and feasible mitigation measures associated with the proposed Project.

Fish and Wildlife Coordination Act. The Fish and Wildlife Coordination Act (FWCA) (16 U.S.C. § 661 *et seq*.) provides authority for the USFWS to evaluate impacts to fish and wildlife from proposed water resource development projects. FWCA section 2 requires federal agencies to consult with the USFWS when the waters or channel of a stream or other body of water are proposed to be modified pursuant to a federal permit or license (16 U.S.C. § 662). Applicability depends on federal jurisdiction over some aspect of the Project, and the consultation is undertaken with a view toward conservation of wildlife resources by preventing loss of and damage to such resources. With regard to the proposed Project, the Corps will comply with these requirements in coordination with the USFWS.

Migratory Bird Treaty Act. The Migratory Bird Treaty Act (16 U.S.C. §§ 703–711) includes provisions for the protection of migratory birds, and prohibits the non-permitted take of most migratory birds, under the authority of the USFWS and CDFG.

Bald and Golden Eagle Protection Act. In addition to the provisions of the Migratory Bird Treaty Act, the Bald and Golden Eagle Protection Act (16 U.S.C. § 668 *et seq*.) includes specific protection for bald eagles and golden eagles.

4.5.2.2 State Authorities and Administering Agencies

4.5.2.2.1 California Endangered Species Act (CESA) (Fish & G. Code, § 2050 *et seq*.).

The California Endangered Species Act (CESA) is intended to conserve, protect, restore, and enhance species designated as endangered or threatened, and their habitat. (Fish & G. Code, §

2052). The California Fish and Game Commission, a constitutionally established commission distinct from CDFG, has exclusive statutory authority under CESA to designate species as endangered or threatened under CESA. (Cal. Const., art. IV, § 20, subd. (b); Fish & G. Code, 2070). Animal species designated as endangered or threatened under CESA are listed in California Code of Regulations, title 14, section 670.5. Plant species designated as endangered or threatened under CESA, or designated as a rare plant species under the California Native Plant Protection Act (Fish & G. Code, § 1900 *et seq*.), are listed in California Code of Regulations, title 14, section 670.2.

CESA directs all state agencies, boards, and commissions to seek to conserve endangered and threatened species, and to utilize their authority in furtherance of that policy (Fish & G. Code, § 2055). For purposes of CESA, "conserve," "conserving," and "conservation" mean to use, and the use of all methods and procedures which are necessary to bring any endangered species or threatened species to the point at which the species protections provided by CESA are no longer necessary. These methods and procedures include, but are not limited to, all activities associated with scientific resources management, such as research, census, law enforcement, habitat acquisition, restoration and maintenance, propagation, live trapping, and transplantation, and, in the extraordinary case where population pressures within a given ecosystem cannot be otherwise relieved, may include regulated taking (Fish & G. Code, § 2061). CESA also emphasizes, consistent with its goal to conserve species, that it is policy of the State of California to acquire lands for habitat for endangered and threatened species (Fish & G. Code, § 2052). Finally, CESA emphasizes that state agencies should not approve projects as proposed which would jeopardize the continued existence of any endangered or threatened species or result in the destruction or adverse modification of habitat essential to the continued existence of those species, if there are reasonable and prudent alternatives available consistent with conserving the species or its habitat that would prevent jeopardy (Fish & G. Code, § 2052.1).

With respect to lands in private ownership, CESA underscores that the cooperation of the owners of land identified as habitat for endangered or threatened species is essential for the conservation of those species and that it is the policy of the State of California to foster and encourage that cooperation in furtherance of CESA's conservation goals (Fish & G. Code, § 2056). To the extent that CESA requires a person to provide mitigation measures or alternatives to address a particular impact on a designated endangered, threatened, or candidate species, the Fish and Game Code provides that any required measures or alternatives shall be roughly proportional in extent to any impact on those species caused by that person. Likewise, where various measures or alternatives are available to meet this requirement, CESA directs that those measures or alternatives shall maintain the person's objectives to the greatest extent possible (Fish & G. Code, § 2052.1). To that same end, CESA directs CDFG to work with project proponents to develop reasonable and prudent alternatives, consistent with CESA's conservation goals, while at

the same time maintaining the project purpose to the greatest extent possible (Fish & G. Code, § 2053; see also Cal. Code Regs., tit. 14, § 783.2, subd. (b)).

Species designated as endangered or threatened under CESA, and species designated as candidates for listing or delisting under CESA, are subject to what is commonly known as CESA's "take" prohibition. In general, this prohibition provides that no person shall import into the State of California, or export out of the State of California, or take, possess, purchase, or sell within this state (or attempt to do any of those acts), any species, or any part or product thereof, designated by the Fish and Game Commission as protected under CESA, except as otherwise provided by law (Fish & G. Code, §§ 2080, 2085; see also Cal. Code Regs., tit. 14, § 670.2, subd. (i)(1)(B)1). "Take" is defined specifically in the Fish and Game Code to mean "hunt, pursue, catch, capture, or kill," or an attempt to do any such act, and violations of CESA's take prohibition are criminal misdemeanors under State of California law (Fish & G. Code, §§ 86, 12000; see also *Department of Fish and Game v. Anderson-Cottonwood Irrigation District* (1992) 8 Cal.App.4th 1554).

For purposes of CESA and the proposed Project, the applicant seeks two Incidental Take Permits pursuant to Fish and Game Code section 2081, subdivisions (b) and (c). The specific details regarding the two Incidental Take Permits requested by the applicant are discussed below in **Subsection 4.5.2.2.1.3**. With respect to Fish and Game Code section 2081, this provision provides, in pertinent part, that CDFG may authorize, by permit, the take of endangered, threatened, or candidate species if all of the following conditions are met (Fish & G. Code, § 2081, subds. (b), (c); see also Cal. Code Regs., tit. 14, § 783.4 subds. (a)–(c)):

(1) The authorized take is incidental to an otherwise lawful activity;

(2) The impacts of the authorized take are minimized and fully mitigated, which is defined to mean all impacts on the species that result from any act that would cause the proposed taking;

(3) The measures required to minimize and fully mitigate the impacts of the authorized take:

  (a) Are roughly proportional in extent to the impact of the take on the species;

  (b) Maintain the applicant's objectives to the greatest extent possible; and

  (c) Are capable of successful implementation, including new or other measures without an as yet established record of success, as long as there is a reasonable basis for utilization and a reasonable prospect for success;

(4) Adequate funding is provided to implement the required minimization and mitigation measures and to monitor compliance with, and the effectiveness of, the measures; and

(5) Issuance of the permit will not jeopardize the continued existence of a state-listed species.

Recent case law provides important guidance regarding the issuance criteria for an Incidental Take Permit under Fish and Game Code section 2081, subdivision (b). In *Environmental Protection and Information Center v. California Dept. of Forestry and Fire Protection* (2008) 44 Cal.4th 459, for example, the California Supreme Court clarified with respect to an Incidental Take Permit issued pursuant to Fish and Game Code section 2081, subdivision (b), that "'take' in this context means to catch, capture or kill" (44 Cal.4th, p. 507, citing Fish & G. Code, § 86). Similarly, in *Environmental Council of Sacramento v. City of Sacramento* (2006) 142 Cal.App.4th 1018, the Third District Court of Appeal underscored that the issuance criteria necessarily involve a complex mix of quantitative and qualitative factors that CDFG must balance and gauge in the exercise of its independent judgment. Likewise, with respect to the requirement that the permittee minimize and fully mitigate all the impacts of the authorized take, the court rejected "any insinuation that the definition of 'take' under Fish and Game Code section 2081, subdivision (b)(2), encompasses the taking of habitat alone or the impacts of the taking. As section 86 of the Fish and Game Code makes clear, proscribed taking involves mortality (142 Cal.App.4th, p. 1040).

In short, the incidental take of listed species is authorized by CDFG on a discretionary basis. Typically, mitigation measures, including species and habitat avoidance, minimization, restoration or enhancement, acquisition, and permanent protection of compensatory habitat, along with monitoring and management and funding assurances, are necessary to demonstrate that project impacts are fully mitigated. Full mitigation for take of listed species is determined on a project-specific basis, and a variety of combinations of mitigation actions can form the basis for a conclusion that the impacts of the taking caused by any particular project are fully mitigated as required by CESA. Generally, though, full mitigation can be achieved by offsetting the project's incidental take of individuals of the covered species, along with the other spatial, temporal, direct, indirect, and cumulative impacts, including habitat loss, that constitute "impacts of the taking" as that term is used in CESA, such that the covered species continues to survive and thrive after completion of the project and required mitigation.

4.5.2.2.1.1 *Fish and Game Code Sections 1600–1616.*

Fish and Game Code section 1602 (Chapter 6, Fish and Wildlife Protection and Conservation) states that it is unlawful for any person to "substantially divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of, any river, stream, or lake" without first notifying CDFG of that activity. Thereafter, if CDFG determines and informs the entity that the activity will not substantially adversely affect any existing fish or wildlife resources, the entity may commence the activity. If, however, CDFG determines that the activity may substantially adversely affect an existing fish or wildlife resource, the entity may be required to obtain from CDFG a Streambed Alteration Agreement, which will include reasonable

measures necessary to protect the affected resource(s), before the entity may conduct the activity or activities described in the notification. (Fish & G. Code, § 1602).

Streambed Alteration Agreements are typically required for activities such as excavation or placement of fill within a stream channel, vegetation clearing, installation (and sometimes operation) of structures that divert the flow of water, installation of culverts and bridge supports, cofferdams for construction dewatering, and bank reinforcement. "Steams," "rivers," and "lakes" are not defined in Fish and Game Code section 1600 *et seq*., and CDFG has not defined those terms in its regulations. However, generally speaking, CDFG would agree with the California Fish and Game Commission's definition of a stream or river in California Code of Regulations, title 14, section 1.72, as:

> [A] body of water that flows at least periodically or intermittently through a bed or channel having banks and supports fish or other aquatic life. This includes watercourses having a surface or subsurface flow that supports or has supported riparian vegetation.

Further, CDFG interprets "streambed" to encompass all portions of the bed, banks, and channel of any stream, including intermittent and ephemeral streams, extending laterally to the upland edge of riparian vegetation. In the case of watercourses with vegetated floodplains, such as the Santa Clara River, this interpretation often results in an asserted jurisdictional area that is much wider than the active channel of the stream. The upstream limit of CDFG's asserted jurisdiction is the point upstream of which there is no evidence of a defined bed and bank, and riparian vegetation is not present.

It should be noted that the Corps' CWA section 404 jurisdiction is a subset of CDFG's Fish and Game Code section 1600 jurisdiction. That is, although the two may be coterminous, as is the case in many smaller, ephemeral streams lacking riparian plant communities, CDFG jurisdictional area will never be smaller than that defined using the Corps' "ordinary high-water mark" criterion.

Although Fish and Game Code section 1600 *et seq*. does not specifically contain provisions regulating activities that would impact wetlands, isolated areas containing riparian vegetation, or wetland hydrology, such activities are considered by CDFG to be subject to the Streambed Alteration Agreement program. However, there is no Fish and Game Code analogous to the "special aquatic site" concept found in the CWA.

4.5.2.2.1.2 *Master Streambed Alteration Process*

The development and issuance of a CDFG Master Streambed Alteration Agreement would follow the same general procedures described above for the section 404 Permit, including all

noticing and agency coordination requirements, and all project-specific and annual reports. However, there are several differences between the procedures, including timeframes for responding, terminology for correspondence, and forms to be used by the applicant and CDFG. A summary of CDFG's process is provided below.

The proposed Master Streambed Alteration Agreement would include avoidance, minimization and mitigation measures, all or some of which the applicant must implement for a specific covered activity, and maintenance procedures that the applicant must follow to complete a specific covered activity. The measures and procedures applied to a covered activity would be those that CDFG and the applicant agree are necessary to protect fish and wildlife resources that the activity could substantially adversely affect. The Master Streambed Alteration Agreement would be a long-term agreement (*i.e.*, greater than five years) authorized and governed by Fish and Game Code section 1605, subdivision (g).[2]

Prior to initiating a specific activity covered by the Master Streambed Alteration Agreement, the applicant would seek authorization from CDFG to begin the activity. The authorization request would be in writing, describe the activity, include construction plans when appropriate, and identify the avoidance, minimization, and mitigation measures and maintenance procedures identified in the Master Streambed Alteration Agreement that the applicant intends to apply to the activity.

Upon receipt of an authorization request, CDFG would first determine whether the activity is covered by the Master Streambed Alteration Agreement. If the activity is not covered, the applicant could request that CDFG amend the Master Streambed Alteration Agreement to include the activity after CDFG completes any necessary additional environmental review under CEQA (see below). If the activity is covered, the CDFG would determine whether the avoidance, minimization, and mitigation measures and maintenance procedures identified in the authorization request are necessary and adequate to protect the fish and wildlife resources that the activity could substantially adversely affect.

If the measures and procedures are necessary and adequate, CDFG would authorize the activity without additional environmental review under CEQA. If CDFG identifies a measure or procedure in the authorization request that is not necessary, CDFG would exclude that measure or procedure in its authorization. If CDFG determines that the measures and procedures identified in the authorization request are not adequate, CDFG would include additional measures that the applicant must apply to the activity described in the authorization request and complete any necessary additional environmental review under CEQA before authorizing the

[2] The applicant has submitted its application to the CDFG for the Master Streambed Alteration Agreement, and the proposed agreement. Please refer to **Appendix 2.0** for a copy of the proposed agreement.

activity. Any additional measures and/or procedures CDFG requires might or might not be identified in the Master Streambed Alteration Agreement. If the applicant disagrees with any of those additional measures, CDFG and the applicant would follow the process set forth in Fish and Game Code section 1605, subdivision (g)(3), to resolve the disagreement. If CDFG determines that individual projects and mitigation are not consistent, then CDFG would deny the authorization request.

Minor Amendment. The applicant may submit a request for a minor amendment to the Master Streambed Alteration Agreement for any project that has been denied under an authorization request, or for a project identified in the Final EIS/EIR that has been modified beyond the approved project limits. The request for an authorization for a minor amendment must be submitted with appropriate construction plans and mitigation information. If CDFG determines that the project would have no additional substantial adverse effects on fish and wildlife resources, CDFG would deem the mitigation information to be satisfactory under the Master Streambed Alteration Agreement, and approve the request for authorization of a minor amendment after completion of any required additional CEQA compliance. If CDFG determines that the project would have additional substantial adverse effects on fish and wildlife resources, CDFG would not deem the mitigation information satisfactory under the Master Streambed Alteration Agreement, and would deny the request for authorization of a minor amendment.

Major Amendment. If a request or authorization of a minor amendment is denied or if the applicant desires to go forward with a project that has not been identified in the Final EIS/EIR, the applicant may request a major amendment (Request for Amendment) to the Master Streambed Alteration Agreement, which would include appropriate construction plans and mitigation information. If the project identified in the request for a major amendment is consistent with the Final EIS/EIR and any substantial adverse effects to fish and wildlife can be mitigated to CDFG's satisfaction according to the Final EIS/EIR mitigation measures, CDFG could approve the request for a major amendment after completion of any additional required CEQA compliance. If the new project or project for which a request for authorization for variance was denied would impact areas not covered in the Final EIS/EIR, CDFG may require additional compensatory mitigation and any other necessary measures.

4.5.2.2.1.3 *CESA "Take" Authorizations.*

The proposed Project activities may affect some species listed as threatened or endangered under CESA. As described above in **Subsection 4.5.2.2.1,** CDFG may authorize the incidental take of these species under CESA through issuance of an Incidental Take Permit pursuant to Fish and Game Code section 2081, subdivisions (b) and (c). These provisions of the Fish and Game

Code, coupled with CDFG's "CESA Implementing Regulations" (Cal. Code Regs., tit. 14, § 783.0 *et seq.*), authorize CDFG to issue an Incidental Take Permit for a project as proposed if: (1) the take is incidental to an otherwise lawful activity; (2) the impacts of the taking are minimized and fully mitigated by measures that are roughly proportional to the project-related impact to the species and, where various measures are available, the measures maintain the applicant's objectives to the maximum extent possible; (3) the measures are capable of successful implementation; (4) the applicant ensures adequate funding to implement the measures, and for monitoring compliance with and effectiveness of those measures; and (5) the issuance of the permit would not jeopardize the continued existence of the species.

With respect to the proposed Project, the applicant has submitted applications to CDFG for issuance of two section 2081 Incidental Take Permits. The first application covers CESA-listed wildlife species observed in the Project area (western yellow-billed cuckoo (*Coccyzus americanus occidentalis*), southwestern willow flycatcher, and least Bell's vireo)), special-status wildlife species observed in the Project area (arroyo toad, tricolored blackbird (*Agelaius tricolor*), and western burrowing owl (*Athene cunicularia hypugaea*)), and undescribed plant and wildlife species observed in the Project area (sunflower (*Helianthus* sp. *nova*), everlasting (*Gnaphalium* sp. *nova*), and spring snail (*Pyrgulopsis* sp. *nova*)). If CDFG issues an Incidental Take Permit in response to this application, incidental take authorization would be granted for species that are listed at the time of permit issuance. All other species would be considered "unlisted covered species" in the permit. If, during the effective period of the permit, any unlisted covered species were subsequently listed under CESA, CDFG would give due consideration to the applicant's avoidance, minimization, and mitigation measures contained in the permit when evaluating a request to amend the permit to add the species to the take authorization provided by the permit. The second application covers the CESA-listed San Fernando Valley spineflower (*Chorizanthe parryi* var. *fernandina*) only. The applicant submitted formal applications to CDFG for the requested Incidental Take Permits on May 9, 2008. (See generally Cal. Code Regs., tit. 14, §§ 783.2, 783.3, 783.5). These applications comprise part of Project-related documents being released by CDFG as part of the public review process required by both CEQA and CESA (see, *e.g.*, Cal. Code Regs., tit. 14, § 783.5, subd. (d)(2)).

4.5.2.2.1.4 *CEQA Actions*

CDFG is the lead agency under CEQA responsible for review of the environmental impacts of the proposed Project. In that capacity, CDFG must assess, and is analyzing in this EIS/EIR, the potential for significant direct and indirect impacts on the environment that may result from approval of the RMDP and SCP components of the proposed Project, and issuance of the Master Streambed Alteration Agreement and Incidental Take Permit(s). That analysis includes significant environmental impacts within CDFG's permitting authority, and impacts to other

natural resources within CDFG's jurisdiction as the state's trustee for fish and wildlife resources resulting from approval and implementation of the proposed Project. Where any such impacts are significant, CEQA's substantive mandate requires CDFG to avoid or substantially lessen those impacts to the extent feasible. In this respect, the EIS/EIR, RMDP, and SCP include feasible mitigation measures that would avoid or substantially lessen significant Project-related environmental impacts, including impacts on natural resources held in trust for the people of California.

Native Plant Protection Act of 1977. The Native Plant Protection Act of 1977 (Fish & G. Code, § 1900 *et seq*.) authorizes the California Fish and Game Commission to designate rare and endangered native plants, and provides specific protection measures for these listed species.

Public Resources Code 21083.4. This portion of CEQA provides for the conservation of oak woodlands through conservation easements and mitigation measures and includes certain exemptions. Specifically, the section requires that a county determine whether a project in its jurisdiction may result in a conversion of oak woodlands ("oak" is defined to apply only to those oak trees that are 5 inches or more in diameter at breast height [dbh]) that will have a significant effect on the environment. If the county determines that there may be a significant effect to oak woodlands, the county must require one or more of the following mitigation measures:

(1) Conserve oak woodlands, through the use of conservation easements;

(2) Plant an appropriate number of trees, including maintaining plantings and replacing dead or diseased trees. (There is a requirement to maintain planted trees for seven years after the trees are planted. And the planting of oak trees shall not fulfill more than one-half of the mitigation requirement for the project.);

(3) Contribute funds to the Oak Woodlands Conservation Fund; or

(4) Other mitigation measures developed by the county.

4.5.2.3 Other Permits and Approvals

In addition to the Corps, USFWS, and CDFG permitting requirements, other permits or approvals may be required to implement the proposed Project. Specifically, regulatory agencies, known as responsible agencies under CEQA, may identify the need for additional permits and approvals for the proposed Project. The other permits and approvals, which are known to be needed, or may be needed, are as follows:

- Specific Plan amendments, conditional use permits, tentative tract map approvals, zone changes, oak tree removal permits, and parking permits from Los Angeles County;

- Grading and building permits from Los Angeles County;
- Encroachment permits from Caltrans and Federal Highway Administration (FHWA) for bridge and roadwork involving Caltrans and FHWA facilities;
- Encroachment permits from Southern California Edison (SCE) for transmission line right-of-way access, and from DPW for channel and road work access;
- Individual NPDES permits for dewatering activities; and
- Stormwater mitigation plan approvals from Los Angeles RWQCB.

The above description of other required permits and approvals is not intended to provide a complete and final listing of future agency actions, permits, and approvals required to implement the proposed Project. Other additional permits/approvals may be required in the future.

4.5.2.3.1 County of Los Angeles Oak Tree Ordinance (CLAOTO)

The County of Los Angeles Oak Tree Ordinance (codified at Los Angeles County Code Chapter 22.56, Part 16) prohibits damaging or removing oak trees with trunks that are at least 8 inches in diameter (or that have two trunks totaling at least 12 inches in diameter) as measured 4.5 feet above natural ground (County of Los Angeles 1988). A heritage oak, as defined by CLAOTO, is any oak tree measuring 36 inches or more in diameter as measured 4.5 feet above natural ground, or any oak of 36 inches or less in diameter having a significant historical or cultural importance to the community. CLAOTO requires that all potential impacts to oak trees regulated by this ordinance be preceded by an application to the County that includes a detailed oak tree report. Mitigation for impacts to oak trees is usually required as a condition of an Oak Tree Permit issued by the County.

INTENTIONALLY LEFT BLANK

4.5.3 ENVIRONMENTAL SETTING AND ALTERNATIVE 1

The RMDP is a conservation, mitigation, and permitting plan for the long-term management of special-status biological resources within the 11,999-acre Newhall Ranch Specific Plan (Specific Plan) area (County of Los Angeles 2003A). The RMDP would consist of development-related infrastructure improvements in or adjacent to the Santa Clara River and tributaries located in the RMDP study area that are needed to implement the approved Specific Plan. The RMDP infrastructure improvements are composed of various flood control features, bridges/road crossings, stream bank stabilization, drainage facilities, roads, building pads, utility corridors, pipeline and utility river crossings, nature trails, the discharge outfall for the previously approved Newhall Ranch Water Reclamation Plant (WRP), and drainage facility maintenance activities.

The 13,651-acre RMDP study area is located in the Santa Clara River Valley in unincorporated northwestern Los Angeles County and northeastern Ventura County (**Figure 4.5-1**, Regional Map, and **Figure 4.5-2**, Vicinity Map). The RMDP encompasses the same area as the boundary of the previously approved Newhall Ranch Specific Plan, except that it includes Specific Plan-related traffic/utility infrastructure and the Salt Creek area in Ventura County, adjacent to the Specific Plan. It lies west of Interstate 5 (I-5) and largely southwest of the junction of I-5 and State Route 126 (SR-126), with portions of the study area site located in San Martinez Grande and Chiquito canyons north of SR-126. Site elevations range from 825 feet above mean sea level (AMSL) in the Santa Clara River bottom at the Ventura County/Los Angeles County line to approximately 3,200 feet AMSL on the ridgeline of the Santa Susana Mountains along the southern boundary.

On a regional level, the City of Santa Clarita is located to the east of the Project area, and the Los Angeles County/Ventura County jurisdictional boundary line is to the west. This region and much of the proposed RMDP and SCP study areas is located in a broad ecological and biogeographic transition zone for the coastal and mountain ecoregions. This alluvial valley also provides access *via* the Santa Clara River to the edges of the Mojave Desert and the foothills of the San Gabriel Mountains. While much of the region has been subject to rapid urbanization and historical agricultural and oil development practices, large areas of open space and natural lands border the region. The Los Padres National Forest is located to the north of the Project area and the Angeles National Forest lies to the north and east. The Santa Susana Mountains; a region of gently rolling hills and sharp, steep walled canyons; border the Project area to the south.

The biological resources that occur in the RMDP and SCP study areas are adapted to a Mediterranean climate with cool, wet winters and hot, dry summers. Rainfall occurs primarily between October and March, with the heaviest rainfall occurring in mountainous regions in the Angeles and Los Padres National Forests. According to the Piru 2 ESE weather station in Los Angeles County, the mean annual rainfall for the region is 17.4 inches of rain per year (WRCC

2008); however, some sections of the planning area remain in the rain shadow of the Santa Susana Mountains and receive considerably less rainfall than areas north of the Santa Clara River.

The combination of unique geological, tectonic, and climatic conditions that are present in the Santa Clarita Valley create and maintain contact zones between coastal–desert subspecies and species pairs in the Specific Plan area that are of significant taxonomic and evolutionary value. For example, the San Fernando Valley spineflower—a state-listed species—has been documented to occur only within the RMDP and SCP study areas and at Ahmanson Ranch, which is situated at the headwaters of Las Virgenes Creek in Ventura County. Likewise, previously undescribed species of sunflower and snail have been located within a spring seep community at the mouth of Middle Canyon on a terrace along the Santa Clara River.

On a more local scale, the Santa Clara River and its floodplain are considered a regionally important habitat linkage, and the area supports numerous state- and federally listed species, including the least Bell's vireo and the unarmored three-spine stickleback (*Gasterosteus aculeatus williamsoni*). Maintenance of habitat quality and wetland functions and services of the Santa Clara River and its floodplain are considered important for species utilizing this area. The RMDP and SCP study areas and the proposed open space designations and development areas are depicted on **Figure 4.5-3**, RMDP Study Area. The sensitive biological areas that occur within this study area include the Specific Plan's River Corridor SMA, High Country SMA, and Salt Creek area. Each of these specific resource areas is discussed in detail in **Subsection 4.5.3.3** (Existing Conditions by Project Planning Area).

The 333-acre VCC and 392-acre Entrada planning areas are not included in the RMDP. These planning areas have been included in the SCP (Dudek 2007E) to address the spineflower preserve areas within the applicant's land holdings in Los Angeles County (**Figure 4.5-4**, SCP Study Area). The SCP has been prepared to facilitate the conservation of San Fernando Valley spineflower on all of the applicant's land holdings that contain known spineflower populations.

Combined, the RMDP and SCP study areas constitute the Project area for purposes of the RMDP/SCP EIS/EIR. **Figure 4.5-5,** RMDP/SCP – Listed and California Fully Protected Wildlife Species Occurrences, **Figure 4.5-6,** RMDP/SCP – Special-Status Wildlife Species Occurrences, and **Figure 4.5-7**, RMDP/SCP – Special-Status Plant Species Occurrences, depict the Project area with point locations of special-status plants and animals (for animals, only those which are listed and/or fully protected are shown).

4.5.3.1 Summary of Literature Review and Biological Studies Conducted in Project Area

The purpose of Section 4.5, Biological Resources, is to document the existing biological resources that occur within the vicinity of the Project area (with special emphasis on special-status plants, wildlife species, and habitats, as well as habitat linkages ands wildlife corridors) and to analyze the effects of the proposed Project and identified alternatives on these biological resources. This documentation and analysis is based on a comprehensive literature review of existing biological information for the Project region and numerous biological studies that have been conducted in the Project area and immediate vicinity since 1988. Combined, these sources provide a substantial information base for the description of biological resources in the Project area and analysis of the impacts of the proposed Project and identified alternatives.

Information used to evaluate the potential occurrence of special-status plants and wildlife in the Project area was obtained from a number of sources, including a review of existing published and unpublished literature, personal communication with recognized experts, agency databases including CDFG 2007 California Natural Diversity Database (CNDDB) (CDFG 2007A), the California Native Plant Society (CNPS) online inventory (CNPS 2007), and the Federal Register.

Special-status biological resources present or potentially present in the Project area were identified through literature searches of the CNDDB (CDFG 2007A) and the CNPS online inventory (CNPS 2007). These searches included a review of all United States Geological Survey (USGS) 7.5-minute topographic maps that encompass portions of the RMDP/SCP boundary and all maps directly contacting these maps, as shown in Figure 4.5-8. USGS maps that encompass a portion of the RMDP/SCP boundary are the Val Verde, Newhall, Simi Valley East, and Oat Mountain quadrangles. USGS maps that border these four maps are the Cobblestone Mountain, Whitaker Peak, Green Valley, Piru, Mint Canyon, Simi Valley West, San Fernando, Thousand Oaks, Calabasas, Canoga Park, and Van Nuys quadrangles.

Additional background information regarding the potential occurrence of special-status species, as well as policies relating to special-status biological resources, was compiled from the following sources:

- A Flora of the Santa Barbara Region, California (Smith 1976);
- A Flora of the Santa Monica Mountains (Raven *et al.* 1986);
- Biology of the San Fernando Valley Spineflower, Ahmanson Ranch, Ventura County, California (Glenn Lukos Associates, Inc. and Sapphos Environmental, Inc. 2000);
- Biological Resource Assessment of the Proposed Santa Susana Mountains/Simi Hills Significant Ecological Area (PCR 2002);
- Biota Report, Newhall Ranch Specific Plan (RECON and Impact Sciences, Inc. 1996);

- CalFlora (CalFlora 2008);
- Checklist of Ventura County Rare Plants (Magney 2007);
- Herbarium specimens from Rancho Santa Ana Botanic Garden (RSA) and the University of California, Riverside (UCR) Herbarium;
- Inventory of Rare and Endangered Plants of California (CNPS 2001);
- List of "Threatened and Endangered Species and Species of Concern, Los Angeles County" (Los Angeles Almanac 2008);
- Report to the Fish and Game Commission on the Status of San Fernando Valley Spineflower (CDFG 2001);
- U.S. Fish and Wildlife Service (USFWS 1999C);
- Vascular Flora of the Liebre Mountains, Western Transverse Ranges, California (Boyd 1999);
- State and Federally Listed Endangered and Threatened Animals of California (CDFG 2008D);
- List of "Special Animals" (CDFG 2008C);
- List of "Special Vascular Plants, Bryophytes, and Lichens List" (CDFG 2007C).

General vegetation community information was obtained from Holland (1986), Sawyer and Keeler-Wolf (1995), and CDFG (2003; updated 2007). Plant species nomenclature follows Hickman (1993).

Information used in preparing this subsection was also compiled from more than 160 biological surveys completed in or adjacent to the Project area from 1988 to 2008 (**Table 4.5-6**). These biological surveys address a broad spectrum of biological resources, and they include 33 plant surveys (including four oak tree inventories), four vegetation mapping studies, two jurisdictional delineations of the wetlands and streambeds, 70 bird surveys, 25 amphibian and reptile surveys, 14 fish surveys, five butterfly surveys, one general insect study (associated with a spineflower pollinator study), two mammal surveys (including bats), and eight general biological resource surveys. Many of the studies listed in **Table 4.5-6** were focused surveys for special-status species; however, any special-status species that were not the focus of the survey were recorded if observed on site. These surveys represent a broad time span and were conducted for various projects in the Project vicinity. Many of the pre-2003 surveys were conducted in support of the Newhall Ranch Specific Plan EIR (County of Los Angeles 2003A), and most of the surveys since 2003 were conducted in support of this EIS/EIR, tentative tracts in the Specific Plan area (*e.g.*, Landmark Village), or the VCC and Entrada planning areas. The General Methods column in **Table 4.5-6** provides additional information for the specific areas and projects for which the surveys were conducted.

Plant Surveys	**FL*x***	May 5–27, 2001	Focused plant surveys were conducted at various locations throughout the Specific Plan area by FL*x* in 2001 and 2002. The 2004 surveys focused on the Santa Clara River corridor. 2004, 2005, and 2006 surveys focused on San Fernando Valley spineflower and slender mariposa lily at the Entrada site fireworks area, and 2006 surveys focused on the San Fernando Valley spineflower at the Potrero Irrigation Project site. In addition, vegetation types and plant species associations were noted and their dominant species recorded. The surveys were floristic in nature and were conducted according to accepted scientific protocol.	FL*x* 2002A, 2002B, 2002C,

			Natural Diversity Database" (CDFG 2003).	
Oak Tree Surveys	**Impact Sciences, Land Design Consultants, Richard Johnson & Associates, Inc., Dudek**	2003–2006	Biologists conducted on-site surveys and evaluations of the oak trees pursuant to the County of Los Angeles Oak Tree Ordinance (CLAOTO) from 2003 through 2006. The Specific Plan area was covered on foot through areas where oak trees occur within the proposed Project development area (including a 200-foot buffer). Only oak trees subject to CLAOTO were mapped. Oak trees subject to CLAOTO were also mapped within the VCC and Entrada planning areas. Tree stands (tree groupings) outside of these areas, in undisturbed or preserved areas, were delineated on aerial images and evaluated in the field *via* a sampling protocol and later statistically analyzed for population estimates.	Impact Sciences 2006B, 2006C, 2006D County of Los Angeles 1999; Land Design Consultants 2007; RJA 2007; Dudek 2007D
Jurisdictional Delineation of Waters and Streambeds	**URS**	2003	The focus of the delineation was the Santa Clara River and its tributaries within the Specific Plan area. Published Corps/CDFG delineation protocols were utilized in the field.	URS 2003 (found in **Appendix 4.6**)
	Glenn Lukos Associates, Inc	2006	The focus of the delineation was the Santa Clara River and its tributaries within the Entrada planning area. Published Corps/CDFG delineation protocols were utilized in the field.	Glenn Lukos Associates, Inc 2006 (found in **Appendix 4.6**)
Invertebrates (Fairy Shrimp)	**Dudek**	December 2007 to March 2008	Wet season vernal pools surveys were conducted in five previously identified depressions associated with western spadefoot surveys in the Specific Plan area, three in Potrero Canyon (Crawford 2007), one between Lion Canyon and Grapevine Mesa, and one east of Lion Canyon (Compliance Biology 2006C). Two of the five depressions retained water in 2007/2008 and were surveyed for shrimp presence.	Dudek 2008E

Taxonomic Group/ Technical Report	Consultant	Survey Dates/ Season	General Methods	Survey References
	Sandburg, Nancy	May 8–May 29, 2001	Focused surveys for arroyo toad and California red-legged frog east of the Project area, along the Santa Clara River from the River's End vacation park to the Transit Mix Concrete Company mine. These were not conducted using USFWS survey protocols.	Sandburg 2001
	BonTerra Consulting	2003	Surveys were conducted in 35 earth-bottom channels, including some channels in the Project area for unarmored threespine stickleback and Santa Ana sucker.	BonTerra Consulting 2003
	Compliance Biology	March 19–June 25, 2004	USFWS protocol surveys for arroyo toad were conducted in portions of the Santa Clara River and adjacent uplands near the confluence of Castaic Creek, downstream to the Los Angeles County border within the Specific Plan and VCC planning areas. Surveys for southwestern pond turtle and two-striped garter snake were conducted concurrently with the arroyo toad surveys.	Compliance Biology 2004D, 2004E, 2004F, 2006B, 2006C
		March 10 and March 23, 2004	Surveys for potential western spadefoot toad breeding habitat were conducted in the Mission Village area within the Specific Plan area during the known breeding season. Surveys consisted of habitat evaluations with a focus on the presence of temporary or seasonal rain pools. All flat lowland areas were surveyed for standing water, dirt roads were inspected for deep road ruts that may fill with rainwater, and temporary man-made retention basins were surveyed.	
		May 9 and May 23, 2004	Surveys for potential western spadefoot toad breeding habitat were conducted in the River Village project site and associated borrow sites (now referred to as Landmark Village). Surveys consisted of habitat evaluations with focus on the presence of temporary or seasonal rain pools. All flat lowland areas were surveyed for standing water, dirt roads were inspected

			for deep road ruts that may fill with rainwater, and temporary man-made retention basins were surveyed.	
		May 12, 2004	Surveys for potential western spadefoot toad breeding habitat were conducted in the West Creek area near Copperhill Drive and San Francisquito Creek. Surveys consisted of habitat evaluations with focus on the presence of temporary or seasonal rain pools. All flat lowland areas were surveyed for standing water, dirt roads were inspected for deep road ruts that may fill with rainwater, and temporary man-made retention basins were surveyed.	
		February–March 2006	Surveys for potential western spadefoot toad breeding habitat were conducted in the Castaic Mesa area upstream of the VCC planning area near Castaic Lagoon. Surveys consisted of habitat evaluations with focus on the presence of temporary or seasonal rain pools. All flat lowland areas were surveyed for standing water, dirt roads were inspected for deep road ruts that may fill with rainwater, and temporary man-made retention basins were surveyed.	
	ENTRIX	March 31, April 1, November 8, 10, 2004; February 1, 2005	Reconnaissance-level (non-USFWS protocol) field surveys were conducted, focusing on arroyo toad, California red-legged frog, southwestern pond turtle, and two-striped garter snake, and identifying habitat within portions of the Santa Clara River floodplain between Castaic Creek and Chiquito Canyon Creek within the Specific Plan area. Limited seining and dipnetting were also conducted.	ENTRIX 2006A, 2006B

Table 4.5-6
Biological Surveys Conducted in the Project Area and Immediate Vicinity – 1988 to Present

Taxonomic Group/ Technical Report	Consultant	Survey Dates/ Season	General Methods	Survey References
	Peter H. Bloom	April-June 2007	USFWS protocols surveys for arroyo toad were conducted along approximately 8 miles of the Santa Clara River adjacent to the proposed Landmark Village project area. The survey area encompassed all habitats within the River channel and up to 700 meters from the River in some areas.	Bloom 2007
	San Marino Environmental Associates	May–September 1994	Surveys focused on trapping two-striped garter snake and southwestern pond turtle as part of the ARCO natural resource damage assessment.	SMEA 1994A, 1994B, 1995A
		May–July 1995	Surveys focused on documenting presence/absence and distribution of unarmored threespine stickleback, arroyo chub, Santa Ana sucker, arroyo toad, California red-legged frog, and western spadefoot toad. Surveys did not use the USFWS survey protocol. Surveys included the Santa Clara River between Castaic Creek confluence and Bouquet Canyon Road bridge within the Specific Plan, VCC, and Entrada planning areas.	
	Haglund and Baskin	June 3 and July 14, 2000	Focused surveys for unarmored threespine stickleback, arroyo chub, and Santa Ana sucker were conducted using a seine in the Santa Clara River at the I-5 Bridge.	Haglund and Baskin 2000
	Aquatic Consulting Services, Inc.	May–September 2000	Reconnaissance surveys were conducted along the Santa Clara River within the Specific Plan, Entrada, and VCC planning areas in the following areas: Castaic Junction, Commerce Center Bridge, west of Commerce Center Bridge to the Ventura County line, and Ventura County line to Las Brisas Bridge. Surveys focused on aquatic habitats with emphasis on state and federally listed species. In addition, other species of fish, amphibians, and reptiles were also surveyed.	Aquatic Consulting Services 2002A, 2002B, 2002C, 2002D

Table 4.5-6

	Impact Sciences	March–June 2002	Focused surveys were conducted for unarmored threespine stickleback and other special-status fish species in the portion of the Santa Clara River from near its confluence with Castaic Creek, (east) upstream approximately 7.2 miles.	Impact Sciences 2003A, 2003B, 2003C, 2003D
		September 16 and 25, 2002	Focused surveys were conducted for unarmored threespine stickleback and other special-status fish species in the Natural River Management Plan area.	
		May 2003	Focused surveys were conducted for unarmored threespine stickleback and other special-status fish species in Castaic Mesa and Castaic Creek.	
	UCLA, Thomas Haglund, Ph.D.	1989	The report presents the results of a field and laboratory study on the occurrence of threespine stickleback in portions of the Santa Clara River on the Specific Plan site.	Haglund 1989
	ENTRIX	2004–2005	This report summarizes the focused assessment of fish presence, aquatic habitat quality and quantity, and potential project effects on threatened or endangered fish species inhabiting the Newhall Ranch reach of the Santa Clara River as well as tributary drainages to the Santa Clara River. This assessment covered the mainstem Santa Clara River from Salt Creek Canyon upstream to the Middle Canyon confluence and included the Salt Creek and Potrero Creek tributaries. Specifically, this report focused on potential impacts to the state and federally listed unarmored threespine stickleback and other fish species, including arroyo chub and Santa Ana sucker.	ENTRIX 2009
Terrestrial Reptiles	**Impact Sciences**	September–October 2004; August 2006	Pitfall trap lines were placed throughout the Specific Plan area in representative habitat types in September and October 2004 and August 2006. All pitfall traps were active (open) for five consecutive days and nights, and they were checked once per day (in the morning).	Impact Sciences 2006A

			reports focused on least Bell's vireo monitoring, as well as documenting other avian species.	
			These surveys focused on impacts to the avian community and impacts to listed species, including monitoring of known least Bell's vireo population; other surveys were conducted for western yellow-billed cuckoo and southwestern willow flycatcher. Although this survey was a follow-up to the 1996 survey, the overall surveyed area was increased in order to understand the distribution of endangered species and subsequent restoration planning.	
	PCR	1998	USFWS protocol surveys for coastal California gnatcatcher surveys were conducted in upland habitats on the east and west sides of Castaic Creek (upstream of the VCC planning area).	PCR 1998
	Daniel Guthrie	2000 and 2004	USFWS protocol surveys for coastal California gnatcatcher as well as surveys for other upland birds were conducted in upland portions of the Specific Plan area.	Guthrie 2000A, 2000B, 2000D, 2000F, 2000H, 2004A, 2004B, 2004C, 2004D, 2004E, 2004G, 2004I
	Haglund and Baskin	April–July 2000	Surveys using USFWS survey protocol for least Bell's vireo and southwestern willow flycatcher were conducted along Santa Clara River at the I-5 Bridge.	Haglund and Baskin 2000
	Impact Sciences	May–June 2000	Six USFWS protocol surveys for coastal California gnatcatcher were conducted in a 156-acre portion of the Specific Plan site where California sagebrush scrub occurs.	Impact Sciences 2000
	Compliance Biology	2003	Six USFWS protocol surveys for coastal California gnatcatcher were conducted in a 2-acre area in Riverpark where California sagebrush scrub occurs,	Compliance Biology 2003A, 2003B

Table 4.5-6

			Ventura County to I-5 and on all lands within Newhall Ranch, including both sides of SR-126, lower Salt Creek, and Potrero Canyon. Upon detection, foraging and nesting individuals were observed for up to several hours if possible.	
		April –June 2007	Six USFWS protocol surveys for coastal California gnatcatcher were conducted in Landmark Village.	Priest 2007B; Lemons 2008
		July 2007–January 2008	Nine USFWS protocol surveys for coastal California gnatcatcher were conducted in Mission Village.	
	Impact Sciences	March–September 2004 July 2006	Field surveys were conducted to sample mammal species in dominant vegetation communities throughout the Specific Plan site during 2004. Survey locations were in representative dominant vegetation communities within the Specific Plan area. Five different survey methods were utilized: small mammal trapping, scent/track stations, spotlighting, cameras, and ANABAT bat detector recording.	Impact Sciences 2005; Johnson 2006
Mammals	**San Marino Environmental Associates**	August 7–10, 2006 (bats)	Additional bat surveys were conducted within the Project area to determine occurrence of, and habitat use by, bat species. Standard visual, acoustic, and mist-netting sampling methods were used to survey bats. Sampling was conducted near roosting sites and in potential foraging areas; acoustic devices and mist nests were deployed where bats were expected to fly low or in a somewhat defined air space; and visual surveys were conducted during the day and night at potential roost sites, and at dusk while observing bats in flight.	SMEA 1995B
		May 1993–September 1994	This report provides results of a number of surveys conducted to document the presence of rare plants and animals within approximately 80 square miles of the Santa Clarita water district service area, which includes a portion of Los Angeles County Sensitive Ecological Area (SEA) 23 (also known as the River Corridor

			SMA). This document contains lists of anticipated species and indicates the species actually found during the surveys.	
General Biological Surveys	**RECON and Impact Sciences**	1995	This report provides general biological resources information derived from surveys conducted on the Specific Plan area and its vicinity during the spring and summer months. These surveys included habitat, vegetation identification, percentages and mapping; avian surveys; river surveys that included documentation of fish, reptiles, and amphibian species; plant species documentation; butterfly surveys; and other wildlife surveys that included small mammal trapping methods.	RECON and Impact Sciences 1996
	Impact Sciences	Spring 1999	This habitat assessment report was created based on the results of vegetation surveys along the Santa Clara River on the portion of the Specific Plan site. Data were collected based on structure and composition of habitat and were used to assess the likelihood or potential for occurrence of special-status species that may occur on this portion of the river. In addition, during this study the potential for mitigation through habitat creation or enhancement of riparian habitat was also assessed.	RECON 1999B
		1996	This report provides results from a number of surveys conducted at four sites, two of which were located within the Specific Plan area. The focus of these surveys was to study the relation between upland habitat quality and use by riparian bird species and small mammals along the edge of the Santa Clara River in order to make habitat buffer recommendations.	Impact Sciences 1997
	Dudek	November and	Biologists conducted general wildlife surveys throughout the High Country SMA portion of the Specific Plan and Salt Creek areas in 2005 and within	Dudek and Associates 2006B, 2006C,

			the VCC and Entrada planning areas in 2006.	2006D, 2006E
	Compliance Biology	December 2005 September 2006 2006	This report was conducted upstream of the VCC planning area in Castaic Mesa. The purpose was to assess the existing on-site biological conditions and the suitability of on-site habitats to support sensitive biological resources.	Compliance Biology 2006D

Information compiled from the literature review, field study observations listed in **Table 4.5-6**, and professional judgment were used to generate a list of special-status plant and wildlife species that were observed or have the potential to occur within the Project area, including Project construction zones and designated open space areas. For the purposes of the analysis presented in this subsection, special-status species are defined as plants or wildlife that:

- Have been designated as either rare, threatened, or endangered by CDFG or the USFWS and are protected under either the California Endangered Species Act (CESA) (Fish & G. Code, § 2050 et seq.) or federal Endangered Species Act (ESA) (16 U.S.C. 1531 et seq.);
- Are candidate species being considered or proposed for listing under these same acts;
- Are fully protected by the California Fish and Game Code sections 3511, 4700, 5050, or 5515; or
- Are of expressed concern to resource/regulatory agencies or local jurisdictions.

Table 4.5-7 includes those special-status plant species observed within the Project area, and **Table 4.5-8** includes those special-status plant species not likely to occur on site. **Table 4.5-9** includes those special-status wildlife species observed within the Project area, **Table 4.5-10** includes those special-status wildlife species potentially occurring on site, and **Table 4.5-11** includes those special-status wildlife species not expected to occur or rarely occurring on site.

Table 4.5-7
Special-Status Plant Species Observed within the Project Area

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage (CNDDB) Element Ranking	Primary Habitat Associations/Life Form/Blooming Period	Occurrence on Site
Artemisia tridentata ssp. *parishii*	Parish's sagebrush	None/ None	None	N/A	big sagebrush scrub on the margins of drainage channels/ perennial shrub/ November–August	Parish's sagebrush was observed in the Salt Creek watershed and the Specific Plan area in 2006 (Dudek and Associates 2006B, 2006C). Plants were found primarily intermixed with big sagebrush. This species has not been observed within the VCC planning area (Dudek and Associates 2002C, 2004B, 2004G, 2006H, 2006K; Dudek 2007H). This species was not observed in the Entrada planning area (Dudek and Associates 2002B, 2004E, 2004H, 2006E, 2006G, 2006J; Dudek 2007G), but there is suitable big sagebrush scrub habitat on site. Co-occurs with *Artemisia tridentata* ssp. *tridentata*. Considered special-status by the County of Los Angeles.
Calochortus clavatus var. *gracilis*	slender mariposa lily	None/ None	1B	S1.1	chaparral and coastal sage scrub/perennial herb (geophyte)/ March–May	Slender mariposa lily was observed within the VCC area in 2004 and 2005 (Dudek and Associates 2004G, 2006H). Plants were found primarily on northwest- and southwest-facing ridges and slopes located just east of Hasley Canyon. Within the Entrada area, slender mariposa lily was recorded annually from 2003 to 2005 (Dudek and Associates 2004E, 2004H, 2006G) throughout the area, occurring primarily on south-facing slopes (70% of all individuals identified) and, to a lesser extent, on southeast-facing slopes (20% of all individuals identified). Slender mariposa lily was documented annually within the Specific Plan area from 2003 to 2006 (Dudek and Associates 2004C, 2004F, 2006F, 2006I), where it was found primarily on east-, northeast-, and southwest-facing ridges and slopes in the following areas: the San Martinez Grande

Table 4.5-7
Special-Status Plant Species Observed within the Project Area

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage (CNDDB) Element Ranking	Primary Habitat Associations/Life Form/Blooming Period	Occurrence on Site
						Canyon, Chiquito Canyon, Off-Haul Canyon, Potrero Canyon, Long Canyon, Middle Canyon, Grapevine Mesa, and Airport Mesa areas as well as the lower Castaic Creek area. Slender mariposa lily was observed primarily in the northern portion and at the southwestern end of the Salt Creek area as well as along the southern end of the High Country SMA. Within the High Country SMA and Salt Creek area, slender mariposa lily was found primarily on east-, northeast-, and southwest-facing ridges and slopes. Observations were made within the High Country SMA and Salt Creek area from 2003 through 2006 (Dudek and Associates 2004F, 2004I, 2006B, 2006F). Slender mariposa lily was observed in the Entrada site fireworks area in 2004, 2005, and 2006 (FL*x* 2004B, 2005, 2006A). The estimated number of individuals in the study area ranged from 693 in 2006 to 65,297 in 2004. CNDDB records also exist for mouth of Pico Canyon.
Calochortus plummerae	Plummer's mariposa lily	None/ None	1B	S3.2	chaparral, coastal sage scrub, cismontane woodland, grasslands on rocky granitic substrate/perennial herb (geophyte)/ May–July	Three polygons and two point locations of Plummer's mariposa lily were mapped within the High Country SMA in 2006, with an estimated number of approximately 78 individuals (Dudek and Associates 2006B). Observed on steep southwest-facing slopes in the High Country SMA. No CNDDB records exist for the Project area quads or adjacent quads; however, records exist for the Santa Susana Mountains and Simi Hills.

Table 4.5-7
Special-Status Plant Species Observed within the Project Area

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage (CNDDB) Element Ranking	Primary Habitat Associations/Life Form/Blooming Period	Occurrence on Site
Calochortus weedii var. *vestus*	late-flowered mariposa lily	None/ None	1B	S2.2	chaparral, cismontane and riparian woodland/ perennial herb (geophyte)/ June–August	Three polygons of late-flowered mariposa lily were mapped within the High Country SMA in 2003, with an estimated number of approximately 250 individuals (Dudek and Associates 2004I). Observed in chaparral and walnut woodlands at the head of the Salt Creek drainage on the crest of the Santa Susana Mountains. No CNDDB records exist for the Project area quads or adjacent quads.
Calystegia peirsonii	Peirson's morning-glory	None/ None	4	S3.2	chaparral, coastal sage scrub, cismontane woodland, grassland/ perennial herb/ May–June	Peirson's morning-glory was observed within the Entrada planning area in 2002, 2003, 2004, and 2005 (Dudek and Associates 2002B, 2004C, 2004E, 2004H, 2006G). This species was observed within the VCC planning area in 2003, 2004, 2005, and 2006 (Dudek and Associates 2004B, 2004G, 2006H, 2006K). Within the Specific Plan area, Peirson's morning-glory was recorded annually from 2002 to 2006 (Dudek 2002A, 2004C, 2004F, 2006F, 2006I; FL*x* 2002A). Observations of this species were made within the High Country SMA and Salt Creek area in 2003 and 2006 (Dudek and Associates 2004I, 2006B). This species is widespread on site and was observed on ridges and slopes, weakly climbing over chaparral, coastal scrub, and grasslands throughout the Specific Plan, VCC, and Entrada planning areas.
Cercocarpus betuloides var. *blancheae*	island mountain-mahogany	None/ None	4	S3.3	chaparral, closed-cone coniferous forest/evergreen shrub/February–May	Island mountain-mahogany was observed within the Entrada planning area in 2003, 2004, and 2005 (Dudek and Associates 2002B, 2004E, 2004H). Within the Specific Plan area, island mountain-mahogany was recorded annually from 2002 to

Table 4.5-7
Special-Status Plant Species Observed within the Project Area

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage (CNDDB) Element Ranking	Primary Habitat Associations/Life Form/Blooming Period	Occurrence on Site
						2006 (Dudek and Associates 2002A, 2004C, 2004F, 2006F, 2006I). Observations of this species were made within the Salt Creek area in 2003 (Dudek and Associates 2004I). In all three areas, plants were found primarily in chaparral at the base of north-facing slopes. Occurrences of this species were not mapped due to its low sensitivity status (CNPS List 4.3). This species has not been observed within the VCC planning area (Dudek and Associates 2002C, 2004B, 2004G, 2006H, 2006K; Dudek 2007H).
Chorizanthe parryi var. *fernandina*	San Fernando Valley spineflower	FC/SE	1B	S1.1	coastal sage scrub, sandy soils/annual herb/April–June	In each year from 2002 through 2007, SFVS has been observed in four general areas within the Specific Plan area: Airport Mesa, Grapevine Mesa, Potrero Canyon, and San Martinez Grande Canyon (Dudek and Associates 2002A, 2004C, 2004F, 2006F, 2006I; Dudek 2007F). This species has also been observed from 2002 through 2007 in several areas at the Entrada planning area (Dudek and Associates 2002B, 2004E, 2004H, 2006G, 2006J; Dudek 2007G; FL*x* 2004B, 2005, 2006A), and on the western side of the VCC planning area, just east of Hasley Canyon (Dudek and Associates 2002C, 2004B, 2004G, 2006H, 2006K; Dudek 2007H). An estimated 760 to 7.4 million individuals were observed between the 2002-2007 growing seasons.
Gnaphalium sp. *nova*[a]	undescribed everlasting	None/ None	None	N/A	secondary alluvial benches/perennial herb/late summer	Within the VCC planning area, individuals were observed in 2004, 2005, and 2007 in the portion of Castaic Creek west of I-5 Bridge and east of Commerce Center Drive on secondary alluvial benches (Dudek and Associates 2004G, 2006H;

Table 4.5-7
Special-Status Plant Species Observed within the Project Area

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage (CNDDB) Element Ranking	Primary Habitat Associations/Life Form/Blooming Period	Occurrence on Site
						Causey 2007). Two main populations and a number of smaller populations of this undescribed species were documented within the Specific Plan area during the 2003, 2004, 2005, and 2007 field seasons (Dudek and Associates 2004C, 2004F, 2006F; Causey 2007; FL*x* 2004B). These occurrences are primarily on secondary alluvial benches in the Santa Clara River near the mouth of Long Canyon and where Castaic Creek and the Santa Clara River converge, south of SR-126. This species was not observed at Entrada.
Helianthus sp. nova	undescribed sunflower	None/ None	None	N/A	seeps/perennial herb/ mid-summer	A population of 10 undescribed sunflowers was found in 2002 at Middle Canyon Spring on the south side of the Santa Clara River between Middle Canyon and San Jose Flats within the Specific Plan development area (Dudek and Associates 2002A).
Juglans californica	southern California black walnut	None/ None	4	S3.2	chaparral, cismontane woodland, coastal sage scrub, alluvial scrub/deciduous tree/March–May	Southern California black walnut was observed within the Entrada planning area in 2004 and 2005 (Dudek and Associates 2004H, 2006G). Within the Specific Plan area, southern California black walnut was recorded annually in 2002, 2003, and 2004 (Dudek and Associates 2002A, 2004C, 2004F; FL*x* 2004A). Observations of this species were made within the High Country SMA and Salt Creek area in 2003 and 2006 (Dudek and Associates 2004I, 2006B) and within the VCC planning area in 2004 and 2005 (Dudek and Associates 2004G and 2006H). Within the Specific Plan area, southern California black walnut dominates California walnut woodland and is found as an occasional component of chaparral,

Table 4.5-7
Special-Status Plant Species Observed within the Project Area

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage (CNDDB) Element Ranking	Primary Habitat Associations/Life Form/Blooming Period	Occurrence on Site
						coastal scrub, and oak woodland (Dudek and Associates 2002A, 2004C, 2004F, 2004I, 2006B). Within the VCC planning area, an individual southern California black walnut occurs within southern cottonwood–willow riparian forest along the south side of Castaic Creek (Dudek and Associates 2004G and 2006H). Within the Entrada planning area, this species is found in chaparral, coastal scrub, and alluvial scrub (Dudek and Associates 2004H, 2006G).
Juncus acutus ssp. *leopoldii*	southwestern spiny rush	None/ None	4	S3.2	coastal dunes, meadows, seeps, marshes, and swamps/perennial herb/May–June	Within the Specific Plan area, southwestern spiny rush individuals were observed annually from 2001 through 2006 (Dudek and Associates 2004C, 2004F, 2006F, 2006I; FL*x* 2002A, 2002B, 2004A). Southwestern spiny rush is known to occur in secondary channels of the floodplain of the Santa Clara River.
Navarretia ojaiensis	Ojai navarretia	None/ None	1B	N/A	grasslands and openings in California sagebrush scrub/annual herb/May–July	The Ojai navarretia species was located in surveys of the Salt Creek watershed (the majority of the High Country SMA and the Salt Creek area) conducted from April to July of 2003 (Dudek and Associates 2004I). Two main populations totaling approximately 60,000 individuals were found growing on clay lenses with a gentle to moderate north-facing slope.
Nemophila parviflora var. *quercifolia*	oak-leaved nemophila	None/ None	4	S3.3	cismontane woodland, lower montane coniferous forest/annual herb/May–June	In 2003 and 2004, one occurrence of oak-leaved nemophila was found along a northeast-facing slope in an oak woodland east of Grapevine Mesa within the Specific Plan area (Dudek and Associates 2004C, 2004F). This species has not been observed within the VCC planning area

Table 4.5-7
Special-Status Plant Species Observed within the Project Area

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage (CNDDB) Element Ranking	Primary Habitat Associations/Life Form/Blooming Period	Occurrence on Site
						(Dudek and Associates 2002C, 2004B, 2004G, 2006H, 2006K; Dudek 2007H) or within the Entrada planning area (Dudek and Associates 2002B, 2004E, 2004H, 2006G, 2006J; Dudek 2007G).
Prunus ilicifolia ssp. *ilicifolia*	mainland (holly-leaf) cherry	None/ None	None	N/A	undifferentiated chaparral, big sagebrush scrub, and river wash/ perennial/March–May	Mainland cherry was observed within the Entrada planning area as an occasional component of undifferentiated chaparral, big sagebrush scrub, and river wash in 2003, 2004, 2005, and 2006 (Dudek and Associates 2004E, 2004H, 2006G, 2006J). Within the Specific Plan area, mainland cherry was recorded annually from 2001 through 2006 within undifferentiated chaparral, big sagebrush scrub, and river wash (Dudek and Associates 2002A, 2004C, 2004F, 2006F, 2006I; FL*x* 2002A). Observations of this species were made within VCC in 2003, 2004, 2005, and 2006 within undifferentiated chaparral, big sagebrush scrub, and river wash (Dudek and Associates 2004B, 2004G, 2006H, 2006K).
Quercus spp., including *Quercus agrifolia*, *Quercus berberidifolia*, *Quercus lobata*, *Quercus x. alvordiana*, and *Quercus*	oak trees including coast live oak, scrub oak, valley oak, Alvord oak, and interior live oak	None/ None	None	N/A	southern coast live oak riparian forest, coast live oak woodland, mixed oak woodland, valley oak/grass, and valley oak woodland /perennial shrub/tree/Spring	In total, 3,766 trees were inventoried and assessed within the development portion of the Specific Plan, VCC, and Entrada planning areas. The majority of these trees are native coast live oak trees, which are primarily associated with drainage bottoms, north-facing slopes, and along secondary drainages on non-north-facing slopes. Present at lower, but substantial, levels are valley oak trees are strongly associated with open grassland areas on gentler slopes and valley bottoms. Preserved trees outside the GPS inventory areas were estimated with sampling and regression analysis

Table 4.5-7

wislizeni						and total 156 trees in the River Corridor SMA (Impact Sciences 2006B, 2006C, 2006D; County of Los Angeles 1999; Land Design Consultants 2007; Richard Johnson & Associates 2007), 13,732 trees in the High Country SMA and 5,640 trees in the Salt Creek area (Dudek 2007K).

[a] Some experts identify this species as white-headed cudweed (*Gnaphalium leucocephalum*), which is a CNPS List 2.2 species (S3.2). See the analysis of the undescribed everlasting in **Subsection 4.5.5.3** for more detail.

Legend

FE:	Federally listed as endangered	CNPS List 1A:	Plants presumed extinct in California
FT:	Federally listed as threatened	CNPS List 1B:	Plants rare, threatened, or endangered in California and elsewhere
FC: Federal candidate for listing	**CNPS List 2:**	**Plants rare, threatened, or endangered in California but more common elsewhere**	
SC: State candidate for listing	**CNPS List 3:**	**Plants about which we need more information – a review list**	

California Heritage (CNDDB) Element Ranking

S1: Less than 6 Eos OR less than 1,000 individuals OR less than 2,000 acres
- S1.1 = very threatened
- S1.2 = threatened
- S1.3 = no current threats known.

S2: 6 to 20 Eos OR 1,000 to 3,000 individuals OR 2,000 to 10,000 acres
- S2.1 = very threatened
- S2.2 = threatened
- S2.3 = no current threats known.

S3: 21 to 80 Eos or 3,000 to 10,000 individuals OR 10,000 to 50,000 acres
- S3.1 = very threatened
- S3.2 = threatened
- S3.3 = no current threats known.

S4: Apparently secure within California. This rank is clearly lower than S3, but factors exist to cause some concern; *i.e.*, there is some threat, or somewhat narrow habitat. NO THREAT RANK.

S5: Demonstrably secure to ineradicable in California. NO THREAT RANK.

Notes:

1. Other considerations used when ranking a species or natural community include the pattern of distribution of the element on the landscape, fragmentation of the population/stands, and historical extent as compared to its modern range. It is important to take a **bird's eye or aerial view** when ranking sensitive elements rather than simply counting element occurrences.
2. Uncertainty about the rank of an element is expressed in two major ways: First, by expressing the ranks as a **range** of values: *e.g.*, S2S3 means the rank is somewhere between S2 and S3. Second, by adding a "?" to the rank: *e.g.*, S2? This represents more certainty than S2S3, but less certainty than S2.

Table 4.5-8
Special-Status Plant Species Not Expected to Occur within the Project Area

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage (CNDDB) Element Ranking	Primary Habitat Associations/Life Form/Blooming Period	Presence or Likelihood of Occurrence On Site
Arenaria paludicola	marsh sandwort	FE/SE	1B	S1.1	dense freshwater marsh/perennial herb/May–August	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads; nearest occurrence is in the Santa Ana River. Limited suitable habitat on site; very low likelihood of occurrence within the study area.
Astragalus brauntonii	Braunton's milk-vetch	FE/None	1B	S2.1	chaparral, coastal sage scrub, grasslands; often on carbonate substrates/perennial herb/March–July	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads; nearest occurrence is in the Simi Hills. Suitable habitat exists on site. Moderate likelihood of occurrence within study area.
Atriplex coulteri	Coulter's saltbush	None/ None	1B	S2.2	coastal sage scrub and grasslands on alkaline or clay substrate/perennial herb/March–October	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads; however, suitable habitat present on site. Moderate likelihood of occurrence within study area.
Atriplex serenana var. *davidsonii*	Davidson's saltscale	None/ None	1B	S2?	coastal bluff scrub and coastal sage scrub on alkaline substrate/annual herb/May–October	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads. *Atriplex serenana var. serenana* observed on site. Low likelihood of occurrence within the study area.
Baccharis malibuensis	Malibu baccharis	None/ None	1B	S1.1	chaparral, coastal sage scrub, cismontane woodland/deciduous shrub/August	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads; closest known populations in the western Santa Monica Mountains near Malibu. Not expected to occur within the study area.

Table 4.5-8
Special-Status Plant Species Not Expected to Occur within the Project Area

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage (CNDDB) Element Ranking	Primary Habitat Associations/Life Form/Blooming Period	Presence or Likelihood of Occurrence On Site
Berberis nevinii	Nevin's barberry	FE/SE	1B	S2.2	chaparral, coastal sage scrub, riparian scrub, cismontane woodland on sandy or gravelly substrate/evergreen shrub/March–April	Not observed during the 2002 through 2007 field seasons. CNDDB records exist for San Francisquito Canyon at confluence with Santa Clara River; suitable habitat present on site. Moderate likelihood of occurrence within study area.
Brodiaea filifolia	thread-leaved brodiaea	FT/SE	1B	S2.1	clay substrate openings in chaparral, sage scrub, and grasslands/perennial herb (geophyte)/ March–June	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads; nearest occurrence is in San Dimas. Suitable habitat present on site. Low likelihood of occurrence within study area.
Calochortus clavatus var. *clavatus*	club-haired mariposa lily	None/ None	4	S3.3	chaparral and coastal sage scrub/perennial herb (geophyte)/ March–May	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for Newhall and Val Verde quads. Very low likelihood of occurrence in study area.
Calystegia sepium ssp. *binghamiae*	Santa Barbara morning-glory	None/ None	1A	SH	marshes and swamps/perennial herb/April–May	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads; however, limited suitable habitat present on site. Low likelihood of occurrence within study area.
Centromadia [=*Hemizonia*] *parryi* ssp. *australis*	southern tarplant	None/ None	1B	S2.1	mesic edges of marshes in grasslands/annual herb/May–November	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads; however, suitable habitat present on site. likelihood of occurrence within study area.Low
Deinandra [=*Hemizonia*] *minthornii*	Santa Susana tarplant	None/ SR	1B	S2.2	chaparral and coastal sage scrub on rocky substrate/deciduous shrub/July–November	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads; however, records exist for the Simi Hills and Oat Mountain. Suitable habitat exists on site. Moderate likelihood of occurrence

Table 4.5-8

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage (CNDDB) Element Ranking	Primary Habitat Associations/Life Form/Blooming Period	Presence or Likelihood of Occurrence On Site
						within study area.
Delphinium parryi ssp. *blochmaniae*	dune larkspur	None/ None	1B	S2.2	maritime chaparral, coastal dunes/perennial herb/April–may	Not observed during the 2002 through 2007 field seasons. No likelihood of occurrence.
Dodecahema leptoceras	slender-horned spineflower	FE/SE	1B	S1.1	Alluvial scrub on sandy substrate/annual herb/April–June	Not observed during the 2002 through 2007 field seasons. Historic CNDDB records exist for the Newhall or Val Verde quads in alluvial habitat similar to those present on site. Moderate likelihood of occurrence within Santa Clara River in study area.
Dudleya blochmaniae ssp. *blochmaniae*	Blochman's dudleya	None/ None	1B	S2.1	clay openings in chaparral and coastal sage scrub, grasslands/perennial herb/April–June	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads. Suitable habitat present on site. Low likelihood of occurrence within study area.
Dudleya cymosa ssp. *marcescens*	marcescent dudleya	FT/CR	1B	S2.2	chaparral, often on volcanic substrate/perennial herb (geophyte)/ April–June	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for Newhall and Val Verde quads. Low likelihood of occurrence within study area.
Dudleya cymosa ssp. *ovatifolia*	Santa Monica Mountains dudleya	FT/None	1B	S2.2	chaparral and coastal sage scrub, often on volcanic substrate/perennial herb (geophyte)/March–June	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for Newhall and Val Verde quads. Low likelihood of occurrence within study area.
Dudleya multicaulis	many-stemmed dudleya	None/ None	1B	S2.1	coastal bluff scrub, coastal sage scrub, valley and foothill grassland, rocky, often clay substrate/perennial herb/April–June	Not observed during the 2002 through 2005 field seasons. No CNDDB records exist for the Project area quads or adjacent quads; closest known occurrences are in Calabasas and San Dimas. Suitable habitat exists on site. Low to moderate likelihood of occurrence within study area.

Table 4.5-8
Special-Status Plant Species Not Expected to Occur within the Project Area

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage (CNDDB) Element Ranking	Primary Habitat Associations/Life Form/Blooming Period	Presence or Likelihood of Occurrence On Site
Dudleya parva	Conejo dudleya	FT/None	1B	S2.1	coastal sage scrub and grassland on rocky, gravelly clays/perennial herb/May–June	Not observed during the 2002 through 2005 field seasons. No CNDDB records exist for the Project area quads or adjacent quads. Suitable habitat exists on site. Low likelihood of occurrence within study area.
Erodium macrophyllum	round-leaved filaree	None/ None	2	SN/A	cismontane woodland and grasslands on clay substrate/annual herb/March–May	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads; however, records exist for Simi Valley, and this plant was observed in the hills east of Castaic Lake in 2003. Suitable habitat present on site; moderate likelihood of occurrence in study area.
Horkelia cuneata var. *puberula*	mesa horkelia	None/ None	1B	S2.1	chaparral, cismontane woodland, coastal sage scrub on sandy or gravelly substrate/ perennial herb/February–December	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads. Suitable habitat present on site. Low likelihood of occurrence within study area.
Malacothamnus davidsonii	Davidson's bush mallow	None/ None	1B	S1.1	chaparral, coastal sage scrub, riparian woodland/ deciduous scrub/June–January	Not observed during the 2002 through 2007 field seasons. Nearest occurrences are in San Fernando and Sunland. Suitable habitat present on site. Moderate likelihood of occurrence within study area.
Nama stenocarpum	mud nama	None/ None	2	S1S2	edges of lakes, rivers, ponds, vernal pools/annual/January–July	Not observed during the 2002 through 2007 field seasons. Moderate likelihood of occurrence on banks of Santa Clara River and other mesic areas on site. No CNDDB records exist for the Project area quads or adjacent quads. Limited suitable habitat present on site. Low likelihood of occurrence within study area.

Table 4.5-8
Special-Status Plant Species Not Expected to Occur within the Project Area

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage (CNDDB) Element Ranking	Primary Habitat Associations/Life Form/Blooming Period	Presence or Likelihood of Occurrence On Site
Nolina cismontane	chaparral nolina	None/ None	1B	S1.1	chaparral, coastal sage scrub on sandstone or gabbro substrate/perennial shrub April–July	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads. Suitable habitat present on site. Low likelihood of occurrence within study area.
Opuntia basilaris var. *brachyclada*	short-joint beavertail	None/ None	1B	S1.2	chaparral, Joshua tree woodland, Mojavean desert scrub/succulent shrub/ April–June	Not observed during the 2002 through 2007 field seasons. This plant was identified as on site by Dudek and Associates in 2002; however, recent investigations indicate that the *Opuntia basilaris* plants on Newhall Ranch are not *O. basilaris* var. *brachyclada*, but are *O. basilaris* var. *ramosa*.
Pentachaeta lyonii	Lyon's pentachaeta	FE/SE	1B	S1.1	openings in chaparral and coastal sage scrub, grasslands/annual herb/March–August	Not observed during the 2002 through 2007 field seasons. No CNDDB records exist for the Project area quads or adjacent quads; nearest occurrences are in the Simi Valley. Suitable habitat present on site. Moderate likelihood of occurrence within study area.
Rorippa gambelii	Gambel's watercress	FE/ST	1B	N/A	Marsh and swamps (freshwater and brackish)/perennial herb/April–September	Not observed during the 2002 through 2005 field seasons. No CNDDB records exist for the Project area quads or adjacent quads. Limited suitable habitat present on site. Very low likelihood of occurrence within study area.
Senecio aphanactis	rayless ragwort	None/ None	2	S1.2	chaparral, coastal sage scrub, cismontane woodland on alkaline substrate/annual herb/January–April	Not observed during the 2002 through 2005 field seasons. Historic CNDDB record for Saugus, south of Santa Clara River. Suitable habitat on site. Moderate likelihood of occurrence within study area.
Sidalcea neomexicana	salt spring checkerbloom	None/ None	2	S2S3	chaparral, coastal sage scrub, and playas on alkaline	Not observed during the 2002 through 2005 field seasons. No CNDDB records exist for the Project area quads or adjacent quads; suitable habitat

Second, by adding a "?" to the rank: *e.g.*, S2? This represents more certainty than S2S3, but less certainty than S2.						

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
			Insects (Butterflies)	
monarch butterfly (wintering sites) *Danaus plexippus*	—	***	Roosts located in wind-protected tree groves (eucalyptus, Monterey pine, Monterey cypress), with nectar and water sources nearby.	Individual monarchs have been observed within the Newhall Ranch Specific Plan area (NRSP), including the High Country (Compliance Biology 2004A, 2005; Dudek and Associates 2006B) and Entrada (Compliance Biology 2004C); due to sites distance from coast, it is unlikely that the Project site would be used by large numbers of overwintering adults (Compliance Biology 2004A). Not expected to occur in Salt Creek area or VCC.
San Emigdio blue butterfly *Plebulina emigdionis*	—	***	Often near streambeds, washes, or alkaline areas. Associated with four-wing saltbush (*Atriplex canescens*) and quail brush (*Atriplex lentiformis*).	A colony was observed in Potrero Canyon in NRSP in association with *Atriplex lentiformis* plants (Compliance Biology 2004A and 2005). Suitable habitat occurs within Salt Creek, VCC, and Entrada.
			Mollusks	
undescribed species of Snail	—	—	Occupies groundwater-dependent spring, occurring on muddy and gravelly substrate and in water of depths up to several centimeters.	This species was observed on the project site in 2006 at the Middle Canyon Spring complex (Dudek 2007C).
			Fish	
Santa Ana sucker *Catostomus santaanae*	FT	CSC	Occupies small- to medium-sized perennial streams with water ranging in depth from a few centimeters to a meter or more.	This species is known to occur in the Santa Clara River and has been sparsely observed in the portion of the river within NRSP (CDFG 2007A; Impact Sciences 2003A), and within or adjacent to Entrada (SMEA 1995; Haglund and Baskin 2000; Impact Sciences 2003B). Population in the Santa Clara River system is not listed as threatened because it is introduced to the area. Not expected to occur in Salt Creek or VCC.
unarmored threespine stickleback *Gasterosteus aculeatus williamsoni*	FE	CE, CFP	Slow-moving and backwater areas.	This species is known to occur in the Santa Clara River and has been observed evenly distributed in the portion of the river within NRSP (Aquatic Consulting Services 2002B, 2002C; Impact Sciences 2003A, 2003B; ENTRIX 2005) and within Entrada (Aquatic Consulting Services 2002D;

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
				SMEA 1995; Haglund and Baskin 2000; Impact Sciences 2003B). It was also observed in Castaic Creek (Haglund 1989).
arroyo chub *Gila orcutti*	—	CSC	Slow-moving or backwater sections of warm to cool streams with mud or sand substrates.	This species is known to occur in the Santa Clara River and has been observed abundantly in the portion of the river within NRSP (Aquatic Consulting Services 2002B, 2002C; Impact Sciences 2003A, 2003B; ENTRIX 2005), within Entrada (Aquatic Consulting Services 2002D; SMEA 1995; Haglund and Baskin 2000), and within VCC (Haglund 1989). Not expected to occur in Salt Creek.
			Amphibians	
arroyo toad *Bufo californicus*	FE	CSC	Restricted to rivers with shallow, gravely pools adjacent to sandy terraces that have a nearly complete closure of cottonwoods, oaks or willows, and almost no herbaceous cover. Requires shallow pools with minimal current, little to no emergent vegetation and a sand or pea gravel substrate overlain with flocculent silt for egg deposition.	Numerous focused surveys have been conducted for the arroyo toad throughout the Project site and along the Santa Clara River east of the Project site. Surveys include SMEA (1995); RECON (1999A); Aquatic Consulting Services (2002A, 2002B, 2002C, 2002D); Nancy Sandburg (2001); Impact Sciences (2001, 2002); Ecological Sciences (2003A, 2003B, 2003C, 2003D, 2003E, 2003F, 2004A, 2004B, 2004C, 2004D); Compliance Biology 2004D). Adult toads have been documented in limited numbers upstream of the Project area along the Santa Clara River and tributaries (Impact Sciences 2001; Sandburg 2001). One study (Aquatic Consulting Services 2002A) detected three arroyo toad tadpoles in the river within NRSP site, downstream of the Commerce Center Drive bridge site; and another study (Aquatic Consulting Services 2002D) detected three arroyo toad tadpoles, two near the Valencia Water Treatment Plant and one upstream of Commerce Center Drive.
western spadefoot toad *Spea hammondii*	—	CSC	Open areas in lowland grasslands, chaparral and pine–oak woodlands; requires temporary rain pools that last approximately three weeks.	Two pools were found with western spadefoot toad tadpoles, one near the western boundary of Mission Village and the other near Grapevine Mesa (Compliance Biology 2006C). Western spadefoot toad eggs and tadpoles were

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
				observed in VCC in an area that has now been developed (Dave Crawford, Compliance Biology, pers. comm., 2007; Compliance Biology, Inc. 2004G). Upstream of the Commerce Center Bridge, one western spadefoot toad was observed in an isolated pool (Aquatic Consulting Services 2002A). Seasonal backwater areas within NRSP, as well as seasonal stock ponds and depressions within existing dirt roads, provide breeding habitat. Given documented occurrences of the species at several on-site locations, and the presence of suitable breeding habitat, the species could occupy additional suitable on-site habitats. Not expected to occur in Entrada.
			Reptiles	
silvery legless lizard *Anniella pulchra pulchra*	—	CSC	Stabilized dunes, beaches, dry washes, chaparral, scrubs, pine, oak, and riparian woodlands; associated with sparse vegetation and sandy or loose, loamy soils.	This species has been observed within NRSP in 2004 (Impact Sciences 2006) in leaf litter of coast live oak woodland; suitable habitat occurs within Salt Creek, VCC, and Entrada in association with California sagebrush scrub, chaparral, oak woodland, and riverbank habitats.
coastal western whiptail *Aspidoscelis tigris stejnegeri*	—	***	Open areas in semiarid grasslands, scrublands, and woodlands.	Observed within NRSP in the High Country (Dudek and Associates 2006B) and one was observed off site in Castaic Mesa (Compliance Biology 2006D); suitable habitat occurs within Salt Creek, VCC and Entrada in association with grassland, scrub, oak woodland and riverbank habitats.
southwestern pond turtle *Actinemys marmorata pallida*	—	CSC	Streams, ponds, freshwater marshes, and lakes with growth of aquatic vegetation.	This species was observed in the reach of the Santa Clara River within NRSP (SMEA 1995; Aquatic Consulting Services 2002D; Impact Sciences 2002; Compliance Biology 2004D), within the Santa Clara River in Entrada (Impact Sciences 2001; Ecological Sciences 2004A; Dudek and Associates 2006E), and in Salt Creek (Dudek and Associates 2006B); river and riparian habitats within NRSP, Salt Creek, and VCC provide suitable habitat.

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
coast horned lizard *Phrynosoma coronatum*	—	CSC	Exposed gravelly-sandy soils with minimal shrubs, riparian woodland clearings, dry chamise chaparral, and annual grasslands with scattered seepweed or saltbush.	This species was also observed during reptile surveys in 2004 and 2006 (Impact Sciences 2006). Suitable habitat occurs within NRSP, Salt Creek, VCC, and Entrada in association with scrub, chaparral, and riverbank habitats; species presumed to occur on site within suitable habitat.
two-striped garter snake *Thamnophis hammondii*	—	CSC	Perennial and intermittent streams with rocky or sandy beds and artificially-created aquatic habitats (manmade lakes and stock ponds); requires dense riparian vegetation.	This species was observed in the reach of the Santa Clara River within and adjacent to the NRSP (Aquatic Consulting Services 2002C; Impact Sciences 2002; Compliance Biology 2004), within Entrada (Impact Sciences 2001), and within VCC (Ecological Sciences 2003A); river and riparian habitats within Salt Creek, VCC, and Entrada provide suitable habitat.
Birds				
Cooper's hawk (nesting) *Accipiter cooperii*	—	WL	Dense stands of live oak, riparian woodlands, or other woodland habitats near water.	This species is known to be a year-round resident within the NRSP (Bloom Biological 2007A) and Entrada and VCC (Guthrie 2001A); it occurs commonly along the Santa Clara River and in Potrero Canyon (Bloom Biological 2008). This species has been observed nesting within NRSP near Grapevine Mesa and in Entrada north of the Santa Clara River (Guthrie 2000B; Bloom Biological 2007A, respectively), and with active territories in NRSP (Bloom Biological 2007A). It has observed over multiple years foraging within Salt Creek, VCC, and Entrada adjacent to the Santa Clara River during annual bird surveys. The Project site provides foraging and nesting habitat for the species.
sharp-shinned hawk (nesting) *Accipiter striatus*	—	WL	Nests in woodlands and forages over dense chaparral and scrublands.	This species has been observed within the NRSP hunting along agriculture fields along the Santa Clara River (Bloom Biological 2008) and was observed by Guthrie in the NRSP (Guthrie 1997B, 1999C) and Entrada (Guthrie 2002A). It was also observed east of the site along the Santa Clara River (Guthrie 1995A) and one individual was observed in Salt Creek (Bloom Biological 2008). All

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
				observations were thought to be migrants and/or wintering birds. The Project site is outside the known breeding range for this species. This species forages in woodlands, chaparral, scrublands, and edge/ecotone areas between habitats which occur throughout the Project site.
tricolored blackbird (nesting colony) *Agelaius tricolor*	BCC, USBC	CSC	Freshwater marshes and riparian scrub (nesting). Grassland and agriculture (foraging).	This species has been observed on the Project site during focused bird surveys. A flock of approximately 200 breeding pairs of tricolored blackbirds was observed in Castaic Junction (Guthrie 1994A). Another flock of approximately 20 breeding pairs of tricolored blackbirds was observed next to Castaic Creek (Guthrie 1994A). In 1995 (Guthrie 1995A) and 1996 (Guthrie 1996A) small flocks visited the Castaic Creek site again in April and May, but did not breed there. Labinger *et al.* (1995) observed a small nesting colony within the Project site (specific location is not known). Migrants have also been observed within the RMDP (Guthrie 1996B, 1999B), VCC (Guthrie 1999A, 2006E) and Entrada (Guthrie 2000E, 2001A, 2006A; Dudek and Associates 2006E) boundaries during surveys, but no breeding colonies have been observed since 1994, despite annual surveys through 2007. A flock of 20 tricolored blackbirds was observed in Potrero Canyon in 1994 (Guthrie 1994), and a flock of 50 birds was seen on the Newhall Ranch property north of Mayo Crossing (County of Los Angeles 2003A).
southern California rufous-crowned sparrow *Aimophila ruficeps canescens*	—	WL	Coastal scrub.	This species has been observed over multiple years as a fairly common resident within the Coastal scrub within NRSP, Salt Creek, VCC, and Entrada during annual bird surveys and has been observed foraging in upland scrub on the south side of the Santa Clara River, and in upland areas (Bloom Biological 2008), and near the Santa Clara River (Guthrie 2000A, 2000B, 2001A, 2002C, 2004A, 2004D), and nesting in 2007 (Bloom Biological 2007A); the Project

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
				site provides suitable nesting and foraging habitat with large concentrations of coastal scrub in the northeastern portion of NRSP and southeastern portion of High Country.
golden eagle (nesting and wintering) *Aquila chrysaetos*	BCC	WL CFP	Nests on cliff-walled canyons and large trees in open areas. Forage in open shrublands, agriculture, and grassland.	One pair was seen frequently in upper Potrero Canyon and a juvenile was seen once in the same area; this is likely a resident pair, but no nests have been observed to date (Bloom Biological 2008). An individual was observed over the Santa Clara River corridor in Castaic Junction area in 1993 and 1995 (Guthrie 1993A, 1993B, 1995) and another was flushed in a woodland west of Grapevine Mesa in the NRSP in 2000 (Guthrie 2000B); no nesting eagles have been observed on the Project site but suitable nesting and foraging habitat is present within NRSP, Salt Creek, VCC, and Entrada. These species have also been observed along Santa Clara River east and west of the project site (Guthrie 1993A, 1997A, 2004F, 2006A; Labinger *et al*. 1997A).
short-eared owl (nesting) *Asio flammeus*	USBC	CSC	Grassland, prairies, dunes, meadows, irrigated lands, saline and freshwater emergent wetlands.	This species was observed in the Salt Creek area just west of the Ventura/Los Angeles County line in the fall of 2005 (Dudek and Associates 2006B). A freshly dead individual was found at the edge of a cultivated field just west of I-5 during the Santa Clarita Bird Count in December 2006 (Olson 2007). This species is likely a winter visitor and is not known to nest in the Project vicinity.
long-eared owl (nesting) *Asio otus*	—	CSC	Dense, riparian and live oak thickets near meadow edges, nearby woodland and forest habitats. Also found in dense conifer stands at higher elevations. Forages in grassland and agriculture.	This species was observed within NRSP near Via Canyon in Fall 2005 (Dudek and Associates 2006B). Some suitable nesting habitat is present along the Santa Clara River and Castaic Creek, and foraging habitat is present throughout the NRSP, Salt Creek, VCC, and Entrada.

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
western burrowing owl (burrow sites) *Athene cunicularia*	BCC	CSC	Grasslands, open scrub, and agriculture, particularly with ground squirrel burrows.	A single individual was observed within NRSP (Babcock 2007). Given the timing of the sighting (winter 2006), the observed individual may have been wintering on site or temporarily using the site during migration. Another individual was observed in December 2006 and on April 11, 2007 (Miller 2007). NRSP, Salt Creek, VCC, and Entrada provide suitable foraging and nesting habitat for the species; California ground squirrel burrows occur on the Project site.
oak titmouse (nesting) *Baeolophus inornatus*	USBC	***	Montane hardwood-conifer, montane hardwood, blue oak, valley oak and coastal oak woodlands, montane and valley foothill riparian habitats.	This species is a common resident and nests on site in cottonwood riparian and coast live oak communities; it has been observed over multiple years in the NRSP, Entrada and VCC sites. Recent observations have been in 2006 (Guthrie 2006C) and 2007 and 2008 (Bloom Biological 2007A, 2008).
ferruginous hawk (wintering) *Buteo regalis*	BCC	WL	Grasslands, agricultural fields, and open scrublands.	This species is an infrequent seasonal migrant. Individuals of this species were observed almost every day in east alfalfa fields, Wolcott fields, and Potrero Canyon, and other agriculture fields along the Santa Clara River in winter 2008 (Bloom Biological 2008). Although suitable foraging habitat is present on the Project site, this species has not been documented to nest in California and is expected to forage on the site.
Costa's hummingbird (nesting) *Calypte costae*	USBC	***	Shrubs and arid habitats. Edges of desert riparian and valley foothill riparian, coastal scrub, desert scrub, desert succulent scrub, arid shrublands, lower elevation chaparral, and palm oasis.	This species has been observed over multiple years within the NRSP, Entrada and VCC sites; it is thought to be a summer resident, although does not appear to be an abundant species within the Project site based on the number of sightings each year. Recent observations have been in 2006 (Guthrie 2006C).
Lawrence's goldfinch *Carduelis lawrencei*	BCC, USBC	***	Valley foothill hardwood, valley foothill hardwood-conifer; and, in southern California, desert riparian, palm oasis, pinyon-juniper and lower montane habitats.	This species has been observed as a resident in the coastal scrub in the northern and northeaster portions of the Project site, and has been observed within the riparian habitats of the Santa Clara River over multiple years within NRSP and

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
				Entrada during annual bird surveys. Recent observations have been in 2006 (Guthrie 2006C) and 2007 and 2008 (Bloom Biological 2007A, 2008). Suitable nesting and foraging habitat is present within NRSP, Salt Creek, VCC, and Entrada.
turkey vulture *Cathartes aura*	—	†	Rangeland, agriculture, grassland; uses cliffs and large trees for roosting, nesting and resting.	This species has been observed over multiple years within NRSP, Salt Creek, VCC, and Entrada; recent observations in the Project site have been made in 2006 (Guthrie 2006C; Bloom Biological 2007A); nesting opportunities are also present within the Project site.
northern harrier (nesting) *Circus cyaneus*	—	CSC	Coastal salt marsh, freshwater marsh, grasslands, and agricultural fields.	This species has been observed within NRSP in 1999 and 2000 (Guthrie 1999B, 2000A) and in 2007 and 2008 near the Santa Clara River in the NRSP and Entrada sites (Bloom Biological 2007A, 2008). This species has also been observed within the vicinity of the project site (Compliance Biology 2003, 2006); suitable foraging and nesting habitat is present within NRSP, Salt Creek, VCC, and Entrada.
western yellow-billed cuckoo (nesting) *Coccyzus americanus occidentalis*	FC BCC	CE	Nests along the broad, lower flood-bottoms of larger river systems. Also nests in riparian forests and riparian jungles of willow often mixed with cottonwoods, with an understory of blackberry, nettles, or wild grape.	One individual was heard at the Magic Mountain (Entrada) area in 1997 and thought to be a migrant (Labinger *et al.* 1997B). Single individuals (thought to be migrants) were observed along the Santa Clara River east of the Project site in 1997 and 1998 (Guthrie 1997A; Labinger and Greaves 1999A), and west of the Ventura county line (Guthrie 1997B); none have been observed since then; species has not been observed nesting on site; suitable nesting and foraging habitat present within NRSP, VCC and Entrada. This species has been observed historically in 1979, 1981 and 1992 (Labinger *et al.* 1997A).
hermit warbler (nesting) *Dendroica occidentalis*	—	***	Breeds in mature ponderosa pine, montane hardwood-conifer, mixed conifer, Douglas fir, redwood, red fir and Jeffrey pines. Uses live oak woodlands and deciduous trees	Individuals of this species have been observed within or adjacent to the Specific Plan in 1994, 1996, and 2002 (Guthrie 1994B, 1996B, 2002C). All observations were thought to be migrants. The Project site is within this

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
			during migration, and valley foothill hardwood in winter.	species winter range. Suitable habitat for migration and wintering habitat occurs on site, but no suitable nesting occurs on site.
yellow warbler (nesting) *Dendroica petechia brewsteri*	—	CSC	Riparian thickets and woodlands.	This species has been observed over multiple years during annual bird surveys and nests in the riparian areas within NRSP, Salt Creek, VCC, and Entrada. These species have been observed both during nesting season and migration. Recent observations of these species within the Project site in 2006 (Guthrie 2006A, 2006B, 2006C) and 2007 (Bloom Biological, Inc. 2007A).
white-tailed kite (nesting) *Elanus leucurus*	—	CFP	Inhabits herbaceous and open stages of most habitats, common in cismontane in California. Nests are placed near top of dense oak, willow or other tree stand; usually 6 to 20 meters (20 to 100 feet) above ground. Nest located near open foraging area.	This species has been observed successfully nesting on site and in the vicinity of the project site along the Santa Clara River over multiple years within NRSP, Salt Creek, VCC, and Entrada during annual bird surveys (Guthrie 1994A, 1995A, 1997A, 1998B, 2000E, 2000F, 2006B) and during focused survey (Bloom Biological 2007A, 2009); suitable foraging and nesting habitat is present on the Project site.
willow flycatcher (nesting) *Empidonax traillii*	USBC	CE	Riparian woodlands that contain water and low willow thickets.	This species has been observed along the Santa Clara River over multiple years within the NRSP, Entrada and VCC project sites. The observations have usually been of individual species, thought to be migrants passing through the area based on their behavior and time of year (no observations occurred after June 22). Recent observations along the Santa Clara River within the NRSP, Entrada, and VCC have been made in 2005 and 2006 (Guthrie 2005B, 2006B). These species have also been observed adjacent to the project site. No nesting has been observed.
southwestern willow flycatcher (nesting) *Empidonax traillii extimus*	FE, USBC	CE	Riparian woodlands that contain water and low willow thickets.	Most of the observations of the willow flycatcher have not identified individuals to the subspecies level. Individuals were considered to be migrating through the site as they were not located after June 22. Within the vicinity of the project site, two individuals identified as southwestern willow flycatchers were observed in Castaic Creek in 2006

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
				(Forde Biological Consultants 2006). These individuals, however, were not displaying any nesting behavior. Suitable nesting and foraging habitat is present within NRSP, VCC, and Entrada. The most recent observation of this subspecies displaying territorial behavior is downstream approximately 18 miles, near Saticoy (Labinger and Greaves 1999A).
California horned lark *Eremophila alpestris actia*	—	WL	Grasslands, disturbed areas, agriculture fields, and beach areas.	This species has been observed within NRSP, Entrada, and VCC during annual bird surveys foraging in plowed and graded fields near the Santa Clara River and Castaic Creek over multiple years. In winter 2008 flocks of 250-500 individuals were observed in the Wolcott agriculture fields and east alfalfa field on several occasions (Bloom Biological 2008), and was observed in agriculture fields in 2007 (Bloom Biological 2007A); this species is thought to be a resident with recent observations (Guthrie 2000A, 2000C, 2001A, 2005B, 2006C); no nesting has been observed, but suitable foraging and nesting habitat is present on the Project site.
merlin (wintering) *Falco columbarius*	—	WL	Coastlines, wetlands, woodlands, agricultural fields, and grasslands.	Several individuals observed on different occasions hunting over agriculture fields along the Santa Clara River and in Potrero Canyon (Bloom Biological 2008). A male and female were observed flying over agriculture fields bordering riparian habitat near Indian Dunes in the NRSP in March 2007 (Bloom Biological 2007A). Although this species does not nest in California, CDFG considers wintering birds to be of Special Concern.
prairie falcon (nesting) *Falco mexicanus*	BCC	WL	Grasslands, savannas, rangeland, agricultural fields, and desert scrub; requires sheltered cliff faces for shelter and nesting.	At least 2 individuals were observed on several occasions in Potrero Canyon; and two other individuals were observed along the Santa Clara River on single occasions (Bloom Biological 2008). Individuals observed foraging within NRSP in 2000 (Guthrie 2000A), along Castaic Creek in 2001 (Guthrie 2001A), and Salt Creek in 2005

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
				(Dudek and Associates 2006B); it was observed flying north over the NRSP on April 29, 2007 (Bloom Biological 2007A); all of these occurrences were thought to be migrants in the Project site; moderate potential to occur within Entrada. No nesting individuals have been observed and available nesting habitat is marginal.
American peregrine falcon *Falco peregrinus anatum*	BCC, Delisted	CE[1] CFP	Nests near wetlands, lakes, rivers, or other water bodies, on cliffs, banks, dunes, and other human-made structures.	One individual was observed on one occasion over Wolcott agriculture field (Bloom Biological 2008). An individual was observed foraging over the Santa Clara River corridor near the Grapevine Mesa area within NRSP in 2000 (Guthrie 2000B); no other occurrences of this species have been documented on site during annual bird surveys. No nesting peregrine falcons have been observed on the Project site. Moderate potential for foraging within NRSP, Salt Creek, VCC, and Entrada. The species may nest in the Santa Susana Mountains, south of the Project site (Guthrie 2000B).
California condor *Gymnogyps californianus*	FE, USBC	CE CFP	Forages over wide areas of open rangelands, roosts on cliffs and in large trees and snags.	Until April 2008, California condors had not been known to nest or land within the Project area within the last 25 years (Bloom Biological 2007A, 2008). In April 2008, a California condor was observed feeding on a dead calf in a Potrero side canyon by wildlife biologist Chris Niemela (Carpenter 2008). It is a wide-ranging species that nests on remote cliffs, but forages over hundreds of square miles and is known to at least fly over the site (Bloom Biological 2008).
yellow-breasted chat (nesting) *Icteria virens*	—	CSC	Riparian thickets and riparian woodlands with a dense understory.	This species was observed nesting in riparian thickets in 2007 (Bloom Biological 2007A) and has been observed over multiple years along the Santa Clara River within dry riparian woodland habitat in the NRSP, Salt Creek, Entrada, and VCC during annual bird surveys. Recent observations were made within the Project site in 2006 (Guthrie 2006A, 2006C); suitable foraging and nesting

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
				habitat is present on the Project site.
loggerhead shrike *Lanius ludovicianus*	BCC	CSC	Grasslands and open shrublands with scattered shrubs, trees, fences, or other perches.	This species is a resident on site (Bloom Biological 2007A, 2008). In winter 2008 it was observed regularly in Potrero Canyon, Tapo Canyon, near Magic Mountain ranch gate, and Wolcott agriculture fields (Bloom Biological 2008). Observed to be fairly common within California sagebrush scrub and grasslands in the NRSP and also observed within VCC (Guthrie 1995A, 2004H), Salt Creek (Dudek and Associates 2006B) and Entrada (Dudek and Associates 2006E); it was observed nesting near Potrero Canyon and near an agriculture field near the Santa Clara River in 2007 (Bloom Biological 2007A); it was thought to have nested within and adjacent to the Entrada site (Guthrie 2000D, 2004G); suitable nesting and foraging habitat is present on the Project site.
black-crowned night-heron (rookery) *Nycticorax nycticorax*	—	***	Riparian; nests in dense-foliaged trees and dense emergent wetlands.	This species has been observed along the Santa Clara River within the NRSP, most recently in 2007 (Bloom Biological 2008), and in 2006 (Guthrie 2006A and Bloom Biological 2007A); within Entrada, in 2006 (Guthrie 2006C); and along Castaic Creek, in 2000 (Guthrie 2000E). This species was observed early in the year and is thought to be a wintering or migratory species within the Project site. No rookery sites have been detected on or near the site (Bloom Biological 2008). It is not known if this species has a rookery site within or adjacent to the Project site (Bloom Biological 2007A). Some suitable foraging and nesting habitat is present on site.
Nuttall's woodpecker (nesting) *Picoides nuttallii*	USBC	***	Lower elevation riparian deciduous and oak habitats.	This species is a common, year-round resident in cottonwood and willow riparian habitat along the Santa Clara River and Castaic Creek (Bloom Biological 2007A, 2008). It has been observed nearly every year since surveys began in 1988 (see Guthrie and Bloom Biological surveys).

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
summer tanager (nesting) *Piranga rubra*	—	CSC	Cottonwood-willow riparian habitats, especially older, dense stands along rivers and streams.	Individuals have been observed during annual bird surveys within NRSP in 1994 (Guthrie 1994B), in Entrada in 1991 and 1993 (Guthrie 1991A, 1993A, 1993B); it has also been observed east of the project site in 2000 and 2003 (Guthrie 2000E, 2003A); suitable nesting and foraging habitat present along the Santa Clara River and Castaic Creek within NRSP, VCC, and Entrada.
coastal California gnatcatcher *Polioptila californica californica*	FT, USBC	CSC	Various sage scrub communities, often dominated by California sage and buckwheat; generally avoids nesting in areas with a slope of greater than 40%, and typically less than 820 feet in elevation.	Suitable nesting and/or foraging habitat types are present on site, but all at higher elevations and/or with steeper slopes than typical of this species. The species has not been observed on site during numerous annual bird surveys (including USFWS protocol surveys). Focused protocol surveys have been conducted throughout the Project site in 2000 (Guthrie 2000A, 2000B, 2000D) 2004 (Guthrie 2004A, 2004B, 2004D, 2004E, 2004G) and 2007 (Dudek 2007B). Focused surveys have also been conducted off site in Legacy Village (Guthrie 2004C; Impact Sciences, Inc 2000; SAIC 2003) and other areas (Compliance Biology 2002, 2006A; PCR 1998). However, during the course of biological monitoring conducted in the VCC planning area, an individual California gnatcatcher was observed on October 5, 2007 by Dudek biologist Jeff Priest and biologist Ron Francis, a sub-consultant to Dave Crawford, Compliance Biology, Inc. (Priest 2007A). Given the time of year and the fact that no other California gnatcatchers have ever been observed within the Project site (despite extensive focused and general surveys), this observation is believed to have been that of a dispersing or transient individual.

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
vermilion flycatcher (nesting) *Pyrocephalus rubinus flammeus*	—	CSC	Breeding habitat includes riparian woodlands, riparian scrub, and freshwater marshes.	A single individual was observed along the Santa Clara River in 1993 (Guthrie 1993B); suitable breeding and foraging habitat present on site along the Santa Clara River in the NRSP and Entrada and along Castaic Creek in VCC; some suitable habitat exists in Salt Creek.
Allen's/Rufous hummingbird (nesting) *Selasphorus sasin/rufus*	USBC/ USBC, BCC	***	Breeds in coastal scrub, valley foothill hardwood, and valley foothill riparian habitats. Migrates in woodland and scrub habitats.	This species has been observed along the Santa Clara River within and adjacent to the NRSP (Bloom Biological 2008; Guthrie 1998A, 1999B, and 2004F), in the upland area of the Entrada site (Guthrie 2004G), and along Castaic Creek in VCC (Guthrie 2004B). These observations were thought to be of migrants. The Project site provides suitable foraging, nesting, and migrating habitat throughout the NRSP, Entrada and VCC. The Project site is within this species' year-long range.
chipping sparrow (nesting) *Spizella passerina*	—	***	Open woodlands with sparse or low shrubs.	This species has been observed as a common migrant in the Project site (Bloom Biological 2007A); additional observations are within and adjacent to the NRSP near the Santa Clara River (Guthrie 1994B, 1997B, 1999B, and 2002A), near Grapevine Mesa (Guthrie 2000B) and Homestead Canyon (Guthrie 2004A), in Entrada (Guthrie 1991A, 1992, 1993A, and 1999A), and in VCC (Guthrie 1991B). Suitable habitat occurs on site, mostly in High Country with some open woodland areas in Potrero Canyon as well. The Project site is within this species' year-long range.
least Bell's vireo (nesting) *Vireo bellii pusillus*	FE, USBC, BCC	CE	Riparian vegetation with extensive willows below 2,000 feet.	This species has been observed almost every year along the Santa Clara River within the NRSP, and over multiple years in Entrada and VCC. It has been observed nesting within NRSP and Entrada most recently in 2007 (Bloom Biological 2007A) during annual bird surveys; on-site nesting sites in willow riparian habitats associated with the Santa Clara River and Castaic Creek. Suitable nesting and foraging habitat present within NRSP, VCC, and Entrada.

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
yellow-headed blackbird *Xanthocephalus xanthocephalus*	—	CSC	Nests in freshwater marsh and forages in annual grassland, native grassland and agriculture.	This species has been observed within the NRSP (Guthrie 1996B, 1997B, 1999B, 2001B), in Entrada (Guthrie 1988, 2000E), and in VCC (Guthrie 1997A, 2006C). All observations were thought to be migrants. While suitable nesting and foraging habitat occurs on the Project site, this species is expected to occur very rarely on site.
			Mammals	
pallid bat *Antrozous pallidus*	—	CSC	Arid habitats, including grasslands, shrublands, woodlands and forests; prefers rocky outcrops, cliffs and crevices with access to open habitats for foraging.	This species was detected within NRSP during ANABAT surveys (Impact Sciences 2005) and in 2006 (Johnson 2006); on-site habitats and structures (*e.g.*, oak woodlands, buildings, SR-126 bridge) provide suitable roosting habitat within NRSP, Salt Creek, VCC, and Entrada.
western mastiff bat *Eumops perotis californicus*	—	CSC	Occurs in many open, semi-arid to arid habitats, including conifer and deciduous woodlands, coastal scrub, annual and perennial grasslands, palm oases, chaparral, desert scrub and urban.	This species was not detected within NRSP during ANABAT surveys (Impact Sciences 2005), but it was observed in 2006 (Johnson 2006) within the NRSP; suitable roosting and foraging habitat is present within the Project site.
western red bat *Lasiurus blossevillii*	—	CSC	Occurs in a wide variety of habitats, including scrub, grassland, woodland, and riparian areas.	There were three acoustic detections of the western red bat in the Project area. Two 2004 detections (Impact Sciences 2005) were in willow riparian habitat, and the 2006 detection was under The Old Road Bridge (Johnson 2006). Suitable roosting and foraging habitat is present throughout the Project site.
San Diego black-tailed jackrabbit *Lepus californicus bennettii*	—	CSC	Open chaparral and California sagebrush scrub, grassland and agriculture.	Observed at mouth of Potrero Canyon within NRSP (Impact Sciences 2005). Suitable habitat is present within California sagebrush scrub and chaparral habitats within NRSP, Salt Creek, High Country, VCC, and Entrada.

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
fringed myotis *Myotis thysanodes*	—	***	Occurs in a wide variety of habitats. Optimal habitats include pinyon–juniper, valley foothill hardwood and hardwood-conifer woodlands. Forms maternity colonies and roosts in caves, mines, buildings and crevices.	This species was detected within NRSP in coast live oak habitat during ANABAT surveys (Impact Sciences 2005); suitable roosting and foraging habitat is present within the Project site in oak woodlands scattered throughout NRSP and larger concentrations in High Country.
Yuma myotis *Myotis yumanensis*	—	***	Inhabits open forests and woodlands with sources of water. Species is closely tied to bodies of water, over which it feeds. Forms maternity colonies in caves, mines, buildings, or crevices.	This species was not detected within NRSP during ANABAT surveys (Impact Sciences 2005), but it was observed in 2006 (Johnson 2006) within the NRSP; suitable roosting and foraging habitat is present within the Project site.
San Diego desert woodrat *Neotoma lepida intermedia*	—	CSC	Open chaparral, California sagebrush scrub, cactus patches and the understory of tree thickets.	A species of desert woodrat was observed during 2004 small mammal surveys within NRSP (Impact Sciences 2004). Single woodrat middens were observed within Entrada (Dudek and Associates 2006E) and within High Country (Dudek and Associates 2006B). Moderate potential to occur within Salt Creek and VCC. Based on the known range of this species, It is assumed that the animals observed were the San Diego (*intermedia*) subspecies.
pocketed free-tailed bat *Nyctinomops femorosaccus*	—	CSC	Occurs in a wide variety of habitats, including scrub, grassland, woodland, and riparian areas.	The pocketed free-tailed bat was acoustically detected in 2006 in lower Potrero Creek (Johnson 2006). It roosts in crevices in cliffs and forages in open air in all habitats. The Project area is at the extreme northwestern part of pocketed free-tailed bat range in California and does not contain the desert habitats typically used by this species. Though present on site, it is probably an occasional visitor.
mule deer *Odocoileus hemionus*	—	†	Variety of habitats including forests, woodlands, brush, meadows and standing waters.	This species has been observed during surveys within Entrada (Dudek and Associates 2006E), NRSP (Impact Sciences 2005), and High Country and Salt Creek (Dudek and Associates 2006B). Suitable habitat exists throughout the Project site.

Table 4.5-9
Special-Status Wildlife Species Observed on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	On-Site Status
mountain lion *Puma concolor*	—	✦	Occurs in a variety of scrub and forested habitats.	This species has been observed within NRSP (Impact Sciences 2005), and High Country and Salt Creek (Dudek and Associates 2006B); the Project site is expected to host transient individuals and to be part of local lion(s)' home range.
American badger *Taxidea taxus*	—	CSC	Grasslands, agriculture, drier open stages of shrub, forest, and herbaceous habitats with friable soils.	Observed during small mammal surveys within NRSP (Impact Sciences 2004; Dudek and Associates 2006B). Suitable habitat exists within central portions of NRSP. Moderate potential to occur in some areas of VCC and Entrada.
black bear *Ursus americanus*	—	†	Dense forests; forages in brush forests, valley foothill riparian and wet meadows.	Observed within High Country in 2005 (Dudek and Associates 2006B). Some suitable habitat occurs within the southern portion of High Country.

[1] On October 11, 2007, the California Fish and Game Commission designated the American peregrine falcon (*F. p. anatum*) as a candidate for delisting under CESA (California Regulatory Notice Register 2007).

Table 4.5-10
Special-Status Wildlife Species with Potential to Occur on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	Habitat Suitability
			Fish	
southern steelhead *Oncorhynchus mykiss*	FE	—	As juveniles and for spawning: relatively cool freshwater streams, well oxygenated water with adequate depth and cover in the way of gravel, cobble, boulder, undercut banks, large and small woody debris, and overhanging vegetation. As non-spawning adults: Pacific Ocean.	Within the Santa Clara River drainage, southern steelhead historically inhabited Piru Creek, Sespe Creek, Santa Paula Creek, Hopper Creek, and possibly Pole Creek (Titus *et al.* n.d.). Presently, southern steelhead occur downstream of the proposed Project in the Santa Clara River watershed in Piru Creek between the confluence with the Santa Clara River and Santa Felicia Dam, in Sespe Creek, in Santa Paula Creek, and possibly in Hopper and Pole Creeks (Stoeker and Kelly 2005). Although reconnaissance surveys conducted along the Santa Clara River and tributary drainages within the Specific Plan area of the RMDP were negative in 2004 and 2005 (ENTRIX 2009), this species was included in this category (Potential to Occur on Site) due to potential downstream effects of the proposed Project.
			Amphibians	
California red-legged frog *Rana aurora draytonii*	FT	CSC	Water sources such as ponds, lakes, reservoirs, streams, and adjacent riparian woodlands.	Field investigations indicate that potential breeding or summer habitat is generally absent from the portion of the Santa Clara River within the NRSP (ENTRIX 2006B); the species generally avoids large river channels with widely fluctuating flows because such habitat does not permit successful reproductive activity (Hayes and Jennings 1989). Not documented in the Santa Clara River (CDFG 2008E). Surveys for this species were conducted within the Santa Clara River in 1995 (SMEA 1995) and 2001 (Sandburg 2001) with negative results. The species has been documented within the Piru Creek and San Francisquito Creek tributaries to the River; given the occurrence of California red-legged frog in nearby upstream and downstream tributaries, non-breeding frogs could occur within the portion of the Santa Clara River (and other drainages) on the Project site. Additionally, the stock ponds on the NRSP provide suitable habitat and could support breeding frogs, although none have been found there.

Table 4.5-10
Special-Status Wildlife Species with Potential to Occur on Site

Common Name *Scientific Name*	Status		Habitat Requirements	Habitat Suitability
	Federal	State		
			Reptiles	
rosy boa *Charina trivirgata* ssp. *roseofusca*	—	***	Inhabits desert and chaparral habitats with rocky soils in coastal canyons and hillsides, desert canyons, washes and mountains.	Suitable scrub and chaparral habitat occurs within the Project site with large concentrations in the northeastern portion of NRSP and southeastern portion of High Country, and some in Potrero Canyon; riverbank habitat occurs on site along the Santa Clara River and Castaic Creek; oak woodlands are sparsely scattered throughout the NRSP with larger concentrations in High Country; this species is known to occur in the Project region and presumed to occur on site.
San Bernardino ringneck snake *Diadophis punctatus modestus*	—	***	Inhabits open, relatively rocky areas, often in somewhat moist microhabitats near intermittent streams. Avoids moving through open or barren areas by restricting movements to areas of surface litter or herbaceous vegetation.	Suitable habitat occurs within the Project site in association with oak woodland and riverbank habitats; riverbank habitat occurs on site along the Santa Clara River and Castaic Creek; oak woodlands are sparsely scattered throughout the NRSP with larger concentrations in High Country; species is known to occur in the Project region and presumed to occur on site.
coast patch-nosed snake *Salvadora hexalepis virgultea*	—	CSC	Inhabits brushy or shrubby vegetation. Requires small mammal burrows for refuge and overwintering sites.	Suitable habitat occurs throughout the Project site in association with shrub habitats (upland and riparian scrub, chaparral and riverwash); California ground squirrel and Botta's pocket gopher burrows occur on site; species is known to occur in the Project region and presumed to occur on site.
south coast garter snake *Thamnophis sirtalis* spp.	—	CSC	Inhabits scrub, chaparral, annual and native grassland, freshwater marsh, and agriculture.	Suitable habitat occurs throughout the Project site in association with scrub, chaparral, grassland, and agriculture habitats.
			Birds	
grasshopper sparrow *Ammodramus savannarum*	—	***	Dense, dry or well-drained annual and native grasslands with mix of grasses and forbs. May occur in fallow agricultural fields, especially those periodically planted in oats and barley.	The Project site is just south of the southern edge of the portion of this species' summer range which occurs at approximately the Los Angeles/Kern County boundary. There is at least moderate potential for this species to breed/forage in grasslands and some agricultural areas which occur mostly in the central portion of NRSP, San Martinez Grande, along portions of the Santa Clara River and Castaic Creek, and some portions of VCC and Entrada.

Table 4.5-10
Special-Status Wildlife Species with Potential to Occur on Site

Common Name *Scientific Name*	Status		Habitat Requirements	Habitat Suitability
	Federal	State		
Bell's sage sparrow (nesting) *Amphispiza belli belli*	BCC	WL	Coastal scrub and chaparral.	This species has been observed off site in Castaic Mesa (Compliance Biology 2006A), near Soledad Canyon in 2002 (Compliance Biology 2003), and in the Legacy Village project site, adjacent to the NRSP and Salt Creek area (Guthrie 2004C). Suitable nesting and foraging habitat present within the Project site with concentrations of coastal scrub and chaparral in the northeastern portion of the NRSP and southeastern portion of High Country.
black-chinned sparrow (nesting) *Spizella atrogularis*	BCC, USBC	***	Chaparral and sagebrush scrub.	Suitable habitat occurs within Project site in association with chaparral and coastal scrub habitats which are concentrated in the northeastern portion of the NRSP and the southeastern portion of High Country.
			Mammals	
ringtail *Bassariscus astutus*	—	CFP	Mixture of forest and shrubland in close association with rocky areas and riparian habitats; uses hollow trees, snags, and logs for cover and reproduction.	This species was surveyed for during the mammal surveys in 2004 (Impact Sciences 2005). Cameras, scent/track stations and spotlight survey techniques were used to detect these species. Low potential to occur based on lack of suitable habitat, such as hollow trees, logs, snags and abundant rocky areas. In addition, these species are not usually found more than 1 kilometer away from permanent water; therefore these species would most likely have been detected during the numerous studies performed near the Santa Clara River and its tributaries (Haglund & Baskin 2000; Impact Sciences 2005; Dudek and Associates 2006D, 2006E).
Townsend's big-eared bat *Corynorhinus townsendii*	—	CSC	Utilizes a variety of communities, including conifer and oak woodlands and forests, arid grasslands and deserts and high-elevation forests and meadows. Requires appropriate roosting, maternity and hibernacula sites free from human disturbance.	This species was not detected within NRSP during ANABAT surveys (Impact Sciences 2005). Suitable roosting and foraging habitat is present within the Project site.

Table 4.5-10
Special-Status Wildlife Species with Potential to Occur on Site

Common Name *Scientific Name*	Status		Habitat Requirements	Habitat Suitability
	Federal	State		
western small-footed myotis *Myotis ciliolabrum*	—	CSC	Occurs in a wide variety of habitats, including scrub, grassland, woodland, and riparian areas. Requires appropriate roosting, maternity and hibernacula sites free from human disturbance.	Impact Sciences (2005) identified the 40 kHz frequency range species in 2004 as the western small-footed myotis, but without additional information (*e.g.*, longer time-series recording or capture), this identification could not be confirmed because this frequency is characteristic of at least two other species that could occur on site: long-legged myotis and little brown bat. In 2006, 40 kHz bat species were recorded in all three survey locations along Potrero Creek, along the Santa Clara River at Walcott Road, and at the plant nursery site in upper Long Canyon. Without definitive presence/absence information, for the purpose of this analysis, it is assumed that the western small-footed myotis occurs in the Project area.
long-legged myotis *Myotis volans*	—	CSC	Occurs in a wide variety of habitats, including scrub, grassland, woodland, and riparian areas. Requires appropriate roosting, maternity and hibernacula sites free from human disturbance.	The presence of the long-legged myotis was not confirmed in the Project area during the acoustic and mist netting surveys conducted in 2004 and 2006 (Impact Sciences 2005; Johnson 2006). However, bats with acoustic signatures in the 40 kHz range, which is the range for the long-legged myotis, were detected on site in 2004 and 2006. Impact Sciences (2005) identified the 40 kHz frequency-range species in 2004 as the western small-footed myotis, but without additional information (*e.g.*, longer time-series recording or capture), this identification could not be confirmed. Based on the frequency data alone, the 40 kHz species could be western small-footed myotis, long-legged myotis, or little brown bat; therefore, all three species should be considered to be potentially present on site. In 2006, 40 kHz bat species were recorded in all three survey locations along Potrero Creek, along the Santa Clara River at Walcott Road, and at the plant nursery site in upper Long Canyon.

Table 4.5-10
Special-Status Wildlife Species with Potential to Occur on Site

Common Name *Scientific Name*	Status Federal	Status State	Habitat Requirements	Habitat Suitability
southern grasshopper mouse *Onychomys torridus ramona*	—	CSC	Inhabits desert areas, especially scrub habitats with friable soils for digging. Prefers low to moderate shrub cover.	This species has not been detected within the NRSP during small mammal trapping (Impact Sciences 2005). This species has potential to occur at least in low densities on site within coastal scrub and grassland vegetation communities; it is not expected to occur within other habitats on the Project site.

Table 4.5-11
Special-Status Wildlife Species Not Expected to Occur or Rarely Occurring on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	Habitat Suitability
			INVERTEBRATES	
			Crustacea Order Anostraca (fairy shrimp)	
vernal pool fairy shrimp *Branchinecta lynchi*	FT	—	Vernal pools.	Wet season vernal pool surveys were conducted in December 2007 to March 2008 in five previously identified depressions associated with western spadefoot surveys, including three in Potrero Canyon, one between Grapevine Mesa and Lion Canyon, and one east of Lion Canyon (Compliance Biology 2006C; Crawford 2007). Two of the five pools retained adequate water for testing, and results were negative. One depression located between Grapevine Mesa and Lion Canyon was a detention basin, and the other depression in Potrero Canyon was located on an oil well pad and storage area where water collected next to a bermed area. Neither of these depressions exhibited typical fairy shrimp habitat characteristics. No discernable depressions that could collect water were found at the other three previously identified locations, and water was not retained at these sites. All three were on dirt access roads. There is no indication of vernal pools or other seasonal pools on site that are suitable for fairy shrimp. The nearest documented vernal pools in relation to the Project area that could be source populations for fairy shrimp include at least two vernal pools located in the Plum Canyon area of Los Angeles County (Cruzan Mesa), approximately 10 miles from the Project area, and the Carlsberg vernal pools in Moorpark in Ventura County, approximately 15 miles from the Project area (Root 2008). Both the Carlsberg and Cruzan Mesa pools support the vernal pool fairy shrimp (USFWS 1998A). The USFWS is in concurrence that the Project is not likely to adversely affect listed fairy shrimp because these species are not known to occur in the Project area and suitable habitat is not known to occur in the Project area (Root 2008).
San Diego fairy shrimp *Branchinecta sandiegonensis*	FE	—	Vernal pools.	
Riverside fairy shrimp *Streptocephalus woottoni*	FE	—	Vernal pools.	

Table 4.5-11
Special-Status Wildlife Species Not Expected to Occur or Rarely Occurring on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	Habitat Suitability
			Insecta Order Lepidoptera (butterflies and moths)	
Quino checkerspot butterfly *Euphydryas editha quino*	FE	—	Occurs in localized colonies, always closely associated with the larval foodplant dot-seed plantain (*Plantago erecta*) and clay or cryptobiotic soils.	Based on a focused habitat assessment, it was concluded that the primary larval food plant (*Plantago erecta*) does not occur on the site (Compliance Biology 2004A, 2004C). This butterfly was last documented in the Santa Susana Mountains, approximately 30 miles south and southwest of the Project site in 1954.
			AMPHIBIANS	
coast range newt *Taricha torosa torosa*	—	CSC	Often occurs in areas where streams and ponds dry up in the summer. Occurs beneath logs, boards, rocks, and in rodent burrows, but adults must return to water to breed. May be found in drier habitats, such as oak forests, chaparral, and rolling grasslands. Commonly found in or near ditches, ponds, lakes, and streams; however, a permanent water source is not necessary. Stream-breeding populations typically breed in slow moving or stagnant pools in streams.	While suitable habitat occurs in the Project area, this species is not known to occur in the Project area. The nearest current occurrences range from 20 to 25 miles from the Project site, in the Santa Monica Mountains. Other southern California occurrences are in the Angeles National Forest in the San Gabriel Mountains, the Coast Ranges in Santa Barbara County, and the Cuyamaca Range in San Diego County.
			BIRDS	
coastal (San Diego) cactus wren *Campylorhynchus brunneicapillus sandiegensis*	BCC	CSC	Southern cactus scrub, maritime succulent scrub, cactus thickets in coastal sage scrub	No observations of cactus wrens have been made in the Project area, and the coastal (San Diego) cactus wren subspecies is not expected to occur on site based on its range. There are no large concentrations of cactus thickets on site that provide the necessary habitat constituent for nest sites.

Table 4.5-11
Special-Status Wildlife Species Not Expected to Occur or Rarely Occurring on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	Habitat Suitability
great egret (rookery) *Ardea alba*	—	***	Nests colonially in large trees. Rookery sites are typically located near marshes, tide-flats, irrigated pastures, and margins of rivers and lakes.	Individuals commonly observed over multiple years foraging within the Santa Clara River in NRSP, Entrada, and VCC; moderate potential for foraging within Salt Creek. Recent observations were made in 2006 (Guthrie 2006A, 2006C). No rookery sites have been observed on the Project site during annual bird surveys.
great blue heron (rookery) *Ardea herodias*	—	***	Nests colonially in tall trees, cliffsides, and sequestered spots on marshes. Rookery sites are usually in close proximity to foraging areas such as marshes, lake margins, tide-flats, wet meadows, rivers, and streams.	Individuals commonly observed over multiple years foraging within the Santa Clara River within NRSP, Entrada and VCC; moderate potential for foraging within Salt Creek. Recent observations were made in 2006 (Guthrie 2006A, 2006C). No rookery sites have been observed on the Project site during annual bird surveys.
Swainson's hawk *Buteo swainsoni*	BCC, USBC	CT	Open grassland, shrublands, croplands.	This species is a seasonal migrant. One individual (thought to be a migrant) was observed in 2000 in the NRSP (Guthrie 2000C). Two more observations were made within the vicinity of the Project site: one individual was observed northeast of VCC (Compliance Biology 2006A), and another east of Old Road bridge (Guthrie 1997A). Although suitable foraging habitat is present on the Project site, this species has not been documented to nest in southern California and is only expected to rarely forage over the site.
mountain plover *Charadrius montanus*	BCC, USBC	CSC	Nests in open, shortgrass prairies or grasslands; winters in shortgrass plains, plowed fields, open sagebrush, and sandy deserts.	Some suitable habitat exists on site in agriculture and California annual grassland communities, which primarily are located in the central portion of the NRSP, San Martinez Grande, and adjacent to the Santa Clara River riparian areas. These communities have marginal habitat quality on site to support this species. This species only winters in southern California and only rarely occurs. It is not expected to breed on the project site.
bald eagle *Haliaeetus leucocephalus*	Delisted	CE, CFP	Seacoasts, rivers, swamps, large lakes; winters at large bodies of water in lowlands and mountains.	No suitable lake habitat exists on the project site and no records of nesting on the project site. There are no large bodies of water, large rivers, or seacoasts within the vicinity of the Project site.

Table 4.5-11
Special-Status Wildlife Species Not Expected to Occur or Rarely Occurring on Site

Common Name *Scientific Name*	Status Federal	Status State	Habitat Requirements	Habitat Suitability
least bittern (nesting) *Ixobrychus exilis*	—	CSC	Dense emergent wetlands of cattails and tules are essential.	Cattails and tules occur within the Santa Clara River corridor; however, these areas do not contain the dense emergent vegetation characteristic of nesting habitat of this species.
long-billed curlew (nesting) *Numenius americanus*	BCC, USBC	WL	Nests in grazed, mixed grass and short-grass prairies. Localized nesting along the California coast. Coastal estuaries, mudflats, open grasslands and croplands are used in winter for foraging.	Some suitable habitat exists on site in agriculture and California annual grassland communities, which primarily are located in the central portion of the NRSP, San Martinez Grande, and adjacent to the Santa Clara River riparian areas. This species may occur rarely in the winter in the Project vicinity, but the Project site is outside its nesting range.
osprey (nesting) Pandion haliaetus	—	WL	Large waters (lakes, reservoirs, rivers) supporting fish; usually near forest habitats, but widely observed along the coast.	Ospreys need areas that support fish for long periods of time. There are no large bodies of water on site or adjacent to the Project site that could support fish for long periods of time. One individual was observed on March 31 (Guthrie 2000B) and was probably in migration.
double-crested cormorant *Phalacrocorax auritus*	—	WL	Lakes, rivers, reservoirs, estuaries, ocean; nests in tall trees, rock ledges on cliffs, rugged slopes.	No suitable lake habitat exists on the project site and no records of nesting on the project site. There are no large bodies of water, large rivers, estuaries or seacoasts within the vicinity of the Project site.
white-faced ibis (rookery site) *Plegadis chihi*	—	WL	Nests in dense emergent wetlands and marshes; winter foraging in shallow lacustrine waters, muddy ground of wet meadows, marshes, ponds, lakes, rivers, flooded fields and estuaries.	Very little marsh habitat exists on site, and is primarily located south of the Santa Clara River in Potrero Canyon. This species is not known to regularly breed in California anymore, and there is not enough suitable habitat on the Project site to support rookery sites.
purple martin (nesting) *Progne subis*	—	CSC	Nests in tall sycamores, pines, oak woodlands, coniferous forest; forages over riparian, forest and woodland.	This species may occasionally forage in the Project vicinity, but the site is outside its nesting range. There is limited suitable nesting habitat because there are no tall sycamores, pines, or coniferous forest communities on the Project site, and this species is not expected to nest on site. One individual was observed within NRSP (Guthrie 1994B).

Table 4.5-11
Special-Status Wildlife Species Not Expected to Occur or Rarely Occurring on Site

Common Name *Scientific Name*	Status Federal	Status State	Habitat Requirements	Habitat Suitability
bank swallow (nesting) *Riparia riparia*	—	CT	Colonial nester; nests primarily in riparian and other lowland habitats west of the desert. Requires vertical banks/cliffs with fine-textured/sandy soils near streams, rivers, lakes, or the ocean to dig a nesting hole.	The Project site is not within this species' range. The required nesting habitat does not exist on the Project site, and no recent records of nesting in the area. Typically these species nest in areas such as the Sacramento and Feather rivers.
California spotted owl *Strix occidentalis occidentalis*	BCC, USBC	CSC	Old growth oak and oak–conifer habitats.	The Project site is within the species' yearlong range. However, this species generally requires dense, old growth forest areas for foraging and cover; breeds in mature, multi-layered forest stands and nests generally in a tree or snag cavity. No conifer habitats occur on site. Oak woodlands exist on site, but are generally more open and often occur as oak savannahs. Dense, mature coast live oak woodlands exist within canyons in High Country and Salt Creek that may be suitable habitat for these species; however in the Angeles National Forest (east of the Project site), these species have been documented using canyon live oak habitats with co-dominant conifer species (Stephenson 1991). In the Cleveland National Forest in San Diego, they have been documented in woodlands dominated by both coast and canyon live oak, but also with co-dominant conifer species (Stephenson 1991). Overall, there is limited dense oak woodland on site to support this species.
			MAMMALS	
Mexican long-tongued bat *Choeronycteris mexicana*	—	CSC	Desert and montane riparian, desert succulent scrub, desert scrub, and pinyon–juniper woodland. Roosts in caves, mines, and buildings.	The Project site is not within this species' range. The closest range (and only known range in California) is in coastal San Diego County, approximately 100 miles southwest. This species requires habitats associated with desert habitats, and these are not found within the Project site.

Table 4.5-11
Special-Status Wildlife Species Not Expected to Occur or Rarely Occurring on Site

Common Name *Scientific Name*	Status Federal	 State	Habitat Requirements	Habitat Suitability
spotted bat *Euderma maculatum*	—	CSC	Occupies a wide variety of habitats from arid deserts and grasslands, to mixed conifer forests. Feeds over water and along washes. Needs rock crevices in cliffs or caves for roosting.	The Project site is within this species' yearlong range. This species was not detected within NRSP during ANABAT surveys conducted in 2004 (Impact Sciences 2005) or in 2006 (Johnson 2006). There are no cliffs or caves on site; therefore there is limited suitable roosting habitat on or bordering the Project site. Some suitable foraging habitat may occur in grasslands on site; however no desert or mixed conifer habitats occur on site or near the Project site. Only rare to occasional spotted bat sightings have been recorded in the Project vicinity.
Los Angeles pocket mouse *Perognathus longimembris brevinasus*	—	CSC	Inhabits lower elevation grasslands and California sagebrush communities on open ground with fine sandy soils. May not dig extensive burrows, hiding instead under weeds and dead leaves.	This species has not been detected within NRSP during small mammal live trapping (Impact Sciences 2005). Some suitable habitat may exist on site in grasslands; however there are no fine sandy soils associated with grassland or coastal scrub communities on site. The coastal scrub communities may be too in high elevation for the species. This species is not expected to occur on other portions of the Project site because the known range is south of Project site.
big free-tailed bat *Nyctinomops macrotis*	—	CSC	Rugged, rocky canyons.	This species has not been observed during wildlife surveys within the Project site. The closest range is in southwest San Diego County and is rare in California. This species is not expected to occur on site due to the distance from its known range.

4.5.3.2 Survey Methods

A cumulative list of biological surveys conducted within the Project area and vicinity is included above in **Table 4.5-6** in **Subsection 4.5.3.1**, Summary of Literature Review and Biological Studies Conducted in Project Area. This subsection describes in detail the general methods employed in the surveys conducted between 1988 and 2008; for additional specific survey information (*e.g.*, whether surveys were USFWS protocol surveys), refer to the Survey Dates/Season and General Methods columns in **Table 4.5-6**.

4.5.3.2.1 Vegetation Communities Mapping

Vegetation communities were mapped in the field directly onto 200- and 400-scale (1 inch=200 feet and 1 inch=400 feet) false-color digital orthographic maps (AirPhotoUSA 2005) of the RMDP and SCP study areas in July and August 2006. Biologists covered the study areas by foot and vehicle, traversing existing dirt roads and traveling along canyons and ridgelines. Dudek Geographic Information Systems (GIS) technician Mark McGinnis digitized the vegetation boundaries into an ArcView file and created a GIS coverage for vegetation communities (Dudek and Associates 2006A, 2006B, 2006C).

Vegetation community and land cover classifications used in this EIS/EIR generally follow the Vegetation Classification and Mapping Program "List of California Terrestrial Natural Communities Recognized by the California Natural Diversity Database" system (CDFG 2003, updated in October 2007 (CDFG 2007D)). Community classifications were selected based on site factors, descriptions, distribution, and characteristic species present within an area. In some areas, the vegetation communities observed in the field did not match those described in CDFG (2003). In these instances, Dudek generated additional site-specific vegetation community classifications later described as "modified" and defined by the dominant plant species. Existing field conditions also necessitated the addition of adjectives such as "burned" and "disturbed." Those in a "burned" condition had recently burned and vegetation was observed to be recovering, with shrub species stump sprouting. Vegetation communities classified as "disturbed" were those where native vegetation communities were visually estimated to contain 20% to 50% native species by absolute cover. Areas where native species cover was visually estimated to be less than 20% were mapped as disturbed land. Areas mapped as agriculture have been or are in cultivation. Areas mapped as developed represent paved roads, structures, and other hardscape features. Where a grassland vegetation community was visually estimated to contain 10% or more absolute cover of native perennial grasses (*e.g.*, *Nassella pulchra*), the area was mapped as a native grassland. The 10% threshold is an industry standard for identifying perennial native grasslands (Keeler-Wolf *et al.* 2007). Oak woodland is defined as areas with 20% to 50% cover by oak trees. Oak/grass includes areas where oak trees comprise less than 20% of the total cover.

4.5.3.2.2 Botanical Surveys

Multi-year focused surveys for special-status plants were conducted in the spring and summer by Dudek and FL*x* throughout the Project area from 2001 to 2007. Dudek conducted focused botanical surveys in the spring and summer from 2002 through 2005 on the development portion of the Specific Plan, VCC, and Entrada planning areas; these surveys excluded agricultural fields and the River Corridor SMA and overlapped slightly with the High Country SMA (Dudek and Associates 2002A, 2002B, 2002C, 2004B, 2004C, 2004E, 2004F, 2004G, 2004H, 2006F, 2006G, 2006H). Additional botanical surveys of the majority of the High Country SMA and the Salt Creek area were conducted between April and July of 2003 (Dudek and Associates 2004I); the remainder of the High Country SMA was surveyed between May and July of 2006 (Dudek and Associates 2006B). In 2006 and 2007, surveys focused on known locations of the state-listed endangered San Fernando Valley spineflower (SFVS) (Dudek and Associates 2006I, 2006J, 2006K; Dudek 2007F, 2007G, 2007H). In 2007, surveys also focused on known occurrences of the undescribed everlasting (Causey 2007). FL*x* conducted surveys in May and June of 2001 at four project locations within the Specific Plan area: River Village (now referred to as Landmark Village), Homestead (comprising the areas formerly known as Homestead, Homestead Estates, and Chiquito Canyon Residential), Salt Creek Canyon area, and a portion of Airport Mesa (FL*x* 2002A). FL*x* conducted surveys in October 2002 for the undescribed sunflower in the mesic areas of Castaic Junction and the River Village (now referred to as Landmark Village) and Water Reclamation Plant (WRP) sites within the Specific Plan area (FL*x* 2002B, 2002C). In 2004, FL*x* also conducted surveys along the Santa Clara River from the WRP westward to the Los Angeles/Ventura County line and along the tributary Castaic Creek from I-5 southwest to its confluence with the main River channel; these surveys focused on the SFVS in May and June and on the late-blooming undescribed sunflower in September (FL*x* 2004A). FL*x* conducted special-status plant surveys at the Entrada site fireworks area focusing on the SFVS and the slender mariposa lily (*Calochortus clavatus* var. *gracilis*) in April and May 2004, 2005, and 2006 (FL*x* 2004B, 2005, 2006A), and they conducted special-status plant surveys focusing on the SFVS at the Potrero Irrigation Project site on April 24, 2006 (FL*x* 2006B).

These surveys were conducted by Dudek staff biologists and by Anuja Parikh and Nathan Gale of FL*x*. All surveys were conducted on foot. Surveys were conducted in teams of two or more biologists, with at least one senior-level biologist with extensive botanical experience included on each team. Biologists were able to observe reference populations of the SFVS and other special-status plant species in order to develop a search-image prior to conducting surveys of the Project site. Precipitation was variable across the time span surveys were conducted. During the 2006–2007 rain season (October 2006 to September 2007), the Piru 2 ESE weather station in Los Angeles County experienced its driest year in recorded history, with 4.1 inches of rain—less than one quarter of the mean amount (17.40 inches; WRCC 2008). There was a less-than-average

amount of rainfall in the 2001–2002, 2003–2004 and 2005–2006 rain seasons. There was a greater-than-average rainfall in the 2002–2003 and 2004–2005 rain seasons (WRCC 2008). With the numerous surveys conducted over several consecutive years and under conditions varying from less-than-average to greater-than-average rainfall, these surveys provide a comprehensive botanical database for the analysis of impacts to botanical resources in the Project area.

The focused botanical surveys conducted by Dudek typically did not include all portions of the Santa Clara River: Surveys along the Santa Clara River were conducted in areas where bank stabilization projects were likely to occur. However, focused botanical surveys were conducted along the River by FL*x* (2002B, 2002C, 2004A). For all focused botanical surveys, areas of dense chaparral were surveyed where feasible.

Based on the literature review described for botanical resources in **Section 4.5.3.1** above, surveys focused on the identification and location of the SFVS and other potentially occurring special-status plant species, including state- and federally-listed species and California Native Plant Society (CNPS) List 1B, 2, and 4 species. **Table 4.5-12** lists those species, based on the presence of suitable habitat and soils.

Table 4.5-12
Special-Status Plant Species Potentially Occurring at Newhall Ranch

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage Ranking	Primary Habitat Associations/ Life Form/Blooming Period
Arenaria paludicola	marsh sandwort	FE/SE	1B	S1.1	dense freshwater marsh/perennial herb/May–August
Astragalus brauntonii	Braunton's milk-vetch	FE/None	1B	S2.1	chaparral, coastal sage scrub, grasslands; often on carbonate substrates/perennial herb/March–July
Atriplex coulteri	Coulter's saltbush	None/None	1B	S2.2	coastal sage scrub and grasslands on alkaline or clay substrate/perennial herb/March–October
Atriplex serenana var. *davidsonii*	Davidson's saltscale	None/None	1B	S2?	coastal bluff scrub and coastal sage scrub on alkaline substrate/annual herb/May–October
Baccharis malibuensis	Malibu baccharis	None/None	1B	S1.1	chaparral, coastal sage scrub, cismontane woodland/ deciduous shrub/August
Berberis nevinii	Nevin's barberry	FE/SE	1B	S2.2	chaparral, coastal sage scrub, riparian scrub, cismontane woodland on sandy or gravelly substrate/evergreen shrub/March–April
Brodiaea filifolia	thread-leaved Brodiaea	FT/SE	1B	S2.1	clay substrate openings in chaparral, sage scrub, and grasslands/perennial herb (geophyte)/March–June
Calochortus clavatus var. *clavatus*	club-haired mariposa lily	None/None	4	S3.3	chaparral and coastal sage scrub/perennial herb (geophyte)/March–May
Calochortus clavatus var. *gracilis*	slender mariposa lily	None/None	1B	S1.1	chaparral and coastal sage scrub/perennial herb (geophyte)/March–May
Calochortus plummerae	Plummer's mariposa lily	None/None	1B	S3.2	chaparral, coastal sage scrub, cismontane woodland, grasslands on rocky granitic substrate/perennial herb (geophyte)/May–July
Calochortus weedii var. *vestus*	late-flowered mariposa lily	None/None	1B	S2.2	chaparral, cismontane, and riparian woodland/perennial herb (geophyte)/June–August
Calystegia peirsonii	Peirson's morning-glory	None/None	4	S3.2	chaparral, coastal sage scrub, cismontane woodland, grassland/ perennial herb/May–June
Calystegia sepium ssp. *binghamiae*	Santa Barbara morning-glory	None/None	1A	SH	marshes and swamps/perennial herb/April–May
Centromadia [=*Hemizonia*] *parryi* ssp. *australis*	southern tarplant	None/None	1B	S2.1	mesic edges of marshes in grasslands/annual herb/May–November

Table 4.5-12
Special-Status Plant Species Potentially Occurring at Newhall Ranch

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage Ranking	Primary Habitat Associations/ Life Form/Blooming Period
Cercocarpus betuloides var. *blancheae*	island mountain-mahogany	None/None	4	S3.3	chaparral, closed-cone coniferous forest/evergreen shrub/February–May
Chorizanthe parryi var. *fernandina*	San Fernando Valley spineflower	FC/SE	1B	S1.1	Coastal sage scrub, sandy soils/annual herb/April–June
Deinandra [=*Hemizonia*] *minthornii*	Santa Susana tarplant	None/SR	1B	S2.2	chaparral and coastal sage scrub on rocky substrate/deciduous shrub/July–November
Delphinium parryi ssp. *blochmaniae*	dune larkspur	None/None	1B	S2.2	maritime chaparral, coastal dunes/perennial herb/April–May
Dodecahema leptoceras	slender-horned spineflower	FE/SE	1B	S1.1	Alluvial scrub on sandy substrate/annual herb/April–June
Dudleya blochmaniae ssp. *blochmaniae*	Blochman's dudleya	None/None	1B	S2.1	clay openings in chaparral and coastal sage scrub, grasslands/perennial herb/April–June
Dudleya cymosa ssp. *marcescens*	marcescent dudleya	FT/CR	1B	S2.2	chaparral, often on volcanic substrate/perennial herb (geophyte)/April–June
Dudleya cymosa ssp. *Ovatifolia*	Santa Monica Mountains dudleya	FT/None	1B	S2.2	chaparral and coastal sage scrub, often on volcanic substrate/perennial herb (geophyte)/April–June
Dudleya multicaulis	many-stemmed dudleya	None/None	1B	S2.1	coastal bluff scrub, coastal sage scrub, valley and foothill grassland, rocky, often clay substrate/perennial herb/April–June
Dudleya parva	Conejo dudleya	FT/None	1B	S2.1	coastal sage scrub and grassland on rocky, gravelly clays/perennial herb/May–June
Erodium macrophyllum	round-leaved filaree	None/None	2	N/A	cismontane woodland and grasslands on clay substrate/annual herb/March–May
Helianthus nuttallii ssp. *parishii*	Los Angeles sunflower	None/None	1A	SH	marshes and swamps/perennial herb/August–October
Horkelia cuneata ssp. *puberula*	mesa horkelia	None/None	1B	S2.1	chaparral, cismontane woodland, coastal sage scrub on sandy or gravelly substrate/perennial herb/February–December

Table 4.5-12
Special-Status Plant Species Potentially Occurring at Newhall Ranch

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage Ranking	Primary Habitat Associations/ Life Form/Blooming Period
Juglans californica var. *californica*	southern California black walnut	None/None	4	S3.2	chaparral, cismontane woodland, coastal sage scrub, alluvial scrub/deciduous tree/March–May
Juncus acutus ssp. *leopoldii*	southwestern spiny rush	None/None	4	S3.2	coastal dunes, meadows, seeps, marshes, and swamps/ perennial herb/May–June
Malacothamnus davidsonii	Davidson's bush mallow	None/None	1B	S1.1	chaparral, coastal sage scrub, riparian woodland/ deciduous scrub/June–January
Nama stenocarpum	mud nama	None/None	2	S1S2	edges of lakes, rivers, ponds, vernal pools/annual/January–July
Nemophila parviflora var. *quercifolia*	oak-leaved nemophila	None/None	4	S3.3	cismontane woodland, lower montane coniferous forest/annual herb/May–June
Nolina cismontana	chaparral nolina	None/None	1B	S1.1	chaparral, coastal sage scrub on sandstone or gabbro substrate/ perennial shrub/May–July
Opuntia basilaris var. *brachyclada*	short-joint beavertail	None/None	1B	S1.2	chaparral, Joshua tree woodland, Mojavean desert scrub/succulent shrub/April–June
Pentachaeta lyonii	Lyon's pentachaeta	FE/SE	1B	S1.1	openings in chaparral and coastal sage scrub, grasslands/annual herb/March–August
Rorippa gambelii	Gambel's watercress	FE/ST	1B	N/A	Marsh and swamps (freshwater and brackish)/perennial herb/April–June
Senecio aphanactis	rayless ragwort	None/None	2	S1.2	chaparral, coastal sage scrub, cismontane woodland on alkaline substrate/annual herb/January–April
Sidalcea neomexicana	salt spring checkerbloom	None/None	2	S2S3	chaparral, coastal sage scrub, and playas on alkaline substrate/perennial herb/March–June
Thelypteris puberula var. *sonorensis*	Sonoran maiden fern	None/None	2	S2.2	meadows and seeps/perennial herb/fertile January–September

Legend

FE: Federally listed as endangered
FT: Federally listed as threatened
FC: Federal candidate for listing
SC: State candidate for listing
SE: State-listed as endangered

CNPS List 1A: Plants presumed extinct in California
CNPS List 1B: Plants rare, threatened, or endangered in California and elsewhere
CNPS List 2: Plants rare, threatened, or endangered in California but more common elsewhere
CNPS List 3: Plants about which we need more information–a review list
CNPS List 4: Plants of limited distribution–a watch list

Table 4.5-12
Special-Status Plant Species Potentially Occurring at Newhall Ranch

Scientific Name	Common Name	Status Federal/ State	CNPS List	California Heritage Ranking	Primary Habitat Associations/ Life Form/Blooming Period

ST: State-listed as threatened
SR: State-listed as rare

California Heritage (CNDDB) Element Ranking

S1: Less than 6 Eos OR less than 1,000 individuals OR less than 2,000 acres
- S1.1 = very threatened
- S1.2 = threatened
- S1.3 = no current threats known.

S2: 6 to 20 Eos OR 1,000 to -3,000 individuals OR 2,000 to 10,000 acres
- S2.1 = very threatened
- S2.2 = threatened
- S2.3 = no current threats known.

S3: 21 to 80 Eos or 3,000 to 10,000 individuals OR 10,000 to 50,000 acres
- S3.1 = very threatened
- S3.2 = threatened
- S3.3 = no current threats known.

S4: Apparently secure within California; This rank is clearly lower than S3 but factors exist to cause some concern; *i.e.*, there is some threat, or somewhat narrow habitat. NO THREAT RANK.

S5: Demonstrably secure to ineradicable in California. NO THREAT RANK.

Notes:

1. Other considerations used when ranking a species or natural community include the pattern of distribution of the element on the landscape, fragmentation of the population/stands, and historical extent as compared to its modern range. It is important to take a **bird's eye or aerial view** when ranking sensitive elements rather than simply counting element occurrences.
2. Uncertainty about the rank of an element is expressed in two major ways: First, by expressing the ranks as a **range** of values: *e.g.*, S2S3 means the rank is somewhere between S2 and S3. Second, by adding a "?" to the rank: *e.g.*, S2? This represents more certainty than S2S3, but less certainty than S2

.

Focused botanical surveys were generally conducted between late April and August. Two of the special-status species listed in the table above have blooming times on the outside limits of the survey periods: Nevin's barberry (March through April) and rayless ragwort (January through April). Nevin's barberry is a large perennial shrub and would have been observed on site during the annual surveys conducted between 2002 and 2007 whether blooming or not. Rayless ragwort is an herbaceous shrub, one to two meters tall and would have been observed even at the end of its blooming cycle. Three other ragwort species were observed on site during the annual surveys conducted between 2002 and 2007, and rayless ragwort would have been observed if present.

All plant species encountered during the botanical field surveys were identified and recorded for inclusion in the survey reports. Latin and common names of plants follow *The Jepson Manual* (Hickman 1993) or other recent published taxonomic treatments. Where not listed in Hickman (1993), common names were taken from Abrams (1923). Where not found in this reference, a variety of sources were used (*e.g.*, Abrams 1923; Dale 1985; or Roberts 1998).

SFVS occurrences were mapped as polygons. Where plants were less than four meters (13.1 feet) from one another, they were mapped in the same polygon. Where they were four meters or farther from one another, they were mapped as separate polygons. The four-meter distance was selected based on topography, vegetation density, detectability of the plants, the general accuracy of the Global Positioning System (GPS), and time constraints. The distance is not specifically tied to SFVS biology (*i.e.*, reproductive biology, seed dispersal) and thus is not intended to reflect reproductively isolated sub-populations, the total extent of the SVFS seed bank, or any other feature of the species' life history.

Field botanists walked around the perimeter of each spineflower polygon, defining the boundary by SFVS occurrence at a less-than-four-meter (13.1-foot) distance. Polygon boundaries were defined by manually storing GPS location data in a hand-held Trimble GPS unit (sub-meter precision) every one to four meters (3.3 to 13.1 feet) along the polygon boundary. Each SFVS polygon was given a unique identifier (*i.e.*, numbers and/or letters) in the field. Field data sheets, which included estimated plant numbers and associated species, were completed for each polygon. GPS data were analyzed using GIS or Computer Assisted Drafting software (*e.g.*, ArcGIS, AutoCAD), then delineated so that the outer boundary was defined as a "minimum convex polygon" (*i.e.*, the smallest polygon whose outer perimeter is made up of convex angles).

SFVS numbers (or numbers of other sensitive species, where observed) in each polygon were estimated by counting or estimating the number of individuals in a rectangular "sample estimation area" (to account for the "clumped" distributions) within the polygon. Sample estimation areas ranged from 0.02 square meters (10 centimeters by 20 centimeters (3.9 inches by 7.9 inches)) to two square meters (one meter by two meters (3.3 feet by 6.6 feet)); the size, location, and number of samples were selected based on the professional judgment and

experience of the field biologists, depending on polygon size, plant density, and variation in plant density. SFVS numbers as estimated within each sample estimation area were extrapolated (based on area) and rounded to one significant figure (*e.g.*, 500; 100; 1,000) to represent the entire polygon.

Polygons for other special-status plant species were mapped utilizing aerial photography and topographic maps. The exception was CNPS List 4 species, which were considered to have a relatively low sensitivity level and were not specifically mapped. Professional judgment and experience were used to delineate these polygons based on the detectability of the species, topography, and vegetation. Perennial special-status plants were mapped at a 10- to 20-meter (32.8- to 65.6-foot) scale due to their population dynamics (including seed dispersal and pollination range), observability, habit, habitat limitations, and mapping accuracy.

4.5.3.2.3 Oak Tree Surveys

Oak tree surveys were conducted within the proposed Project development area (including a 200-foot buffer), while the number of oak trees to be preserved within protected areas (*e.g.*, High Country and River Corridor SMAs, the Salt Creek area, proposed spineflower preserves, and Open Area) has been estimated (Impact Sciences 2006B, 2006C, 2006D; Land Design Consultants 2007; RJA 2007; Dudek 2007D). Trees within the proposed development areas within the Specific Plan, VCC, and Entrada planning areas were mapped using a global positioning system (GPS). Tree stands (tree groupings) outside of these areas, in undisturbed or preserved areas, were delineated on aerial images and evaluated in the field *via* a sampling protocol and later statistically analyzed for population estimates.

In proposed development areas (including a 200-foot buffer), trees with minimum trunk diameters (eight inches for single trunks or a combined 12 inches for two stems on a multi-stemmed tree) were inventoried. Additionally, trees with trunks of five inches or larger diameter were recorded from specific areas in consideration of the Oak Woodlands Conservation Act (Pub. Resources Code, § 21083.4), the state law applicable to County oak woodland impact analysis (for counties without an oak ordinance in substantial conformance with the state law). Trees are measured at breast height (4.5 feet or 54 inches above grade). Each tree was evaluated for health, structural qualities, and aesthetic qualities. Dripline radius and the height of the branch at the dripline were also recorded.

Within the High Country SMA and the Salt Creek area, the density of oaks in the oak/grass vegetation communities was estimated from aerial photo interpretation, and the density of oaks in the oak woodland vegetation communities was estimated from a series of random samples within each oak woodland vegetation community. For the random samples, the number of oak trees was counted in the field within several polygons. A regression analysis was used to generate a linear formula relating number of acres to number of trees. The total number of oak

trees within oak woodland vegetation communities was estimated by extrapolating these calculated densities across all oak woodland vegetation communities within the study area that were not surveyed as part of this analysis. Using the density estimates for oak woodlands described above in combination with the aerial photo estimate of oaks in valley oak/grass and individual oak trees mapped in non-oak vegetation communities, the total number of oaks in the High Country SMA and Salt Creek area was estimated.

4.5.3.2.4 Wildlife Surveys

Documentation and determinations of the potential for special-status wildlife species to occur within the Project area have been supported by over 120 surveys completed between 1988 and 2008 by numerous biological consultants, including independent contractors and consulting firms, and have consisted of general, focused, and USFWS protocol-level surveys for a variety of wildlife species. As described in **Subsection 4.5.3.1** (Summary of Literature Review and Biological Studies Conducted in Project Area), prior to the field surveys, a literature review was performed to determine the special-status wildlife species that may be present in the Project area and vicinity and their suitable habitat types. **Table 4.5-6** in **Subsection 4.5.3.1** contains the list of the wildlife surveys completed in the Project area. In addition, the December 2008 Audubon Society Christmas Bird Count data for Castaic Junction (Cooper 2009), which is adjacent to the Project area on Newhall Land property, were reviewed to ensure that the special-status wildlife species database is current and accurate. A concise discussion of the survey components, including the survey methods used for five general taxonomic groups, is presented below. These taxonomic groups, including general guilds within each group, include birds (raptors, riparian, upland), invertebrates (butterflies, general insects, and aquatic mollusks (undescribed snail)), fish, reptiles and amphibians (low mobility ground dwelling and semi-aquatic), and mammals (bats, terrestrial mammals).

4.5.3.2.4.1 *General Wildlife*

General wildlife surveys typically involve general daytime walkover surveys of an area using meandering routes that sample all habitat types in an area and record all observations of species detected directly, visually or by vocalization (call or song), or by diagnostic sign, such as burrows, tracks, scat (fecal pellets), hair and fur, feathers, and bones. Many common or highly detectable species can be observed during general wildlife surveys, but reliable detection of seasonal, nocturnal, or cryptic species usually requires focused surveys conducted under suitable survey conditions, such as a certain time of year, time of day, or specific weather conditions, or using special survey methods, such as trapping or netting.

General wildlife surveys were conducted by RECON and Impact Sciences (1996) in the Specific Plan area and vicinity during spring and summer months. Impact Sciences (1997) conducted studies of upland habitat use by riparian associated bird species and small mammals along the

edge of the Santa Clara River. Dudek conducted general wildlife surveys in the High Country SMA and Salt Creek area in November and late December of 2005 and May through August of 2006 (Dudek and Associates 2006B), the VCC area in September (Dudek and Associates 2006D), and the Entrada area in September 2006 (Dudek and Associates 2006E). The Dudek surveys recorded all wildlife species observed using the various detection methods described above. In addition, many of the other surveys described in **Table 4.5-6** and described below recorded an inventory of all the species, both common and special-status, observed during the surveys. The Dudek surveys (Dudek and Associates 2006B, 2006D, 2006E) also provided evaluations of special-status species that were not observed, but have potential to occur based on existing habitat conditions.

4.5.3.2.4.2 *Invertebrates*

Butterflies. Focused surveys for the San Emigdio blue butterfly (*Plebulina emigdionis*) were conducted throughout the RMDP and Entrada sites in April and May 2004. A total of 64 site visits was completed in these areas in 2004 under suitable survey conditions, including air temperatures ranging from 58°F to 95°F, generally sunny skies, and calm winds (Compliance Biology 2004A, 2004B, 2004C). In April and May of 2005, three site visits for this species were conducted in Salt Canyon, which is within the High Country SMA, and Potrero Canyon, which is in the Specific Plan area of the RMDP (Compliance Biology 2005). Survey conditions included air temperatures ranging from 64°F to 90°F, partly cloudy to sunny skies, and calm winds. These studies also included a general butterfly inventory and a habitat assessment for the quino checkerspot butterfly (*Euphydryas editha quino*), a federally listed endangered species. The butterfly surveys were conducted by Guy P. Bruyea (Bruyea Biological Consulting), an independent butterfly consultant under contract to Compliance Biology with more than 16 years consulting experience and extensive knowledge of the Lepidoptera (butterfly) species expected to occur in the region. The surveys focused on areas where the San Emigdio blue butterfly and quino checkerspot butterfly would be expected to occur based on the presence of host plants, nectar sources, native vegetation communities associated with the host plant, and microhabitat features such as hilltops and ridgelines. An inventory was made of all butterfly species observed during the surveys.

RECON (1999) also conducted a habitat assessment for the quino checkerspot butterfly in early April 1999 in the Specific Plan Phase 1 development area (the northern portion of the Specific Plan area, including the Santa Clara River Valley, Homestead Canyon, Off-Haul Canyon, San Martinez Grande, Mid-Martinez Grande, and Chiquito Canyon). The habitat assessment focused on presence of the host plant dot-seed plantain (*Plantago erecta*) and suitable habitat features, such as ridges, hilltops, and valley bottoms and associated coastal scrub, chaparral, and grassland vegetation communities.

General Insects. A census of general insects in portions of the Project area was compiled by Jones *et al.* (2004) as part of the pollinator study for the SFVS. Because the study was focused on potential SFVS pollinators, observations and sampling were conducted in the vicinity of SFVS populations and thus did not sample the full range of habitat types in the Project area. Observations and sampling were conducted in April and May of 2004. Observations were conducted from dawn to dusk, with all insect visitors to SFVS recorded during the observation period. Sampling was conducted with aspirators, nets, and pitfall traps. Insect information for aquatic habitats was also collected by ACBL (2008) as part of the 2007 annual bioassessment monitoring of the Santa Clara River as part of the pre-discharge monitoring requirements for the Newhall Wastewater Reclamation Plant. Two sampling locations were visited in July 2007 and October 2007 using field protocols and assessment procedures in accordance with the draft Surface Water Ambient Monitoring Program (SWAMP) protocols.

Aquatic Mollusk. Focused surveys for aquatic mollusks have not been completed within the entire Project area. Until the discovery of the undescribed snail at the seep community in Middle Canyon Spring and subsequent observation of the snail in the lower Middle Canyon drainage, there was no indication that potentially sensitive gastropods are present in the Specific Plan area. Comprehensive surveys for the undescribed snail species therefore have not been completed on the Project site to date; therefore, their distribution is unknown beyond Middle Canyon. In 2007, Dudek biologists conducted a site visit to the Middle Canyon Spring as well as the lower reach of the Middle Canyon drainage to document the biotic conditions of the spring area (Dudek 2007C).

4.5.3.2.4.3 *Birds*

More than 65 surveys for avian species have been conducted from 1988 to 2008 along the Santa Clara River, along Castaic Creek, and in upland habitats of the Specific Plan, Entrada, and VCC planning areas (**Table 4.5-6**). Surveys were conducted by multiple permitted and qualified biologists including Daniel Guthrie, Zev Labinger, James Greaves, Pete Bloom, and biologists employed by RECON, Impact Sciences, PCR, Compliance Biology, SAIC, Forde Biological Consultants, and Dudek.

Generally the surveys were conducted on foot, and species were recorded through direct observation of individuals or by identification of calls and songs. Special-status species and active nests and territories were generally documented, if observed, either on aerial or topographic maps or by using a GPS receiver. Because most of the surveys were focused on federally and/or state-listed species, such as the least Bell's vireo, southwestern willow flycatcher, and coastal California gnatcatcher (*Polioptila californica californica*), and thus were

conducted according to USFWS survey protocols from 1992 on (see **Table 4.5-6**), the seasonal and daily timing of the surveys, as well as weather conditions (ambient temperature and wind), were appropriate for detecting most diurnal nesting and breeding birds.

The riparian bird surveys were conducted along both sides of the Santa Clara River within riparian vegetation and included the agriculture fields immediately adjacent to the River. The upland bird surveys were generally conducted within coastal scrub and buckwheat habitats, but also included chaparral, woodland, grasslands, and agriculture areas. With the exception of the winter survey (February 2007) conducted by Bloom Biological, Inc. (2007A), and described in more detail below, the surveys were conducted from the spring to mid-summer (March through July). The daytime surveys generally were conducted between the hours of 5:30 a.m. and 12:00 p.m., when birds are mostly likely to be vocalizing and detectable. Nocturnal surveys were conducted in 2000 (Guthrie 2000A, 2000D), and in 2007 (Bloom Biological 2007A).

Birds—Riparian. Riparian bird surveys have been conducted throughout the Project area since 1988 and comprise the largest component of the bird surveys. These surveys have generally focused on least Bell's vireo, southwestern willow flycatcher, and yellow-billed cuckoo, but all bird species observed during surveys were recorded. Many of these surveys were conducted by Daniel Guthrie from 1988 through 2006 within the portion of the Santa Clara River and Castaic Creek in and adjacent to the Project area boundary. In 1988 and 1989 these surveys focused on least Bell's vireo (two surveys) (Guthrie 1988, 1989, 1990); in 1990 and 1991 these surveys focused on southwestern willow flycatcher and yellow-billed cuckoo in addition to least Bell's vireo (three surveys) (Guthrie 1991A, 1991B); and from 1992 through 2006 Guthrie performed focused surveys for the least Bell's vireo generally following USFWS protocol guidelines, but also focused on observing southwestern willow flycatcher and yellow-billed cuckoo (Guthrie 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C).

Labinger and Greaves conducted surveys in 1994 and 1996 through 1998 within portions of the Santa Clara River corridor (Labinger *et al.* 1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A). Dudek conducted surveys within Castaic Creek, Salt Creek area, High Country SMA, and portions of the River corridor adjacent to the Project site in 2005 and 2006 (Dudek and Associates 2006B, 2006D, 2006E). Bloom Biological, Inc. conducted surveys within Castaic Creek and the Santa Clara River corridor from the I-5 bridge to Las Brisas Bridge west of the Ventura County line (Bloom Biological 2007A).

The surveys by Guthrie from 1988 to 1991 were generally conducted in April, May, and June in the early morning hours (6:00 a.m. to 10:00 a.m.). Suitable habitat was surveyed

for the least Bell's vireo, including southern willow scrub and southern cottonwood–willow riparian forest. Guthrie's surveys from 1992 to 2006 were generally conducted according to USFWS survey protocol guidelines, with some variation in the number of repeated site visits (*e.g.*, six instead of eight visits in 1995) and number of days between visits. The Bloom Biological, Inc. 2007 survey for least Bell's vireo and southwestern willow flycatcher followed USFWS protocol guidelines, was conducted from March through July, and covered the Santa Clara River and its tributaries within and adjacent to the Project site (Bloom Biological, Inc. 2007A).

Birds—Uplands. Surveys for upland bird species were conducted throughout the Project area and in nearby areas between 1995 and 2008. Upland habitats include coastal scrub, chaparral, grassland, and woodland as well as agriculture. Surveys in the Specific Plan area were conducted by a variety of the independent biologists and biological consulting firms listed above and covered the Landmark Village, Mission Village, and Homestead East and West areas as well as Potrero, Long, and Chiquito canyons and the upland habitats along the Santa Clara River (Bloom Biological, Inc. 2007A; Dudek and Associates 2006C; Guthrie 2000A, 2000B, 2004A, 2004D, 2004E; Impact Sciences 2000; RECON and Impact Sciences 1996; SAIC 2003). The High Country SMA and Salt Creek area (in the Specific Plan area) were surveyed by Dudek in 2005 and 2006 (Dudek and Associates 2006B). Upland surveys have also been conducted in the VCC (Dudek and Associates 2006D; Guthrie 2004B) and Entrada areas by Dudek and Guthrie (Dudek and Associates 2006E; Guthrie 2004G). Areas near the Project area that have been surveyed for upland bird species include the Legacy Village area adjacent to the Project site on the south and east (Guthrie 2004C) and the Castaic Junction area just north of the Entrada planning area (Guthrie 2004F, 2004I).

These upland surveys included USFWS protocol surveys for the federally-listed threatened coastal California gnatcatcher and were conducted by USFWS-permitted biologists in various locations in the Project area. Guthrie conducted surveys in 2000 and 2004 in Grapevine Mesa, Airport Mesa, VCC, Homestead, Chiquito Canyon, Long Canyon, Potrero Canyon, and Magic Mountain Entertainment (Entrada) (Guthrie 2000A, 2000B, 2000D, 2004A, 2004B, 2004D, 2004E, 2004G, 2004I). Dudek conducted USFWS protocol surveys within the Mission Village and Landmark Village proposed Project sites in 2007 through January 2008 (Priest 2007B; Lemons 2008). Focused surveys for the coastal California gnatcatcher have also been conducted off site in the Legacy Village area (Guthrie 2004C; Impact Sciences, Inc. 2000; SAIC 2003) and other adjacent off-site areas (Compliance Biology 2003B, 2006A; PCR 1998).

The survey methods for the coastal California gnatcatcher included conducting six or nine (Lemons 2008 only) USFWS protocol presence/absence surveys within suitable

coastal scrub habitat. Surveys were performed in the early morning hours (5:30 a.m. to 12:00 p.m.) between March and January. Surveys were conducted on foot, using both visual and auditory methods (call playback and pishing) to detect birds according to USFWS survey guidelines**.**

Birds—Raptors: Raptor surveys have been conducted by Bloom Biological, Inc. (2007A, 2008, 2009), beginning in late February 2007 and extending into June 2008, including burrowing owl surveys, white-tailed kite nesting and foraging surveys, and other raptor nest surveys. Most surveys were conducted up to one mile out from the Landmark Village project impact area boundary. The white-tailed kite surveys included an approximately 10-mile reach of the Santa Clara River from west of I-5 to Las Brisas Bridge in Ventura County, as well as all lands on Newhall Ranch, including both sides of SR-126, lower Salt Creek, and Potrero Canyon (Bloom Biological 2009). The raptor surveys generally were conducted during daylight hours, as well as up to six hours after sunset, by walking and/or driving systematically along dirt roads, footpaths, streambeds, and canyon bottoms throughout the survey area. Special emphasis was placed on thoroughly surveying all agricultural and abandoned fields, at dusk and dark hours, for presence of burrowing owls. In addition, several nights were spent surveying and camping in selected oak woodlands, in an attempt to detect the presence of long-eared owls. When white-tailed kites were detected foraging or nesting, they were observed for several hours if possible. Although all birds detected were recorded, special emphasis was placed on finding those considered to be of special status by federal and state resource agencies and conservation organizations. GPS waypoint locations were recorded for all special-status species locations. All active raptor nests were monitored throughout the survey period to determine outcome.

4.5.3.2.4.4 *Fish*

Three special-status fish species are known to occur in the Santa Clara River and Castaic Creek within the Specific Plan area: arroyo chub (*Gila orcutti*), Santa Ana sucker (*Catastomas santaanae*), and unarmored threespine stickleback (*Gasterosteus aculeatus williamsoni*). As described in **Table 4.5-6**, focused fish surveys have been conducted over multiple years since 1988 by various independent biologists and consulting firms to document the presence/absence of special-status fish species within the Project area.

The most recent and comprehensive fish surveys were conducted by ENTRIX (2009) in 2004 and 2005 in the portions of the Santa Clara River and Castaic Creek that occur within the proposed Specific Plan area. The tributary drainages of Salt Canyon, Potrero Canyon, Long Canyon, San Martinez Grande Canyon, Chiquito Canyon, Humble Canyon, Lion Canyon, and Middle Canyon were also surveyed. The surveys included habitat assessments and direct fish

sampling using dip nets or a small seine. At certain locations, bank observation was used when direct sampling was not feasible due to lack of access.

The ENTRIX (2009) habitat assessment and surveys focused on the three known special-status species in the area (the unarmored threespine stickleback, arroyo chub, and Santa Ana sucker). The survey and habitat assessment for unarmored threespine stickleback used a modified level-two version of CDFG protocols of the California Salmonid Stream Habitat Restoration Model. The survey reach for the stickleback survey was between Salt Creek Canyon and The Old Road Bridge, within which habitat type, length, mean width, mean and maximum depth, substrate composition, water and air temperature, and percent edgewater vegetation were recorded. All fish species observed in this reach were recorded during these surveys.

Additional surveys for fish species were conducted in 1988, 1995, 2000, 2002, and 2003 (Aquatic Consulting Services 2002A, 2002B, 2002C, and 2002D; Haglund 1989; SMEA (San Marino Environmental Associates) 1995, 2000; Impact Sciences 2003A, 2003B, 2003C, 2003D).

4.5.3.2.4.5 *Reptiles and Amphibians*

Surveys for reptiles and amphibians are separated into two categories—semi-aquatic reptiles and amphibians and terrestrial reptiles—because the life histories of these two groups are distinctly different and require different survey methods.

Semi-Aquatic Reptiles and Amphibians. Semi-aquatic reptiles and amphibians depend on riparian or aquatic resources and terrestrial habitats for at least a portion of their life histories. Semi-aquatic reptiles known or with potential to occur in the Project area include southwestern pond turtle, two-striped garter snake (*Thamnophis hammondii*), and south coast garter snake (*Thamnophis sirtalis*). Semi-aquatic amphibians known or with potential to occur in the Project area include arroyo toad and western spadefoot toad (*Spea hammondii*), and the more aquatic-obligate California red-legged frog (*Rana draytonii*).

Numerous surveys have been conducted for semi-aquatic reptiles and amphibians in the Santa Clara River and Castaic Creek within and in the vicinity of the Project area over multiple years between 1994 and 2007 (**Table 4.5-6**). In most cases, USFWS protocol surveys were conducted for the arroyo toad and other special-status reptiles and amphibians were noted anecdotally, although, as described below, some trapping for southwestern pond turtle and two-striped garter snake was conducted by San Marino Environmental Associates. After 1995, surveys for the arroyo toad were conducted according to USFWS protocol survey guidelines and included at least one senior-level biologist with an arroyo toad federal section 10(a)(1)(A) Recovery Permit or otherwise considered by the USFWS to be qualified to conduct arroyo toad surveys. Focused

surveys were also conducted for western spadefoot toad (Compliance Biology 2004E, 2006C). Surveys were conducted in suitable habitats, including in riparian and aquatic and immediately adjacent terrestrial habitats, on foot during the day in March through June during suitable weather conditions. Nocturnal surveys were also conducted for the arroyo toad per the USFWS survey protocol and western spadefoot toad. These surveys generally rely on visual or auditory (calls) detection of egg masses, tadpoles, metamorphs, juveniles, sub-adults, and adults.

San Marino Environmental Associates (SMEA 1995A) surveyed the Santa Clara River for aquatic species between Castaic Creek and Bouquet Canyon Road Bridge in May 1995. The surveys included nocturnal and diurnal surveys for arroyo toad (pre-1996 non-USFWS protocol), California red-legged frog, and western spadefoot toad, and trapping of southwestern pond turtles and two-striped garter snakes. Aquatic Consulting Services, Inc. (2002A, 2002B, 2002C, 2002D) conducted surveys for aquatic species through daytime walkover surveys from May to September 2000 along the Santa Clara River near the Commerce Center Drive Bridge, Castaic Junction area, and west of the Project area just upstream of the Salt Creek confluence with the River and upstream of the Las Brisas Bridge. Surveys by RECON (1999A), Aquatic Consulting Services (2002A, 2002B, 2002C, 2002D), Nancy Sandburg (2001), Impact Sciences (2001 and 2002), Ecological Sciences (2003A, 2003B, 2003C, 2003D, 2003E, 2003F, 2004A, 2004B, 2004C, 2004D, 2005A), (Compliance Biology 2004D), and Bloom (2007) included focused protocol surveys (except Sandburg 2001) and habitat evaluations for the arroyo toad. Compliance Biology (2004E, 2006C) conducted focused surveys for the western spadefoot toad within Landmark Village and Mission Village areas in March 2004. The focused surveys conducted for specific species also documented all aquatic species observed during the surveys.

In addition, Dudek conducted general wildlife surveys in Entrada (Dudek and Associates 2006E) and Salt Creek (Dudek and Associates 2006B) and recorded observed semi-aquatic species.

Terrestrial Reptiles. Terrestrial reptiles include various snakes and lizards that primarily use dry upland habitats, such as grasslands, coastal scrub, and chaparral, but also may use riparian scrubs, such as alluvial scrub, big sagebrush scrub, and river wash habitats. They may also occur in riparian habitats, but usually when conditions are relatively dry. Common and generally highly visible terrestrial reptiles include gopher snake (*Pituophis melanoleucus*), western rattlesnake (*Crotalus viridis*), coastal western whiptail (*Aspidoscelis tigris stejnegeri*), side-blotched lizard (*Uta stansburiana*), and western fence lizard (*Sceloporus occidentalis*). Other more cryptic or less detectable reptiles include silvery legless lizard (*Anniella pulchra pulchra*), coast horned lizard

(*Phrynosoma coronatum blainvillei*), San Bernardino ringneck snake (*Diadophis punctatus modestus*), and coast patch-nosed snake (*Salvadora hexalepis virgultea*).

Most reptile species, even if present in an area, are difficult to detect because of their thermoregulatory and behavioral (*e.g.*, foraging) patterns and cryptic nature. Most species are only active within relatively narrow thermal limits, avoiding both cold and hot conditions, and most take refuge in microhabitats that are not directly visible to the casual observer, such as rodent burrows, in crevices, under rocks and boards, and in dense vegetation where they are protected from unsuitable environmental conditions and predators. They may only be observed when disturbed from refugia.

Pitfall trapping is an effective technique for sampling terrestrial reptiles, although its efficacy depends on the species, and some species probably are under-sampled by this method. It may be biased toward highly mobile species or active hunters, such as whipsnakes, and biased against more larger, more sedentary species that are sit-and-wait predators, such as rattlesnakes or those that move beneath the surface, such as the legless lizard. Common anurans that use upland areas, such as western toad (*Bufo boreas*), also may be commonly captured in pitfall traps

Two rounds of pitfall surveys were conducted by Impact Sciences (2006A) within the Mission Village, Landmark Village, Homestead, and Potrero Village development areas. The focus of the surveys was to develop a general understanding of the diversity of reptile species occurring in a variety of habitat types within these areas. The first round occurred from September 29 through October 6, 2004, and the second occurred from August 21 through August 25, 2006. Pitfall trap lines were installed in various habitat types to obtain a representative sample of reptile distribution. The habitat types surveyed included, but were not limited to, California sagebrush scrubs, chaparrals, oak woodland, riparian, and grassland. Five-gallon buckets, used as pitfall traps, were placed at ground level and spaced 40 feet apart along transects made of two-foot-high silt fencing (drift fences). On average, 10 buckets occurred on each transect. Trap lines were surveyed for five consecutive days, and each trap line was checked twice a day, once during the morning hours between 6:00 a.m. and 9:00 a.m. and again between 4:00 p.m. and 6:00 p.m.

A focused survey was also conducted for the silvery legless lizard, a species that is less likely to encounter pitfall traps because of its underground activity. An effective sampling method for the legless lizard is hand raking in suitable habitats, including sandy or loose soils in coastal scrub, chaparral, cottonwood, and oak vegetation communities. Impact Sciences (2006A) conducted hand raking surveys in 10 locations with potential habitat in the Specific Plan area from October 3 through October 7, 2004, in the late

afternoon or early morning in ambient temperatures ranging from 80°F to 90°F. Although early fall is not an optimum time for such surveys because individuals may have been estivating at this time, legless lizards were found, as described in more detail in **Subsection 4.5.5.3**.

General wildlife surveys also recorded any reptile species observed.

4.5.3.2.4.6 *Mammals*

The discussion of mammal surveys is separated into a discussion of bat surveys and terrestrial mammal surveys because of the specialized survey methods used for these two groups.

Bats. Two focused bat surveys were conducted in the Project area by Impact Sciences in 2004 and 2006 (Impact Sciences 2005, Johnson 2006). The 2004 survey used the Anabat II Bat Detector, which converts ultrasonic echolocation signals of bats into audible electronic signatures that, in many cases, can be used to identify the species of bat emitting the signal using standard reference computer programs. The Anabat has limitations, however, because some species are not readily detected by the Anabat Detector and also because signals may be incomplete and only allow identification of frequency ranges that are diagnostic of several bat species. For example, Anabat systems are typically set to detect bat echolocation calls in the 20 to 100 kHz range, and western mastiff bat (*Eumops perotis californicus*) typically emits pulses in the range of 9 to 14 kHz. However, this species is audibly detectable to the human ear and is one of only three California bat species easily detected by the unaided human ear. The Townsend's big-eared bat (*Corynorhinus townsendii*) is typically a high-altitude foraging species, which also can limit its detection with the Anabat Detector. Because of the limitation of the Anabat, mist netting was used in 2006 to capture bats that may not have been reliably identified using the Anabat Detector.

The 2004 acoustic surveys using the Anabat Detector were conducted throughout the Project area in a variety of habitats that could support special-status and common bat species, including coast live oak woodland, riparian, agriculture, mule fat scrub, and grassland. The survey areas included Salt Creek Canyon, Potrero Canyon, Santa Clara River corridor, Homestead Village, Landmark Village, and Mission Village (Impact Sciences 2005). The 2006 surveys using the Anabat Detector, mist netting, and visual/audible detection methods were conducted in Landmark Village, in Potrero Canyon, and near The Old Road (Johnson 2006). The 2006 surveys were conducted both during the daytime and nighttime near roosting sites and in areas where concentrated bat activity was expected, such as streams, hydric areas, ponds, and stock tanks. During the day, structures were visually inspected with the aid of flashlights and spotlights, and the presence of bats was detected based on the presence of bats or their sign (*e.g.*, guano,

urine stains). During the night, surveys consisted of visual observations, capture with mist nets, and acoustic monitoring of free-flying bats.

Terrestrial Mammals. One focused terrestrial mammal assessment and survey was conducted in the Project area by Impact Sciences in 2004 (Impact Sciences 2005). This assessment and survey was designed to collect information for high-mobility species (*e.g.*, mountain lion (*Puma concolor*) and mule deer (*Odocoileus hemionus*)), moderate-mobility species (*e.g.*, American badger (*Taxidea taxus*)), and low-mobility species (*e.g.*, most rodents). Survey methods included camera and scent/track stations and spotlight surveys to detect the high- and moderate mobility species and small mammal live trapping to inventory rodents species throughout the Project area in a variety of habitats. Camera stations were set up in March and April near the Santa Clara River and Chiquito Canyon, west of Grapevine Mesa, and near an agriculture field and along the Santa Clara River near Potrero Mesa. Scent/track stations were set up between March and September in various habitats in canyons, ridges, along agriculture fields, and near the Santa Clara River. The stations were baited, and flour was used to check for tracks. Spotlight surveys were conducted in July through September with two biologists scanning the vegetation while driving slowly along roads throughout the Project area. The small mammal live trapping was conducted from July through September using Sherman live traps, which were placed in all habitat types and were baited with canned cat food, which is appropriate for attracting most small rodents, including the special-status southern grasshopper mouse (*Onychomys torridus ramona*). Thirty-four grids were used with 80 traps per grid, resulting in a total of 13,500 trap nights.

Other general wildlife surveys that recorded mammal observations included those conducted by Dudek in the High Country SMA and Salt Creek area (Dudek and Associates 2006B), Valencia Commerce Center (Dudek and Associates 2006D), and the Entrada area (Dudek and Associates 2006E).

4.5.3.3 Existing Conditions by Project Planning Area

This section provides an overview of the physical and biological conditions present within the RMDP, VCC, and Entrada planning areas; areas designated as Open Area; and the natural areas such as the River Corridor SMA, the High Country SMA, and Salt Creek area.

4.5.3.3.1 RMDP

The RMDP study area is depicted on **Figure 4.5-9**, RMDP/SCP – Landscape Features, along with the proposed open space designations and development areas. The special-status biological areas within this study area encompass the Specific Plan's River Corridor SMA, High Country SMA, Salt Creek area, and Open Area. More detailed information regarding the River Corridor SMA, High Country SMA, Salt Creek area, and Open Area is provided in this subsection, following a general discussion of the RMDP area.

The RMDP study area includes areas north of SR-126 between Chiquito Canyon and the Ventura County line. South of SR-126, the RMDP study area includes areas between Airport Mesa and Salt Creek, including Middle, Humble, Lion, Long, and Potrero canyons. Salt Creek extends south into the High Country SMA and the Salt Creek area.

The RMDP study area is topographically diverse with slope gradients ranging from moderate to steep in the hillsides, to very gentle in the Santa Clara River floodplain and in major tributary canyons. Two large mesas (*e.g.*, Grapevine Mesa and Airport Mesa) are adjacent to the Santa Clara River (**Figure 4.5-9**, RMDP/SCP – Landscape Features). This study area is dominated by east-, west-, and northwest-trending primary ridges, with north- and south-trending secondary ridges. Distinctive ridges in the Specific Plan site include the Sawtooth Ridge, along the northeastern side of Long Canyon, and Ayres Rock, south of Potrero Mesa. Site elevations range from 825 feet above mean sea level (AMSL) in the Santa Clara River bottom at the Ventura County/Los Angeles County line to approximately 3,200 feet AMSL on the ridgeline of the Santa Susana Mountains along the southern boundary.

4.5.3.3.1.1 *Past and Current Land Use.*

Most of the RMDP study area has been subject to various anthropogenic (human-related) disturbances for decades. SR-126 parallels the Santa Clara River, and both Southern California Edison (SCE) and Southern California Gas Company (SCGC) have utility and transmission corridors along the southern portion of the site. The existing utilities and access roads are actively maintained by the SCE and SCGC. Newhall Land has also historically leased, and continues to lease, portions of the RMDP for oil and natural gas production, cattle grazing, and agricultural operations (*e.g.*, food crop production, dryland farming, honey farming). See **Figure 4.5-10**, RMDP/SCP – Ongoing Agricultural, Grazing Practices, and Oil Leases under No

Action/No Project Alternative, for the locations of these land use practices. These ongoing activities have resulted in the degradation or elimination of habitat within portions of the RMDP (*e.g.*, road construction, grazing lots, and oil pad construction) and have affected the types of biological resources that occur in those areas. For example, there are over 30 historical or occupied oil pads between Airport Mesa and Grapevine Mesa that remain cleared of vegetation. Oil pads and their associated access roads are also present within Humble and Potrero canyons. Extensive agricultural practices have been conducted across the RMDP, particularly on Grapevine Mesa, Potrero Mesa, Onion Fields, and within many of the tributary canyons that flow into the Santa Clara River. Both dry land and irrigated agricultural practices have been conducted in Middle, Humble, Long, and Potrero canyons and in portions of Salt Creek canyon. Agricultural operations have long occurred within the alluvial soils bordering the Santa Clara River, and they abut the northern border of the riparian corridor in many areas.

The long-term effects of cattle grazing are apparent in many sections of the RMDP area. Cattle can affect the vegetation community in an area by reducing native vegetation, increasing erosion, and impairing water quality. Extensive grazing can also facilitate the colonization of weedy annual species that quickly become the dominant plant community on site. In Middle and Potrero canyons, cattle remain the dominant foragers within portions of the remaining riparian communities. By grazing on riparian vegetation, cattle may alter the successional pathways of riparian systems and limit the establishment of woody vegetation. Extensive cattle grazing may also "powder out" soft soils that quickly become denuded of vegetation.

Portions of the RMDP site also have been subject to periodic wildfires. Although periodic fires are part of the natural ecosystem, fires burning too frequently can have significant long-term ecological effects, such as degradation of habitat (temporal loss of habitat and non-native plant species invasion) and loss of special-status species. The biodiversity of coastal scrub and chaparral communities is uniquely adapted to low rainfall, rugged topography, and wildfires. However, fires have become more frequent with growth of the human population, creating a situation in which vegetation communities (and, therefore, habitats for plant and animal species) are changed dramatically and may not recover. This change in vegetation community is called "type conversion" and can occur in any native vegetation community. When burned too frequently, vegetation communities are often taken over by highly flammable, weedy, non-native plant species that burn even more often and provide minimal habitat value for native plant and animal species, especially those of special status. The widespread disturbance from the Verdale and Simi wildfires of 2003 is still visible in the RMDP area, primarily within the western and southern portions of the Specific Plan site. The effects of these fires, particularly in areas experiencing grazing pressure, have resulted in type conversion from scrubland to annual grasslands. In 2007, portions of the RMDP near Lion and Exxon canyons were also subject to wildfires.

4.5.3.3.1.2 *Vegetation Communities and Land Covers.*

The broad, alluvial Santa Clara River Valley is botanically diverse, wedged between the Santa Susana Mountains, the Los Padres National Forest, and the Angeles National Forest. Though varied floristic influences exist at the RMDP today, the pre-development vegetation type was probably characterized by various pure stands of riparian, coastal scrub, and chaparral communities. While many sections of the RMDP have been altered and disturbed, the area still supports many high-quality native plant associations found in the ecosystems of the Santa Susana Mountains and the Santa Clara River.

As in much of the Santa Clara River Valley, historical disturbance has altered much of the pre-existing vegetation in the RMDP. The vegetation communities on the RMDP site vary in quality from high-biological-value riparian and upland habitat to highly disturbed land, such as agricultural areas and graded oil well pads (**Figures 4.5-11-A1** through **4.5-11-C2**, RMDP/SCP – Vegetation Communities and Land Covers). As described above, the long-term management of the RMDP site for agriculture and grazing has led to the establishment of weedy annual species in some areas. Fire and other anthropogenic disturbances have also altered some community types. Upland vegetation communities dominate the landscape within the Specific Plan site, both north and south of the Santa Clara River. The dominant upland vegetation communities include coastal scrub, chaparral, coast live oak woodlands, valley oak woodlands and grasses, California annual grasslands, and big sagebrush scrub. Agriculture also occurs in many upland areas and is bordered by various coastal scrub communities.

Some of the upland areas supporting agricultural practices in the RMDP include Chiquito Canyon, Indian Dunes, Airport Mesa, Middle Canyon, Grapevine Mesa, Potrero Mesa, Onion Fields, Salt Creek Canyon, and areas along SR-126. Depending on the season, these areas may be subject to a variety of crops, including cereal grains, cilantro, cabbage, onions, and sod. At other times these areas are left fallow and may quickly become dominated by common non-native invasive species. Fallow areas are dominated by herbaceous, introduced, pioneering plant species that readily colonize open, disturbed soil and thrive as a result of human impacts.

Airport Mesa has been used for agricultural activities for a number of years, typically for irrigated crops. During the spring of 2008, Airport Mesa was fallow and supported dense populations of weedy annuals, including brome grasses (*Bromus madritensis*, *B. diandrus*, *B. hordeaceus*), barley (*Hordeum* sp.), wild oats (*Avena barbata*, *A. fatua*), and rye grasses. In many locations non-native annual species, such as cheeseweed (*Malva parviflora*) black mustard (*Brassica nigra*), short-podded mustard (*Hirschfeldia incana*), and red-stemmed filaree (*Erodium cicutarium*) comprised the dominant vegetative cover. Wildflowers were also common and included redmaids (*Calandrinia ciliata*), blue dicks (*Dichelostemma capitatum*), California poppy (*Eschscholzia californica*), Lindley's annual lupine (*Lupinus bicolor*), and

various species of phacelia (*Phacelia* spp.). San Fernando Valley spineflower is located to the east, south, and west of Airport Mesa.

To the south of Airport Mesa, Magic Mountain Canyon supports river wash and big sagebrush scrub along the canyon bottom, with adjacent areas supporting coastal scrub and disturbed land. Disturbed land is land that has been recently or repeatedly disturbed by grading or compaction (*e.g.*, dirt roads) and is primarily lacking vegetation. The river wash occurs within the low-flow channel, and it includes sporadic native shrubs, such as Great Basin sagebrush (*Artemisia tridentata*) and scale-broom (*Lepidospartum squamatum*), as well as a variety of herbaceous species, including native herbs such as common eucrypta (*Eucrypta chrysanthemifolia*), wild rhubarb (*Rumex hymenosepalus*), telegraph weed (*Heterotheca grandiflora*), and prickly cryptantha (*Cryptantha muricata*) and non-native herbs such as tree tobacco (*Nicotiana glauca*) and tocalote (*Centaurea melitensis*). The big sagebrush scrub includes native shrubs (Great Basin sagebrush, yerba santa (*Eriodictyon crassifolium*), and California sagebrush (*Artemisia californica*)) as well as herbaceous species, including native plants (such as California aster (*Lessingia filaginifolia*), wild cucumber (*Marah macrocarpus*), shrubby phacelia (*Phacelia ramosissima*), and common owl's clover (*Castilleja exserta*)) and non-native herbs (red-stemmed filaree, tree tobacco, milk thistle (*Silybum marianum*), and horehound (*Marrubium vulgare*))**.** The coastal scrub includes areas that are characterized as heterogeneous scrub as well as areas dominated by California sagebrush, purple sage (*Salvia leucophylla*), and California buckwheat (*Eriogonum fasciculatum*). These coastal scrub vegetation communities also include native shrubs, such as squaw bush (*Rhus trilobata*) and chaparral bush mallow (*Malacothamnus fasciculatus*), and smaller native species, such as blue dicks, deerweed (*Lotus scoparius*), California encelia (*Encelia californica*), California poppy, chaparral nightshade (*Solanum xanti*), chick lupine (*Lupinus microcarpus*), common owl's clover, and California wishbone-bush (*Mirabilis laevis* var. *crassifolia*); non-native herbs, such as short-podded mustard and red-stemmed filaree, are also present.

East and west of Airport Mesa, coastal scrub and California annual grassland are the most common vegetation communities. The coastal scrub includes areas that are characterized as California sagebrush, as well as areas dominated by purple sage and California buckwheat. These coastal scrub vegetation communities also include native shrubs, such as Mexican elderberry (*Sambucus mexicana*), white sage (*Salvia apiana*), California encelia, and coastal prickly-pear (*Opuntia littoralis*); smaller native species, such as deerweed, wild cucumber, chick lupine, California wishbone-bush, silver puffs (*Uropappus lindleyi*), yellow pincushion (*Chaenactis glabriuscula*), slender woolly buckwheat (*Eriogonum gracile var. gracile*), yellow fiddleneck (*Amsinckia menziesii*), and California melic (*Melica imperfecta*); and non-native species (red-stemmed filaree, tocalote, and tree tobacco). In addition to non-native grasses (bromes, wild oat, and goldentop (*Lamarckia aurea*)), California annual grassland includes a variety of native herbaceous species, such as blue dicks, yellow fiddleneck, silver puffs,

Lindley's annual lupine, angel gilia (*Gilia angelensis*), strigose deerweed (*Lotus strigosus*), and slender pectocarya (*Pectocarya linearis*), and non-native species, including red-stemmed filaree and milk thistle. San Fernando Valley spineflower is present within the coastal scrub and California annual grassland vegetation communities to the north, east, and south of Airport Mesa.

Grapevine Mesa, although typically in active, irrigated agricultural use, was fallow in the spring of 2008 and also supported weedy herbaceous annual plant communities. Most of Grapevine Mesa was dominated by cheeseweed, red-stemmed filaree, short-podded mustard, London rocket (*Sisymbrium irio*), and California bur-clover (*Medicago polymorpha*). Russian thistle (*Salsola tragus*), milk thistle, and horehound were also present. San Fernando Valley spineflower is located to the east and west of Grapevine Mesa.

To the east of Grapevine Mesa, Lion Canyon runs along a northwest/southeast trending line and is a tributary to the Santa Clara River. Lion Canyon supports a variety of vegetation communities, including river wash and big sagebrush scrub along the canyon bottom with coast live oak woodland, coastal scrub, and chaparral along the canyon slopes. The river wash includes scattered native shrubs, such as scale-broom and mulefat (*Baccharis salicifolia*), and smaller herbaceous species, such as yellow pincushion, butterweed (*Senecio flaccidus* var. *douglasii*), deerweed, silver puffs, lacy phacelia (*Phacelia tanacetifolia*); non-native herbaceous plants are also present, including common groundsel (*Senecio vulgaris*), lamb's-quarters (*Chenopodium album*), and tocalote. The big sagebrush scrub includes native shrubs (Great Basin sagebrush, squaw bush, and scale-broom) but also includes a variety of native herbaceous species, such as blue fiddleneck (*Phacelia distans*), wild rhubarb, globe gilia (*Gilia capitata*), angel gilia, annual burweed (*Ambrosia acanthicarpa*), California fluffweed (*Filago californica*), and rusty popcorn flower (*Plagiobothrys canescens*), and non-native plants, including bull thistle (*Cirsium vulgare*), rubber rabbitbrush (*Chrysothamnus nauseosus*), and Russian thistle. In addition to coast live oak trees (*Quercus agrifolia*), the coast live oak woodland includes a variety of native herbaceous species, including blue fiddleneck, chaparral nightshade, American bowlesia (*Bowlesia incana*), California goosefoot (*Chenopodium californicum*), blue dicks, wild cucumber, globe gilia, and angel gilia, and non-native plants (tocalote, red-stemmed filaree, common chickweed (*Stellaria media*), and tree tobacco). The coastal scrub includes areas that are characterized as heterogeneous scrub as well as areas dominated by coastal sagebrush and California buckwheat. These coastal scrub vegetation communities also include native shrubs, such as purple sage, Great Basin sagebrush, and Our Lord's candle (*Yucca whipplei*); smaller native plants, such as California wishbone-bush, yellow pincushion, California dodder (*Cuscuta californica*), lacy phacelia, long-stem golden yarrow (*Eriophyllum confertiflorum*), common forget-me-not (*Cryptantha intermedia*), and common owl's clover; and non-native plants (red-stemmed filaree, short-podded mustard, and horehound). The chaparral includes native shrubs (squaw bush, golden currant (*Ribes aureum*), mainland cherry, and California

buckwheat); native herbaceous species, such as blue dicks, yellow pincushion, California poppy, sacapellote (*Acourtia microcephala*), lacy phacelia, angel gilia, California peony, yellow fiddleneck; and non-native herbaceous species (tocalote and red-stemmed filaree).

To the west of Grapevine Mesa, Humble Canyon supports river wash and coast live oak woodland along the canyon bottom (and along unnamed tributaries to Humble Canyon), and chaparral and California annual grassland along the canyon slopes. The river wash includes scattered native shrubs, such as goldenbush (*Isocoma menziesii*) and mulefat, and smaller native species, such as Lindley's annual lupine, lacy phacelia, deerweed, common forget-me-not, mustard primrose (*Camissonia californica*), and common eucrypta, as well as the non-native milk thistle. In addition to coast live oak trees, the coast live oak woodland includes native shrub and herbaceous plants, such as goldenbush, Great Basin sagebrush, common owl's clover, California aster, yellow fiddleneck, wild cucumber, elegant clarkia (*Clarkia unguiculata*), miner's lettuce (*Claytonia perfoliata*), wild pea (*Lathyrus vestitus*), Parry's larkspur (*Delphinium parryi*), and California mugwort (*Artemisia douglasiana*), and non-native herbaceous species, such as hedge mustard (*Sisymbrium officinale*), common sow-thistle (*Sonchus oleraceus*), and goose grass (*Galium aparine*). In addition to non-native grasses, such as bromes and wild oat, the California annual grassland is populated by a variety of herbaceous species, including native plants (common owl's clover, California poppy, rusty popcorn flower, Lindley's annual lupine, chick lupine, silver puffs, and yellow fiddleneck) and non-native plants (short-podded mustard, yellow sweet-clover (*Melilotus indica*), Russian thistle, and tocalote). The chaparral includes native shrubs, such as squaw bush, chamise (*Adenostoma fasciculatum*), chaparral bush mallow, and mountain mahogany (*Cercocarpus betuloides*); and smaller, more herbaceous native species, such as California wishbone-bush, Lindley's annual lupine, California poppy, rusty popcorn flower, whispering bells (*Emmenanthe penduliflora*), globe gilia, sacapellote, and redmaids; non-native herbaceous species are also present, including short-podded mustard, red-stemmed filaree, and Russian thistle.

Onion Fields, located at the mouth of Long Canyon on a terrace above the Santa Clara River, is maintained as an irrigated sod farm. Additional agricultural areas extend up into Long Canyon; left fallow in 2008, these agricultural areas are dominated by many of the same weedy annual herbaceous plants described for Airport Mesa and Grapevine Mesa. Long Canyon supports a variety of vegetation communities, including river wash and big sagebrush scrub along the canyon bottom with coast live oak woodland, coastal scrub, and chaparral along the canyon slopes. The river wash includes scattered native plants (scale-broom, yellow fiddleneck, common forget-me-not, mustard primrose, common eucrypta, annual burweed, yellow pincushion, and sun cup (*Camissonia hirtella*)). The big sagebrush scrub includes native plants (Great Basin sagebrush, whispering bells, lacy phacelia, strigose deerweed, Coulter's lupine (*Lupinus sparsiflorus*), common owl's clover, blue dicks, lastarriaea (*Lastarriaea coriacea*), wild cucumber, and wild rhubarb) and non-native plants (yellow sweet-clover, common sow-thistle,

and tumble mustard (*Sisymbrium altissimum*)). The coastal scrub includes areas that are characterized as heterogeneous scrub as well as areas dominated by coastal sagebrush, black sage (*Salvia mellifera*), and purple sage. These coastal scrub vegetation communities also include native shrubs, such as California encelia, giant rye grass (*Leymus condensatus*), bush monkeyflower (*Mimulus aurantiacus*), and chaparral bush mallow; smaller native plant species, such as common eucrypta, blue dicks, granny's hairnet (*Pterostegia drymarioides*), shrubby phacelia, California dodder, and cliff malocothrix (*Malacothrix saxatilis*); and non-native herbaceous species, including yellow sweet-clover, short-podded mustard, and red-stemmed filaree. The chaparral includes densely vegetated areas that are characterized as heterogeneous chaparral as well as areas dominated by chamise chaparral. These chaparral vegetation communities also include additional native shrubs, such as squaw bush, chaparral bush mallow, prickly phlox (*Leptodactylon californicum*), and mountain mahogany; smaller native plant species, such as heart-leaf penstemon (*Keckiella cordifolia*), common forget-me-not, California butterweed (*Senecio californicus*), white snapdragon (*Antirrhinum coulterianum*), California goosefoot, and California peony; and non-native herbaceous species (red-stemmed filaree).

Potrero Mesa, located above and between Ayers and Potrero canyons, also supports various agricultural practices. Fallow in the spring of 2008, this area is also dominated by many of the same weedy herbaceous annuals described for the Airport and Grapevine mesas, but also includes small populations of non-native plants (shepherd's purse (*Capsella bursa-pastoris*) and common sow thistle) as well as native wildflowers, such as Lindley's annual lupine, California poppy, and yellow fiddleneck.

A small narrow ridge bisects the northwest portion of Potrero Mesa. Both the narrow ridge and the surrounding terrain support coastal scrub and California annual grassland. The coastal scrub includes areas that are characterized as heterogeneous scrub, as well as areas dominated by coastal sagebrush and black sage. These coastal scrub vegetation communities also include native shrubs, such as purple sage, California sagebrush, squaw bush, Mexican elderberry, giant ryegrass, California encelia, and coyote brush (*Baccharis pilularis*); smaller native plants, such as arroyo lupine (*Lupinus succulentis*), yellow fiddleneck, California melic, sacapellote, Santa Barbara locoweed (*Astragalus trichopodus*), chaparral nightshade, and California aster; and non-native annuals, such as winter vetch (*Vicia villosa*), red-stemmed filaree, tocalote, and common sow-thistle. In addition to non-native grasses, such as bromes and wild oat, the California annual grassland is populated by a variety of herbaceous species, including native plants (California poppy, arroyo lupine, western jimson weed (*Datura wrightii*), yellow fiddleneck, and Indian tobacco (*Nicotiana quadrivalvis*)) and non-native plants (cheeseweed (*Malva parviflora*), Russian thistle, tree tobacco, prickly sow-thistle (*Sonchus asper*), and Mediterranean canary grass (*Phalaris minor*)).

Potrero Canyon, a tributary to the Santa Clara River, is connected to the High Country SMA through Windy Gap at the downstream end and through Via Canyon at the upstream end. Potrero Canyon has been substantially altered over the years through oil agricultural operations. Virtually all of the flat and gently sloping areas along the canyon bottom have been actively disked on an annual basis, and oil platforms, distribution centers and associated dirt roads are actively maintained. These activities account for the substantial areas mapped as agriculture and disturbed land within the canyon. Through many years of cattle grazing, large expanses of California grassland have become intermixed with the agriculture and disturbed land. As described above, disturbed land is land that has been recently or repeatedly disturbed by grading or compaction, and is primarily lacking vegetation. The California annual grassland includes native wildflower species, such as arroyo lupine, yellow fiddleneck, California poppy, California aster, and California fuchsia, and non-native weedy species, such as milk thistle, short-podded mustard, red-stemmed filaree, and shepherd's purse. A narrow riparian corridor hugs the northeast slope of the canyon. Based on a review of topographic maps and visual observations, it appears that the riparian corridor may have been more centrally located in the channel bottom, prior to the long-time agricultural operations. The upper reaches of Potrero Canyon Creek include river wash and big sagebrush scrub. The middle reaches include narrow bands of southern willow scrub, mulefat scrub, and southern cottonwood–willow riparian forest. The lower reaches include cismontane alkali marsh, coastal and valley freshwater marsh, and patches of mulefat scrub, southern willow scrub, shrub tamarisk, Mexican elderberry scrub, and southern cottonwood–willow riparian forest. River wash supports scattered native herbaceous plants, including chia (*Salvia columbariae*), western jimson weed, California fluffweed, southern sun cup (*Camissonia bistorta*), and common forget-me-not, and non-native plants, such as short-podded mustard, tree tobacco and red-stemmed filaree. Big sagebrush scrub includes native shrubs (Great Basin sagebrush and quail brush (*Atriplex lentiformis*)); smaller native plants, such as cocklebur (*Xanthium strumarium*); and non-native plants, such as Australian saltbush (*Atriplex semibaccata*), milk thistle, and tocalote. Mulefat scrub includes native shrubs (mulefat, quail brush, and coyote brush); smaller native species, such as cocklebur, western ragweed (*Ambrosia psilostachya*), California mugwort (*Artemisia douglasiana*), and wild heliotrope (*Heliotropium curassavicum*); and non-native species, such as cheeseweed, yellow sweet-clover, and tamarisk (*Tamarix ramosissima*). Southern willow scrub includes native trees and shrubs (arroyo willow (*Salix lasiolepis*), quail brush, mulefat, coyote brush, and giant ryegrass); and non-native species, such as yellow sweet-clover, tamarisk, short-podded mustard, and cheeseweed. Shrub tamarisk is dominated by tamarisk but also includes scattered native plants (coyote brush and mulefat) and the non-native short-podded mustard. Mexican elderberry scrub includes Mexican elderberry shrubs as well as an understory of non-native plants, such as milk thistle, short-podded mustard, and tree tobacco. Southern cottonwood–willow riparian forest supports an overstory of Fremont cottonwood (*Populus fremontii*) and arroyo willow; native shrubs, such as Great Basin sagebrush, quail brush, giant creek nettle (*Urtica dioica*), and

mulefat; native herbaceous species, such as wild cucumber; and non-native plants (Italian thistle (*Carduus pycnocephalus*), horehound, and milk thistle). The cismontane alkali marsh in Potrero Canyon is an herbaceous community dominated by salt grass (*Distichlis spicata*); the higher elevations and edges support native plants (yerba mansa (*Anemopsis californica*), western ragweed, and spearscale (*Atriplex triangularis*)) and non-native plants (yellow sweet-clover, five-hooked bassia (*Bassia hyssopifolia*), and peppergrass (*Lepidium latifolium*)). Where water is actually flowing in small rills at the surface, winged three-square (*Scirpus americanus*) and Mexican rush (*Juncus mexicanus*) also occur. Coastal and valley freshwater marsh supports native herbaceous species, such as broad-leaved cattail (*Typha latifolia*) and winged three-square, with native plants (yerba mansa and western ragweed) and non-native plants (wild celery (*Apium graveolens*) and rabbit's-foot grass (*Polypogon monspeliensis*)) occurring at the fringes.

The steeper portions of Potrero Canyon include coastal scrub areas that are characterized as heterogeneous scrub, as well as areas dominated by California sagebrush and purple sage. These coastal scrub vegetation communities also include native shrub species, such as white sage, Great Basin sagebrush, and chaparral bush mallow; smaller native plants, such as coastal lotus (*Lotus salsuginosus*), California peony, chick lupine, whispering bells, silver puffs, and California aster; and non-native herbaceous plants, such as milk thistle, yellow sweet-clover, and tocalote. Valley oak grassland is also present at higher elevations on the south side of the downstream end of the canyon. In addition to the scattered valley oak (*Quercus lobata*) trees and non-native grasses, such as bromes and wild oat, this vegetation community includes an understory of native herbaceous species, such as miner's lettuce, California fuchsia, common owl's-clover, yellow fiddleneck, blue dicks, common lomatium (*Lomatium utriculatum*), and chaparral nightshade, and non-native herbaceous species, such as common chickweed, short-podded mustard, black mustard, and common sow-thistle. Coast live oak woodland occurs in the upper reaches of the canyon and includes an overstory of coast live oak, with native shrubs (Mexican elderberry and yerba santa) and smaller native plants, such as miner's lettuce, long-stem golden yarrow, common eucrypta, common owl's-clover, Pacific sanicle (*Sanicula crassicaulis*), and California melic, and non-native herbaceous plants, such as hedge mustard, goose grass, horehound, and cheeseweed.

Chiquito Canyon lies primarily to the north of SR-126 and supports agriculture areas along the flatter portions of the canyon bottom, on either side of the incised creek, on the east side of Chiquito Canyon Road. The incised creek supports a pocket of southern cottonwood–willow riparian forest at the upstream end of the creek, and the remaining portions of the creek include river wash and big sagebrush scrub. The southern cottonwood–willow riparian forest includes a canopy of Fremont cottonwood trees, as well as native shrubs and trees, such as mulefat, Mexican elderberry, arroyo willow, and red willow (*Salix laevigata*); native herbaceous species, such as California mugwort and broad-leaved cattail; and non-native plants, such as tree tobacco.

The river wash supports scattered native plants, including scale-broom, Great Basin sagebrush, lacy phacelia, chaparral nightshade, globe gilia, sun cup, and woolly star (*Eriastrum densifolium*), and non-native species, such as abumashi grass (*Schismus barbatus*), tree tobacco, castor-bean (*Ricinus communis*), and horehound. The big sagebrush scrub supports native shrubs (Great Basin sagebrush, yerba santa, mulefat, and coyote brush); smaller native species, including lacy phacelia, arroyo lupine, wild rhubarb, Coulter's lupine, and yellow pincushion; and non-native species, including winter vetch, tree tobacco, and red-stemmed filaree. The steeper canyon sides include coastal scrub areas that are characterized as heterogeneous scrub, as well as areas dominated by California buckwheat, black sage, and purple sage. These coastal scrub vegetation communities also include native shrub species, such as yerba santa, California sagebrush, California encelia, giant ryegrass, and Mexican elderberry; native wildflowers (blue dicks, yellow fiddleneck, arroyo lupine, southern sun cup, chaparral nightshade, and lacy phacelia); and non-native species (short-podded mustard). Several south-facing slopes are dominated by chamise chaparral, which supports native shrubs, including chamise, black sage, giant rye grass, bladderpod (*Isomeris arborea*), California buckwheat, hoaryleaf ceanothus (*Ceanothus crassifolius*), and toyon (*Heteromeles arbutifolia*); smaller native species, such as deerweed, California peony, sacapellote, wild cucumber, California wishbone-bush, and California aster; and non-native species, such as short-podded mustard and black mustard.

San Martinez Grande Canyon lies to the west of Chiquito Canyon, primarily north of SR-126. The incised creek supports a pocket of southern cottonwood–willow riparian forest at the upstream end of the creek, and the remaining portions of the creek include river wash, mulefat scrub, and big sagebrush scrub. The southern cottonwood–willow riparian forest supports a canopy of Fremont cottonwood trees as well as other native trees and shrubs, such as arroyo willow, red willow, coyote brush, and mulefat, and non-native plants, such as yellow sweet-clover. The river wash supports scattered native plants (scale-broom, whispering bells, yellow fiddle-neck, annual burweed, and salt grass) and non-native plants (tree tobacco, yellow sweet-clover, and red-stemmed filaree). The big sagebrush scrub supports native shrubs (Great Basin sagebrush, quail brush, and Mexican elderberry); smaller native species, including chaparral nightshade, common forget-me-not, blue fiddleneck, globe gilia, and whispering bells; and non-native plants (black mustard, tocalote, and cheeseweed). Mulefat scrub supports native shrubs (mulefat and coyote brush); smaller native species, such as yellow fiddleneck; and non-native plants (tamarisk and yellow sweet-clover). The steeper canyon sides include coastal scrub areas that are characterized as heterogeneous scrub, as well as areas dominated by California buckwheat, black sage, and purple sage. These coastal scrub vegetation communities also include native shrub species, such as California sagebrush, coyote brush, giant ryegrass, and Mexican elderberry; smaller native species, including chaparral nightshade, morning-glory (*Calystegia macrostegia*), coast paintbrush (*Castilleja affinis*), mustard primrose, and arroyo lupine; and non-native plants (short-podded mustard and tree tobacco). Most of the west side of San Martinez Grande Canyon was burned in the 2003 fires, and the California sagebrush scrub is

still recovering (*i.e.*, stump sprouting). Extensive expanses of California annual grassland are also present. In addition to non-native grasses, such as bromes and wild oats, the grasslands support native wildflowers (such as arroyo lupine, yellow fiddleneck, California poppy, common forget-me-not, and annual burweed) and non-native herbaceous plants (including London rocket, black mustard, bull thistle, milk thistle, and common sow-thistle).

The quality of native upland habitats in the RMDP area is varied and includes a range of conditions. The assessment of habitat quality may be dependent upon a number of factors, including the successional stage of the community, the topography, the historical level of disturbance (*e.g.*, grazing, oil production), and the recent fire ecology. Although the quality of habitat in some areas is degraded, it is important to note that numerous sensitive and common plant and wildlife species have been recorded in the RMDP area. For example, scrub communities adjacent to some riparian areas have been extensively grazed by cattle and the dominant native plants occur within a mosaic of non-native species. This is evident in sections of Lion, Long and Potrero canyons. Conversely, classic stands of coastal scrub and other upland plant communities occur throughout the RMDP area. For example, large stands of relatively undisturbed coastal scrub were identified near Onion Fields, Potrero Canyon, Long Canyon, and near the Salt Creek area.

The Santa Clara River and some of its tributary waters support a variety of riparian vegetation communities, including southern cottonwood–willow riparian forest, southern willow scrub, mulefat scrub, arrow weed scrub, alluvial scrub, herbaceous wetlands, coastal and valley freshwater marsh, and river wash. These communities represent the many successional stages that occur in riverine ecosystems. The ecological integrity of riparian systems in the southwest United States is related to disturbance, regeneration, and competition (Busch and Smith 1995). Flooding and regular scour—both regular occurrences in this section of the Santa Clara River—are forms of disturbance to which many plant and animal species are well adapted, and they are often required for the development of suitable nesting or breeding habitat for some species (Busch and Smith 1995). Many riparian species, such as cottonwoods and willows (which dominate much of the riparian habitat in the RMDP area), require periodic disturbance from scour to provide suitable sites for seedling germination (Mahoney and Rood 1998). Although still subject to periodic flooding and scour, the Santa Clara River ecosystem has been affected by the construction of dams on some of the River's major tributaries, including Castaic and Piru creeks.

Depending on the location of the river, habitat conditions can be considered excellent, with well-established multi-canopy southern cottonwood–willow riparian forest along the upper terraces of the Santa Clara River (*i.e.*, along both the north and south sides of the River at Mayo Crossing, along the north side of the River between the mouth of Chiquito Canyon and the mouth of San Martinez Grande, along the north side of the River at Indian Dunes, and along the

south side of the River at the mouth of Middle Canyon). Non-native, invasive species, such as giant reed (*Arundo donax*) and tamarisk, are present as occasional components along the River, and both giant reed and tamarisk occur in several concentrated clumps in the River, upstream of the confluence with Castaic Creek.

As described above in the canyon descriptions, tributary drainages that include portions of San Martinez Grande, Chiquito, Middle, Potrero, and Long canyons also support localized populations of riparian vegetation. Surface water flows in the tributary drainages are ephemeral in nature, with the exception of the lower portions of Potrero Canyon, where groundwater discharges to the creek. These drainages support several plant associations, including cismontane alkali marsh, river wash, mulefat scrub, big sagebrush scrub, and alluvial scrub. Both dry land and irrigated agricultural practices have been conducted in or adjacent to some of the drainages in Middle, Humble, Long, Potrero, and portions of Salt Creek canyons; and most of the drainages in the RMDP have been subject to periodic grazing by livestock. For the most part, the creeks in these canyons are restricted to a thin ribbon of riparian vegetation adjacent to agricultural land. Cattle are typically present and herbaceous understory vegetation is limited.

4.5.3.3.1.3 *Open Space within the RMDP*

The Specific Plan Land Use Plan designates a total of approximately 5,182 acres for the River Corridor and High Country SMAs (**Figure 4.5-3**, RMDP Study Area). The River Corridor SMA is generally 1,500 to 2,000 feet wide and is located along the north and south sides of the Santa Clara River. The High Country SMA is located in the southern portion of the Specific Plan site. The SMAs are designed primarily to protect the existing natural resources within Los Angeles County's Significant Ecological Areas (SEAs), SEA 20 and SEA 23. Limited public access through the SMAs would be provided by the trail system to be developed, consistent with the Specific Plan Master Trails Plan.

The 977-acre River Corridor SMA includes the Santa Clara River within the Specific Plan site and associated habitats. The value of the River Corridor SMA is derived from the inherent value of its wetland and riparian habitats and associated species, and from its function as a regional east-west wildlife corridor.

The largest land use designation of the Newhall Ranch Specific Plan Land Use Plan is the 4,205-acre High Country SMA. The High Country SMA is located in the southern portion of the site and includes oak savannahs, high ridgelines, and various canyon drainages, including the Salt Creek watershed in Los Angeles County. Salt Creek is a regionally significant wildlife corridor that provides an important habitat link to the Santa Clara River.

As part of its approval of the Specific Plan in 2003, the Los Angeles County Board of Supervisors imposed an off-site condition requiring the applicant to dedicate to the public the

remaining 1,517-acre portion of the Salt Creek watershed in Ventura County, adjacent to the western boundary of the Specific Plan site. Although the Salt Creek area was identified as an off-site area during the Specific Plan approval process by Los Angeles County, the area is within the RMDP boundary, and is considered on site for purposes of this plan.

The two SMAs (River Corridor and High Country), and other important preserve/conservation areas (Salt Creek area and Open Area) on and adjacent to the Specific Plan site, are summarized below.

River Corridor SMA. The 977-acre River Corridor SMA comprises a portion of the County's SEA 23 and would include the preservation of areas along the Santa Clara River, a regionally significant biological resource. As part of the development of the Specific Plan, the River Corridor SMA has been delineated to be sufficiently wide to handle the capital flood while retaining nearly all of the riparian vegetation existing along the River. **Figures 4.5-12** through **4.5-15** show the biological resources present within the River Corridor SMA.

The Santa Clara River and other riparian resources in the Southwestern United States have been subject to ongoing disturbance from human activities. Urban development, stream channelization, dam construction, and water diversion have played a significant role in the loss of riparian habitat statewide. In some circumstances, these actions have resulted in the deterioration and loss of riparian plant communities (Howe and Knopf 1991). For example, in California, 95% to 97% of riparian habitats that were present prior to European settlement have been severely degraded or destroyed (Smith 1977; Katibah 1984; Faber *et al.* 1989).

In the Project area, the River is routinely subject to ongoing human disturbance related primarily to agriculture, the augmentation of flows from the Santa Clarita Water Treatment Plant, and urban development. Earth and culvert stream crossings occur at several locations, including Humble and Potrero canyons, and agricultural fields abut the river at many locations. These locations often result in the formation of standing ponds, which provide suitable breeding habitat for exotic species, including African clawed frogs (*Xenopus laevis*) and mosquitofish (*Gambusia affinis*). Routine discharges from the wastewater treatment plant further alter the natural dynamics of the River by alternatively raising and lowering the water surface elevation of the River. This can have adverse effects on numerous species, by washing away egg masses or by stranding fish in temporary pools.

The construction of SR-126 and the establishment of residential and agricultural communities including Travel Village, a recreational vehicle campground and storage facility near Commerce Center Drive, have also affected the River.

The Santa Clara River is also considered an important riparian corridor that connects the Specific Plan area with habitat to the east and west. The Santa Clara River flows from its origins in the San Gabriel Mountains to where it eventually empties into the Pacific Ocean, approximately 50 miles to the west. The River Corridor SMA is an important migration and genetic dispersion corridor for many wildlife species, including aquatic taxa; riparian obligate species (resident and migratory); and larger, more mobile terrestrial animals.

Special-Status Species. The River Corridor SMA supports a variety of state- and federally listed endangered species and numerous special-status plant and wildlife species. Some of the special-status species identified as occurring along the River include arroyo toad, black-crowned night-heron, Cooper's hawk, and least Bell's vireo. Northern harrier, white-tailed kite, willow flycatcher, yellow warbler, yellow-breasted chat, and yellow-headed blackbird have also been identified. As many portions of the RMDP support perennial water, several aquatic or semi-aquatic species have been observed, including arroyo chub, Santa Ana sucker, unarmored threespine stickleback, southwestern pond turtle, and two-striped garter snake. Three special-status plants have been recorded in the River Corridor SMA: an undescribed everlasting, an undescribed sunflower, and slender mariposa lily. See **Table 4.5-6** in **Subsection 4.5.3.1**, Summary of Literature Review and Biological Studies Conducted in Project Area, for a list of biological surveys conducted in the Project area and immediate vicinity from 1988 to the present.

Implementation of the RMDP has the potential to result in construction- and development-related disturbance to portions of the Santa Clara River. To minimize or reduce these effects, the RMDP provides for "transition" or buffer areas between the River and development, restricts recreational uses in the River, and provides for the long-term management of the River Corridor SMA and floodplain areas. Riparian ecosystems in the southwestern United States are highly dynamic and have adapted to a predictable cycle of disturbance resulting from winter rainfall and spring snowmelt. Streams form a steady state condition or "dynamic equilibrium" between dramatic, short-lived bursts of change. Floodplains constitute the buffer that allows streams the flexibility for these bursts. By definition, floodplains and riparian systems are active depositional and erosional environments, prone to floods and shifting materials, storing excess sediments at times of low water and providing sediments in floods. In addition to the physical processes of rivers, there are biological and biogeochemical processes that work to shape the ecosystem as a whole. In addition, many species utilize riparian buffer or transition areas for critical life history events, such as breeding or aestivation. The use of buffers and the placement of the project outside of the Capital Flood event would

ensure the protection of riparian habitat and minimize effects to sensitive biological resources within the Santa Clara River.

Vegetation Communities and Land Covers. Vegetation community classifications used in this RMDP follow the "Vegetation Classification and Mapping Program List of California Terrestrial Natural Communities Recognized by the California Natural Diversity Database" (CDFG 2003; Dudek and Associates 2006B, 2006C, 2006D). Southern cottonwood–willow riparian forest and river wash comprise the majority of the land in the River Corridor SMA, with 32.6% and 20.6%, respectively. In addition, many other plant associations are present in the Santa Clara River and occur in various states of succession, depending on their proximity to the active channel and the recent cycles of rainfall and scour. **Table 4.5-13** shows the distribution of vegetation communities/land cover types in the River Corridor SMA.

In addition to the main river channel, several dry secondary channels meander across the width of the floodplain. Some of these channels flow in response to periodic water releases from the local wastewater treatment facility located upstream of the RMDP. In some areas, non-native grasses and elements of coastal scrub have colonized these dry, sand-dominated channels. Small populations of alluvial scrub species, such as California buckwheat, yerba santa, scale broom (*Lepidospartum squamatum*), and cudweed aster (*Lessingia* sp.), occur in the riparian scrub community.

Depending on the timing of the year or the location on the River, the active channel may be very narrow and limited to only a few feet in width. Conversely, winter storms often inundate many of the existing river terraces for several days. Where perennial water is present, thick mats of water speedwell (*Veronica anagallis-aquatica*), willow weed (*Polygonum lapathifolium*), and water cress (*Rorippa nasturtium-aquaticum*) occur. During the dry season, river wash—consisting of the non-perennial portion of the active channel area and the secondary channels—contains scattered native species, such as scale-broom, chia, California fluffweed, western ragweed, mulefat, golden aster (*Heterotheca sessiliflora*), butterweed, California croton (*Croton californicus*), and miniature sun cup (*Camissonia micrantha*), and non-native plants (blessed thistle (*Cnicus benedictus*), abumashi, and red-stemmed filaree). During the rainy season, the river wash may contain flowing water for several consecutive days or months. The adjacent herbaceous wetlands include thick stands of juvenile native shrubs, including mulefat, narrow-leaved willow (*Salix exigua*), arrow weed (*Pluchea sericea*); native herbaceous species, such as broad-leaved cattail, sedges (*Carex* spp.), cocklebur, California cottonweed (*Epilobium ciliatum*), and bulrush (*Scirpus* ssp.); and non-native plants, including whorled dock (*Rumex conglomerates*), curly dock (*Rumex crispus*), and pepperweed. Where adjacent terraces are low, mulefat scrub is supported, as well as

southern willow scrub and southern cottonwood–willow riparian forest in various successional states, ranging from emerging to mature. Mulefat scrub includes native shrubs, such as mulefat, Great Basin sagebrush, quail brush, and giant ryegrass; smaller native plants, including yellow fiddleneck and western ragweed; and non-native plants (winter vetch, cheeseweed, and yellow sweet-clover). The southern willow scrub includes red willow, arroyo willow, and Goodding's black willow (*Salix gooddingii*) trees; native shrubs, including mulefat, narrow-leaved willow, and arrow weed; native herbaceous species, including western ragweed, arroyo lupine, yellow fiddleneck, and caterpillar phacelia (*Phacelia cicutaria* var. *hispida*); and non-native plants (white sweet-clover (*Melilotus alba*), tumble mustard, hedge mustard, and milk thistle).

In the project area, large galleries of mature cottonwood and willows and their associated herbaceous understory occur at several locations. Some of the largest pure stands of southern cottonwood–willow riparian forest occur along both the north and south sides of the River at Mayo Crossing, along the north side of the River between the mouth of Chiquito Canyon and the mouth of San Martinez Grande, along the north side of the River at Indian Dunes, and along the south side of the River at the mouth of Middle Canyon. These stands occur in areas that have been outside the major scour zone for many years. These areas are dominated by multi-canopied forests with dense thickets of understory vegetation, including native species such as juvenile willows, mulefat, California rose (*Rosa californica*), horseweed (*Conyza canadensis*), California mugwort, western ragweed, and giant creek nettle. Non-native herbaceous species, such as white sweet-clover, prickly sow-thistle, and brome grasses, are associated with the margins of these forests.

Arrow weed scrub and big sagebrush scrub occur within the River Corridor SMA at higher elevations along the floodplain. The arrow weed scrub is dominated by the native shrub arrow weed, but it also supports native shrubs such as mule fat and California sagebrush; native herbaceous species, such as chaparral nightshade, common eucrypta, caterpillar phacelia, and western ragweed; and non-native species, such as tamarisk, yellow sweet-clover, red-stemmed filaree, horehound, and short-podded mustard. The big sagebrush scrub supports native shrubs (Great Basin sagebrush and scale-broom), as well as native herbaceous species, such as mustard primrose, sun cup, California fluffweed, dwarf stonecrop (*Crassula connata*), slender woolly buckwheat (*Eriogonum gracile*), and slender pectocarya and non-native plants (abumashi, red-stemmed filaree, and yellow sweet-clover).

Non-native, invasive species, such as giant reed and tamarisk, are present as occasional components along the River and throughout the river valley, and both giant reed and

tamarisk occur in several concentrated clumps in the River, upstream of the confluence with Castaic Creek.

A complete description of the plant communities present in the RMDP Project area is described in **Subsection 4.5.3.4.1**, Vegetation Communities and Land Cover Types.

Table 4.5-13
River Corridor SMA Vegetation Communities/Land Cover

General Physiognomic and Physical Location	General Habitat Type	Floristic Alliance	Association	RMDP Acreage	Percent of Total
Grass and Herb Dominated Communities	Non-Native Grassland	California annual grassland	Not mapped to association level	9.4	1.0%
Scrub and Chaparral	Coastal Scrub	California sagebrush scrub	Not mapped to association level	22.3	2.3%
			California sagebrush–*Artemisia californica*	0.4	<0.1%
			California sagebrush–purple sage	31.4	3.2%
		California sagebrush–California buckwheat scrub	Not mapped to association level	0.1	<0.1%
		California sagebrush scrub–undifferentiated chaparral	Not mapped to association level	2.6	0.3%
	Undifferentiated Chaparral Scrubs	Not mapped to alliance level	Not mapped to association level	1.5	0.2%
Broad Leafed Upland Tree Dominated	Oak Woodland and Forest	Coast live oak forest and woodland	Coast live oak woodland	16.1	1.6%
Riparian and Bottomland Habitat	Other Riparian/Wetland	Herbaceous wetland	Not mapped to association level	182.2	18.6%
		River wash	Not mapped to association level	201.1	20.6%
		Big sagebrush scrub	Not mapped to association level	2.7	0.3%
		Giant reed	Not mapped to association level	5.6	0.6%
	Low to High Elevation Riparian Scrub	Arrow weed scrub	Not mapped to association level	12.6	1.3%
		Mulefat scrub	Not mapped to association level	15.0	1.5%
	Riparian Forest and Woodland	Southern willow scrub	Not mapped to association level	13.1	1.3%
		Tamarisk scrub and woodland	Shrub tamarisk	2.3	0.2%
		Coast live oak forest and woodland	Southern coast live oak riparian forest	0.6	0.1%

Table 4.5-13
River Corridor SMA Vegetation Communities/Land Cover

General Physiognomic and Physical Location	General Habitat Type	Floristic Alliance	Association	RMDP Acreage	Percent of Total
		Fremont cottonwood riparian forest and woodland	Southern cottonwood–willow riparian	318.5	32.6%
Man-Made Land Cover Types		Agriculture	NA	101.8	10.4%
		Disturbed land	NA	37.1	3.8%
		Total		976.4	100.0%

NOTE: The acreages and vegetation types depicted in this table were determined during field mapping in 2006 (Dudek and Associates 2006B).

Soils. Soils in the River Corridor SMA are mapped as the Mocho-Sorrento association, within a 2% to 9% slope. Because the mapping was done at a generalized level, there are areas within the SMA with lesser slopes and other soil types that were not mapped. These soils are gently sloping to moderately sloping alluvial fans with brown to grayish-brown loam. Erosion hazard is slight to moderate, and the runoff rate is slow to medium (USDA 1969).

High Country SMA. The Newhall Ranch High Country SMA is located in an unincorporated portion of the Santa Clara River Valley on the north slopes of the Santa Susana Mountains (**Figure 4.5-16**, High Country SMA and Salt Creek Area – Generalized Vegetation Communities and Land Covers, and **Figure 4.5-17**, High Country SMA and Salt Creek Area – Special-Status Species Occurrences). Site elevations range from 800 feet AMSL in the Santa Clara River bottom in Ventura County to approximately 3,500 feet AMSL on the ridgeline of the Santa Susana Mountains along the southern boundary. This study area is dominated by rugged terrain, with the main feature being a south-to-north drainage area for Salt Creek and its associated tributaries. The High Country SMA is a part of the County's SEA 20, and the value of the habitats within the area are increased by their continuity and connectivity with the large areas of undeveloped and recently acquired public land in the Santa Susana Mountains, which are also part of SEA 20. As noted by the Penrod *et al.* (2006) least cost analyses, the High Country SMA is an important component of regional habitat connectivity for a variety of species, including a number of special-status species. The High Country SMA also provides live-in habitat for a number of special-status species.

Special-Status Species. The High County SMA supports a variety of state- and federally listed endangered species and numerous special-status plant and wildlife species. Rocky outcrops and soft friable soils support populations of reptiles, such as coastal western whiptail and coast horned lizard. Birds are common in the High Country SMA and include white-tailed kite, Cooper's hawk, loggerhead shrike, prairie falcon, long-eared owl, short-eared owl, and rufous-crowned sparrow. Access to a wide prey base of small mammals and mule deer ensure the presence of wide-ranging carnivores, such as mountain lion and American badger. Several species of plants have also been identified in this area and include slender mariposa lily, Plummer's mariposa lily, late-flowered mariposa lily, and Ojai navarretia. See **Table 4.5-6** in **Subsection 4.5.3.1** for a list of biological surveys conducted in the Project area and immediate vicinity from 1988 to the present.

While much of the High Country SMA is considered open space and supports a variety of native and exotic vegetation, Newhall Land continues to lease portions of the High Country SMA for oil and natural gas production, cattle grazing, and agricultural

operations (*e.g.*, food crop production, dryland farming, honey farming). Grazing activities and oil and natural gas production have had a noticeable effect on much of the natural habitat on site. Scrub vegetation communities in some areas have been displaced by California annual grassland as a result of grazing and wildfires. In addition, SCE and SCGC maintain transmission and distribution lines within the site.

Vegetation Communities and Land Covers. The High Country SMA supports both native and naturalized habitats that are representative of those found in this region. Similar to the RMDP area, upland habitats dominate the landscape within the High Country SMA. The major upland vegetation communities include coastal scrub, undifferentiated chaparral, coast live oak woodland, valley oak/grass, and California annual grassland. More than half of the coastal scrub and chaparral vegetation communities in the High Country SMA were burned in the 2003 fires, but these areas appear to be recovering (*i.e.*, stump sprouting, natural recruitment of native shrub and herbaceous species). The coastal scrub includes native shrubs (California sagebrush, purple sage, goldenbush, yerba santa, coyote brush, California buckwheat, squaw bush, and chaparral bush mallow); smaller native plants, including California wishbone-bush, redmaids, California aster, chaparral nightshade, California poppy, yellow fiddleneck, blue dicks, and deerweed; and non-native plants (horehound, red-stemmed filaree, and cheeseweed). In some areas, heavy grazing has left only remnant populations of coastal scrub communities dominated by California sagebrush and isolated California buckwheat. Non-native annual grasses are common in these areas, as are herbaceous weedy annuals such as short-podded mustard, milk thistle, and tocalote. The chaparral supports sugar bush (*Rhus ovata*), squaw bush, coyote brush, bush monkeyflower, giant ryegrass, yerba santa, prickly phlox, and poison oak (*Toxicodendron diversilobum*); native herbaceous species, including Santa Barbara locoweed (*Astragalus trichopodus*), wild pea (*Lathyrus vestitus*), blue dicks, wind poppy (*Stylomecon heterophylla*), valley clover (*Trifolium willdenovii*), climbing bedstraw (*Galium porrigens*), arroyo lupine, long-stem golden yarrow, and cliff malocothrix; and non-native plants (tree tobacco, black mustard, cheeseweed, and horehound). In addition to non-native grasses, the California annual grassland includes native wildflowers (arroyo lupine, blue dicks, Johnny jump-ups (*Viola pedunculata*), California aster, and blue fiddleneck) and non-native plants (horehound, short-podded mustard, tocalote, tree tobacco, Russian thistle, and milk thistle).

Because much of the High Country SMA contains slopes greater than 25%, there remains good quality habitat that has been subject to less grazing pressure. Large areas of the High Country SMA support various forms of coast live oak and valley oak/grass and woodlands and there are an estimated 13,732 oak trees within the High Country SMA. The coast live oak woodland supports a canopy of coast live oak trees and native shrubs

(yerba santa, coyote brush, chaparral bush mallow and squaw bush); smaller native species, including heart-leaf penstemon, chaparral nightshade, common eucrypta, California aster, caterpillar phacelia, morning-glory, blue dicks, and wild cucumber; and non-native plants (yellow sweet-clover, short-podded mustard, and red-stemmed filaree). The valley oak/grass supports valley oak trees with an understory of non-native grasses, including bromes and slender oak, as well as native herbaceous species, including yellow fiddleneck, blue dicks, arroyo lupine, California goosefoot, coast paintbrush, and shrubby phacelia, and non-native plants (milk thistle, cheeseweed and bull thistle). These communities provide important mast crops (acorns) to foraging wildlife, such as mule deer, and potential nest sites for native birds. However, acorns are also favored by cattle as are young oak trees. In areas where grazing pressure is high, the recruitment of juvenile oaks may suffer.

Within the High Country SMA, Salt Creek supports a variety of riparian vegetation communities. These areas are near the top of the watershed and occur in many of the steep-walled canyons and broad drainages that ultimately flow into the Santa Clara River. Except where more perennial or long-term intermittent flow occurs, most of these plant communities support species that can survive periods of limited water availability. Some of these communities include river wash, mulefat scrub, big sagebrush scrub, and Mexican elderberry scrub. The river wash supports scattered native shrubs, such as quail brush and mulefat; native herbaceous species, including Santa Barbara locoweed, cocklebur, wild heliotrope and western ragweed; and non-native plants (short-podded mustard, tocalote, and tamarisk seedlings). The mulefat scrub is dominated by mulefat but also supports other smaller, native species, including common forget-me-not, western ragweed, and California mugwort, and non-native plants (horehound, milk thistle, and tree tobacco). The big sagebrush scrub is dominated by Great Basin sagebrush, but also includes other native plants, such as purple sage, shrubby phacelia, Santa Barbara locoweed, California sagebrush, caterpillar phacelia, and California aster, and non-native plants (yellow sweet-clover, short-podded mustard, and milk thistle). The Mexican elderberry scrub is dominated by Mexican elderberry but also includes other native shrubs, such as Great Basin sagebrush and goldenbush; native herbaceous species, such as yellow fiddleneck, blue dicks, and rusty popcorn flower; and non-native plants (nettle-leaved goosefoot (*Chenopodium murale*), horehound, and tree tobacco).

In more mesic areas, cismontane alkali marsh, bulrush–cattail wetland, and southern willow scrub occur. The cismontane alkali marsh includes native herbaceous species (salt grass, beardless wild rye (*Leymus triticoides*), and winged three-square) and also includes the non-native yellow sweet-clover. The bulrush–cattail wetland is dominated by winged three-square and broad-leaved cattail, with salt grass occurring along the margins. Occasional mulefat seedlings were observed in both the cismontane alkali

marsh and the bulrush–cattail wetland. The southern willow scrub includes a canopy of arroyo willow, with an understory of native shrubs, including mulefat and Mexican elderberry; native herbaceous species, including California mugwort, western ragweed, shrubby phacelia, and yerba de chiva (*Clematis ligusticifolia*); and the non-native milk thistle.

Near the top of Salt Creek, oak dominated canyons support dense understories of chaparral currant (*Ribes malvaceum*), bladder pod, squaw bush, poison oak, American bowlesia and California hedge parsley (*Yabea microcarpa*). Climbing bedstraw, chaparral nightshade, wild cucumber, and annual non-native grasses are also common. In some areas, California black walnut woodlands border the drainages. An abandoned olive grove occurs near a small sulfur spring near the headwaters of Salt Creek. Seeps and springs in the region also support isolated populations of wetland vegetation and are subject to grazing pressure where they occur.

Table 4.5-14 shows the acreage of vegetation communities and land cover types in the High Country SMA; these areas are mapped on **Figure 4.5-16**, High Country SMA and Salt Creek Area – Generalized Vegetation Communities and Land Covers.

Soils. Soils in the High Country SMA are mapped as Balcom-Castaic-Saugus association, 30% to 50% slopes, eroded (USDA 1969). As mentioned earlier, the mapping was done at a generalized level, so there are areas within the High Country SMA with lesser slopes and other soil types that were not mapped. Balcom-Castaic-Saugus association, 15% to 30% slopes, and small areas of San Andreas and San Benito soils may also be found within the High Country SMA (USDA 1969).

Soils found on site are characterized generally by steep to very steep, often eroded slopes. The soils are well drained, with moderate to moderately slow subsoil permeability and medium to very rapid runoff. The erosion hazard is moderate to very high, largely dependent on slope steepness (USDA 1969).

Table 4.5-14
High Country SMA Vegetation Communities/Land Cover

General Physiognomic and Physical Location	General Habitat Type	Floristic Alliance	Association	RMDP Acreage	Percent of Total
Grass and Herb Dominated Communities	Non-Native Grassland	California annual grassland	Not mapped to association level	465.0	11.1%

		Total		4205.5	100.0%

NOTE: The acreages and vegetation types depicted in this table were determined during field mapping in 2006 (Dudek and Associates 2006B).

Salt Creek Area. The Salt Creek watershed encompasses approximately 5,816 acres. Of this total, approximately 1,517 acres of the watershed are within the Salt Creek area; the rest of the watershed is included in the High Country SMA. The Salt Creek area includes the western portion of the watershed in Ventura County (**Figure 4.5-16**, High Country SMA and Salt Creek Area – Generalized Vegetation Communities and Land Covers, and **Figure 4.5-17**, High Country SMA and Salt Creek Area – Special-Status Species Occurrences). As noted in the Penrod *et al.* (2006) least cost analyses, the Salt Creek area, in conjunction with the High Country SMA, is an important component of regional habitat connectivity for a variety of species, including a number of special-status species. The Salt Creek area also provides live-in habitat for a number of special-status species.

Special-Status Species. The Salt Creek area supports a variety of state- and federally listed endangered species and numerous special-status plant and wildlife species. Short-eared owl, loggerhead shrike, white-tailed kite, Cooper's hawk, rufous-crowned sparrow, and prairie falcon have all been observed foraging on site. Mountain lion tracks have been observed along the dirt roads within the Salt Creek area. In addition, two special-status plants have been recorded in the Salt Creek area: Ojai navarretia and slender mariposa lily. See **Table 4.5-6** in **Subsection 4.5.3.1** for a list of biological surveys conducted in the Project area and immediate vicinity from 1988 to the present.

The majority of the Salt Creek area is considered open space and supports a variety of native and non-native vegetation; however, Newhall Land continues to lease portions of the Salt Creek area for cattle grazing and agricultural operations (*e.g.*, food crop production, dryland farming, honey farming). Grazing activities have had a noticeable effect on some of the natural habitat on site. Scrub vegetation communities in some areas have been displaced by California annual grassland as a result of grazing and wildfires. In addition, SCE and SCGC maintain transmission and distribution lines within the site.

Vegetation Communities and Land Covers. The Salt Creek area supports both native and naturalized habitats that are representative of those found in the region. **Table 4.5-15** shows the vegetation communities/land cover types within the Salt Creek area. Native upland habitat comprises the majority of the Salt Creek area, with 630 acres (41.5%) covered in coastal scrub. Mixed chaparral and coast live oak woodland encompass 125 acres (8.2%) and 148 acres (9.7%) within the Salt Creek area, respectively. The majority of the coastal scrub and chaparral vegetation communities in the Salt Creek area were burned in the 2003 fires, but these areas appear to be recovering (*i.e.*, stump sprouting, natural recruitment of native shrub and herbaceous species). The coastal scrub includes native shrubs (California sagebrush, California encelia, deerweed, long-stem buckwheat (*Eriogonum elongatum*), Mexican elderberry, and coyote brush); smaller native plants, including wide-throated yellow monkey flower (*Mimulus brevipes*), common owl's

clover, cliff malocothrix, morning glory, and narrow-leaved bedstraw (*Galium angustifolium*); and non-native plants (horehound, cheeseweed, and tocalote). In some areas, the combination of grazing and wildfires has left only remnant populations of coastal scrub communities dominated by California sagebrush and isolated California buckwheat. Non-native annual grasses are common in these areas, as are herbaceous weedy annuals, such as short-podded mustard, milk thistle, and tocalote. The chaparral supports squaw bush, coyote brush, giant ryegrass, yerba santa, and poison oak; native herbaceous species, including blue dicks, long-stem golden yarrow, and cliff malocothrix; and non-native plants (tree tobacco, black mustard, and cheeseweed). Because of wildfires, much of the chaparral has only stump-sprouting shrubs and is dominated by the herbaceous native and non-native species. In addition to non-native grasses, the California annual grassland includes native wildflowers (rusty popcorn flower, blue dicks, California aster, coyote-melon (*Cucurbita foetidissima*), yellow fiddleneck, and blue fiddleneck) and non-native plants (horehound, short-podded mustard, tocalote, and Russian thistle).

Large areas of the Salt Creek area support various forms of coast live oak and valley oak/grass and woodlands, and there are an estimated 5,640 oak trees within the Salt Creek area. The coast live oak woodland supports a canopy of coast live oak, with scattered shrubby poison oak and Mexican elderberry; native herbaceous species, including California maiden-hair (*Adiantum jordani*), American bowlesia, fiesta flower (*Pholistoma auritum*), California hedge parsley, poison sanicle (*Sanicula bipinnata*), California goldenrod (*Solidago californica*), and miner's lettuce; and non-native plants (yellow sweet-clover and milk thistle). In addition to valley oak trees, valley oak woodland and valley oak/grass support native shrubs (Mexican elderberry and coyote brush); native herbaceous species, including fiesta flower, wild cucumber, common forget-me-not, yellow fiddleneck, common eucrypta, and arroyo lupine; as well as non-native plants (shepherd's purse, milk thistle, cheeseweed, and non-native grasses).

Within the Salt Creek area, Salt Creek supports a variety of riparian vegetation communities, including river wash, Mexican elderberry, mulefat scrub and southern willow scrub. As Salt Creek occurs in both the High Country SMA and the Salt Creek area, the constituents of these vegetation communities are described above in the High Country SMA vegetation communities descriptions.

Table 4.5-15
Salt Creek Area Vegetation Communities/Land Cover

General Physiognomic and Physical Location	General Habitat Type	Floristic Alliance	Association	RMDP Acreage	Percent of Total
Grass and Herb Dominated Communities	Non-Native Grassland	California annual grassland	Not mapped to association level	187.9	12.4%
Scrub and Chaparral	Coastal Scrub	California sagebrush scrub	Not mapped to association level	11.8	0.8%
			Burned California sagebrush scrub	615.5	40.6%
			California sagebrush–purple sage	2.1	0.1%
	Undifferentiated Chaparral Scrubs	Not mapped to alliance level	Not mapped to association level	9.1	0.6%
			Burned undifferentiated chaparral	115.5	7.6%
Broad Leafed Upland Tree Dominated	Upland Walnut Woodland and Forest	California walnut woodland and forest	California walnut woodland	20.4	1.3%

		Mixed oak woodland and forest	Not mapped to association level	94.6	6.2%
		Valley oak forest and woodland	Valley oak woodland	23.9	1.6%
			Valley oak/grass	113.4	7.5%
Riparian and Bottomland Habitat	Other Riparian/Wetland	River wash	Not mapped to association level	7.4	0.5%
		Alluvial scrub	Not mapped to association level	0.4	<0.1%
	Low to High Elevation Riparian Scrub	Arrow weed scrub	Not mapped to association level	0.7	<0.1%
		Mexican elderberry	Not mapped to association level	1.4	0.1%
		Mulefat scrub	Not mapped to association level	20.1	1.3%
	Riparian Forest and Woodland	Southern willow scrub	Not mapped to association level	2.5	0.2%
		Tamarisk scrub and woodland	Shrub tamarisk	0.2	<0.1%
Man-Made Land Cover Types		Agriculture	NA	99.1	6.5%
		Disturbed land	NA	43.9	2.9%
		Total		**1,517.9**	100.0%

NOTE: The acreages and vegetation types depicted in this table were determined during field mapping in 2006 (Dudek and Associates 2006A).

Soils. Soils in the Salt Creek area are similar to those of the High Country SMA and are mapped as Balcom-Castaic-Saugus association, 30% to 50% slopes, eroded. Soils also are mapped as Gaviota rocky sandy loam and Gazos silty clay loam (USDA 1969).

Soils found on site are characterized generally by steep to very steep, often eroded slopes (*i.e.*, 15% to 75% slopes). The soils are well drained, with moderate to moderately slow subsoil permeability and medium to very rapid runoff. The erosion hazard is moderate to very high, largely dependent on slope steepness (USDA 1969).

Open Area. Open Area is a land use designation, which includes a total of approximately 3,420 acres outside of the SMAs, including 1,921 acres which would be preserved to protect significant resources. The areas also will provide open area and community identification for Newhall Ranch residents. The Open Area designation includes community parks, prominent ridges, bluffs, slopes, creek beds, and utility and trail system easements and will often function as a transition between development areas and the SMAs (**Figure 4.5-18**, Open Area – Generalized Vegetation Communities and Land Covers, and **Figure 4.5-19**, Open Area – Special-Status Species Occurrences).

Included in the Open Area are:

- Community parks;
- Major drainages, which are those with flows of 2,000 cubic feet per second or more;
- Significant landforms, such as the river bluffs, Sawtooth Ridge, and Ayres Rock;
- Spineflower conservation areas;
- Oak woodlands and grasses that are not part of the SMAs; and
- Cultural sites.

Within the RMDP, the Open Area includes portions of Potrero Canyon, Humble Canyon, Lion Canyon, San Martinez Canyon, and Chiquito Canyon as well as areas adjacent to Potrero Mesa, Grapevine Mesa, and Airport Mesa. These areas are known to support a variety of special-status species.

Special-Status Species. Based on surveys conducted between 2002 and 2007, special-status wildlife species identified within the preserved portion of the Open Area include California horned lark, Lawrence's goldfinch, least Bell's vireo, Nuttall's woodpecker, rufous-crowned sparrow, southwestern pond turtle, two-striped garter snake, unarmored threespine stickleback, western spadefoot toad, white-tailed kite, willow flycatcher, yellow warbler, arroyo chub, Santa Ana sucker, western burrowing owl, tricolored blackbird (colony), Cooper's hawk, golden eagle, loggerhead shrike, and oak

titmouse (**Figure 4.5-19**, Open Area – Special-Status Species Occurrences). No special-status plant species were identified within the preserved portion of the Open Area. See **Table 4.5-6** in **Subsection 4.5.3.1** for a list of biological surveys conducted in the Project area and immediate vicinity from 1988 to the present.

While the Open Area supports a variety of native and non-native vegetation, Newhall Land continues to lease the mesas and many of the canyons for oil and natural gas production, cattle grazing, and agricultural operations (*e.g.*, food crop production, dryland farming, honey farming). As described above, grazing activities and oil and natural gas production have had a noticeable effect on much of the natural vegetation on site, and SCE and SCGC continue to maintain transmission and distribution lines within the Open Area.

Vegetation Communities and Land Covers. Open Area is configured to protect significant landforms and natural resources, providing an opportunity to integrate the proposed development within its natural context. **Table 4.5-16** provides an overview of the vegetation communities that would be preserved in the Open Area (**Figure 4.5-18**, Open Area – Generalized Vegetation Communities and Land Covers). The vegetation communities preserved include mostly a mixture of grassland, coastal scrub, chaparral scrub, and woodlands. Also present are riparian and wetland communities and disturbed land covers which may be available for restoration. Within the RMDP, the Open Area includes portions of Potrero Canyon, Humble Canyon, Lion Canyon, San Martinez Canyon, and Chiquito Canyon as well as areas adjacent to Potrero Mesa, Grapevine Mesa, and Airport Mesa. The constituent elements of the vegetation communities in these areas, as well as the nature and intensity of past disturbances, are described above. Significant additional biological resources, as yet to be calculated, will be part of the Open Area following project grading and re-establishment of several drainages with restored native plant community treatments as discussed in Section 5.3 of the RMDP.

Table 4.5-16
Open Area (Preserved Portion) Vegetation Communities/Land Cover

General Physiognomic and Physical Location	General Habitat Type	Floristic Alliance	Association	RMDP Acreage	Percent of Total
Grass and Herb Dominated Communities	Non-Native Grassland	California annual grassland	Not mapped to association level	537	28.0%
Scrub and Chaparral	Coastal Scrub	California sagebrush scrub	Not mapped to association level	356	18.5%
			Burned California sagebrush scrub	44	2.3%

NOTE: The acreages and vegetation types depicted in this table were determined during field mapping in 2006 (Dudek and Associates 2006A).

4.5.3.3.2 VCC Planning Area

The VCC planning area is depicted on **Figure 4.5-3**, along with the proposed open space designations and development areas. The VCC planning area is located north of SR-126, east of Commerce Center Drive, and west of I-5. The VCC planning area is dominated by north/south trending ridges that lie north of Castaic Creek, near the confluence with Hasley Canyon. The ridges are generally rounded at the top with slopes that vary from steep to gentle. Portions of two major drainages, including Castaic Creek and Hasley Canyon, occur within the VCC planning area. Site elevations range from approximately 1,000 feet AMSL in the Castaic Creek bottom to just over 1,100 feet AMSL at the top of the north central ridge. Castaic Creek is tributary to the Santa Clara River, the confluence of which is located southwest of the VCC planning area, on the south side of SR-126.

4.5.3.3.2.1 *Past and Current Land Use*

The Project applicant historically leased portions of the VCC planning area for sand and gravel production, cattle grazing, and agricultural operations (*e.g.*, food crop production, dry land farming); only agricultural operations are ongoing. Approximately 7% of the VCC planning area has been developed with commercial/industrial uses. There is significant development influence within the VCC study area, including I-5, SR-126, and secondary roads to the west and east; medium-density residential housing to the north; and major commercial land uses immediately to the west and east of the VCC planning area. Additionally, direct disturbances, primarily from existing overhead and buried utilities, dirt roads, and included widespread soil disturbance, have resulted in non-native plant colonization. Immediately to the west of Livingston Avenue, a significant amount of soil erosion has occurred, presumably resulting from the installation of a large concrete drainage pipe. Hasley Canyon, a tributary of Castaic Creek, contains the majority of disturbance, most likely from excessive scouring. Along Hasley Canyon, near the confluence with Castaic Creek, there is an energy dispersing outfall structure from the upstream channelization and bank stabilization.

4.5.3.3.2.2 *Vegetation Communities and Land Covers*

Vegetation communities on the VCC planning area vary in quality from high biological value to highly disturbed land associated with existing development and former sand/gravel production (see **Figure 4.5-20**, VCC SCP Site – Vegetation Communities and Land Covers). Native and naturalized vegetation communities present are representative of those vegetation communities found in the Santa Susana, Topatopa, and Liebre mountains and the Santa Clara River and Castaic Creek ecosystems. The dominant upland vegetation community is California annual grassland, with agriculture and coastal scrub also prevalent. In addition to non-native annual grasses, the California annual grassland supports a variety of native wildflowers, including coast goldfields (*Lasthenia californica*), Lindley's annual lupine, common owl's-clover, California poppy, California chicory (*Rafinesquia californica*), redmaids, silver puffs, California lotus

(*Lotus wrangelianus*), and Peirson's morning glory, and non-native plants (pineapple weed (*Chamomilla suaveolens*), California burclover, and common sow-thistle). The coastal scrub is dominated by California sagebrush and California buckwheat scrub and includes other native shrubs, such as deerweed, white sage, purple sage, and our Lord's candle; native herbaceous species, including silver puffs, blue dicks, California wishbone-bush, California fluffweed, Turkish rugging (*Chorizanthe staticoides*), prickly cryptantha, granny's hairnet, slender pectocarya, and dwarf stonecrop; and non-native plants (abumashi, common sow-thistle, and cheeseweed). Castaic Creek supports the majority of southern cottonwood–willow riparian forest on site, with a small remnant of this vegetation community located at the southern terminus of Hasley Canyon. The remaining riparian area supports river wash. The southern cottonwood–willow riparian forest supports a canopy of Fremont cottonwood and arroyo willow trees, with an understory of Mexican elderberry, narrow-leaved willow, scale-broom, tamarisk, and giant reed; native herbaceous species, including prickly cryptantha, western jimsonweed, yellow fiddleneck, Santa Barbara locoweed, and common eucrypta; and non-native herbaceous species (yellow sweet-clover, abumashi, and tree tobacco). The river wash supports scattered native shrubs, including scale-broom, yerba santa, mulefat, and deerweed; native herbaceous species (wild heliotrope, California fluffweed, western ragweed, and mustard primrose); and non-native plants (tamarisk, giant reed, curly dock, and abumashi). On the north side of the site, in an area of heavy disturbance, there is a small depression occupied by herbaceous wetlands and a ditch that supports mulefat scrub. The herbaceous wetlands are dominated by curly dock, and the mulefat scrub is dominated by mulefat with herbaceous native plants (arroyo lupine and California chicory) and non-native plants (horehound, tocalote, yellow sweet-clover and short-podded mustard). The agricultural areas on site are regularly leased for irrigated farming, and the disturbed land on site is primarily denuded of vegetation through repeated scraping and/or stockpiling of construction materials.

4.5.3.3.2.3 *Soils*

Soils on site include: Castaic-Balcom silty clay loam (30% to 50% slopes); Cortina sandy loam (0% to 2% slopes); Hanford sandy loam (2% to 9% slopes); Metz loam (2% to 5% slopes); Mocho loam (0% to 2% slopes); Mocho loam (2% to 9% slopes); Saugus loam (30% to 50% slopes); Sorrento loam (2% to 5% slopes); Yolo loam (0% to 2% slopes); and Yolo loam (2% to 9% slopes) (USDA 1969).

4.5.3.3.2.4 *Special-Status Species*

Based on surveys conducted between 1994 and 2007, special-status wildlife species identified within the VCC planning area include Cooper's hawk, willow flycatcher, tricolored blackbird colony, least Bell's vireo, white-tailed kite, yellow warbler, Nuttall's woodpecker, California gnatcatcher, and two-striped gartersnake (**Figure 4.5-6**, RMDP/SCP – Special-Status Wildlife Species Occurrences). The following special-status plant species were identified within the VCC

planning area: San Fernando Valley spineflower, slender mariposa lily, Peirson's morning glory, mainland cherry, California black walnut, coast live oak, and undescribed everlasting. See **Table 4.5-6** in **Subsection 4.5.3.1** for a list of biological surveys conducted in the Project area and immediate vicinity from 1988 to the present.

4.5.3.3.3 Entrada Planning Area

The Entrada planning area is depicted on **Figure 4.5-3**, along with the proposed open space designations and development areas. The Entrada planning area is located west of The Old Road and I-5, south of Six Flags Magic Mountain Amusement Park, and north of Stevenson Ranch. The Entrada planning area consists of two pieces separated by a portion of the RMDP study area (the Magic Mountain Parkway extension footprint). The southern portion of the Entrada planning area is dominated by several north/south trending ridges and contains native and non-native vegetation communities and land covers. The northern portion of the Entrada planning area consists primarily of disturbed land; this area is immediately adjacent to the Six Flags Magic Mountain Amusement Park fireworks discharge area and is routinely mowed and scraped for fire suppression purposes. Site elevations range from approximately 1,000 feet AMSL along the Santa Clara River to approximately 1,550 feet AMSL on the ridges in the southwestern portion of the site.

4.5.3.3.3.1 *Past and Current Land Use*

The Project applicant has historically leased, and continues to lease, portions of the Entrada planning area for oil and natural gas production as well as for cattle grazing and agricultural operations. There is direct disturbance from past and ongoing oil and natural gas operations, including associated dirt road and oil pad ground clearance. There is soil scraping disturbance adjacent to the amusement park for fire suppression related to fireworks displays within the northern portion of the site, and an active borrow site is located within the eastern portion of the site. Additionally, SCE and SCGC have utility and transmission corridors within easements along the southern portion of the Entrada planning area. The easements/utility lines and access roads are actively maintained.

There is substantial existing development influence in the vicinity of the Entrada planning area, including I-5, SR-126, and secondary road infrastructure to the south, east, and north; medium-density residential housing and integrated golf course to the south and southeast; and major commercial land uses adjacent to the north and east, including the Six Flags Magic Mountain Amusement Park (County of Los Angeles 2007).

4.5.3.3.3.2 *Vegetation Communities and Land Covers*

Native and naturalized vegetation communities within the Entrada planning area are representative of the vegetation communities found in the Santa Susana Mountains and the Santa

Clara River ecosystems (**Figure 4.5-21**, Entrada RMDP/SCP Site – Vegetation Communities and Land Covers). The dominant upland vegetation community is coastal scrub; disturbed land and California annual grasslands are also prevalent. Undifferentiated chaparral and developed land are also present. The coastal scrub includes areas that are characterized as heterogeneous scrub, as well as areas dominated by California sagebrush and California buckwheat. These coastal scrub vegetation communities also include native shrubs, such as squaw bush, deerweed, California encelia, yerba santa, and chaparral bush mallow; smaller native species, such as blue dicks, California poppy, foothill needlegrass (*Nassella lepida*), California melic, chaparral nightshade, chick lupine, coast goldfields, common owl's clover, and California wishbone-bush; and non-native herbs, such as short-podded mustard and red-stemmed filaree. In addition to non-native annual grasses, the California grassland includes native wildflowers (yellow fiddleneck, blue dicks, common forget-me-not, and rusty popcorn flower) and non-native plants (short-podded mustard and red-stemmed filaree). The chaparral supports native shrubs (squaw bush, beaver-tail cactus (*Opuntia basilaris* var. *ramose*), and California sagebrush); native wildflowers, such as California wishbone-bush, arroyo lupine, coast goldfields, sacapellote, California aster, and common owl's-clover; and non-native plants (red-stemmed filaree, tree tobacco, and short-podded mustard). The intermittent drainage is deeply incised and supports river wash along the channel bottom, with big sagebrush scrub occurring on the adjacent terraces. The river wash supports scattered native shrubs, such as Great Basin sagebrush and scale-broom, native herbaceous species (telegraph weed, common eucrypta, and prickly cryptantha), and non-native plants (tocalote and tree tobacco). The big sagebrush scrub is dominated by Great Basin sagebrush and also supports native shrubs (California buckwheat, goldenbush, and Mexican elderberry), native wildflowers (common owl's-clover, coast paintbrush, tansy-leaved phacelia (*Phacelia tanacetifolia*), sticky phacelia (*Phacelia viscida*), chick lupine, and slender pectocarya), and non-native plants (red-stemmed filaree, tocalote, and milk thistle). There are several ephemeral drainages on site, but these do not experience sufficient hydrology to manifest vegetation communities different from the surrounding areas.

4.5.3.3.3.3 *Soils*

Soils on site include: Castaic-Balcom silty clay loams (30% to 50%) eroded; Cortina sandy loam (0% to 2% slopes); Cortina sandy loam (2% to 9% slopes); Hanford sandy loam (0% to 2% slopes); Hanford sandy loam (2% to 9% slopes); Metz loamy sand (0% to 2% slopes); River wash, sandy alluvial land; Sorrento loam (2% to 5% slopes); and Zamora loam (2% to 9% slopes) (USDA 1969).

4.5.3.3.3.4 *Special-Status Species*

Based on surveys conducted between 2000 and 2007, special-status wildlife species identified within the Entrada planning area include white-tailed kite, yellow warbler, Cooper's hawk, southern California rufous-crowned sparrow, loggerhead shrike, turkey vulture, mule deer, and

monarch butterfly (**Figure 4.5-6**, RMDP/SCP – Special-Status Wildlife Species Occurrences). The following special-status plant species were identified within the Entrada planning area: San Fernando Valley spineflower, slender mariposa lily, island mountain mahogany, Peirson's morning glory, mainland cherry, California black walnut, coast live oak, and Parish's sagebrush. See **Table 4.5-6** in **Subsection 4.5.3.1** for a list of biological surveys conducted in the Project area and immediate vicinity from 1988 to the present.

4.5.3.4 Existing Conditions by Biological Resource

4.5.3.4.1 Vegetation Communities and Land Cover Types

This subsection describes the existing setting for vegetation communities and land cover types in the Project area, including the RMDP, and Entrada planning areas.

Vegetation community and land cover classifications used in this EIS/EIR generally follow the Vegetation Classification and Mapping Program "List of California Terrestrial Natural Communities Recognized by the California Natural Diversity Database" system (CDFG 2003, updated in October 2007 (CDFG 2007D)), as described in **Subsection 4.5.3.2**, Survey Methods. The vegetation community types, along with their floristic alliances and associations, and human-dominated land cover types are described below. Additional information regarding special-status vegetation communities is provided in **Subsection 4.5.3.4.4**. The classification code number given for each community, alliance, or association, as applicable, under this classification system in the following descriptions is noted parenthetically after the vegetation community, alliance, or association name. Where vegetation types observed on site do not conform with CDFG (2003) vegetation community classification system, they are defined for this EIS/EIR based on the dominant plant species. Communities that are recovering from burns were mapped as "burned" associations, and native communities that contain 20% to 50% native species by percent cover were mapped as "disturbed" associations. Areas where native species cover was visually estimated to be less than 20% were mapped as disturbed land. Areas mapped as "agriculture" have been or are in cultivation. Areas mapped as "developed" represent paved roads, structures, and other hardscape features. Where a grassland vegetation community was visually estimated to contain 10% or more percent absolute cover of native perennial grasses (*e.g.*, *Nassella pulchra*), the area was mapped as a native grassland. The 10% threshold is an industry standard for identifying perennial native grasslands (Keeler-Wolf *et al.* 2007). Oak woodland is defined as areas with 20% to 50% cover by oak trees. Oak/grass includes areas where oak trees comprise less than 20% of the total cover.

Fourteen general vegetation community types and three human-dominated land cover types (*i.e.*, active and inactive agriculture, disturbed land, and developed land) were identified in the Project area (RMDP, VCC, and Entrada planning areas) during the field investigations. The vegetation and land use types are mapped on **Figures 4.5-11-A1** through **4.5-11-C2**, **4.5-20**, and **4.5-21** and are summarized in **Table 4.5-17**. The descriptions below are organized by general vegetation community type, floristic alliance (as applicable), and association (as applicable).

Table 4.5-17
Existing Vegetation Communities, Floristic Alliances and Associations, and Land Cover Types in Project Area

General Physiognomic and Physical Location	General Habitat Type	Floristic Alliance	Association	RMDP Acreage	VCC Acreage	Entrada Acreage

		Total		13,651.1	321.4	316.0

4.5.3.4.1.1 *Non-Native Grassland (42.000.00)*

California Annual Grassland (42.040.00). California annual grassland is characterized by a mixture of weedy, introduced annuals, primarily grasses (Sawyer and Keeler-Wolf 1995; Holland 1986). California annual grassland typically includes wild oat (*Avena* spp.), bromes (*Bromus diandrus, B. madritensis, B. hordeaceus*), black mustard (*Brassica nigra*), filaree (*Erodium* spp.), and Russian thistle (*Salsola tragus*). It may occur where disturbance by maintenance (*e.g.*, mowing, scraping, disking, and spraying), grazing, repetitive fire, agriculture, or other mechanical disruption has altered soils and removed native seed sources from areas formerly supporting native vegetation (Holland 1986).

On site, California annual grassland occurs within the Specific Plan, VCC, and Entrada planning areas. It occurs in large, contiguous patches north of the Santa Clara River in the San Martinez Grande Canyon, Off-Haul Canyon, and Homestead Canyon areas, and south of the River in Potrero Canyon. Smaller, scattered patches are present in the Salt Creek area and High Country SMA in the western portion of the Project area, and in very scattered, small patches in the eastern portion of the Project area. Most of the California annual grassland within the Specific Plan area is affected by cattle grazing practices, primarily in Potrero Canyon. Disturbance of annual grasslands in the VCC planning area consists primarily of non-native weedy plant colonization (black mustard, bromes, and tocalote (*Centaurea melitensis*)), dirt roads, and widespread soil disturbance from the concrete drainage pipe described above, resulting in substantial soil erosion. California annual grassland in the Entrada planning area and the western portion of the Specific Plan area appears to be, at least in part, the result of post-fire growth following the 2003 Verdale and Simi wildfires.

On site, California annual grassland consists of various annual non-native grasses and annual forbs, including wild oat (*Avena fatua*), slender oat (*Avena barbata*), bromes, and goldentop (*Lamarckia aurea*). California annual grassland includes a variety of native wildflowers, such as blue dicks (*Dichelostemma capitatum*), yellow fiddleneck (*Amsinckia menziesii*), silver puffs (*Uropappus lindleyi*), Lindley's annual lupine (*Lupinus bicolor*), angel gilia (*Gilia angelensis*), strigose deerweed (*Lotus strigosus*), common owl's clover (*Castilleja exserta*), California poppy (*Eschscholzia californica*), rusty popcorn flower (*Plagiobothrys canescens*), chick lupine (*Lupinus microcarpus*), and slender pectocarya (*Pectocarya linearis*), and non-native species, including red-stemmed filaree (*Erodium cicutarium*), short-podded mustard (*Hirschfeldia incana*), yellow sweet-clover (*Melilotus indica*), Russian thistle, tocalote, and milk thistle (*Silybum marianum*). Some of these grasslands include occasional California sagebrush scrub species as described below. It was unclear during vegetation mapping whether

these California sagebrush scrub component species represent transitional vegetation recolonizing grassland areas or scrub that was being replaced with annual grassland.

4.5.3.4.1.2 *Native Grassland (41.000.00)*

Purple Needlegrass (41.150.00). Purple needlegrass is defined as containing at least 10% absolute cover of perennial native grasses. The 10% threshold is an industry standard for identifying perennial native grasslands (Keeler-Wolf *et al.* 2007). According to Holland (1986), valley needlegrass grassland is a mid-height (to two feet) grassland dominated by perennial, tussock-forming purple needlegrass (*Stipa* [*Nassella*] *pulchra*). Native and introduced annuals occur between the perennials, often outnumbering the bunchgrass in cover. This habitat type usually is found on fine-textured, clay soils that are moist or waterlogged during the winter months, but very dry in the summer. This habitat type often intergrades with oak woodlands on moister, better drained sites. Common species include California melicgrass (*Melica californica*), boreal yarrow (*Achillea borealis*), brome grasses (*Bromus* spp.), and melic grasses (*Melica* spp.).

The California Department of Fish and Game (CDFG 2007D) proposes to recognize foothill needlegrass and nodding needlegrass grasslands as distinct associations, but CDFG has not yet compiled needed data. The three common needlegrass species tend to segregate from one another, based on substrate and slope factors (Sawyer and Keeler-Wolf 1995).

There is a very small area of purple needlegrass (less than one acre) in the High Country SMA, in the south-central portion of the Specific Plan area, surrounded by coastal scrub and burned coastal scrub.

On site, purple needlegrass supports the following native species: purple needlegrass, foothill needlegrass (*Nassella lepida*), blue dicks, yellow fiddleneck, common owl's clover, and Lindley's annual lupine; as well as a variety of brome grasses, red-stemmed filaree, and tocalote.

4.5.3.4.1.3 *Coastal Scrub (32.000.00)*

Coastal scrub (including alliances and associations) is a native plant community characterized by a variety of soft, low, aromatic, drought-deciduous shrubs, such as California sagebrush (*Artemisia californica*), California buckwheat (*Eriogonum fasciculatum*), California bush sunflower (*Encelia californica*), and true sages (*Salvia* spp.), along with scattered evergreen shrubs that can include lemonadeberry (*Rhus integrifolia*), laurel sumac (*Malosma laurina*), and

toyon (*Heteromeles arbutifolia*) (Holland 1986). It typically develops on south-facing slopes and other xeric situations.

The plant community structure of the coastal scrub on site appears to be relatively intact, although some relatively large areas in the Specific Plan area have burned or are subject to grazing impacts. Other disturbances of coastal scrub on site include dirt roads and utility tower footprints in the VCC planning area, although overall this community is relatively intact in VCC. Although the Entrada planning area is influenced by nearby and adjacent disturbance and development, overall this community is relatively intact in Entrada. However, non-native plant elements, such as mustards (primarily short-podded mustard), Russian thistle, and brome grasses, are evident where there is adjacent direct disturbance, such as bladed dirt roads, oil pads, and other disturbed lands.

Coastal scrub is a general vegetation community. On site, coastal scrub is mapped to at least the alliance level and, in some cases, to the association level. Each is dominated by a particular species that characterizes the alliance or association. In some cases, the dominant plant species may be the only species present (Sawyer and Keeler-Wolf 1995). Four alliances of coastal scrub were mapped in the Project area: California sagebrush scrub, California sagebrush-black sage scrub, California sagebrush-California buckwheat scrub, and California sagebrush-undifferentiated chaparral.

On site, coastal scrub occurs primarily in wide areas on the central and northeastern portions of the Specific Plan area, including Chiquito Canyon, San Martinez Grande Canyon, Potrero Canyon, and within the High Country SMA and Salt Creek area. Much of this community within the High Country SMA, Salt Creek area, and San Martinez Grande was burned during the Simi Fires of 2003. These areas appear to exhibit traditional post-fire coastal scrub recovery, *via* resprouting and seed germination (Rundel 2007). Primary disturbances in this vegetation are dirt roads and utility tower footprints in the VCC planning area and edge effects of adjacent land uses in the Entrada planning area. In general, coastal scrub was relatively intact in both these planning areas. However, non-native plants, such as mustards (primarily *Hirschfeldia incana*), Russian thistle, and brome grasses, were evident where there was adjacent direct disturbance, such as bladed dirt roads, oil pads, and other disturbed lands.

California Sagebrush Scrub (32.010.00). The California sagebrush scrub alliance comprises the large majority of the coastal scrub in the Project area. It is mapped where California sagebrush is the dominant shrub on site (Sawyer and Keeler-Wolf 1995).

On site, unburned California sagebrush scrub is distributed throughout the Project area on the drier south- or west-facing slopes, with large patches north of East Fork of Salt Creek, High Country SMA, the eastern portion of Chiquito Canyon, and in the eastern portion of

the Project area, including Middle, Lion and Dead-End canyons. Burned areas mapped as California sagebrush scrub primarily occur in the Salt Creek area and the western portion of High Country SMA, with a smaller burned area in the San Martinez Grande Canyon area. Much of this community within the western one-third of the Specific Plan area was affected by the Simi Fires of 2003. In burned areas with active grazing, it appears that California annual grassland has replaced at least some pre-existing coastal scrub. Less accessible backcountry areas appear to exhibit more natural post-fire sagebrush recovery, including crown-sprouting and successional growth.

The unburned California sagebrush scrub on site is includes a mixture of California sagebrush, black sage (*Salvia mellifera*), purple sage (*Salvia leucophylla*), and California buckwheat. Other native shrubs in this community on site include our Lord's candle (*Yucca whipplei*), Mexican elderberry (*Sambucus mexicana*), white sage (*Salvia apiana*), California encelia (*Encelia californica*), chaparral bush mallow (*Malacothamnus fasciculatus*), giant ryegrass (*Leymus condensatus*), bush monkeyflower (*Mimulus aurantiacus*), coastal prickly-pear (*Opuntia littoralis*), and squaw bush (*Rhus trilobata*); smaller native species, such as California wishbone-bush (*Mirabilis laevis* var. *crassifolia*), yellow pincushion (*Chaenactis glabriuscula*), California dodder (*Cuscuta californica*), lacy phacelia (*Phacelia tanacetifolia*), long-stem golden yarrow (*Eriophyllum confertiflorum*), common forget-me-not (*Cryptantha intermedia*), common owl's clover, deerweed (*Lotus scoparius*), wild cucumber (*Marah macrocarpus*), chick lupine, silver puffs (*Uropappus lindleyi*), slender woolly buckwheat (*Eriogonum gracile* var. *gracile*), yellow fiddleneck, common eucrypta (*Eucrypta chrysanthemifolia*), blue dicks, granny's hairnet (*Pterostegia drymarioides*), shrubby phacelia (*Phacelia ramosissima*), cliff malocothrix (*Malacothrix saxatilis*), and California melic (*Melica imperfecta*); and non-native species (red-stemmed filaree, tocalote, Russian thistle, yellow sweet-clover, short-podded mustard, horehound (*Marrubium vulgare*), and tree tobacco (*Nicotiana glauca*)).

Two associations of California sage scrub alliance are also present on site: California sagebrush–*Artemisia californica* (32.010.01) and California sagebrush–purple sage (32.010.04), including disturbed. These associations were mapped in areas where California sagebrush and purple sage are the co-dominant species, although lesser amounts of the other species listed above may occur. A relatively small amount of California sagebrush–*Artemisia californica* is present is several scattered patches through the lower elevations of the Project area in Salt Creek, Potrero Canyon, Ayers Canyon, Long Canyon, Magic Mountain Canyon, and Lion Canyon. California sagebrush–purple sage occurs in relatively large patches in lower Salt Creek, Lion Canyon, and Magic Mountain Canyon, and in smaller patches in Off-Haul Canyon, San Martinez Grande

Canyon, Chiquito Canyon, upper Potrero Canyon, and along the south side of the Santa Clara River near Grapevine Mesa.

Coyote Brush Scrub (32.060.00). The coyote brush scrub alliance is dominated by coyote brush (*Baccharis pilularis*) (Sawyer and Keeler-Wolf 1995). Coyote brush scrub occurs mostly in uplands, but because it is an effective colonizer of disturbed sites, it can be found in xeric to seasonally mesic areas, in heavily disturbed upland areas and flat areas, or canyons and drainages that receive low seasonal flow or urban runoff. It generally develops over time into coastal scrub, under suitable conditions.

On site, this vegetation community occurs north of the Santa Clara River in the vicinity of Homestead Canyon (in areas burned in 2003), where it is establishing very locally on east-facing slopes at lower elevations and is gradually colonizing upslope. These portions of slopes may be providing just enough moisture to maintain the coyote brush while other slope aspects may be too dry for the species to effectively spread. This alliance also occurs in several small patches on the south side of the Onion Fields and in the upper reaches of eroding drainages south of the Santa Clara River, such as the East Fork of Salt Creek, but is uncommon in the Specific Plan area.

Coyote brush scrub on site is dominated by coyote brush and also includes smaller native species, such as chaparral bush mallow, morning-glory (*Calystegia macrostegia*), caterpillar phacelia (*Phacelia cicutaria*), and arroyo lupine (*Lupinus succulentis*), and non-native species, such as horehound, short-podded mustard, milk thistle, and yellow sweet-clover.

California Sagebrush–California Buckwheat Scrub (32.110.00). This alliance is characterized by a co-dominance of California sagebrush and California buckwheat (Sawyer and Keeler-Wolf 1995).

The largest patches of California sagebrush-California buckwheat on site occur in the upper portion of Chiquito Canyon and in the Entrada planning area, with smaller patches in San Martinez Grande and Mid-Martinez canyons, Lion Canyon, and in VCC.

On site, this vegetation community is dominated by California sagebrush and California buckwheat, and also supports native shrubs such as squaw bush, purple sage, Mexican elderberry, goldenbush (*Ericameria palmeri* var. *pachylepis*), and chaparral bush mallow; native wildflowers including California wishbone-bush, California poppy, blue dicks, coast goldfields (*Lasthenia californica*), globe gilia (*Gilia capitata*), and angel gilia; and non-native species (red-stemmed filaree and short-podded mustard).

California Sagebrush–Black Sage Scrub (32.120.00). This alliance was mapped to the California sagebrush–black sage (32.120.01) association level, indicating that California sagebrush is the dominant shrub species, with black sage as the co-dominant.

This association primarily occurs on site in three main areas: Ayers Canyon/Ayres Rock, between San Martinez Grande and Chiquito canyons, and generally between Long and Potrero canyons. Smaller patches of this association occur between Exxon and Lion canyons.

In addition to California sagebrush and black sage, this vegetation community supports the following species on site: shrubs, such as yerba santa (*Eriodictyon crassifolium*), our Lord's candle, Great Basin sagebrush (*Artemisia tridentata*), Mexican elderberry, giant ryegrass, and California encelia; native herbaceous species, including yellow-fiddleneck, common forget-me-not, California dodder, sacapellote, common eucrypta, California chicory (*Rafinesquia californica*), wild cucumber, and southern sun cup (*Camissonia bistorta*); and non-native species (short-podded mustard, red-stemmed filaree, yellow sweet-clover, and horehound.

California Sagebrush Scrub–Undifferentiated Chaparral (modified from 32.300.00 Coastal Sage Chaparral Scrub). California sagebrush scrub–undifferentiated chaparral is not a CDFG (2003) alliance, but on site occurs as a co-dominance of California sagebrush and chaparral scrub species, as described below for undifferentiated chaparral.

This vegetation community occurs in two main areas on site: in the Sawtooth Ridge northeast of Long Canyon and southwest of Lion Canyon. A small patch occurs in the upper portion of Potrero Canyon, contiguous with off-site patches on the Legacy Village site.

On site, this vegetation community includes native shrubs, such as California sagebrush, squaw bush, California buckwheat, purple sage, and chaparral bush mallow; smaller native species (coastal lotus (*Lotus salsuginosus*), angel's gilia, California goosefoot (*Chenopodium californicum*), leafy daisy (*Erigeron foliosus*), blue dicks, California peony (*Peonia californica*), California aster (*Lessingia filaginifolia*), whispering bells (*Emmenanthe penduliflora*), fascicled tarweed (*Hemizonia fasciculata*), and tansy-leaved phacelia (*Phacelia tanacetifolia*)); and non-native species (red-stemmed filaree and short-podded mustard).

4.5.3.4.1.4 *Undifferentiated Chaparral Scrubs (37.000.00)*

The vast majority of chaparral on site was mapped as undifferentiated chaparral scrub, including burned areas, at a general vegetation community type level. Chaparral in general is a drought- and fire-adapted community of broad-leafed shrubs one and one-half to three meters tall, typically forming dense, impenetrable stands when mature. It develops primarily on mesic, north-facing slopes and in canyons. Undifferentiated chaparral scrubs, as designated by CDFG (2003), correlates to Holland's (1986) southern mixed chaparral community, where no one species dominates the shrub canopy; typically, there is a mixture of chamise (*Adenostoma fasciculatum*), ceanothus (*Ceanothus* spp.), manzanita (*Arctostaphylos* spp.), scrub oak (*Quercus dumosa*), laurel sumac, sugar bush (*Rhus ovata*), toyon, and sages (*Salvia* spp.).

The distribution of undifferentiated chaparral scrubs in the Project vicinity forms part of a complex mosaic of vegetation, and generally occurs as a transition community between oak woodlands in the wetter, deeper soils and coastal scrubs on drier, shallower soils. The highly complex geomorphology of the region contributes to this complexity and variety of microclimatic conditions.

Undifferentiated chaparral scrubs occur in the higher elevations of the Specific Plan area, including north Chiquito Canyon, south of Grapevine Mesa, and in the southern portion of the High Country SMA. Most of the undifferentiated chaparral scrubs in the Specific Plan area are relatively intact and undisturbed, probably because of their distribution in the higher and steeper elevations. However, large areas of burned undifferentiated chaparral scrubs resulting from the Simi Fires of 2003 occur through the center of the Specific Plan area along Salt Creek and eastward to Pico Canyon. Intact and relatively undisturbed undifferentiated chaparral scrubs in the Entrada planning area are limited to relatively small areas within the southern portion of the Entrada planning area.

The undifferentiated chaparral on site includes a mixture of native shrubs (squaw bush, chamise, hoaryleaf ceanothus (*Ceanothus crassifolius*), mainland cherry (*Prunus ilicifolia* ssp. *ilicifolia*), spiny redberry (*Rhamnus crocea*), sugar bush, holly-leaf redberry (*Rhamnus ilicifolia*), poison oak (*Toxicodendron diversilobum*), toyon, prickly phlox (*Leptodactylon californicum*), chaparral bush mallow, purple sage, and mountain mahogany (*Cercocarpus betuloides*)) and smaller, more herbaceous native species, such as California wishbone-bush, California peony, chaparral nightshade (*Solanum xanti*), Lindley's annual lupine, California poppy, rusty popcorn flower, whispering bells, globe gilia, sacapellote, heart-leaf penstemon (*Keckiella cordifolia*), common forget-me-not, California butterweed (*Senecio californicus*), white snapdragon (*Antirrhinum coulterianum*), California goosefoot, and redmaids; non-native herbaceous species are also present, including short-podded mustard, red-stemmed filaree, and Russian thistle.

4.5.3.4.1.5 *Chaparral with Chamise (37.100.00)*

Chamise Chaparral (37.101.00). The chamise chaparral alliance is defined as having at least 60% cover of chamise in the canopy (Sawyer and Keeler-Wolf 1995). Other chaparral species may occur as well, including chamise, ceanothus, mountain mahogany, manzanita, scrub oak, laurel sumac, sugar bush, toyon, and sages. Mature stands of chamise chaparral are very dense, up to three meters in height, and generally support a very limited herbaceous understory (Holland 1986).

Chamise chaparral on site is limited to a few locations, including upper Chiquito Canyon, west of lower Long Canyon, along the Specific Plan/Legacy Village boundary in upper Long Canyon, and east of Lion Canyon.

On site, this vegetation community is dominated by chamise and also supports native shrub species, such as hoaryleaf ceanothus, squaw bush, toyon, bladder pod (*Isomeris arborea*), California buckwheat, giant ryegrass, black sage, and California encelia; smaller native plants, including California peony, sacapellote, California aster, California wishbone-bush, California dodder, common forget-me-not, globe gilia, wild cucumber, and chaparral nightshade; and non-native species (black mustard and short-podded mustard).

4.5.3.4.1.6 *Chaparral with Oak (37.400.00)*

Scrub Oak Chaparral (37.407.00). The scrub oak alliance is defined as having at least 60% cover of scrub oak in the canopy (Sawyer and Keeler-Wolf 1995). According to Holland (1986), this vegetation community can attain heights of 20 feet, and it is typically dominated by scrub oak with mountain mahagony also typically present. Characteristic species include scrub oaks (*Quercus* spp.), ceanothus, mountain mahogany, toyon, holly-leaf cherry (*Prunus ilicifolia*), poison oak, redberry (*Rhamnus* spp.), silk-tassel bush (*Garrya* veatchii), and narrow-leaved bedstraw (*Galium angustifolium*) (Holland 1986).

Scrub oak chaparral occurs in only one location, in the upper portion of the East Fork of Salt Creek.

On site, scrub oak chaparral is dominated by scrub oak, and also supports other native shrubs, such as poison oak, sugar bush, Mexican elderberry, yerba santa, black sage, purple sage, and California sagebrush; smaller native species including wild cucumber, caterpillar phacelia, and western jimsonweed (*Datura wrightii*); and non-natives abumashi (*Schismus barbatus*) and horehound.

4.5.3.4.1.7 *Other Scrubs*

Eriodictyon Scrub. Eriodictyon scrub is dominated by yerba santa (*Eriodictyon crassifolium* var. *nigrescens*). It does not conform with CDFG (2003) defined vegetation communities and is defined here as a scrub community dominated by yerba santa.

Eriodictyon scrub occurs in the Specific Plan area along the southern end of Magic Mountain Canyon and is contiguous with an off-site patch on Legacy Village. It is adjacent to big sagebrush scrub, California sagebrush scrub, California annual grassland, chaparral, and disturbed land and is relatively intact.

On site, eriodictyon scrub is dominated by an almost monotypic stand of yerba santa. This vegetation community does support a few other sparsely distributed native shrubs, including California buckwheat, goldenbush, black sage, and purple sage; native herbaceous species western jimsonweed (*Datura wrightii*) and butterweed (*Senecio flaccidus* var. *douglasii*); and the non-native tocalote.

4.5.3.4.1.8 *Oak Woodland and Forest (71.000.00)*

Coast Live Oak Forest and Woodland (71.060.00). This alliance on site is mapped to the association level as coast live oak woodland (71.060.19). According to Holland (1986), coast live oak woodland is dominated by a single evergreen species: coast live oak (*Quercus agrifolia*). Canopy height ranges from 30 to 80 feet. The shrub layer is poorly developed, but may include toyon, gooseberry (*Ribes* spp.), laurel sumac, or Mexican elderberry. The herb component is continuous, dominated by a variety of introduced species, such as brome grasses (Holland 1986).

On site, coast live oak woodland is defined as areas with 20% to 50% cover by coast live oak. Most of the coast live oak woodland on the RMDP study area occurs in the southern half, generally in south-facing canyons in the High Country SMA and Salt Creek area. In accessible areas along Salt Creek, the understory of this woodland community has been impacted by historical and ongoing grazing practices and is dominated by non-native grasses, such as wild oat, slender oat, and bromes. Smaller patches of coast live oak woodland generally occur in south-facing canyons throughout the Project area, including along the East Fork of Salt Creek and, to a lesser extent, along the Santa Clara River tributary canyons, such as Ayers Canyon, Long Canyon, Humble Canyon, Lion Canyon, Exxon Canyon, and upper Chiquito Canyon.

In addition to coast live oak trees, the coast live oak woodland includes occasional valley oak trees (*Quercus lobata*); a variety of native shrubs, such as goldenbush, Mexican

elderberry, yerba santa, currants (*Ribes* spp.), and Great Basin sagebrush; native herbaceous species, including common owl's clover, California aster, yellow fiddleneck, wild cucumber, elegant clarkia (*Clarkia unguiculata*), miner's lettuce (*Claytonia perfoliata*), wild pea (*Lathyrus vestitus*), Parry's larkspur (*Delphinium parryi*), California mugwort (*Artemisia douglasiana*), blue fiddleneck (*Phacelia distans*), chaparral nightshade, American bowlesia (*Bowlesia incana*), Pacific sanicle (*Sanicula crassicaulis*), California melic, California maiden-hair (*Adiantum jordani*), fiesta flower (*Pholistoma auritum*), California hedge parsley (*Yabea microcarpa*), poison sanicle (*Sanicula bipinnata*), California goldenrod (*Solidago californica*), California goosefoot, blue dicks, wild cucumber, globe gilia, and angel gilia; and non-native species (hedge mustard (*Sisymbrium officinale*), common sow-thistle (*Sonchus oleraceus*), goose grass (*Galium aparine*), tocalote, red-stemmed filaree, yellow sweet-clover, milk thistle, common chickweed (*Stellaria media*), and tree tobacco).

Valley Oak Forest and Woodland (71.040.00). The valley oak forest and woodland alliance includes two associations: valley oak woodland (71.040.08) and valley oak/grass (71.040.05). According to Holland (1986), this vegetation community is typically manifested by valley oak trees providing a canopy over a grassy-understoried savannah. The canopy of the valley oaks rarely exceeds 30 to 40% cover (Holland 1986). On site, valley oak woodland includes a predominance of valley oaks in sufficient numbers to constitute 20% to 50% of the total cover. Valley oak/grass includes areas where valley oak comprises less than 20% of the total cover. This association on site includes valley oaks sparsely occurring in California annual grassland.

On site, valley oak woodland occurs in relatively small patches in the southern portions of Salt Creek, the High Country SMA, and the East Fork of Salt Creek and in other smaller, scattered patches in the Windy Gap area and along the Santa Clara River north of Airport Mesa. Much larger patches of valley oak/grass occur on site in the southern portion of the Salt Creek area and High Country SMA, as well as smaller patches between the East Fork of Salt Creek and Potrero Canyon and the Magic Mountain Canyon area. Valley oak woodland and valley oak/grass appear to relate to grazing pressure, particularly in the southern portion of the Specific Plan area, where open woodland provides cattle with ideal forage and shade.

In addition to valley oak trees, valley oak woodland and valley oak/grass support native shrubs (Mexican elderberry and coyote brush); native herbaceous species, including miner's lettuce, California fuchsia (*Epilobium canum* ssp. *canum*), common owl's-clover, blue dicks, common lomatium (*Lomatium utriculatum*), fiesta flower, wild cucumber, yellow fiddleneck, blue dicks, arroyo lupine, California goosefoot, coast paintbrush

(*Castilleja affinis*), shrubby phacelia, common forget-me-not, yellow fiddleneck, common eucrypta, and arroyo lupine; as well as non-native species (common chickweed, short-podded mustard, black mustard, common sow-thistle, bull thistle (*Cirsium vulgare*), shepherd's purse, milk thistle, cheeseweed, and non-native grasses).

Mixed Oak Woodland and Forest (71.100.00). The mixed oak woodland and forest alliance includes a co-dominance of coast live oak trees and valley oak trees in sufficient numbers to constitute 20% to 50% of the oak woodland cover.

On site, mixed oak woodland and forest is limited to the High Country SMA and Salt Creek area, and typically occurs in patches where other oak woodland associations intergrade, such as coast live oak woodland and valley oak/grass. In areas subject to grazing, the understory of mixed oak woodland is typically dominated by non-native grasses, such as wild oat, slender oat, and bromes.

Mixed oak woodland on site is characterized by a co-dominance of coast live oak and valley oak canopy trees, and also supports many of the same understory species described above for coast live oak woodland, valley oak woodland, and valley oak/grass. Understory species for the mixed oak woodland include native shrubs, such as currants, Mexican elderberry, and poison oak; smaller native species, including California goosefoot, climbing bedstraw (*Galium porrigens*), coast paintbrush, yellow fiddleneck, shrubby phacelia, wild cucumber, and blue dicks; and non-native species (milk thistle, cheeseweed, short-podded mustard, bull thistle, and horehound).

4.5.3.4.1.9 *Upland Walnut Woodland and Forest (72.000.00)*

California Walnut Woodland and Forest (72.100.00). This alliance on site was mapped to the association level of California walnut woodland (72.100.01). Holland (1986) describes California walnut woodland as having an open tree canopy dominated by California walnut (*Juglans californica*), which allows a grassy understory to develop. This association was mapped where a predominance of California walnut occurred in sufficient numbers to constitute 20% to 50% absolute cover.

On site California walnut woodland occurs very locally in the southwestern corner of the RMDP study area, mostly on south-facing slopes within the Salt Creek area and within the southern portion of the High Country SMA. The California black walnut trees in these areas are low (generally less than 20 feet tall) and exhibit multiple trunks that give the trees a shrubby character (in contrast to the tall trees often seen in bottomlands and riparian areas).

The California walnut woodland that occurs on site supports an understory of native shrubs, such as Mexican elderberry, coyote brush, giant ryegrass, yerba santa, and poison oak; smaller native species, including cliff malacothrix, pipestems (*Clematis lasiantha*), common eucrypta, blue dicks, arroyo lupine, chaparral nightshade, wild cucumber, common forget-me-not, fiesta flower, Pacific sanicle, purple Chinese houses (*Collinsia heterophylla*), miner's lettuce, elegant clarkia, California melic, caterpillar phacelia, lacepod (*Thysanocarpus laciniatus*), valley clover (*Trifolium willdenovii*), and climbing bedstraw, and non-native species (yellow sweet-clover, horehound, common chickweed, cheeseweed (*Malva parviflora*), goose grass, black mustard, bull thistle, and California burclover (*Medicago polymorpha*)).

4.5.3.4.1.10 *Marsh (52.000.00)*

Bulrush–Cattail Wetland (52.102.00). Bulrush–cattail wetland is defined on site as marsh consisting of approximately equal dominance of bulrush (*Scirpus* sp.) and cattail (*Typha* sp.) species. This vegetation community is similar to Holland's (1986) description of coastal and valley freshwater marsh, which is dominated by *Scirpus* and *Typha* spp., but that typically includes a variety of other species, as described below.

This vegetation community occurs in only two small locations along lower Salt Creek within the High Country SMA where the soil is saturated enough to sustain this hydrophytic vegetation.

The bulrush–cattail wetland is dominated by winged three-square (*Scirpus americanus*) and broad-leaved cattail (*Typha latifolia*), with salt grass (*Distichlis spicata*) occurring along the margins. Occasional mulefat (*Baccharis salicifolia*) seedlings are also present.

Cismontane Alkali Marsh (52.203.00). According to Holland (1986), cismontane alkali marsh typically occurs in areas that are wet or inundated throughout most to all of the year. Dominant species include rushes (*Juncus* spp.), saltgrass, sedges (*Carex* spp.), yerba mansa (*Anemopsis californica*), and alkali heath (*Frankenia grandifolia*). This community occurs at lake beds and flood plains below 1,000 feet AMSL and is characterized by higher levels of salts than occur in the coastal and valley freshwater marsh. It differs from coastal saltmarsh primarily in that it is not subject to tidal inundation.

Cismontane alkali marsh on site occurs at the confluence of the East Fork and mainstem of Salt Creek and at two reaches in lower and middle Potrero Canyon where the topography flattens and provides suitable conditions for its formation. This marsh type

exhibits low vegetative diversity on site, possibly due to cattle grazing in Potrero Canyon and Salt Creek; however, the vegetation appears resilient and intact.

The cismontane alkali marsh on site includes native herbaceous species (salt grass, beardless wild rye (*Leymus triticoides*), and winged three-square); occasional mulefat seedlings are also present. The higher elevations and edges support native species (yerba mansa, western ragweed (*Ambrosia psilostachya*), and spearscale (*Atriplex triangularis*)); and non-native species (yellow sweet-clover, five-hooked bassia (*Bassia hyssopifolia*), and peppergrass (*Lepidium latifolium*)). Where water is actually flowing in small rills at the surface, winged three-square and Mexican rush (*Juncus mexicanus*) also occur.

Fresh-Brackish Water Marsh (52.100.00). This alliance was mapped to the association level of coastal and valley freshwater marsh (52.100.01). Coastal and valley freshwater marsh is an emergent freshwater wetland vegetation type that occurs where the water table is at or just above the ground surface, such as around the margins of lakes, ponds, slow-moving streams, ditches, and seepages. Due to its being permanently flooded by fresh water, there is an accumulation of deep, peaty soils. It typically is dominated by species such as cattail, woolly sedge (*Carex lanuginosa*), yellow nutsedge (*Cyperus esculentus*), and bulrush (Holland 1986).

This community occurs on site along the lower to middle reach of Potrero Creek. Overall, this community is relatively intact and undisturbed on site.

On site, coastal and valley freshwater marsh supports native herbaceous species, such as broad-leaved cattail and winged three-square, with native species (yerba mansa and western ragweed) and non-native species (wild celery (*Apium graveolens*) and rabbit's-foot grass (*Polypogon monspeliensis*)) occurring at the fringes.

4.5.3.4.1.11 *Low to High Elevation Riparian Scrub (63.000.00)*

Arrow Weed Scrub (63.710.00). The arrow weed scrub alliance occurs in moderate to dense streamside thickets strongly dominated by arrow weed (*Pluchea sericea*). This disturbance-maintained community occurs along streambanks, ditches, and washes with gravelly or sandy channels in most major drainages in the drier southern parts of California. In addition to arrow weed, characteristic species include salt grass, narrow-leaved willow (*Salix exigua*), tamarisk (*Tamarix* spp.), rushes, and slender cattail (*Typha domingensis*) (Holland 1986).

On site, arrow weed scrub occurs in dense patches along the banks of the Santa Clara River or its tributaries, with a few tamarisk individuals interspersed throughout the community.

The arrow weed scrub on site is dominated by the native shrub arrow weed, but also supports native shrubs, such as mulefat and California sagebrush; native herbaceous species, such as chaparral nightshade, common eucrypta, caterpillar phacelia, and western ragweed; and non-native species, such as tamarisk, yellow sweet-clover, red-stemmed filaree, horehound, and short-podded mustard.

Mexican Elderberry (63.410.00). The Mexican elderberry scrub alliance is an open scrub vegetation community that occurs in foothill areas on the upper benches of streams, and it is often associated with sycamore riparian woodland. Sawyer and Keeler-Wolf (1995) describe this vegetation community as supporting Mexican elderberry as the sole or dominant shrub in the canopy. Associated species include poison oak, narrow-leaved willow, Fremont cottonwood (*Populus fremontii*), valley oak, and California wild grape (*Vitis californica*). The canopy can vary from open to continuous, and the ground layer is often grassy (Sawyer and Keeler-Wolf 1995). This vegetation community is not described by Holland (1986).

This plant community occurs in several small patches on site, including upper and lower Salt Creek, tributaries to the East Fork of Salt Creek, between middle Potrero Canyon and the East Fork of Salt Creek, lower Homestead Canyon, San Martinez Grande Canyon, south and west of middle Long Canyon, and along Middle Canyon. Overall, this community is relatively intact and undisturbed on site, although a small area was mapped as disturbed west of Long Canyon. A small area mapped in CDFG wetland jurisdiction is located in lower Potrero Creek.

On site, Mexican elderberry scrub is dominated by Mexican elderberry but also includes other native shrubs, such as Great Basin sagebrush and goldenbush; native herbaceous species, such as yellow fiddleneck, blue dicks, and rusty popcorn flower; and non-native species (nettle-leaved goosefoot (*Chenopodium murale*), horehound, milk thistle, Italian thistle (*Carduus pycnocephalus*), short-podded mustard, and tree tobacco).

Mulefat Scrub (63.510.00). The mulefat scrub alliance is a relatively low (two to three feet in height), dense, shrubby plant community that occurs in riparian vegetation, at the edges of catch basins, and in canyons. It is dominated by mulefat and may contain a small number of arroyo willow (*Salix lasiolepis*) individuals, upland shrubs, and facultative herbs. Mulefat scrub is a seral community that occurs mainly along major drainages and floodplains where the riparian vegetation is open or disturbed. Frequent

flooding and/or scouring apparently maintain this community in an early successional state (Holland 1986). Characteristic plant species in this community include mulefat, coyote brush, western ragweed, and a few other obligate or facultative wetland species (Reed 1988).

Mulefat scrub occurs in post-disturbance areas along the main channel of the Santa Clara River in the Specific Plan area. The main channel of Salt Creek is dominated by this community, which primarily grows in patches along sandy ditches and stream channels in the main and East forks of Salt Creek, lower Salt Creek, upper Potrero Creek, San Martinez Grande Canyon, along the Santa Clara River, in Castaic Creek, and in small, isolated patches in Middle Canyon and Dead-End Canyon. This community is somewhat limited in the VCC planning area and only comprises a small portion of the northern VCC planning area. Two patches of mulefat scrub in middle and upper Potrero Creek occur in CDFG wetland jurisdiction. A small patch of disturbed mulefat occurs in Castaic Creek south of VCC.

On site, mulefat includes native shrubs (mulefat, quail brush (*Atriplex lentiformis*), giant ryegrass, and coyote brush); smaller native species, such as yellow fiddleneck, common forget-me-not, cocklebur (*Xanthium strumarium*), western ragweed, California mugwort, arroyo lupine, California chicory, and wild heliotrope (*Heliotropium curassavicum*); and non-native species, such as cheeseweed, horehound, milk thistle, winter vetch (*Vicia villosa*), yellow sweet-clover, tocalote, short-podded mustard, tree tobacco, and tamarisk (*Tamarix ramosissima*).

4.5.3.4.1.12 *Riparian Forest and Woodland (61.000.00)*

Southern Willow Scrub (61.208.00). According to Holland (1986), southern willow scrub is a dense, broad-leafed, winter-deciduous riparian thicket dominated by several species of willow (*Salix* spp.), with scattered emergent Fremont cottonwood and western sycamore (*Platanus racemosa*). Most stands are too dense to allow much understory development. This alliance is considered seral due to repeated disturbance/flooding, and is, therefore, unable to mature into the taller southern cottonwood–willow riparian forest (Holland 1986).

Southern willow scrub is fairly common on site, with occurrences along the Santa Clara River, upper and lower Potrero Creek, upper and lower Salt Creek, and the East Fork of Salt Creek. This alliance is presumed to be successional and was found to be intact and relatively undisturbed on site, except for the stands in Potrero Creek, which have experienced greater disturbance associated with grazing activities.

Southern willow scrub on site includes native trees (arroyo willow, red willow (*Salix laevigata*), narrow-leaved willow, and Goodding's black willow (*Salix gooddingii*)); native shrubs (quail brush, mulefat, arrow weed, Mexican elderberry, coyote brush, and giant ryegrass); native herbaceous species, including western ragweed, arroyo lupine, California mugwort, shrubby phacelia, yerba de chiva (*Clematis ligusticifolia*), yellow fiddleneck, and caterpillar phacelia; and non-native species, such as yellow sweet-clover, white sweet-clover (*Melilotus alba*), tumble mustard (*Sisymbrium altissimum*), hedge mustard, milk thistle tamarisk, short-podded mustard, and cheeseweed.

Tamarisk Scrub and Woodland (63.810.00). This alliance on site was mapped at the association level as shrub tamarisk (63.810.02). These areas are dominated by tamarisk, typically by *Tamarix ramosissima*. This invasive, non-native plant community is widely implicated in degradation of native riparian habitats throughout southern California and is the target of eradication efforts regionwide. Tamarisk typically occurs on moist soils and in streambeds, and its occurrence, similar to giant reed (*Arundo donax*), may be related directly to soil disturbance or introduction of propagules by grading or flooding. Tamarisk is a slow-growing species; however, once established, its removal is very difficult. Characteristic species include arrow weed, quail brush, narrow-leaved willow, and Palmer's coldenia (*Coldenia palmeri*) (Holland 1986).

Shrub tamarisk occurs on site in small, fairly monotypic patches at the lower end of Salt Creek, in middle and lower Potrero Canyon, in Castaic Creek near the confluence with the Santa Clara River, and just upstream of this confluence in the Santa Clara River.

On site, shrub tamarisk is dominated by tamarisk but also includes scattered native shrubs (coyote brush, quail brush, and mulefat), smaller native species (winged three-square, chaparral nightshade, cocklebur), and non-native species (horehound and short-podded mustard).

Fremont Cottonwood Riparian Forest and Woodland (61.130.00). This alliance was mapped as the association southern cottonwood–willow riparian (61.130.02). Southern cottonwood–willow riparian is a tall, open, broad-leafed winter-deciduous riparian forest dominated by Fremont cottonwood trees and several different species of willow (Holland 1986). It occurs in frequently overflowed lands along rivers and streams.

This association forms dense swaths of established vegetation along the main channel of the Santa Clara River in both the Specific Plan and Entrada planning areas and in Castaic Creek in the VCC planning area, generally occurring on the floodplains beyond the effects of flood scour. Small reaches and/or patches of southern cottonwood–willow

riparian also occur in upper Chiquito Canyon, upper Mid-Martinez Canyon, Potrero Canyon, and lower Middle Canyon.

Along the Santa Clara River, this association is relatively intact and undisturbed in both the Specific Plan and Entrada planning areas. However, edges of this riparian forest community are susceptible to exotic invasive species, such as giant reed and tamarisk, and patches of these exotic species were observed on site. Edge areas that have undergone scouring or sedimentation disturbance have a much higher susceptibility to invasive colonization, primarily by giant reed. This type of disturbance also creates colonization sites for the slow-growing tamarisk, but to a more limited degree.

On site, southern cottonwood–willow riparian forest supports an overstory of Fremont cottonwood, arroyo willow, and red willow; native shrubs, such as Great Basin sagebrush, quail brush, coyote brush, scale-broom, Mexican elderberry, California mugwort, giant creek nettle (*Urtica dioica*), and mulefat; native herbaceous species, such as wild cucumber, broad-leaved cattail, prickly cryptantha (*Cryptantha muricata*), western jimsonweed, yellow fiddleneck, Santa Barbara locoweed (*Astragalus trichopodus*), and common eucrypta; and non-native species (tamarisk, giant reed, Italian thistle, yellow sweet-clover, horehound, tree tobacco, abumashi, and milk thistle).

Coast Live Oak Forest and Woodland (71.060.00). This alliance was mapped as the association of southern coast live oak riparian forest (71.060.20). This association generally is characterized by open to dense woodlands in riparian zones dominated by oak species (*Quercus* sp.), with western sycamore, scalebroom scrub, mulefat scrub, or southern willow scrub as an understory as well as sclerophyllous shrubs, such as holly-leaf redberry, California coffeeberry (*Rhamnus californica*), laurel sumac, Mexican elderberry, fuchsia-flowered gooseberry (*Ribes speciosum*), toyon, poison oak, giant ryegrass, and lemonadeberry (Holland 1986). Large grassland areas dominated by bromes may also be present.

On site, there is a very small area (less than one acre) of southern coast live oak riparian forest at the confluence of Ayers Canyon and the Santa Clara River within terraces along the braided stream channel. This occurrence lies on a north-facing, mesic slope coming down onto the River bench, and is relatively undisturbed and intact.

Southern coast live oak riparian forest on site has a canopy of coast live oak trees with native shrubs (California sagebrush and giant ryegrass); smaller native species (yellow fiddleneck, California chicory, miner's lettuce, blue dicks, and wild cucumber); and non-native species (milk thistle, short-podded mustard, goose grass, Italian thistle, common sow-thistle, and red-stemmed filaree).

4.5.3.4.1.13 *Other Riparian/Wetland Communities*

Riparian/wetland alliances that do not conform to CDFG (2003) defined vegetation communities were mapped on site: herbaceous wetland, river wash, alluvial scrub, big sagebrush scrub, and giant reed. Alluvial scrub and big sagebrush scrub are recognized as upland coastal scrub and Great Basin scrub communities by CDFG (2003) elsewhere in California, but these communities do not apply here because the on-site communities are typically associated with floodplains and riparian communities rather than upland communities. Giant reed is included in Grass and Herb Dominated Communities by CDFG (2003), but is treated as a riparian community by this EIS/EIR because of its close association with native riparian and wetland communities on site.

Herbaceous Wetland. Herbaceous wetland does not conform to a CDFG (2003) defined vegetation community classification and was defined on site by the dominant plant species.

This vegetation community was observed in the Specific Plan area and VCC planning area within the Santa Clara River corridor. Herbaceous wetland on site appears to be an early seral form of riparian vegetation where past flooding (particularly during the winter of 2004/2005) has severely altered the bed of the Santa Clara River by scouring and deposition.

Herbaceous wetland appears to be highly susceptible to invasion by non-native riparian species, particularly giant reed and tamarisk. Giant reed has been observed forming rhizomatic clumps in a wide patchwork throughout this herbaceous wetland community in the Specific Plan area. Additionally, in the VCC planning area, this plant community is located immediately south of residential development and an existing dirt road to the east that is presumably used for utility access. Direct impacts of road disturbance and associated soil disturbance appear to be causing non-native plant colonization in the VCC planning area.

On site, herbaceous wetlands typically include thick stands of juvenile native seedlings and saplings, including Fremont cottonwood, willows, mulefat, arrow weed; native herbaceous species, such as broad-leaved cattail, Hooker's evening primrose (*Oenothera elata*), willow weed (*Polygonum lapathifolium*), cocklebur, California cottonweed (*Epilobium ciliatum*), and bulrushes (*Scirpus* ssp.); and non-native species, including water cress (*Rorippa nasturtium-aquaticum*), whorled dock (*Rumex conglomerates*), curly dock (*Rumex crispus*), tamarisk, giant reed, and pepperweed.

River Wash. River wash does not conform to a CDFG (2003) defined vegetation community classification and is defined on site as open wash that is unvegetated or

sparsely vegetated. River wash includes wash areas of the Santa Clara River and its tributaries that are unvegetated or sparsely vegetated with seedlings, sparse grasses, and forbs and that are subject to scouring by seasonal storm flows. A variety of individual herb, shrub, and even tree species sometimes occur within river wash as waifs or temporary inhabitants that do not persist for long periods because of frequent episodes of winter flooding. Mulefat and willow saplings, sparse grasses, and forbs often begin to establish after these natural disturbance patterns. River wash is a naturally dynamic habitat and may shift and change position within drainages, depending on flood volumes and behavior.

The Specific Plan area contains large areas of river wash, primarily within the Santa Clara River. Alteration of upstream flow on the Hasley Canyon drainage probably has changed more vegetated areas to river wash within the VCC planning area. Non-native plant elements, such as mustards (primarily short-podded mustard), bromes (*Bromus diandrus* and *B. madritensis*), and tocalote, were evident where adjacent road disturbance occurred on the west side of the VCC planning area. Typical species on the edge of river wash include tree tobacco and western jimsonweed. River wash in the Entrada planning area receives runoff from medium-density housing and a golf course uphill of the planning area. A concrete outfall transitions flows from this golf course to the river wash. The limited establishment of plants likely caused by scour during winter and spring rain events may be exacerbated by this alteration of upstream flow.

The river wash on site occurs within the low-flow channel and sporadically includes native shrubs such as Great Basin sagebrush, scale-broom, mulefat, goldenbush (*Isocoma menziesii*), and deerweed; as well as a variety of herbaceous species, including common eucrypta, wild rhubarb (*Rumex hymenosepalus*), common forget-me-not, yellow fiddleneck, mustard primrose (*Camissonia californica*), annual burweed (*Ambrosia acanthicarpa*), telegraph weed (*Heterotheca grandiflora*), Lindley's annual lupine, prickly cryptantha, yellow pincushion, sun cup (*Camissonia hirtella*), butterweed, deerweed, silver puffs, lacy phacelia; and non-native herbs, such as tree tobacco, milk thistle, common groundsel (*Senecio vulgaris*), lamb's-quarters (*Chenopodium album*), and tocalote.

Alluvial Scrub. Alluvial scrub is a general term for a variety of alliances and associations that may occur on alluvium associated with riverine floodways and alluvial fans. The nature of this community is one of periodic natural disturbance by flood action and deposition of alluvial sediments. Species usually found in this community include a mixture of wetland species that can tolerate more xeric conditions and transitional sage scrub species; this atypical assemblage of plant species occurs because of the alluvial

disturbance and sedimentation processes. Alluvial scrub as it occurs in the Project area does not conform to a CDFG (2003) defined vegetation community classification and was defined on site by the dominant plant species observed.

On site, alluvial scrub occurs along the Santa Clara River and its tributaries. It is limited to two small (each less than one acre) alluvial terraces located within the Specific Plan area (one along the Santa Clara River and one along a tributary to the East Fork of Salt Creek, a tributary of the Santa Clara River) and another small terrace in the Entrada planning area along Magic Mountain Canyon, a tributary of the Santa Clara River. This habitat was surrounded by road access and soil disturbance associated with earthworks in the Entrada planning area.

Species found on site within this community include scattered native species (Great Basin sagebrush, mulefat, narrow-leaved willow, tamarisk, deerweed, scale-broom, quail brush, California mugwort, California sagebrush, and cocklebur) and non-native species (short-podded mustard and tree tobacco).

Big Sagebrush Scrub. Big sagebrush scrub is composed mostly of Great Basin sagebrush, which are soft-woody shrubs one-half to two meters tall, usually with bare ground underneath and between shrubs (Holland 1986). As a CDFG (2003) recognized alliance (35.110.00) occurring in Great Basin Scrub, big sagebrush scrub is a widespread and characteristic shrub of the high desert and Great Basin floristic provinces, where it often occurs with pines and junipers. In the Santa Clarita area, however, it seems to occur in vegetation transitional to more typical cismontane coastal scrub.

On site, the big sagebrush scrub alliance generally occurs in alluvial areas along washes and is typically dominated by Great Basin sagebrush. Coastal scrub and chaparral component species also occur within this vegetation type where it intergrades or where transitional margins occur and in mixed patches where alluvial processes have influenced the pattern of vegetation. There is limited edge disturbance in this community in the Entrada planning area in the form of dirt roads and soil disturbances associated with earthworks at the eastern margin of the planning area. In general, however, this community is relatively intact in the Specific Plan and Entrada planning areas.

An association of big sagebrush scrub also occurs on site just north of Indian Dunes and SR-126: big sagebrush-California buckwheat. This small patch of big sagebrush-California buckwheat includes a predominance of Great Basin sagebrush with California buckwheat in sufficient numbers to constitute 20% to 50% of the total cover in the community.

The big sagebrush scrub includes native shrubs (Great Basin sagebrush, yerba santa, mulefat, coyote brush, squaw bush, scale-broom, quail brush, and California sagebrush); herbaceous native species, including California aster, wild cucumber, blue fiddleneck, wild rhubarb, blue dicks, lastarriaea (*Lastarriaea coriacea*), wild rhubarb, globe gilia, angel gilia, annual burweed, shrubby phacelia, whispering bells, lacy phacelia, cocklebur, strigose deerweed, Coulter's lupine (*Lupinus sparsiflorus*), arroyo lupine, yellow pincushion, California fluffweed (*Filago californica*), rusty popcorn flower, and common owl's clover; and non-native herbs (red-stemmed filaree, bull thistle, rubber rabbitbrush (*Chrysothamnus nauseosus*), Russian thistle, Australian saltbush (*Atriplex semibaccata*), tocalote, winter vetch, tree tobacco, yellow sweet-clover, common sow-thistle, tumble mustard, milk thistle, and horehound).

Giant Reed (42.080.00). Giant reed is a non-native, invasive vegetation alliance composed of monotypic or nearly monotypic stands of the species. Giant reed is fairly widespread in southern California riparian systems and, as such, is included in CDFG (2003) defined vegetation communities as a Grass and Herb Dominated Community. This non-native, perennial grass has invaded riverine floodplains and displaced native herb, scrub, and woodland communities and is a serious problem in many southern California watersheds. It has limited habitat value for wildlife, is highly flammable, and consumes large amounts of water. This invasive species is widely implicated in the degradation of native riparian habitats throughout southern California, and is the target of eradication efforts regionwide. Typically, it occurs on moist soils and in streambeds, and its occurrence may be related directly to soil disturbance or introduction of propagules by grading or flooding.

Large stands of giant reed occur along flood-scoured portions of the main channel of the Santa Clara River. Mapped occurrences may include occasional, surrounded native trees and remnant native riparian plant species. Although giant reed is pervasive in small (less than one acre) patches throughout the main channel and tributaries of the Santa Clara River, only those monotypic areas conforming to the vegetation mapping for this project were mapped. While several small isolated clumps occur, they have not been mapped because they did not achieve minimum mapping standards. This distribution of giant reed is suggestive of past disturbances upstream and within the Project area.

On site, the giant reed vegetation community is dominated by giant reed, and also supports scattered native species (mulefat, narrow-leaved willow, sun cup, yellow fiddleneck, and common eucrypta) and other non-native species (short-podded mustard, red-stemmed filaree, yellow sweet-clover, tree tobacco, abumashi, and common sow-thistle).

4.5.3.4.1.14 *Man-Made Land Cover Types*

The Project area includes three main man-made land cover types—agriculture, developed land, and disturbed land—that have resulted from historical, recent, and existing land uses.

Agriculture. Agriculture refers to areas where irrigated row and field crops are being grown (*e.g.*, intensive agriculture) as well as areas that may be recently or currently inactive (fallow). Agriculture may support such grass species as barley (*Hordeum* spp.) and wild oat. Grazing lands are not included in the agriculture classification. When actively farmed, this land has relatively little biological resource value for most native wildlife species because the soils are periodically tilled and vegetation is removed. Intensive agriculture also provides little habitat value where agricultural pest species, such as rabbits and squirrels, are actively controlled. When agricultural areas are left fallow for a period of time, they may become dominated by annual grasses and other weedy species, such as mustards, and while not considered high-quality wildlife habitat, they may provide at least temporary habitat for various rodents, rabbits, passerine (perching) birds, and foraging raptors.

Extensive agricultural practices have been conducted across the RMDP/SCP study area, particularly on Grapevine Mesa, Potrero Mesa, Onion Fields, and within many of the tributary canyons that flow into the Santa Clara River. Both dry land and irrigated agricultural practices have been conducted in Middle, Humble, Long, Potrero, and portions of Salt Creek canyons. Agricultural operations have long occurred within the alluvial soils bordering the Santa Clara River, and they abut the northern border of the riparian corridor in many areas. Intensive agricultural fields occur on the southeastern section of the VCC planning area and throughout areas adjacent to the Santa Clara River channel in the Specific Plan area. Fallow agricultural fields occur throughout Potrero Canyon, the lower reaches of Salt Creek Canyon, and on the major mesa areas (Airport Mesa, Grapevine Mesa, and Potrero Mesa).

Airport Mesa has been used for agricultural activities for a number of years, typically for irrigated crops. During the spring of 2008, Airport Mesa was fallow and supported dense populations of weedy annuals including brome grasses (*Bromus madritensis*, *B. diandrus*, *B. hordeaceus*), barley (*Hordeum* sp.), wild oats (*Avena barbata*, *A. fatua*), and rye grasses. In many locations, non-native annual species, such as cheeseweed, black mustard, short-podded mustard, and red-stemmed filaree comprised the dominant vegetative cover. Wildflowers were also common and included redmaids (*Calandrinia ciliata*), blue dicks, California poppy, Lindley's annual lupine, and various species of

phacelia (*Phacelia* spp.). San Fernando Valley spineflower is located to the east, south, and west of Airport Mesa.

Grapevine Mesa, although typically in active irrigated agricultural use, was fallow in the spring of 2008 and also supported weedy herbaceous annual plant communities. Most of this mesa was dominated by cheeseweed, red-stemmed filaree, short-podded mustard, London rocket (*Sisymbrium irio*), and California burclover (*Medicago polymorpha*). Russian thistle, milk thistle, and horehound were also present. San Fernando Valley spineflower is located to the east and west of Grapevine Mesa.

Onion Fields, located at the mouth of Long Canyon on a terrace above the Santa Clara River, is maintained as an irrigated sod farm. Additional agricultural areas extend up into Long Canyon; left fallow in 2008, these agricultural areas are dominated by many of the same weedy annual herbaceous plants described for Airport Mesa and Grapevine Mesa.

Potrero Mesa, located above and between Ayers and Potrero canyons, also supports various agricultural practices. Fallow in the spring of 2008, this area is also dominated by many of the same weedy herbaceous annuals described for Airport and Grapevine mesas, but also includes small populations of non-native species (shepherd's purse (*Capsella bursa-pastoris*) and common sow thistle) as well as native wildflowers, such as Lindley's annual lupine, California poppy, and yellow fiddleneck.

Developed Land. Developed land refers to areas supporting man-made structures, including industrial and commercial uses, private residences, and roadways, as well as other highly modified lands supporting structures associated with dwellings or other permanent structures.

Within the Specific Plan area, developed land generally refers to existing roads, oil rig pads, and associated infrastructure. This disturbance has resulted in widespread soil disturbance and non-native plant colonization along existing roadsides. These non-native plants have also invaded adjacent native vegetation communities. Mustards (primarily short-podded mustard) are a common indicator of these disturbed areas. There is significant development influence adjacent to the VCC planning area, including I-5, SR-126, and secondary roads to the west and east; medium-density residential housing to the north; and major commercial land uses immediately to the west and east. The secondary impacts of this development have resulted in widespread surface soil alteration and non-native plant colonization along existing roadsides, altering native habitat. Mustards are also a common indicator of these areas adjacent to development.

Disturbed Land. Disturbed land typically occurs in areas where soils have been recently or repeatedly disturbed by grading or compaction (*e.g.*, dirt roads), resulting in the growth of very few native perennials. These areas are usually dominated by bare ground or non-native dicotyledonous species, including filaree, black mustard, thistles (*e.g.*, *Cynara cardunculus*, *Carduus pycnocephalus*, and tocalote), dove weed, and others. Within the Project site, disturbed land occurs on permeable surfaces without vegetation as well as with weedy annual non-native vegetation, including Russian thistle, tocalote, dove weed, black mustard, and bull thistle. Usually, disturbed land has little wildlife habitat value but, similar to fallow agricultural lands, it may provide habitat for rodents and rabbits and raptor foraging habitat. Disturbed land is present throughout the RMDP/SCP study areas and has generally occurred in association with the various past and present land uses, including agriculture, gas and oil operations, and utilities. Much of the disturbed land is the linear dirt road network on site established in relation to these land uses. Larger, non-linear footprints of disturbed lands are particularly prevalent in the area between Potrero and Long canyons in the central portion of the RMDP/SCP study area.

4.5.3.4.2 Unique Landscape Features

This subsection describes the existing setting for three unique landscape features in the RMDP: the River Corridor SMA, High Country SMA/Salt Creek area, and Middle Canyon Spring. At the conclusion of this subsection, the long-term effects of Alternative 1 (No Action/No Project) on these unique landscape features are discussed.

The River Corridor SMA and High Country SMA/Salt Creek area have been designated as Significant Ecological Areas (SEAs) by the County of Los Angeles. The Newhall Ranch Specific Plan (County of Los Angeles 2003B) Land Use Plan designates approximately 5,182 acres for the River Corridor and High Country SMAs (**Figure 4.5-3**). The River Corridor SMA is generally 1,500 to 2,000 feet wide and is located along the north and south sides of the Santa Clara River. The High Country SMA/Salt Creek area is located in the southern portion of the Specific Plan area. Middle Canyon Spring is located at the mouth of Middle Canyon and provides habitat for two previously undescribed species: an undescribed aquatic snail and an undescribed sunflower.

4.5.3.4.2.1 *River Corridor SMA*

The Santa Clara River flows from its origins in the San Gabriel Mountains to the Pacific Ocean, approximately 50 miles to the west. The 977-acre River Corridor SMA includes the Santa Clara River within the Specific Plan area and associated vegetation communities. The main conservation values of the River Corridor SMA are its wetland and riparian vegetation communities that provide resident habitat for numerous wildlife species and its function as a

regional east–west wildlife habitat linkage and wildlife corridor for both resident and transitory species (see **Subsection 4.5.3.4.7**, Wildlife Habitat Connectivity and Buffers). State- and federally listed endangered and threatened species and numerous other special-status species have been observed or detected in riparian habitats of the River, including the state- and federally listed endangered unarmored threespine stickleback, southwestern willow flycatcher, and least Bell's vireo, among others. The River is an important migration and genetic dispersion corridor for many wildlife species, including aquatic taxa; riparian obligate species (resident and migratory); and larger, more mobile terrestrial animals.

The River Corridor SMA comprises a portion of the County's SEA 23. The Newhall Ranch Specific Plan (County of Los Angeles 2003B) delineates a River Corridor SMA that is sufficiently wide to handle the flood (50-year post-fire flood event) while retaining nearly all (91.2%) native vegetation within and along the River.

The biotic resources of the River Corridor SMA are vulnerable to damage from both ongoing and future human activities. As build-out of the Project area occurs, these environmental stressors will increase. To avoid, minimize, and mitigate these future potential impacts, the RMDP provides for transition areas between the River and development, restricts recreational uses in the River, and provides for the long-term management of the River Corridor SMA, including habitat restoration and enhancement. **Figure 4.5-10** shows the vegetation communities and land cover types present in the River Corridor SMA. **Figures 4.5-11** through **4.5-13** show the special-status species occurrences in the River Corridor SMA.

The River Corridor SMA vegetation communities and associated special-status species are described above in detail in **Subsection 4.5.3.3.1**.

4.5.3.4.2.2 *High Country SMA and Salt Creek Area*

The largest land use designation of the Newhall Ranch Specific Plan Land Use Plan is the 4,205-acre High Country SMA. The High Country SMA is located in the southern portion of the Specific Plan area and includes oak/grass savannahs, high ridgelines, and various canyon drainages, including the Salt Creek watershed in Los Angeles County. As part of its approval of the Specific Plan in 2003, the Los Angeles County Board of Supervisors imposed an off-site condition requiring the applicant to dedicate to the public the remaining 1,517-acre portion of the Salt Creek watershed in Ventura County adjacent to the western boundary of the Specific Plan area. Although the Salt Creek area was identified as an off-site area during the Specific Plan approval process by Los Angeles County, the area is within the RMDP boundary, and is included in the RMDP and SCP study areas.

The Newhall Ranch High Country SMA and Salt Creek area are in an unincorporated portion of the Santa Clara River Valley on the north slopes of the Santa Susana Mountains. Site elevations range from 800 feet AMSL in the Santa Clara River bottom in Ventura County to approximately 3,500 feet AMSL on the ridgeline of the Santa Susana Mountains along the southern boundary. This study area is dominated by rugged terrain, with the main feature being a south-to-north drainage area for Salt Creek and its associated tributaries (**Figure 4.5-7**). The High Country SMA and Salt Creek area vegetation communities (**Figure 4.5-14**) and associated special-status species (**Figure 4.5-15**) are described above in detail in **Subsection 4.5.3.3.1**.

As shown in **Figure 4.5-21**, the High Country SMA and Salt Creek area are part of the eastern arm of the conceptual linkage design identified in the South Coast Missing Linkages Project (Penrod *et al.* 2006). This linkage is about 4.5 miles (23,760 feet) wide in this area, with the narrowest portion of the High Country SMA and Salt Creek area being approximately 4,000 feet wide. The combined High Country SMA and Salt Creek area is a regionally significant wildlife habitat linkage that provides an important habitat link between the Santa Susana Mountains south of the Project area and the Santa Clara River.

4.5.3.4.2.3 *Middle Canyon Spring*

Middle Canyon Spring is just west of the mouth of Middle Canyon, on the south bank of the Santa Clara River (**Figure 4.5-22**). The spring is located on what appears to be an upper terrace of the Santa Clara River that is either fluvial in origin or an expression of underlying geological strata that are exposed at the surface. Approximately four feet of elevation separate this terrace from the River floodplain at the point nearest the spring to the north, and approximately eight feet of elevation separate this terrace from the River floodplain at the most westerly point. This terrace extends westward from the spring at a gentle slope and eventually tapers to an end where River flow has eroded the terrace. An intermediate elevation terrace or geological structure is present between the spring terrace and the Santa Clara River. This intermediate terrace slopes in a direction similar to the upper terrace and is marked at the western terminus by River erosion. Riparian vegetation in this near stretch of the Santa Clara River floodplain is likely enhanced by water outflows from both Middle Canyon Spring and the Middle Canyon drainage. It is possible that confluent surface water joins Middle Canyon Spring and the Middle Canyon drainage at peak flow events.

Flows at Middle Canyon Spring currently saturate a core area (approximately 400 square feet by 400 feet) of the spring complex (**Figure 4.5-23**). The core area may be limited in extent by two outflow channels that appear to have been excavated in the northern portion of the spring area. These channels drain water onto the intermediate terrace described above, from which the water

then flows into the Santa Clara River floodplain. Soils in the core area differ from those in the floodplain, as described further below.

This core area of Middle Canyon Spring is defined here as the area currently inundated by flow from the spring, including flowing or standing water or fully saturated soil. Within the core spring area, water appears to flow from numerous points at the toe of slope of the existing road fill. The water proceeds to flow across several benches, periodically coalescing into more distinct channels only to disperse again into sheet flow over lower benched areas.

The Middle Canyon Spring complex occurs in southern cottonwood–willow riparian forest in the Specific Plan area. The vegetation exhibits a clear pattern in response to the flow patterns described above. Bull tule (*Scirpus robustus*) appears to be associated with more consolidated flow, while more broadleaved herbaceous vegetation appears where sheet flow is present.

Southern cottonwood–willow riparian forest surrounds the core area of Middle Canyon Spring. The canopy trees are mature Fremont cottonwoods with heights of 30 to 45 feet and diameters up to three feet and arroyo willow trees with heights up to 20 feet. The dry understory is composed primarily of non-native grasses, such as ripgut brome (*Bromus diandrus*) and *Poa* sp. A heavy accumulation of organic duff is present. A row of Fremont cottonwoods stands on top of a low berm that forms the northwestern border of the current Middle Canyon Spring wetland. Some Fremont cottonwoods farther from the spring exhibit signs of water-deficit stress, indicating likely reliance on soil moisture from annual rainfall instead of the Middle Canyon Spring wetland.

Wetland vegetation of the core area of Middle Canyon Spring includes a perimeter thicket of desert wild grape (*Vitis girdiana*) and an abundance of bull tule. Some patches of cattails and California blackberry (*Rubus ursinus*) are present, interspersed with arroyo willow eight to 16 feet in height. Flowing surface water is present or soil is fully saturated. Substrate is sand and granitic gravel.

Areas of Italian thistle dominate large portions of the berms and basins west of the Middle Canyon Spring. Poverty weed (*Iva axillaris*) and Great Basin sagebrush dominate in an area between the eastern margin of Middle Canyon Spring and the bank of Middle Canyon Creek. This area has dense groundcover and moist soil. Another patch of this vegetation type is on the eastern bank of Middle Canyon Creek, opposite the spring.

An area composed of rushes (*Juncus* sp.) with Great Basin sagebrush is located northeast of Middle Canyon Spring. This area is on an old road berm between Middle Canyon Spring and the coast live oak woodland along the Middle Canyon drainage.

Within this setting, two special-status species are known to occur: the undescribed sunflower and the undescribed snail. See **Subsection 4.5.3.4.5** for a description of the undescribed sunflower and **Subsection 4.5.3.4.6** for a description of the undescribed snail.

4.5.3.4.3 General Wildlife[1]

This subsection describes the existing setting for general wildlife in the Project area, including the RMDP, VCC, and Entrada planning areas.

4.5.3.4.3.1 *RMDP*

Much of the 13,651-acre RMDP area is currently subject to rapidly changing land use practices (*i.e.*, transitioning from rural to residential and commercial), and large areas of previously continuous natural and agricultural lands in the Santa Clarita Valley now consist of urban development. However, large areas of natural uplands, riparian zones, and pastureland still remain in the RMDP area and support a diverse community of both common and special-status wildlife. The various vegetation community types described in **Subsection 4.5.3.4.1** contribute to the diversity and abundance of wildlife in the area, as they provide both resident and seasonal breeding habitat and function as habitat linkages and movement corridors for many of the wildlife species.

Birds. Bird species, including several special-status species, were the most common vertebrates observed in the RMDP area, both because this taxon is typically the largest component of terrestrial vertebrates in general and because most of the wildlife surveys conducted in the RMDP area focused on birds. Riparian areas, including locations adjacent to the Santa Clara River, support many resident and breeding species, including least Bell's vireo (*Vireo bellii pusillus*), yellow warbler (*Dendroica petechia*), yellow-rumped warbler (*Dendroica coronata*), yellow-breasted chat (*Icteria virens*), and the migrant willow flycatcher (*Empidonax traillii*). Common species observed within these same habitats included Anna's hummingbird (*Calypte anna*), cliff swallow (*Petrochelidon pyrrhonota*), American goldfinch (*Carduelis tristis*), dark-eyed junco (*Junco hyemalis*), and red-breasted sapsucker (*Sphyrapicus ruber*). Several common and less common species were observed in chaparral, coastal scrub, and California annual grassland in the RMDP area, including Bewick's wren (*Thryomanes bewickii*), ruby-crowned kinglet (*Regulus calendula*), blue-gray gnatcatcher (*Polioptila caerulea*), rufous-crowned sparrow (*Aimophila ruficeps*), mountain bluebird (*Sialia currucoides*), northern mockingbird (*Mimus polyglottos*), western meadowlark (*Sturnella neglecta*), and loggerhead shrike (*Lanius ludovicianus*). Many species commonly associated with human activity were observed along more developed areas, including American crow (*Corvus brachyrhynchos*), house sparrow (*Passer domesticus*), house finch (*Carpodacus mexicanus*), and European starling (*Sturnus vulgaris*).

[1] Additional reference information for the wildlife observations listed in this subsection appears in **Subsection 4.5.3.1** (**Table 4.5-6**) and in the text of **Subsection 4.5.3.2.3**.

Raptors are plentiful in the region, and suitable nesting and foraging habitat for raptor species occurs throughout the RMDP area. Riparian communities, such as southern coast live oak riparian forest and southern cottonwood–willow riparian and upland oak woodlands, provide suitable nesting habitat for several raptor species, and the annual grasslands and disturbed areas adjacent to the River corridor and adjacent to agricultural areas provide foraging habitat for both nesting residents and winter visitors. Turkey vulture (*Cathartes aura*), Cooper's hawk (*Accipiter cooperii*), red-tailed hawk (*Buteo jamaicensis*), and American kestrel (*Falco sparverius*) were commonly detected foraging during the surveys. In 2007, the state fully protected white-tailed kite (*Elanus leucurus*) was observed in the RMDP area. Other raptors observed foraging on site include northern harrier (*Circus cyaneus*), sharp-shinned hawk (*Accipiter striatus*), peregrine falcon (*Falco peregrinus*), merlin (*Falco columbarius*), prairie falcon (*Falco mexicana*), red-shouldered hawk (*Buteo lineatus*), ferruginous hawk (*Buteo regalis*), golden eagle (*Aquila chrysaetos*), barn owl (*Tyto alba*), great horned owl (*Bubo virginianus*), and burrowing owl (*Athene cunicularia*).

Insects. The RMDP area vegetation communities contribute to the variety of insect species on site. Insect populations can vary widely, depending on the physical characteristics of the substrate and current land use practices within the RMDP. For example, agricultural areas treated with pesticides may have lower abundances of insects when compared to riparian or annual grassland areas. However, numerous insect (ants, crickets, grasshoppers, beetles) and arachnid species (spiders, ticks) were detected in the RMDP. These invertebrates serve as prey for a variety of vertebrate species that are expected to occur in this area. Lepidoptera species (butterflies) were commonly observed in the RMDP area, and the species identified reflect the mosaic of different habitats that occur in this area. Butterfly species observed on site in upland habitat areas (including agriculture) included checkered white (*Pontia protodice*), alfalfa butterfly (*Colias eurytheme*), anise swallowtail (*P. zelicaon*), painted lady (*Vanessa cardui*), west coast lady (*Vanessa annabella*), buckeye (*Junonia coenia*), chalcedon checkerspot (*Euphydryas chalcedona*), Behr's metalmark (*Apodemia mormo virgulti*), Bernardo blue (*Euphilotes bernardino*), pigmy blue (*Brephidium exilis*), and common hairstreak (*Strymon melinus pudicus*). Butterfly species observed within the riparian habitats included western tiger swallowtail (*Papilio rutulus*), cabbage white (*Pierus rapae*), and Lorquin's admiral (*Basalarchia lorquini*).

Fish. The Santa Clara River supports a variety of fish species, including arroyo chub (*Gila orcuttii*), Santa Ana sucker (*Catostomus santaanae*), unarmored threespine stickleback (*Gasterosteus aculeatus williamsoni*), largemouth bass (*Micropterus salmoides*), western mosquitofish (*Gambusia affinis*), and prickly sculpin (*Cottus asper*). With the exception of the mouths of Middle and Potrero canyons, tributaries to the Santa Clara River lack fish and suitable habitat for fish (ENTRIX 2009).

Reptiles. The upland and riparian vegetation communities present in the RMDP area provide habitat for several reptile species. Semi-aquatic reptiles observed on site in association with riparian habitats in the Santa Clara River include southwestern pond turtle (*Actinemys marmorata pallida*) and two-striped garter snake (*Thamnophis hammondii*). While both of these species rely on aquatic sites for parts of their life cycles, they also use upland habitats. Reptiles documented through visual observations and pitfall trapping in upland and dry wash habitats include western whiptail (*Aspidoscelis tigris*), western fence lizard (*Sceloporus occidentalis*), side-blotched lizard (*Uta stansburiana*), coast horned lizard (*Phrynosoma coronatum*), alligator lizard (*Elgaria multicarinata*), silvery legless snake (*Anniella pulchra pulchra*), western skink (*Eumeces skiltonianus*), California whipsnake (*Masticophis lateralis*), coachwhip (*Masticophis flagellum*), western rattlesnake (*Crotalus viridis*), California black-headed snake (*Tantilla planiceps*), California western blindsnake (*Leptotyphlops humilis*), common kingsnake (*Lampropeltis getulus*), and gopher snake (*Pituophis catenifer*).

Amphibians. Amphibians typically require a source of standing or flowing water to complete their life cycle. However, some more terrestrial species can survive in drier areas by remaining in moist environments found beneath leaf litter and fallen logs, or by burrowing into the soil. Riparian habitat located along the Santa Clara River and on-site tributaries and uplands associated with these areas support the California treefrog (*Hyla cadaverina*), Pacific treefrog (*Hyla regilla*), and western toad (*Bufo boreas*). The western spadefoot toad (*Spea hammondii*) has been documented in middle Potrero Canyon, at the northern edge of Grapevine Mesa adjacent to the Santa Clara River, north of Lion Canyon, at the northern edge of Airport Mesa adjacent to the Santa Clara River, and in the Santa Clara River upstream of the Commerce Center Drive Bridge. Adult arroyo toads (*Bufo californicus*) have not been detected in the RMDP area, but arroyo toad tadpoles have been found in the Santa Clara River in the RMDP area in five locations, from the Middle Canyon tributary downstream to the Exxon Canyon tributary. The non-native invasive African clawed frog (*Xenopus laevis*) has been observed in the Santa Clara River in backwater areas at the confluence of the River and Castaic Creek and in isolated floodplain pools, as well as in Potrero Creek (ENTRIX 2009).

While many of the amphibian populations in the RMDP area are expected to be largely restricted to the riverine and riparian habitats (and adjacent upland habitats) and other moist woodland habitats, species such as arroyo toad can be located far from riparian areas. Both the arroyo toad and western toad spend considerable time away from aquatic habitat for most of their life histories.

Mammals. The RMDP area supports habitat for a variety of mammals. Common mammal species identified in the RMDP area include raccoon (*Procyon lotor*), California ground squirrel (*Spermophilus beecheyi*), brush rabbit (*Sylvilagus bachmani*), striped

skunk (*Mephitis mephitis*), coyote (*Canis latrans*), and mule deer (*Odocoileus hemionus*). Botta's pocket gopher (*Thomomys bottae*), California pocket mouse (*Chaetodipus californicus*), kangaroo rat (*Dipodomys* sp.), several murid rodents (rats and mice) (*Peromyscus maniculatus, P. californicus, P. boylii, P. erermicus, Microtus californicus, Neotoma lepida, N. fuscipes,* and *Reithrodontomys megalotis*) are also present. In addition, the RMDP area is frequented by wide-ranging carnivores, including gray fox (*Urocyon cinereoargenteus*) and long-tailed weasel (*Mustela frenata*). Although less-frequently observed, American badger (*Taxidea taxus*), mountain lion (*Puma concolor*), bobcat (*Lynx rufus*), and black bear (*Ursus americanus*) are also present.

Upland and riparian habitats, man-made structures, and the rock outcrops in the region provide habitat for a variety of bat species. Focused bat surveys conducted in 2004 and 2006 using acoustic bat detectors, mist netting, and direct observation confirmed or indirectly established the potential for several common and special-status species in the RMDP area (Impact Sciences 2005, Johnson 2006). A maternity roost used by the special-status pallid bat (*Antrozous pallidus*) is present in a building in middle Potrero Canyon, and a night roost for this species is present in lower Potrero Canyon. Other bat species confirmed on site include the relatively common western pipistrelle (*Pipistrellus hesperus*), big brown bat (*Eptesicus fuscus*) and Mexican free-tailed bat (*Tadarida brasiliensis*), and five special-status species: pocketed free-tailed bat (*Nyctinomops femorosaccus*), western mastiff bat (*Eumops perotis californicus*), western red bat (*Lasiurus blossevillii*), fringed myotis (*Myotis thysanodes*), and Yuma myotis (*Myotis yumanensis*). Bats with high potential to occur based on recorded acoustic signals include the special-status western small-footed myotis (*Myotis ciliolabrum*) and long-legged myotis (*Myotis volans*), and the common California myotis (*Myotis californicus*) and little brown bat (*Myotis lucifugus carissima*). No day roosts for these other common and special-status bats were detected on site during the bat surveys. The Santa Clara River corridor, and particularly the I-5 Bridge over the River, are used extensively by the various bat species for foraging and night roosts. All survey locations in Potrero Creek, the Santa Clara River at Walcott Road, upper Long Canyon, and The Old Road and I-5 area of the Santa Clara River had bat activity by at least several species, and it is likely that bats are fairly widespread in the RMDP area.

Mollusks. In 2006, an undescribed species of snail (*Pyrgulopsis* sp. *nova*) was observed in the RMDP area within portions of the Middle Canyon Spring. A specimen was collected and sent to the Smithsonian Institution in Washington, D.C., for identification and was determined to be an unidentified species of spring snail. The undescribed snail belongs to the genus *Pyrgulopsis* (Hershler 2007), which belongs to the Hydrobiidae (spring snail) family (Liu and Hershler 2007). In 2007, the snail was also observed in the lower reach of the adjacent Middle Canyon drainage (Dudek 2007C).

4.5.3.4.3.2 *VCC*

The 333-acre VCC planning area supports habitat for a large number of upland and riparian wildlife species, although at a much smaller scale than the 13,651-acre RMDP area. Vegetation communities and land covers providing upland wildlife habitat include coastal scrubs (California sagebrush scrub, California sagebrush–California buckwheat scrub), California annual grassland, agriculture, and disturbed land. Castaic Creek, which crosses the site, supports a variety of riparian and wetland communities, including herbaceous wetland, mulefat scrub, southern cottonwood–willow riparian forest, and river wash. Developed land is also present. With the exception of developed land, these vegetation communities and land covers are suitable for supporting some resident species a variety of foraging wildlife species, such as raptors. No focused wildlife surveys were conducted in the VCC planning area, but a general wildlife survey of the site was conducted by Dudek in September 2006 (Dudek and Associates 2006D).

Birds. Bird species are the most common vertebrate found in the VCC planning area. A variety of upland and riparian bird species were observed in the VCC planning area, including turkey vulture, Cooper's hawk, red-tailed hawk, white-tailed kite, California quail (*Callipepla californica*), killdeer (*Charadrius vociferous*), Anna's hummingbird, Costa's hummingbird (*Calypte costae*), black phoebe (*Sayornis nigricans*), western kingbird (*Tyrannus verticalis*), horned lark (*Eremophila alpestris*), western scrub-jay (*Aphelocoma coerulescens*), least Bell's vireo, rufous-crowned sparrow, yellow warbler, lesser goldfinch (*Carduelis psaltria*), oak titmouse (*Baeolophus inornatus*), Nuttall's woodpecker (*Picoides nuttallii*), great egret (*Ardea alba*), and great blue heron (*Ardea herodias*).

Insects. No species of butterflies or moths were recorded in the VCC planning area, probably due to late summer timing of surveys (September 2006). However, 24 species of butterflies were recorded during a butterfly survey on the Entrada site, the core of which is about a mile south of the VCC planning area (Compliance Biology 2004C). The butterflies recorded on the Entrada site during this survey included many of the common species observed in the RMDP (listed above), and it is likely that many of these species are also present in the VCC planning area. It is likely that the numerous insect (ants, crickets, grasshoppers, beetles) and arachnid species (spiders, ticks) detected in the RMDP area also occur in the VCC planning area.

Fish. Castaic Creek is dry during most of the year, except when flow is released from Castaic Lake upstream or when rain events maintain surface flow for an extended period of time (ENTRIX 2009). When the creek is flowing, adequate aquatic habitat exists to support the various fish species found in the Santa Clara River watershed. Fish species collected by ENTRIX, Inc. (2009) during a September 2005 survey were arroyo chubs and Santa Ana suckers. Unarmored threespine sticklebacks have been collected in

Castaic Creek in the past (ENTRIX 2009) when persistent flows and aquatic habitat conditions are present there. Castaic Creek has also supported prickly sculpin and western mosquitofish.

Reptiles. Only the western fence lizard was observed on site during the general wildlife surveys. The upland coastal scrub and annual grassland present in the VCC planning area provide habitat for several additional reptile species, such as side-blotched lizard, alligator lizard, coast horned lizard, western skink, western whiptail, gopher snake, common kingsnake, and coachwhip. The two semi-aquatic reptiles—southwestern pond turtle and two-striped garter snake—have potential to occur in the reach of Castaic Creek that passes through the VCC planning area and to use adjacent upland habitats on site. Two-striped garter snake was observed in Castaic Creek in 2003 (Ecological Sciences, Inc. 2003A). The southwestern pond turtle has been observed just south of the VCC planning area at the confluence of Castaic Creek and the Santa Clara River.

Amphibians. Riparian habitat located along Castaic Creek, and uplands associated with the Creek, are suitable for amphibians. Three species have been recorded in the VCC planning area: African clawed frog, Pacific treefrog, and western toad (Ecological Sciences, Inc. 2003A). Amphibian populations in the VCC planning area are expected to be largely restricted to riverine and riparian habitat and adjacent upland habitats.

Mammals. No focused surveys for mammals (including bats) have been conducted within the VCC planning area. General wildlife surveys noted several mammals, however, including cottontail rabbit (*Sylvilagus* sp.), California ground squirrel, Botta's pocket gopher, coyote, and bobcat. Many of the smaller mammal species listed above for the RMDP area are also expected to occur on the VCC site due to similar habitats on site. Mule deer and mountain lion probably do not occur, or may rarely occur, in uplands on site due to the increasing urbanization of the area, but may pass through the area along Castaic Creek. The black bear probably does not occur in the area. Bat foraging habitat is available in the VCC planning area, and the species listed above for the RMDP area potentially use this area as well.

4.5.3.4.3.3 *Entrada*

The 392-acre Entrada planning area supports several upland and riparian vegetation communities, providing habitat for a variety of upland and riparian/wetland species, although at a much smaller scale than the 13,651-acre RMDP area. Upland vegetation and land cover types include California annual grassland, coastal scrubs (California sagebrush scrub, California sagebrush–California buckwheat scrub), undifferentiated chaparral, disturbed land, and developed land. Riparian communities present on site (apart from the Santa Clara River) include river wash alluvial scrub. The adjacent Santa Clara River supports river wash, herbaceous wetland, southern cottonwood–willow riparian, and southern willow scrub. Wildlife observed on

site and reported below are from bird surveys in the reach of the Santa Clara River adjacent to the Entrada Planning area by Guthrie (2000D, 2004G); general wildlife surveys by Dudek (Dudek and Associates 2006E), which included observations of reptiles, birds, and mammals; and butterfly surveys by Compliance Biology (2004C).

Birds. Birds were the most common vertebrate observed within the Entrada planning area, both because this taxon is typically the largest component of terrestrial vertebrates in general and because most of the wildlife surveys conducted in the Entrada planning area focused on birds. Upland scrub and chaparral species observed included Allen's hummingbird (*Selasphorus sasi*), black-chinned hummingbird (*Archilochus alexandri*), Costa's hummingbird, California quail, western scrub-jay, blue-gray gnatcatcher, wrentit (*Chamaea* fasciata), California thrasher (*Toxostoma redividum*), loggerhead shrike, phainopepla (*Phainopepla nitens*), California towhee (*Pipilo crissalis*), spotted towhee (*Pipilo maculatus*), and rufous-crowned sparrow. The Santa Clara River and on-site tributaries support several riparian and woodland species, such as yellow warbler, Nuttall's woodpecker, northern flicker (*Colaptes auratus*), downy woodpecker (*Picoides pubescens*), cliff swallow, house wren (*Troglodytes aedon*), yellow warbler, Wilson's warbler (*Wilosnia pusilla*), and song sparrow (*Melospiza melodia*). Only one upland woodland species was observed: oak titmouse. Several raptor species were observed on site, including Cooper's hawk, white-tailed kite, red-tailed hawk, red-shouldered hawk, American kestrel, and turkey vulture.

Insects. A total of 24 butterfly species was observed in the Entrada planning area during focused surveys by Compliance Biology (2004C). All of the butterflies listed above for the RMDP area were also observed in the Entrada planning area. It is likely that the numerous insect (ants, crickets, grasshoppers, beetles) and arachnid species (spiders, ticks) detected in the RMDP area also occur in the Entrada planning area.

Fish. The Santa Clara River, in the reach that passes through the Entrada planning area, supports three fish species: arroyo chub, unarmored threespine stickleback, and Santa Ana sucker (ENTRIX 2009).

Reptiles. Only the western fence lizard was observed on site during the general wildlife surveys (Dudek and Associates 2006E). The upland coastal scrub, undifferentiated chaparral, and California annual grassland present in the Entrada planning area provide habitat for several additional reptile species, such as side-blotched lizard, alligator lizard, coast horned lizard, western skink, western whiptail, gopher snake, common kingsnake, and coachwhip. The two semi-aquatic reptiles—southwestern pond turtle and two-striped garter snake—have been observed in the Santa Clara River adjacent to the Entrada planning area and could use adjacent upland habitats on site.

Amphibians. Riparian vegetation along the Santa Clara River and on-site tributaries, and uplands associated with these areas, provides habitat for the Pacific treefrog, arroyo toad, and western toad. Amphibian populations in the Entrada planning area are expected to be largely restricted to riverine and riparian habitats and adjacent upland habitats.

Mammals. No focused surveys for mammals (including bats) have been conducted within the Entrada planning area. General wildlife surveys noted several mammals, however, including cottontail rabbit, California ground squirrel, woodrat (*Neotoma* spp.), long-tailed weasel, coyote, bobcat, and mule deer. Many of the smaller mammal species listed above for the RMDP area are also expected to occur in the Entrada planning area due to similar habitats on site. Mountain lions may use the site occasionally and have been observed in this general area in the past. The black bear probably does not occur in the area. Bat foraging habitat is available in the Entrada planning area, and the species listed above for the RMDP area potentially use this area as well.

4.5.3.4.4 Special-Status Vegetation Communities

Vegetation community and land cover classifications used in this report primarily follow the Vegetation Classification and Mapping Program "List of California Terrestrial Natural Communities Recognized by the California Natural Diversity Database" (CDFG 2003, updated in October 2007 (CDFG 2007D)). Two of the primary purposes of the CNDDB classification are to assist in characterizing vegetation in a consistent manner and to identify rare and declining vegetation types. The ranking of natural communities by rarity or threat is an important facet of this system. For the purposes of this EIS/EIR, vegetation communities denoted on the October 2007 (CDFG 2007D) list as G1, G2, or G3 (high priority for inventory) or otherwise regulated by local, state, and/or federal resource agencies are considered to have "special status."

Of the 41 vegetation communities occurring on the Project site, California walnut woodland, valley oak woodland, valley oak/grass, southern willow scrub, southern coast live oak riparian forest, and southern cottonwood–willow riparian forest are currently denoted as G1, G2, or G3 by CDFG (2007D) and, therefore, are considered special status. In addition to those vegetation communities ranked as G1, G2, G3, riparian and wetland vegetation communities and purple needlegrass (designated G4/S3?) are considered special status. Given the occurrence of *Artemisia tridentata* ssp. *parishii* (which is considered special status by the County of Los Angeles) within the big sagebrush scrub community, for the purposes of this EIS/EIR, big sagebrush scrub is also considered to be a special-status vegetation community. Please see **Table 4.5-17**, Existing Vegetation Communities, Floristic Alliances and Associations, and Land Cover Types in Project Area, and the subsequent vegetation community descriptions in **Subsection 4.5.3.4.1** for a more detailed discussion of these vegetation communities and their distribution on the Project site.

At the conclusion of this subsection, the long-term effects of Alternative 1 (No Action/No Project on special-status vegetation communities are discussed.

4.5.3.4.4.1 *Upland Communities*

Purple Needlegrass (41.150.00/G4S3?[1]). Purple needlegrass is a grassland community ranked as G4S3? by CDFG (2007D), indicating that it is "vulnerable to extirpation or extinction" within the state of California. This ranking is based on historical losses and

[1] Uncertainty about the rank of an element is expressed in two major ways: First, by expressing the ranks as a **range** of values: *e.g.*, S2S3 means the rank is somewhere between S2 and S3. Second, by adding a "?" to the rank: *e.g.*, S2? This represents more certainty than S2S3, but less certainty than S2.

ongoing threats. Much of the former grassland has been converted to other land uses (agriculture, urban and industrial) (Bartolome *et al.* 2007). Remaining California native grassland vegetation has largely been replaced or degraded by invasive non-native species so that much of its former acreage is now dominated by European annual grasses in the genera *Bromus*, *Avena*, and *Hordeum*, plus forbs in the genera *Erodium*, *Brassica*, and *Centaurea* (D'Antonio *et al.* 2007). These non-native species tend to outcompete native grasses at every phase in their life histories, especially the seedling establishment phase, though established perennial grasses can persist with non-native species for many years. Non-native species are commonly favored by natural disturbance processes (*e.g.*, rodent activity and wildfire) and by human-caused changes, such as grazing and increased atmospheric nitrogen deposition (D'Antonio *et al.* 2007). The wholesale shift from native perennial to non-native annual species in these grasslands affects soil water and nutrient dynamics and soil microorganisms, tending to further degrade natural systems and favor invasive species (D'Antonio *et al.* 2007).

California Walnut Woodland (72.100.01/G3S3). California walnut woodland is ranked as G3S3 by CDFG (2007D), indicating that it is "vulnerable to extirpation or extinction" both globally (*i.e.*, across its entire range) and within the state of California. This ranking is based on historical losses and ongoing threats; southern California black walnut is vulnerable to several effects related to urbanization. Due to urban sprawl, much of the California walnut woodlands have been destroyed or threatened. Furthermore, natural processes that encourage seedling development are imperiled. The species requires wet summer conditions and full sunlight for successful propagation (Holstein 1981). Diversion of water and the restriction of waterways have depleted possible natural environments and blocked expansion of already restricted communities. Southern California black walnut can be adversely affected by changes in surface and subsurface hydrologic conditions (changes in irrigation and runoff). Changed hydrologic conditions can alter seed bank characteristics and modify habitat for species such as the southern California black walnut.

Valley Oak Woodland (71.040.00/G3S3). Valley oak woodland is ranked as G3S3 by CDFG (2007D), indicating that it is "vulnerable to extirpation or extinction" both globally (*i.e.*, across its entire range) and within the state of California. This ranking is based on loss of habitat and ongoing threats due to human proximity. Oak damage from human activity can lead to increased susceptibility to diseases. Oak mistletoe (*Phoradendron villosum*), a common parasite in urbanized areas, causes host stems to swell and crack, creating possible entry points for wood-decaying fungi (Swiecki and Bernhardt 1996). Hedgehog fungus (*Hericium erinaceus*), most commonly associated with wounds from fires, cracks, and vandalism, can lead to disintegration of decayed

tissue (Swiecki and Bernhardt 1996). Sunscald, associated with canopy thinning, causes bark to shrink and crack and eventually dry out, providing opportunities for beetle boring and fungi infection (Swiecki and Bernhardt 1996). A variety of oak diseases and blights are associated with modified water regimes, especially from irrigation (Swiecki and Bernhardt 1996). Fires can damage a large percentage of oak trees or even destroy an entire population. Direct scorching can create open areas, which become susceptible to non-native plant and animal invasion. Non-native plants tend to recover from fire more quickly than native species, leading to their domination over native species and destruction of oak succession (Pavlik *et al.* 1991).

Valley Oak/Grass (71.040.05/G3S3). Valley oak/grass is ranked as G3S3 by CDFG (2007D), indicating that it is "vulnerable to extirpation or extinction" both globally (*i.e.*, across its entire range) and within the state of California. The threats for valley oak/grass are the same as described above for valley oak woodland.

4.5.3.4.4.2 *Riparian Waters and Wetlands*

Most natural riparian vegetation in southern California has been lost or degraded due to land use conversions to agricultural, urban, and recreational uses; channelization for flood control; sand and gravel mining; ground water pumping; water impoundments; and various other changes. Smith (1977), Katibah (1984), and Faber *et al.* (1989) estimated that as much as 95% to 97% of riparian habitats have been lost. Riparian habitats are biologically productive and diverse, and they are the exclusive habitat of several threatened or endangered wildlife species and many other special-status plant and wildlife species. For these reasons, each of the riparian vegetation communities listed below is considered to be special status.

Herbaceous Wetlands

Bulrush–Cattail Wetland (52.102.00/G5S3). Bulrush–cattail wetland is ranked as G5S3 by CDFG (2007D), indicating that it is "demonstrably widespread, abundant, and secure" across its entire range, but is "vulnerable to extirpation or extinction" within the state of California.

Cismontane Alkali Marsh (52.203.00/G4S3). Cismontane alkali marsh is ranked as G4S3 by CDFG (2007D), indicating that it is "apparently secure" across its entire range, but is "vulnerable to extirpation or extinction" within the state of California.

Coastal and Valley Freshwater Marsh (52.100.01/NA[2]). Coastal and valley freshwater marsh does not have a global or state ranking.

Herbaceous Wetland (NA/NA). Herbaceous wetland does not have a global or state ranking.

River Wash (NA/NA). River wash does not have a global or state ranking.

Riparian Scrub

Alluvial Scrub (NA/NA). Alluvial scrub does not have a global or state ranking.

Arrow Weed Scrub (63.710.00/G4S3). Arrow weed scrub is ranked as G4S3 by CDFG (2007D), indicating that it is "apparently secure" across its entire range, but is "vulnerable to extirpation or extinction" within the state of California.

Big Sagebrush Scrub (35.110.00/G5S4). Big sagebrush scrub is ranked as G5S4 by CDFG (2007D), indicating that it is "demonstrably widespread, abundant, and secure" across its entire range, but is "apparently secure" within the state of California.

Giant Reed (42.080.00/U[3]). Giant reed does not have a global or state ranking.

Mexican Elderberry (63.410.00/G3S3). Mexican elderberry scrub is ranked as G3S3 by CDFG (2007D), indicating that it is "vulnerable to extirpation or extinction" both globally (*i.e.*, across its entire range) and within the state of California

Mulefat Scrub (63.510.00/G5S4). Mulefat scrub is ranked as G5S4 by CDFG (2007D), indicating that it is "demonstrably widespread, abundant, and secure" across its entire range, but is "apparently secure" within the state of California.

[2] NA = Not Applicable. A conservation status rank is not applicable because the species is not a suitable target for conservation activities.

[3] U = Unranked. Global rank has not yet been assessed.

Southern Willow Scrub (61.208.00/NA). Southern willow scrub does not have a global or state ranking.

Shrub Tamarisk (63.810.02/U). Shrub tamarisk does not have a global or state ranking.

Riparian Forest and Woodland

Southern Coast Live Oak Riparian Forest (71.060.20/G5S4). Southern coast live oak riparian forest is ranked as G5S4 by CDFG (2007D), indicating that it is "demonstrably widespread, abundant, and secure" across its entire range, but is "apparently secure" within the state of California.

Southern Cottonwood–Willow Riparian (61.130.02/G4S3). Southern cottonwood–willow riparian forest is ranked as G4S3 by CDFG (2007D), indicating that it is "apparently secure" across its entire range, but is "vulnerable to extirpation or extinction" within the state of California.

4.5.3.4.5 Special-Status Plant Species

Information compiled from the literature review, (see **Subsection 4.5.3.1**, Literature Review), field study observations listed in **Table 4.5-6**, and professional judgment were used to generate a list of special-status plant species that were observed or have the potential to occur within the Project area, including Project construction zones and designated open space areas. For the purposes of the analysis presented in this subsection, special-status species are defined as plants that:

- Have been designated as either rare, threatened, or endangered by CDFG or the USFWS and are protected under either the California Endangered Species Act (CESA) (Fish & G. Code, § 2050 *et seq*.) or federal Endangered Species Act (ESA) (16 U.S.C. § 1531 *et seq*.); or meet the CEQA definition for endangered, rare, or threatened (Cal. Code Regs., tit. 14, § 15380(b),(d));
- Are candidate species being considered or proposed for listing under these same acts; or
- Are of expressed concern to resource/regulatory agencies or local jurisdictions. This includes those plants included on CDFG Special Plants List (2008) as well as Lists 1, 2, 3, or 4 of the CNPS Inventory of Rare and Endangered Plants of California (CNPS Inventory); species of undescribed taxa; or species designated as special status by the County of Los Angeles. Plants included on the CNPS Inventory are classified as follows:
    - List 1A: plants presumed extinct in California;
    - List 1B: plants rare, threatened, or endangered in California and elsewhere;
    - List 2: plants rare, threatened, or endangered in California, but more common elsewhere;
    - List 3: plants about which more information is needed (a review list); and
    - List 4: plants of limited distribution (a watch list).

In **Subsection 4.5.3.1**, Literature Review, **Table 4.5-7** includes those special-status plant species observed within the Project area and **Table 4.5-8** includes those special-status plant species not likely to occur on site. Those special-status plant species observed within the Project area are carried through the existing conditions descriptions and impacts analyses of this EIS/EIR. Those special-status plant species not likely to occur on site are not analyzed further in this EIS/EIR.

Fifteen special-status plants have been identified in the Project area during plant surveys conducted between 2001 and 2007. These species include San Fernando Valley spineflower (*Chorizanthe parryi* var. *fernandina*), slender mariposa lily (*Calochortus clavatus* var. *gracilis*), an undescribed species of everlasting (*Gnaphalium* sp.), Parish's sagebrush (*Artemisia tridentata* ssp. *parishii*), an undescribed species of sunflower (*Helianthus* sp. *nova*), southern California

black walnut (*Juglans californica* var. *californica*), southwestern spiny rush (*Juncus acutus* ssp. *leopoldii*), late-flowered mariposa lily (*Calochortus weedii* var. *vestus*), Plummer's mariposa lily (*Calochortus plummerae*), island mountain-mahogany (*Cercocarpus betuloides* var. *blancheae*), Peirson's morning glory (*Calystegia peirsonii*), oak-leaved nemophila (*Nemophila parviflora* var. *quercifolia*), an undescribed species of navarretia (*Navarretia ojaiensis*), mainland (holly-leaf) cherry (*Prunus ilicifolia* ssp. *ilicifolia*), and oak trees (*Quercus* spp.). Of these species, only San Fernando Valley spineflower is state-listed; none are federally-listed. These 15 species are shown in **Table 4.5-18. Figure 4.5-7** (Special-Status Plant Species Occurrences) depicts the locations of the listed San Fernando Valley spineflower and six non-listed species (late-flowered mariposa lily, Plummer's mariposa lily, slender mariposa lily, undescribed everlasting, Ojai navarretia, and undescribed sunflower). The listed San Fernando Valley spineflower is also shown in greater detail on **Figures 4.5-25** through **4.5-30**. These species are discussed in more detail below.

Table 4.5-18
Special-Status Plant Species Documented on the Project Site

Common Name *Scientific Name*	Sensitivity Status Federal	State	CNPS	Habitat	Area Where Observed
San Fernando Valley spineflower *Chorizanthe parryi* var. *fernandina*	FC	CE S1.1	1B.1	California sagebrush scrub and associations, California annual grasslands, or at the edge of agricultural fields on mesas	Specific Plan, VCC, and Entrada areas
undescribed everlasting *Gnaphalium* sp. *nova*[a]	—	—	*	Alluvial sage scrub (alluvial benches)	Specific Plan and VCC areas
undescribed sunflower *Helianthus* sp. *nova*	—	—	*	Freshwater springs and adjacent seeps.	A sunflower population was discovered in 2002 at Middle Canyon Spring, within the Specific Plan site. It is currently being described as a new species by Dr. David Keil, California Polytechnic State University, San Luis Obispo (Mary Meyer personal communication October 2006).
island mountain-mahogany *Cercocarpus betuloides* var. *blancheae*	—	S3.3	4.3	Closed-cone coniferous forest and chaparral	Specific Plan, Entrada, and Salt Creek areas
late-flowered mariposa lily *Calochortus weedii* var. *vestus*	—	S2.2	1B.2	Chaparral and coastal woodland and sometimes riparian woodland	Specific Plan area
mainland cherry *Prunus ilicifolia* ssp. *ilicifolia*	—	—	—	Undifferentiated chaparral, big sagebrush scrub, and river wash	Specific Plan, VCC, and Entrada areas
oak trees *Quercus* spp.	—	—	—	Oak woodlands and savannahs	Specific Plan, Salt Creek, VCC, and Entrada areas
oak-leaved nemophila *Nemophila parviflora* var. *quercifolia*	—	S3.3	4.3	Cismontane woodland and lower montane coniferous forest	Specific Plan area
Ojai navarretia *Navarretia ojaiensis*	—	S2	1B.1	Openings in California sagebrush, grasslands, and sparsely vegetated valley needle grasslands	Salt Creek area
Parish's sagebrush *Artemisia tridentata* ssp. *parishii*	—	—	—	Big sagebrush scrub	This species is considered special status by the County of Los Angeles. Observed in big sagebrush scrub within the Specific Plan and Salt Creek areas. Potential to occur within

Table 4.5-18
Special-Status Plant Species Documented on the Project Site

Common Name *Scientific Name*	Sensitivity Status Federal	State	CNPS	Habitat	Area Where Observed
					the Entrada planning area.
Peirson's morning-glory *Calystegia peirsonii*	—	S3.2	4.2	Chaparral, chenopod scrub, cismontane woodland, coastal scrub, lower montane coniferous forest, and valley and foothill grassland	Specific Plan, Salt Creek, VCC, and Entrada areas
Plummer's mariposa lily *Calochortus plummerae*	—	S3.2	1B.2	Chaparral, coastal scrub, cismontane woodland, lower montane coniferous forest, and grassland	Specific Plan area
slender mariposa lily *Calochortus clavatus* var. *gracilis*	—	S2.2	1B.2	Chaparral, coastal scrub, and grasslands	Specific Plan, Salt Creek, VCC, and Entrada areas
southern California black walnut *Juglans californica* var. *californica*	—	S3.2	4.2	Chaparral, cismontane woodland, and coastal scrub/alluvial	Specific Plan, Salt Creek, VCC, and Entrada areas
southwestern spiny rush *Juncus acutus* ssp. *leopoldii*	—	S3.2	4.2	Coastal dunes (mesic), meadows and seeps (alkaline seeps), and marshes and swamps (coastal salt)	Specific Plan area

[a] Some experts identify this species as white-headed cudweed (*Gnaphalium leucocephalum*), which is a CNPS List 2.2 species (S3.2). See the analysis of the undescribed everlasting in **Subsection 4.5.5.3** for more detail.

Key:

Status:

Federal: FC = Federal Candidate

State: CE = California Endangered; CT = California Threatened; CR = California Rare

CNPS: List 1A = Presumed extinct
List 1B = Plants rare and endangered in California and elsewhere
List 4 = Plants of limited distribution (watch list)

Other: * = Undescribed species, no status currently assigned

4.5.3.4.5.1 *San Fernando Valley Spineflower (*Chorizanthe parryi *var.* fernandina*)*

The San Fernando Valley spineflower is a federal candidate plant species, is state-listed as endangered, and is a CNPS List 1B species. San Fernando Valley spineflower has been observed in four general areas within the Specific Plan area: Airport Mesa, Grapevine Mesa, Potrero Canyon, and San Martinez Grande Canyon. This species has also been observed on the Entrada and VCC planning areas. Within the Project area, most of the plants were found on slopes with a south-facing aspect within openings in sparsely vegetated habitat characterized as open California sagebrush scrub and associations, California annual grasslands, or at the edge of agricultural fields on mesas. Most of the observed San Fernando Valley spineflower were found on soils mapped by the USDA (1969) as slightly eroded to eroded Castaic-Balcom silty clay loam (30% to 50% slopes) or Terrace Escarpments. Plants in the vicinities of Grapevine and Airport mesas were observed downslope of terrace surfaces capped by Zamora clay loam (2% to 9% slopes), with a few plants occurring on artificial fill or alluvium derived from adjacent terrace deposits. Vegetative cover in the area of San Fernando Valley spineflower occurrences ranged from 5% to 100%, but was most commonly between 60% and 80%. The soil type for all mapped San Fernando Valley spineflower occurrences in the Project area consisted of sandy loams. Elevations at San Fernando Valley spineflower locations on site range from approximately 1,000 to 1,300 feet AMSL.

Table 4.5-19 presents the San Fernando Valley spineflower occurrence data for the Project area. These data are depicted in **Figures 4.5-25** through **4.5-30**. Observations of SFVS were made in 2002, 2003, 2004, 2005 2006, and 2007 (Dudek and Associates 2002A, 2002B, 2002C, 2004B, 2004C, 2004E, 2004F, 2004G, 2004H, 2006F, 2006G, 2006H, 2006I, 2006J, 2006K; Dudek 2007F, 2007G, 2007H; FL*x* 2004B, 2005, 2006A). In 2002, surveys estimated 7,814 individuals occupying 0.59 acre. In 2003, surveys estimated populations of San Fernando Valley spineflower totaling 5,947,120 individuals occupying 16.37 acres. In 2004, the total population of San Fernando Valley spineflower was estimated to be 558,388 individuals occupying 5.33 acres. In 2005, the total population of San Fernando Valley spineflower was estimated to be 7,391,813 individuals occupying 11.45 acres. In 2006, the total population of San Fernando Valley spineflower was estimated to be 1,773,496 individuals occupying 8.49 acres. In 2007, the total population of San Fernando Valley spineflower was estimated to be 760 individuals occupying 0.12 acre. The surveys conducted for San Fernando Valley spineflower throughout the High Country SMA and Salt Creek area were negative.

4.5.3.4.5.2 *Undescribed Everlasting (*Gnaphalium *sp.* nova*)*

Because this plant is undescribed (a physical description of the plant with known distribution and species name has not been published in a peer reviewed publication) and its extent and distribution are unknown, for the purposes of this EIS/EIR it is considered a special-status species.

The undescribed everlasting was documented within the Specific Plan area during the 2003, 2004, 2005, and 2007 field seasons. Two main populations of this undescribed species, totaling about 530 individuals, were documented in 2003 in the Santa Clara River corridor near the mouth of Long Canyon and in Castaic Creek south of SR-126 within the Specific Plan area. During the 2004 surveys, these two occurrences were noted again with about 700 plants. In addition, a population of about 250 individuals was observed in the portion of Castaic Creek west of the I-5 Bridge and east of Commerce Center Drive within the VCC planning area. In 2005, the two Specific Plan area occurrences consisted of approximately 800 individuals and five individuals, while the VCC occurrences consisted of approximately 65 individuals. During 2007 surveys, the VCC occurrence was estimated at approximately 350 individuals; one main occurrence and a number of smaller occurrences were documented within the Specific Plan area, totaling approximately 85 individuals. These occurrences are primarily on secondary alluvial benches. The vegetation around these plants consists of sparsely vegetated open river wash. **Table 4.5-20** provides a summary of population data for the undescribed everlasting that occurs within VCC and the Specific Plan area.

Table 4.5-20
Population Data for the Undescribed Everlasting That Occurs within VCC and the Specific Plan Area

4.5.3.4.5.3 *Undescribed Sunflower (*Helianthus *sp.* nova*)*

The undescribed sunflower has no federal, state or CNPS status. A population of *Helianthus* was found in 2002 at Castaic Spring, on the south side of the Santa Clara River between Middle Canyon and San Jose Flats within the Specific Plan site. Ten or fewer plants were observed rooted in saturated wetland soils in dense vegetation including cattails, tules, stinging nettle and wild grape. The species is a perennial with a near-surface tuber that produces annual growth stems that are four meters or more in length (16 to 20 feet). The stems produce abundant flowers in late summer through the fall and sometimes topple from their weight and lay about on the vegetation beneath. In 2002, more than 300 flowering stems were estimated in an area under 1 acre in size and appeared to be associated with three to five different clumps of sunflower.

Following its initial discovery, the sunflower was presumed to be the extinct Los Angeles sunflower (*H. nuttallii* ssp. p*arishii*). Further investigations revealed the Castaic Spring sunflower contained 68 chromosomes and therefore is apparently a tetraploid, while its closest known relatives are a hexaploid (*H. californicus*, n=51) and a diploid (*H. nuttallii* ssp. *Nuttallii*, n=17) (Soza, 2003). Based on pollen electron microscopy, it is likely that the *Helianthus* species in question is a hybrid between *H. nuttallii* and *H. californicus* or an intermediate evolutionary step between the two species (Porter and Fraga 2004). Based upon its apparent status as possibly a new species of hybrid origin, Dr. David Keil at the California Polytechnic State University, San Luis Obispo, is currently working on publishing it as a new species. Dr. Keil has indicated that the species is probably of hybrid origin from the Pleistocene period, when wetter, cooler conditions occurred and species of *Helianthus* were more widespread (Mary Meyer, personal communication, October 2007).

A population of 10 undescribed sunflowers was found in 2002 growing in water-saturated soil and gravel along the margin of a slight rise within the Middle Canyon Spring, which drains into the south side of the Santa Clara River just upstream of its confluence with Castaic Creek. This sunflower grows to a height of 10 to 16 feet, rising above surrounding vegetation, and remains in the sun throughout most of the day.

4.5.3.4.5.4 *Island Mountain-Mahogany (*Cercocarpus betuloides *var.* blancheae*)*

The island mountain-mahogany is a CNPS List 4 (S3.3) plant, but it has no federal status. It is an evergreen shrub or shrubby tree that is typically found in chaparral and closed-cone coniferous forests in Los Angeles and Ventura counties, as well as on several of the Channel Islands. Within the Specific Plan, Salt Creek, and Entrada areas, island mountain-mahogany occurs as an occasional component of chaparral communities at the base of north-facing slopes. The species has not been detected in the VCC planning area. Given the low sensitivity status of the species, individual island mountain-mahogany plants have not been mapped.

4.5.3.4.5.5 *Late-Flowered Mariposa Lily (*Calochortus weedii *var.* vestus*)*

The late-flowered mariposa lily is a CNPS List 1B (S2.2) plant, but it has no federal status. This species is typically found in dry, open chaparral and coastal woodland but is sometimes found in riparian woodland on serpentine soils. An estimated 150 individuals observed in two occurrences of this species were mapped on steep ridges and slopes in chaparral within the High Country SMA in 2003.

4.5.3.4.5.6 *Mainland Cherry (*Prunus ilicifolia *ssp.* ilicifolia*)*

The mainland cherry has no state or federal sensitivity status, but it is locally protected through the County of Los Angeles. This large shrub to tree was incidentally observed from 2002 to 2006 in the RMDP, Entrada, and VCC planning areas as an occasional component of undifferentiated chaparral, big sagebrush scrub, and river wash. Given the low sensitivity status of the species, individual mainland cherry trees were not mapped.

4.5.3.4.5.7 *Oak Trees (*Quercus *spp.)*

Oak trees have no state or federal sensitivity status but impacts to oak trees are regulated under the CLAOTO and CEQA (PRC 21083.4). The vast majority of the oaks on the site are coast live oak (*Q. agrifolia*), but valley oak (*Q. lobata*), scrub oak (*Q. berberidifolia*), interior live oak (*Q. wislizeni*), and Alvord oak (*Q. alvordiana*) (a hybrid intermediate between blue oak (*Q. douglassii*) and Tucker oak (*Q. john-tuckeri*)) also occur. Oak tree surveys have been conducted within proposed development areas (including a 200-foot buffer). Oak tree surveys were not conducted within protected areas (*e.g.*, the High Country SMA and River Corridor SMA, proposed spineflower preserves, and Open Areas); the number of oak trees in these areas has been estimated. The surveys identified an estimated 23,294 oak trees potentially regulated by CLAOTO and PRC 21083.4.

4.5.3.4.5.8 *Oak-Leaved Nemophila (*Nemophila parviflora *var.* quercifolia*)*

The oak-leaved nemophila is a CNPS List 4 (S3.3) plant, but it has no federal status. This species typically inhabits cismontane woodlands and lower montane coniferous forests. In 2003 and 2004, one occurrence of oak-leaved nemophila was found on the Project site within the Specific Plan area along a northeast-facing slope in an oak woodland east of Grapevine Mesa. Given the low sensitivity status of the species, this occurrence was not mapped.

4.5.3.4.5.9 *Ojai Navarretia (*Navarretia ojaiensis*)*

The Ojai navarretia is a CNPS List 1B (S2) plant, but it has no federal status. The Ojai navarretia was documented within the Salt Creek watershed during the 2003 field season. The

Ojai navarretia polygons were noted in grasslands and in openings in California sagebrush and sparsely vegetated valley needlegrass grasslands.

4.5.3.4.5.10 *Parish's Sagebrush (*Artemisia tridentata *ssp.* parishii*)*

Parish's sagebrush is considered special status by the County of Los Angeles, but it has no federal, state, or CNPS status. This subspecies co-occurs with the more common big sagebrush (*Artemisia tridentata* ssp. *tridentata*). According to The Jepson Manual (Hickman 1993), the differentiating characteristics between the two subspecies in question are as follows: drooping inflorescence branches and hairy fruit in subspecies *parishii* and erect to spreading inflorescence branches and glandular fruit in subspecies *tridentata*. These differences are confirmed by Shultz (2006A, 2006B). Parish's sagebrush occurs along coastal ranges in Baja California and southern California, extending inland to regions south of the Great Basin (Shultz 2006A, 2006B). It is considered regionally rare by local botanists (Mary Meyer, personal communication, October 2007).

Artemisia tridentata plants were evaluated within the Landmark Village portion of the Specific Plan area in November 2005. There are big sagebrush plants with drooping inflorescence branches and erect inflorescence branches that co-occur there, so collections of both were made. After analysis of the characteristics of numerous samples, including examination of the fruits under a microscope, it was determined that both subspecies probably occur there. However, it appears that these two subspecies may hybridize, as the full range of characteristics (drooping and erect inflorescence branches and hairy and glandular fruit) were found among the collected specimens. The characteristics were generally consistent among individual plants that seemed to fit into either subspecies *parishii* or subspecies *tridentata* (*i.e.*, a plant with drooping inflorescence branches and hairy fruit had drooping inflorescence branches and hairy fruit throughout the plant). Plants that appeared to be hybrids had mixed characters throughout.

Observations of Parish's sagebrush were made in 2006 in the Salt Creek watershed and the Specific Plan area. In both areas, plants were found primarily intermixed with big sagebrush. This species was not observed in the Entrada planning area, but there is suitable big sagebrush scrub habitat on site where Parish's sagebrush potentially exists. There is no big sagebrush scrub found on the VCC planning area, and this species has not been observed within the VCC planning area.

4.5.3.4.5.11 *Peirson's Morning-Glory (*Calystegia peirsonii*)*

The Peirson's morning-glory is a CNPS List 4 (S3.2) plant, but it has no federal status. This species is typically found in chaparral, coastal scrub, chenopod scrub, cismontane woodland, lower montane coniferous forest, and grasslands. While never abundant, Peirson's morning-glory is widespread on site and was observed on ridges and slopes, weakly climbing over chaparral, coastal scrub, and grasslands throughout the RMDP, VCC, and Entrada areas. Given the low sensitivity status of the species, observations were not mapped.

4.5.3.4.5.12 *Plummer's Mariposa Lily (*Calochortus plummerae*)*

The Plummer's mariposa lily is a CNPS List 1B (S3.2) plant, but it has no federal status. This species is typically found in chaparral, coastal scrub, cismontane woodland, lower montane coniferous forest, and grassland, often on granitic and/or rocky soils. Three polygons and two point locations of Plummer's mariposa lily were mapped within the High Country SMA in 2006, with an estimated number of approximately 78 individuals.

4.5.3.4.5.13 *Slender Mariposa Lily (*Calochortus clavatus *var.* gracilis*)*

The slender mariposa lily is a CNPS List 1B (S1.1) plant, but it has no federal status. This species is typically found in chaparral, coastal scrub, and grasslands, often on clay and/or rocky soils. Slender mariposa lily was documented within the Project area from 2002 through 2006. Within the VCC portion of the Project area, this species was found primarily on northwest- and southwest-facing ridges and slopes located just east of Hasley Canyon. Within the Entrada area, this species was found primarily on south-facing slopes (70% of all individuals identified) and, to a lesser extent, on southeast-facing slopes (20% of all individuals identified). Within the Specific Plan area, this species was found primarily on east-, northeast-, and southwest-facing ridges and slopes in the following areas: the San Martinez Grande Canyon, Chiquito Canyon, Off-Haul Canyon, Potrero Canyon, Long Canyon, Middle Canyon, Grapevine Mesa, and Airport Mesa areas as well as the lower Castaic Creek area. This species was also found primarily on east-, northeast-, and southwest-facing ridges within the High Country SMA and Salt Creek area. Occurrences of the lily throughout the RMDP and SCP areas were typically observed in California sagebrush, California buckwheat, and California annual grasslands, and generally were mapped in areas of high vegetative cover and a variety of soil types (*e.g.*, gravelly loam, silty loam, sandy loam, clay loam, and rocky clay). **Table 4.5-21** presents the slender mariposa lily occurrence data for the Project area.

Table 4.5-21
Slender Mariposa Lily Summary of Occurrence Data

	Estimated Number of Individuals by Year				
Project Area	**2002**	**2003**	**2004**	**2005**	**2006**
Specific Plan area (including High Country SMA)	Not observed	7,592	64,888	3,102	692
Salt Creek area	Not surveyed	25,965	Not surveyed	Not surveyed	1
VCC	Not observed	500	4	598	Not observed
Entrada	Not observed	7,870	405	3,903	Not observed

4.5.3.4.5.14 *Southern California Black Walnut (*Juglans californica *var.* californica*)*

The southern California black walnut is a CNPS List 4 (S3.2) plant, but it has no federal status. This species typically inhabits chaparral and cismontane woodlands with Miocene–Pliocene shale and coastal scrub with alluvial soils. This large shrub to tree was incidentally observed in the Specific Plan area in 2002, 2003, and 2004. Observations of this species were made within the High Country SMA and Salt Creek area in 2003 and 2006 and within the VCC planning area in 2004 and 2005. Southern California black walnut was observed within the Entrada planning area as an occasional component of mixed chaparral, coastal scrub, and alluvial scrub in 2004 and 2005. Within the Specific Plan area, southern California black walnut dominates California walnut woodland and is found as an occasional component of chaparral, coastal scrub, and oak woodland. Within the VCC planning area, an individual southern California black walnut occurs within southern cottonwood–willow riparian forest along the south side of Castaic Creek. Occurrences of this species were not mapped due to its low sensitivity status.

4.5.3.4.5.15 *Southwestern Spiny Rush (*Juncus acutus *ssp.* leopoldii*)*

The southwestern spiny rush is a CNPS List 4 (S3.2) plant, but it has no federal status. This species is considered locally and regionally rare by local botanists and has been documented from 10 vouchered collections from LA County, half of which are on Santa Catalina Island (DMEC 2007 comment letter dated January 30 2007, Landmark Village DEIR).

This stout, robust perennial herb is found primarily on coastal dunes with mesic soils, meadows and alkaline seeps, and marshes and coastal salt swamps. Within the Specific Plan area, southwestern spiny rush individuals were observed annually from 2001 through 2006. Southwestern spiny rush is known to occur in bulrush–cattail wetland, coastal and valley freshwater marsh, and herbaceous wetland within the Specific Plan area. The 2001 populations were found in three locations in secondary channels of the floodplain of the Santa Clara River on flat terrain consisting of alluvial soils; elevations ranged from 800 to 900 feet AMSL and plants were associated mostly with wetland species. The 2002 observations (96 clumps) were made at River Village (now referred to as Landmark Village) and at the Water Reclamation Plant site. The River Village populations consisted of 10 clumps of southwestern spiny rush found with mulefat (*Baccharis salicifolia*) and bulrush (*Schoenoplectus microcarpus*) on a low terrace in the riverbed at 925 feet AMSL. Four populations at the Water Reclamation Plant site were documented in secondary channels and on a low terrace on flat terrain at about 850 feet AMSL. The plants at both the River Village and the Water Reclamation Plant sites occurred on alluvial soils and were associated mostly with wetland species. In 2003, 2004, 2005, and 2006, individuals were found to be occasional in mesic riparian areas along the Santa Clara River. Additional surveys in 2004 documented five locations with a total of about 15 plants along the

edges of the western portion of the Santa Clara River. This species is not numerically abundant on site and occurrences of this species were not mapped due to its low sensitivity status.

4.5.3.4.6 Special-Status Wildlife Species

Information compiled from the literature review (see **Subsection 4.5.3.1**, Literature Review), field study observations listed in **Table 4.5-6**, and professional judgment were used to generate a list of special-status wildlife species that were observed or have the potential to occur within the Project area, including Project construction zones and designated open space areas. For the purposes of the analysis presented in this subsection, special-status species are defined as wildlife that:

- Have been designated as either rare, threatened, or endangered by CDFG or the USFWS and are protected under either the California Endangered Species Act (CESA) (Fish & G. Code, § 2050 *et seq*.) or federal Endangered Species Act (ESA) (16 U.S.C. § 1531 *et seq*.); or meet the CEQA definition for endangered, rare, or threatened (Cal. Code Regs., tit. 14, § 15380(b),(d));
- Are candidate species being considered or proposed for listing under these same acts;
- Are fully protected by the California Fish and Game Code sections 3511, 4700, 5050, or 5515;
- Are of expressed concern to resource/regulatory agencies or local jurisdictions. This includes those wildlife that are considered a state Species of Special Concern; are on CDFG Watch List; are designated as a federal Bird of Conservation Concern; or considered a state Special Animal; or
- Are wildlife that the California Natural Diversity Database (CNDDB) is interested in tracking.

In **Subsection 4.5.3.1**, Literature Review, **Table 4.5-9** includes those special-status wildlife species observed within the Project area, **Table 4.5-10** includes those special-status wildlife species potentially occurring on site, and **Table 4.5-11** includes those special-status wildlife species not expected to occur or rarely occurring on site. In most cases, those special-status wildlife species observed within the Project area or potentially occurring on site are carried through the existing conditions descriptions and impacts analyses of this EIS/EIR. There are two special-status species observed in the Project area that are not carried through in this analysis: great egret and great blue heron. While both species are commonly observed on site, they are not carried forward in the analysis because their special status designation is based on the presence of rookeries. During the many surveys conducted in riparian habitats from 1988 through 2007, no rookeries for either species have been observed in the Project area. For this reason, they are included in **Table 4.5-11,** Special-Status Wildlife Species Not Expected to Occur or Rarely Occurring on Site. Those special-status wildlife species not expected to occur or rarely occurring on site are not analyzed further in this EIS/EIR.

As described above in **Tables 4.5-9** and **4.5-10**, 75 special-status wildlife species are addressed in this analysis, with each assigned to one of the following two headings: (1) special-status wildlife species observed within the Project area (addressing the special-status wildlife species observed within the RMDP, VCC, and Entrada areas during the course of various field surveys) and (2) special-status wildlife species not observed within the Project area. Under these two headings, the special-status species are categorized under six general guilds: birds (raptors, riparian, upland grassland, upland scrub and chaparral, and upland woodland), bats, invertebrates (butterflies and aquatic mollusks), fish, reptiles and amphibians (low mobility and semi-aquatic), and mammals (low mobility, moderate mobility, and high mobility).

In total, 59 special-status species have been observed within the Project area during the course of various surveys conducted from 1988 to 2008.

4.5.3.4.6.1 *Special-Status Wildlife Species Observed within the Project Area*

RMDP

Birds

Raptors

American Peregrine Falcon (*Falco peregrinus anatum*). A subspecies of the peregrine falcon, the American peregrine falcon is listed as endangered under the California Endangered Species Act (CESA) and is also a California Fully Protected species. On October 11, 2007, the California Fish and Game Commission designated the American peregrine falcon as a candidate for delisting under CESA (California Regulatory Notice Register 2007, p. 1856). Peregrine falcons in general use a large variety of open habitats for foraging, including tundra, marshes, seacoasts, savannahs, grasslands, meadows, open woodlands, and agricultural areas. One American peregrine falcon was observed hunting along the Santa Clara River Corridor near the Grapevine Mesa area within the Specific Plan area by Guthrie in July 2000 (Guthrie 2000C). No other occurrences of this species have been documented on site during annual bird surveys between 1988 and 2007. American peregrine falcons have never been documented nesting on the Project site.

California Condor (*Gymnogyps californianus*). The California condor is federally and state listed as endangered and is also a California Fully Protected species. California condors require vast expanses of open savannah, grasslands, and foothill chaparral, with cliffs, large trees, and snags for roosting and nesting (Zeiner *et al.* 1990A). Until April 2008, California condors had not been known to nest or land within the Project area in the last 25 years (Bloom Biological

2007A, 2008). In April 2008, a California condor was observed feeding on a dead calf in a Potrero side canyon by wildlife biologist Chris Niemela (pers. comm. M. Carpenter, Newhall Ranch 2008). No other mention of California condor observations have been made during numerous other plant and wildlife surveys conducted over the past 30 years within various portions of the Project area.

Cooper's Hawk (*Accipiter cooperii*). The Cooper's hawk is on CDFG Watch List. Cooper's hawks are found in areas with dense stands of live oak, riparian areas, or other forest communities near water (Zeiner *et al.* 1990A). The Cooper's hawk frequents landscapes where wooded areas occur in patches and groves and often uses patchy woodlands and edges with snags for perching (Beebe 1974). The Cooper's hawk has been regularly observed within riparian and oak woodland habitats over multiple years during the bird surveys conducted from 1988 through 2006 along the Santa Clara River within riparian scrub and woodland habitat (Guthrie 1988–1990, 1991A–B, 1992, 1993A–B, 1994A–B, 1995A–B, 1996A–B, 1997A–B, 1998A–B, 1999A–C, 2000B–C, 2000E–F, 2001A–B, 2002A, 2002C, 2003A–B, 2004F, 2004H–I, 2005A–B, 2006A–C), within portions of the Santa Clara River by Labinger and Greaves in 1995, 1996, 1997, and 1999 (Labinger *et al.* 1995, 1996, 1997A–B; Labinger and Greaves 1999A). This species is known to be a year-round resident within the Project area (Bloom Biological, Inc. 2007A). The Cooper's hawk has been observed nesting within the Specific Plan area west of Grapevine Mesa in the undisturbed dry canyon woodlands (Guthrie 2000B).

Ferruginous Hawk (*Buteo regalis*). The ferruginous hawk is on CDFG Watch List is a Bird of Conservation Concern. The ferruginous hawk forages in open grasslands, agriculture, sagebrush flats, desert scrub, surrounding valleys in low foothills, and fringes of pinyon–juniper habitats (Polite and Pratt 1999). On site, has been observed in the eastern alfalfa fields, Wolcott agricultural fields, Potrero Canyon, and other agriculture fields along the Santa Clara River in winter 2008 (Bloom Biological, Inc. 2008). The Project area is outside of the species' breeding range and it is not expected to nest on site.

Golden Eagle (*Aquila chrysaetos*). The golden eagle is on CDFG Watch List and a California Fully Protected species. The golden eagle requires rolling foothills, mountain terrain, and wide arid plateaus deeply cut by streams and canyons, open mountain slopes and cliffs, and rock outcrops (Zeiner *et al.* 1990A). On site, this species has been occasionally observed during the annual bird surveys conducted from 1988 through 2007 along the Santa Clara River. Observation of a single golden eagle soaring over the Santa Clara River was

recorded on April 22, 1993 (Guthrie 1993A). Two golden eagles were flushed out of coast live oak woodlands west of Grapevine Mesa on the RMDP Project site (Guthrie 2000B).

Loggerhead Shrike (*Lanius ludovicianus*). The loggerhead shrike is a Bird of Conservation Concern and has been designated by CDFG as a California Species of Special Concern. The species occurs most frequently in riparian areas along the woodland edge, grasslands with sufficient perching and butchering sites, scrublands, and open-canopied woodlands, although they can be quite common in agricultural and grazing areas and can sometimes be found in mowed roadsides, cemeteries, and golf courses. The loggerhead shrike is a breeding resident on site (Bloom Biological, Inc. 2007A). It has been observed to be fairly common within California sagebrush scrub and grasslands in the Specific Plan area (Guthrie 1993B, 1996A, 2000A–B, 2002C, 2004A, 2004E, 2005B; Labinger *et al.* 1995; Lemons 2008; Bloom Biological, Inc. 2007A).

Long-Eared Owl (*Asio otus*). The long-eared owl has been designated by CDFG as a California Species of Special Concern. The long-eared owl primarily uses riparian habitat for roosting and nesting, but can also use live oak thickets and other dense stands of trees (Zeiner *et al.* 1990A). It appears to be more associated with forest edge habitat than with open habitat or forest habitat (Holt 1997). Dudek observed a long-eared owl during wildlife transect surveys within the Specific Plan area in live oak woodland south of Via Canyon during fall 2005 (Dudek 2006B). The observed individual was not nesting. The species was not observed during 2007 surveys despite several nights spent camping in oak woodlands surrounding the Landmark Village project area (Bloom Biological, Inc. 2007A).

Merlin (*Falco columbarius*). The merlin is on CDFG Watch List. The merlin uses a wide variety of semi-open to open habitats during breeding and wintering (Garrett and Dunn 1981; Sodhi *et al.* 2005). Individuals frequent coastlines, grasslands, savannahs, open woodlands, lakes, wetlands, edges, and communities in early successional stages while foraging. In 2007, Bloom Biological made four observations of wintering or migrating merlins between March 4 and March 23 (Bloom Biological, Inc. 2007A). One male and one female were documented hunting over agriculture fields bordering riparian habitat near Indian Dunes, which is located east of the Landmark Village site in the Specific Plan area. Merlins were not observed during bird surveys in any other year between 1988 and 2007.

Northern Harrier (*Circus cyaneus*). The northern harrier has been designated by CDFG as a California Species of Special Concern. Northern harriers use a wide variety of open habitats in California, including deserts, coastal sand dunes, pasturelands, croplands, dry plains, grasslands, estuaries, flood plains, and marshes (Macwhirter and Bildstein 1996). The species can also forage over coastal sage scrub or other open scrub communities (Bloom Biological, Inc. 2007A). The northern harrier has been observed in or near the Project area infrequently during the 20 years when surveys were conducted (Guthrie 1999B, 2000A). More recently, Dudek observed a northern harrier in the Mission Village area (Dudek 2008B), and in March 2007, Bloom Biological made three separate observations of a single male at different locations in or near the Project area along the Santa Clara River (Bloom Biological, Inc. 2007A).

Prairie Falcon (*Falco mexicanus*). North America's only endemic falcon, the prairie falcon is a Bird of Conservation Concern and is on CDFG Watch List. Additionally, the prairie falcon is a migratory bird protected under the Migratory Bird Treaty Act (16 U.S.C. § 703 *et seq.*) and the USFWS identified the prairie falcon as a Bird of Conservation Concern (USFWS 2002B). Prairie falcons inhabit open habitats in North America, including arid plains and steppe habitats. In the western states they prefer chaparral, desert grasslands, and creosote bush habitats. Surveys conducted by Guthrie detected two individual prairie falcons foraging during various surveys; one prairie falcon was detected on April 7, 2000, in the Potrero Canyon and Long Canyon area, and the other on July 2, 2001, along Castaic Creek between the confluence with the Santa Clara River and I-5 (Guthrie 2000D, 2001A). Dudek biologists detected a prairie falcon within the Salt Creek watershed in late November 2005 and an incidental sighting was made in late August 2007 over Salt Creek within the High Country SMA (Dudek and Associates, Inc. 2006B; Trow, personal observation, 2007).

Sharp-Shinned Hawk (*Accipiter striatus*). The sharp-shinned hawk is on CDFG Watch List. Sharp-shinned hawks prefer riparian forest and woodlands (NatureServe 2007). They are found in a variety of ponderosa pine, black oak, riparian deciduous, mixed conifer, and Jeffrey pine habitats (Joy *et al.* 1984; Zeiner *et al.* 1990A; NatureServe 2007). Sharp-shinned hawks have been observed several times during the course of the avian surveys conducted along the Santa Clara River corridor. Guthrie observed two adults on two separate occasions in 1995 and again in 1997 and 1999 (Guthrie 1995B, 1997A, 1999B). Another sharp-shinned hawk was observed in March 2007 by Bloom Biological (Bloom Biological, Inc. 2007A).

Turkey Vulture (*Cathartes aura*). Although the turkey vulture has no federal or state status, it is being discussed, for the purposes of this report, as a CDFG trust resource. Turkey vultures use a variety of habitats while foraging for both wild and domestic carrion. They prefer open stages of most habitats. In the western United States, they tend to occur regularly in areas of hilly pastured rangeland, nonintensive agriculture, and areas with rock outcrops suitable for nesting, although they are not generally found in high-elevation mountain areas (Kirk and Mossman 1998; Zeiner *et al.* 1990A). On site, this species has been observed over multiple years during bird surveys conducted from 1988 through 2007 along the Santa Clara River (Guthrie 1993B, 1994B, 1996B, 1997B, 1999B–C, 2000A–B, 2000E–F, 2001A–B, 2002A, 2003B, 2004A, 2004D–F, 2004H, 2005B, 2006A), Dudek (2006B, 2008B), Labinger *et al.* (1995, 1997A–B), and Bloom Biological, Inc. (2007); and off site in the Castaic Junction area by Guthrie (1988, 1990, 1991A, 1993A, 1994A, 1995A, 1996A, 1997A, 1998A, 1999A, 2001A, 2002A, 2003A, 2004I, 2005A, 2006C) and Haglund and Baskin (2000). However, no mapped occurrences of this species were recorded.

Western Burrowing Owl (*Athene cunicularia hypugaea*). The western burrowing owl is a Bird of Conservation Concern and designated by CDFG as a California Species of Special Concern. In California, western burrowing owls are yearlong residents of flat, open, dry grassland and desert habitats at lower elevations (Bates 2006). They can inhabit annual and perennial grasslands and scrublands characterized by low-growing vegetation. On site, the western burrowing owl has been observed anecdotally at two locations. A single western burrowing owl individual was observed twice at the same location within a four-week period (November and December 2006) in the northern portion of Middle Canyon, east of Airport Mesa, in ruderal habitat. Another individual was observed in December 2006 in Middle Canyon, and again on April 11, 2007 (Miller 2007).

White-Tailed Kite (*Elanus leucurus*). The white-tailed kite is a California Fully Protected species. The white-tailed kite is commonly associated with agriculture areas (Grinnell and Miller 1944). It also inhabits low-elevation grasslands, savannah-like habitats, open sage scrub, meadows, wetlands, and oak woodlands, particularly in areas with a dense population of voles (Waian and Stendell 1970). On the Project site, white-tailed kite has been observed primarily along the Santa Clara River, where it nests in associated riparian woodlands and forages in adjacent grasslands, open sage scrub, and agricultural fields (Guthrie 2005C; Bloom Biological, Inc. 2007A, 2009). It has been observed within the Specific Plan, including High Country SMA and Salt Creek (Guthrie 1994B, 1995B, 1996B, 1997B, 1998A, 1999B, 2000A–C, 2002C, 2003B, 2004D, 2004F;

Labinger *et al.* 1995, 1996, 1997A–B; Labinger and Greaves 1999A; Dudek 2006B; Bloom Biological, Inc. 2007A); and off site within Castaic Junction (Guthrie 1988–1990, 1993A, 1994A, 1995A, 1998B, 1999A, 2000E, 2001A, 2003A, 2004F, 2005A, 2006C; Dudek 2006E; Bloom Biological, Inc. 2007A) and within the Santa Clara River and adjacent agricultural areas just upstream of Las Brisas Bridge in Ventura County and just west of the Ventura/Los Angeles County line (Bloom Biological, Inc. 2009).

Riparian

Black-Crowned Night-Heron (*Nycticorax nycticorax*). The black-crowned night heron is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range. Its habitat requirements are varied, including all types of wetland areas, including fresh, brackish, and salt water ecosystems and even man-made ditches, canals, reservoirs, and wet agricultural fields (IHRMP 2001G). On site, this species was observed early in the year and is thought to be a wintering or migratory species within the Project site. In the most recent survey, several adults and juveniles were observed along the Santa Clara River after dusk and before dawn (Bloom Biological, Inc. 2007A). Observations of the species were mapped along the Santa Clara River in the RMDP Project area south of Landmark Village and near the Ventura County line (Bloom Biological, Inc. 2007A). No roosts or rookeries (nesting colonies) have been detected during the surveys within or adjacent to the Project site during any of the surveys that have been conducted over the years.

Least Bell's Vireo (*Vireo bellii pusillus*). The least Bell's vireo was state listed as endangered in 1980 and federally listed as endangered by the USFWS in 1986 (51 FR 16474). The USFWS made a final critical habitat designation for the least Bell's vireo in 1994 (59 FR 4845). Least Bell's vireos primarily occupy riverine riparian habitats that typically feature dense cover within one to two meters of the ground and a dense, stratified canopy. The least Bell's vireo inhabits low, dense riparian growth along water or along dry parts of intermittent streams and is typically associated with southern willow scrub, cottonwood forest, mulefat scrub, sycamore alluvial woodland, southern coast live oak riparian forest, arroyo willow riparian forest, wild blackberry, or mesquite in desert localities. The least Bell's vireo has been observed almost every year along the Santa Clara River within the Specific Plan area (Guthrie 1993B, 1995B, 1996B, 1997B, 1998A, 1999B, 2000C, 2001B, 2002C, 2003B, 2004H, 2005B, 2006A; Labinger *et al.* 1995, 1996, 1997A–B; Labinger and Greaves 1999A; Bloom Biological, Inc. 2007A), and off site in Castaic Junction (Guthrie 1988, 1990, 1991A, 1996A, 1997A, 1998B, 2000E, 2001A, 2002A, 2003A, 2004F, 2004I, 2005A, 2006C; Dudek

2006E; Bloom Biological, Inc. 2007A). Most recently, Bloom Biological observed at least 56 territories and three active nests within the Specific Plan area and adjacent areas (Bloom Biological, Inc. 2007A).

Nuttall's Woodpecker (*Picoides nuttallii*). The Nuttall's woodpecker is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range. The Nuttall's woodpecker is primarily found in oak woodlands, to a lesser extent in riparian woodlands, and rarely in conifer forests. Nuttall's woodpecker has been described as a species characteristic of, if not confined to, oak woodlands in California (Lowther 2000). It has been observed nearly every year along the Santa Clara River since surveys began in 1988. Nuttall's woodpeckers are common residents in cottonwood and willow riparian habitat along Santa Clara River, Castaic Creek and other tributaries, and in coast live oak woodlands in adjoining canyons. Bloom Biological recorded three to 14 daily within the RMDP Project area in 2007 (Bloom Biological, Inc. 2007A).

Tricolored Blackbird (*Agelaius tricolor*). The tricolored blackbird is a California Species of Special Concern and a Bird of Conservation Concern with regard to its nesting colony status. It was petitioned for state and federal listing by the Center for Biological Diversity in 2004, but the USFWS made a decision not to warrant protection in December 2006. These birds prefer to breed in freshwater marshes with dense growths of emergent vegetation dominated by cattails (*Typha* spp.) or bulrushes (*Schoenoplectus* spp.), but have also established colonies in willows (*Salix* spp.), blackberries (*Rubus* spp.), thistles (*Cirsium* and *Centaurea* spp.), and nettles (*Urtica* spp.). This species has been observed on the Project site during focused bird surveys. Labinger *et al.* (1995) observed a small nesting colony within the Project site; however, the specific location is not known and was not mapped. Migrants have also been observed within the Specific Plan area along the Santa Clara River (Guthrie 1996B, 1999B, County of Los Angeles 2003) and within Potrero Canyon in 1994 (County of Los Angeles 2003). Tricolored blackbird has been observed office along Castaic Creek (Guthrie 1994A, 1995A, 1996A, 1999A, 2006C), and at Castaic Junction (Guthrie 1994A, 2000E, 2001A, 2006C; Dudek 2006E). No breeding colonies have been observed since 1994, despite annual surveys through 2007 as described above.

Vermilion Flycatcher (*Pyrocephalus rubinus*). The vermilion flycatcher is designated by CDFG as a California Species of Special Concern. This species is found in riparian thickets near open, mesic habitats. It breeds in cottonwood, willow, mesquite, oak, sycamore, and other vegetation in desert riparian communities that are located adjacent to irrigated fields, irrigated ditches, or

pastures (Zeiner *et al.* 1990A; Wolf and Jones 2000). A single individual was observed along the Santa Clara River on June 19, 1993 (Guthrie 1993B). This is the only observation of a vermilion flycatcher from any of the many years of surveys both within and adjacent to the Project site, and its location was not mapped.

Yellow-Headed Blackbird (*Xanthocephalus xanthocephalus*). The yellow-headed blackbird is designated by CDFG as a California Species of Special Concern. This species is not federally listed as threatened or endangered within any part of its range. It is found primarily within prairie wetlands, but it is also commonly found in wetlands associated with quaking aspen parks, mountain meadows, and arid regions. This species has been observed within the Specific Plan area (Guthrie 1996B, 1997B, 1999B, 2001B; Bloom Biological, Inc. 2007A). Bloom Biological observed one individual in an agriculture field within a flock of red-winged blackbirds on April 1, 2007 (Bloom Biological, Inc. 2007A). No nesting colonies have been observed within the Project site.

Yellow Warbler (*Dendroica petechia brewsteri*). The yellow warbler has no federal or state sensitivity status but is designated as a California Species of Special Concern by CDFG. In general, the yellow warbler breeds most commonly in wet, deciduous thickets, especially those dominated by willows, and in disturbed and early successional habitats (Lowther *et al.* 1999). This species has been observed nearly every year within the Specific Plan during avian surveys from 1992 through 2007 (Guthrie 1992, 1993B, 1994B, 1995B, 1996B, 1997B, 1998A, 1999B, 2000C, 2001B, 2002C, 2003B, 2004H, 2005B, 2006A; Labinger *et al.* 1995, 1996, 1997A–B; Labinger and Greaves 1999A; Bloom Biological, Inc 2007A); in the VCC development area from 1988 to 1989 and 1991 to 2006 (Guthrie 1988, 1989, 1991A, 1992, 1993A, 1994A, 1995A, 1996A, 1997A, 1998B, 1999A, 2000E, 2001A, 2002A, 2003A, 2004F, 2005A, 2006C); and off site in Castaic Junction north of the Entrada development area(Guthrie 1988, 1989, 1990, 1991A, 1992, 1993A, 1994A, 1995A, 1996A, 1997A, 1998B, 1999A, 2000E–F, 2001A, 2002A, 2003A, 2004F, 2005A, 2006C; Haglund and Baskin 2000; Dudek 2006E; Bloom Biological, Inc 2007A). However, no mapped occurrences of this species were recorded.

Yellow-Breasted Chat (*Icteria virens*). The yellow-breasted chat is designated by CDFG as a California Species of Special Concern. This species is not federally listed as threatened or endangered, but has been listed as threatened, endangered, or of special concern in some states and provinces on the periphery of its range (*e.g.*, Connecticut, New Jersey, New York, Ontario, and British Columbia) (Eckerle and Thompson 2001). In southern California, the yellow-

breasted chat is primarily found in dense, relatively wide riparian woodlands and thickets of willows, vine tangles, and dense brush with well-developed understories. On site, this species has been observed On site, this species was observed nesting in riparian thickets in 2007 (Biological, Inc. 2007A) and has also been observed over multiple years during bird surveys conducted from 1988 through 2006 (Guthrie 1988–1990, 1991A, 1992, 1993A–B, 1994A–B, 1995A–B, 1996A–B, 1997A–B, 1998A–B, 1999A–B, 2000B–C, 2000E–F, 2001A–B, 2002A, 2002C, 2003A–B, 2004F, 2004H, 2005A–B, 2006A, 2006C; Labinger *et al.* 1995, 1997B; Labinger and Greaves 1999A).

Upland Grassland

California Horned Lark (*Eremophila alpestris*). The California horned lark is on CDFG Watch List. California horned larks are common and abundant residents in a variety of open habitats, usually where trees and shrubs are absent. California horned larks have been observed regularly foraging in plowed and graded fields near the Santa Clara River within the RMDP Project area Guthrie (1994B, 1995B, 1996B, 1998A, 1999B–C, 2000A–C, 2005B), Labinger *et al.* (1995, 1996, 1997B; Labinger and Greaves 1999A), and Bloom Biological, Inc. (2007A); in the VCC planning area (Guthrie 1990, 1991B, 1992, 1996B, 1997B, 2000C, 2001A, 2002A, 2003A, 2004B, 2005A–B, 2006C; Dudek 2006D); and offsite in the Castaic Junction area (Guthrie 1991B, 1993A, 1994A–B, 1995B, 2000F, 2003A, 2004, 2005A). More recent surveys have observed several individuals in the agricultural fields along the Santa Clara River and a flock of approximately 20 individuals was observed adjacent to the Project site foraging in a dirt agricultural field within the Landmark Village impact area (Bloom Biological, Inc. 2007A).

Upland Scrub and Chaparral

Allen's Hummingbird (*Selasphorus sasin*). The Allen's hummingbird is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range and according to Sauer *et al.* (1996) showed no statistically significant declines in population for the period from 1966 to 1996. The vegetation communities most commonly used by breeding Allen's hummingbirds are coastal scrub, valley foothill hardwood, and valley foothill riparian habitats. Allen's hummingbird has been documented numerous times within the RMDP Project area. Five individuals were observed in March and April 2004 in the southern and western portions of Legacy Village, which includes Long, Potrero, and Pico canyons (Guthrie 2004G).

Chipping Sparrow (*Spizella passerina*). The chipping sparrow is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range and Sauer *et al.* (1997) have concluded that continental populations appear healthy. Chipping sparrows prefer open wooded habitats with a sparse or low herbaceous layer and few shrubs, if any (Zeiner *et al.* 1990A). On site, this species has been observed as a common migrant in the RMDP area, and one to 12 individuals were observed near edges of agricultural fields most days in early March (Bloom Biological, Inc. 2007A). The chipping sparrow has been observed over multiple years during bird surveys conducted from 1988 through 2007 along the Santa Clara River within riparian scrub and woodland habitat; however, there are no mapped occurrences of these observations.

Costa's Hummingbird (*Calypte costae*). The Costa's hummingbird is designated by CDFG as a California Special Animal. It has a CNDDB ranking of global: demonstrably widespread, abundant, and secure; subnational: vulnerable to extirpation or extinction. It is not federally listed as threatened or endangered within any part of its range. Primary habitats are desert wash, edges of desert riparian and valley foothill riparian areas, coastal scrub, desert scrub, desert succulent scrub, lower-elevation chaparral, and palm oasis (Zeiner *et al.* 1990A). The species has been observed over multiple years during bird surveys conducted from 1988 through 2006 along the Santa Clara River within riparian scrub and woodland habitat; however, there are no mapped locations for observations.

Rufous Hummingbird (*Selasphorus rufus*). The rufous hummingbird is designated by CDFG as a California Special Animal and is a Bird of Conservation Concern with regard to its nesting colony status. The rufous hummingbird uses a variety of vegetation communities that provide nectar-producing flowers. In its breeding range, the species uses open areas as well as coniferous forests, deciduous woods, riparian thickets, swamps, meadows, agricultural areas, parks, and residential areas (Calder 2006). Rufous hummingbirds have been observed within and near the Project area in several different years. Three rufous hummingbirds were observed in early April of 1999 by Guthrie north of SR-126 in what is now the Homestead West area (Guthrie 1999B). Another individual was observed in late March 2004 by Guthrie within Potrero Valley, Oak Valley, Long Canyon, or Onion Fields (Guthrie 2004D). Another individual was observed in early April of that year in the southern half of the Legacy Village area (Guthrie 2004C), which is adjacent to the Project area just south of Mission Village and east of Potrero Village. No mapped occurrences of this species were recorded.

Southern California Rufous-Crowned Sparrow (*Aimophila ruficeps canescens*). The southern California rufous-crowned sparrow is on CDFG Watch List. This species is not federally listed as threatened or endangered within any part of its range (Collins 1999B). The rufous-crowned sparrow occupies moderate to steep hillsides that are rocky, grassy, or covered by coastal sage scrub or chaparral. The southern California rufous-crowned sparrow has been observed over multiple years as a fairly common resident in the coastal scrub within the Specific Plan area during annual bird surveys. It has been observed foraging upland and near the Santa Clara River (Guthrie 2000A, 2000B, 2001A, 2002C, 2004A, 2004D) and was observed nesting in 2007 (Bloom Biological, Inc. 2007A).

Upland Woodland

Hermit Warbler (*Dendroica occidentalis*). The hermit warbler is considered a CDFG trust resource for the purposes of this analysis. Hermit warblers are found in conifer and mixed forests, shrubland, chaparral, and conifer and mixed woodlands (NatureServe 2007). On site, this species was observed over multiple years during bird surveys conducted from 1988 through 2006 along the Santa Clara River within woodland habitat (Guthrie 1994B, 1996B, 2002C); however, there are no mapped occurrences of these observations. All observed individuals were thought to be migrants.

Lawrence's Goldfinch (*Carduelis lawrencei*). The Lawrence's goldfinch is designated by CDFG as a California Special Animal. Additionally, this species is recognized under the NatureServe system of Natural Heritage Programs as vulnerable at the state level within California and throughout its range and is listed as a Bird of Conservation Concern by the USFWS. Lawrence's goldfinches are found in cropland and hedgerows, shrubland and chaparral, conifer, hardwood and mixed woodlands (NatureServe 2007). On site, this species was observed in upland areas and riparian thickets in 2007 (Bloom Biological, Inc. 2007A) and has been observed over multiple years during the bird surveys conducted from 1988 through 2006 along the Santa Clara River (Compliance Biology 2006A; Guthrie 1988, 1990, 1992, 1993A–B, 1994A, 1996A–B, 1997A–B, 1998A–B, 1999A–B, 2000A–G, 2001A–B, 2002A, 2002C, 2003A–B, 2004C–E, 2004H–I, 2006C; Labinger *et al.* 1996, 1997A–B; Labinger and Greaves 1999A). Two to 70 were recorded daily throughout March, mostly in migrant flocks (Bloom Biological, Inc. 2007A).

Oak Titmouse (*Baeolophus inornatus*). The oak titmouse is designated by CDFG as a California Special Animal. This species is not federally listed as

threatened or endangered within any part of its range. Oak titmice inhabit a variety of habitat types, but are primarily associated with oaks, especially those in warm, dry habitats (Cicero 2000). The oak titmouse is common and abundant in the Project area, nesting on site in cottonwood riparian and coast live oak communities. It has been observed over multiple years along the Santa Clara River in the Specific Plan area. The oak titmouse was observed most recently by Guthrie in 2006 (Guthrie 2006C) and by Bloom Biological in 2007 (Bloom Biological, Inc. 2007A). Bloom Biological reported seeing between two and 14 individuals of this species daily. Most observations of this species were not mapped, but individuals have been sighted along the Santa Clara River and its tributaries.

Bats

Fringed Myotis (*Myotis thysanodes*). The fringed myotis is designated by CDFG as a California Special Animal. The fringed myotis typically occurs in a wide variety of desert, grass, and woodland habitats at middle elevations of 1,200 to 2,850 meters AMSL (3,937 to 9,350 feet) but is known from lower elevations along the west coast and may occur in pine–fir associations at higher elevations (O'Farrell and Studier 1980). There was one acoustic detection of the fringed myotis in the 2004 surveys and there were no acoustic detections or captures of the species in the 2006 surveys. The 2004 detection of the fringed myotis (Impact Sciences, Inc. 2005) was in coast live oak habitat, which is consistent with the known habitat association for this species.

Pallid Bat (*Antrozous pallidus*). The pallid bat is a listed California Species of Special Concern. The pallid bat is locally common in arid deserts (especially the Sonoran life zone) and grasslands throughout the western United States and also occurs in shrublands, woodlands, and forests at elevations up to 2,440 meters AMSL (8,000 feet) (Hermanson and O'Shea 1983; Hall 1981). There were three acoustic detections of the pallid bat in the 2004 acoustic surveys (Impact Sciences, Inc. 2005): two were in coast live oak habitat and one was in southern willow riparian habitat. In 2006, there were both captures and acoustic detections of pallid bats (Johnson 2006).

Pocketed Free-Tailed Bat (*Nyctinomops femorosaccus*). The pocketed free-tailed bat is a listed California Species of Special Concern. The pocketed free-tailed bat primarily occurs in desert habitats but may forage over most available habitats where it occurs (Kumirai and Jones 1990). It occurs at elevations from sea level to 2,500 meters AMSL (7,380 feet). The pocketed free-tailed bat was

acoustically detected in 2006 in lower Potrero Creek. It was not detected in Anabat surveys in 2004 (Impact Sciences, Inc. 2005).

Western Mastiff Bat (*Eumops perotis californicus*). The western mastiff bat is a listed California Species of Special Concern. The western mastiff bat occurs in a wide variety of chaparral, coastal scrub, coniferous and deciduous forest and woodland, and desert scrub habitats (Best *et al.* 1996; Zeiner *et al.* 1990B). The western mastiff bat was audibly detected in 2006 along the Santa Clara River at Walcott Road (Johnson 2006). Western mastiff bat was observed in Piru Canyon and Blue Canyon, north of the Santa Clara River in 1989 (Chris Huntley, personal communication, October 2006).

Based on known habitat associations and its generalist foraging behavior, the western mastiff bat is assumed to potentially use all suitable habitats throughout the Project area for foraging, including riparian, upland woodlands and forests, grasslands, and shrublands (scrubs and chaparral).

Yuma Myotis (*Myotis yumanensis*). The Yuma myotis is a listed California Special Animal. Forests and woodlands are primary habitats for this species, and foraging usually occurs within open, uncluttered habitats and low over water sources, such as ponds, streams, and stock ponds (Brigham *et al.* 1992; Zeiner *et al.* 1990B). Its potential presence was acoustically recorded in middle Potrero Creek and at the plant nursery site in upper Long Canyon in 2006.

Insects (Butterflies)

Monarch Butterfly (*Danaus plexippus*). The monarch butterfly is a listed California Special Animal. The species' distribution is controlled by the distribution of its larval host plants (*i.e.*, various milkweeds, genus *Asclepias*). Individual monarch butterflies were observed during surveys conducted in April and May of 2004 and 2005 as well as during various other wildlife and plant surveys that have been conducted. However, no wintering sites have been observed, and, due to the site's distance from the coast, it is unlikely that the Project area would be used by large numbers of overwintering adults (Compliance Biology, Inc. 2004A).

San Emigdio Blue Butterfly (*Plebulina emigdionis*). The San Emigdio blue butterfly is designated by CDFG as a California Special Animal. This butterfly can be locally abundant in association with its primary host plant, four-wing saltbush (*Atriplex canescens*), but has also been observed in association with quail brush (*A. lentiformis*) (Compliance Biology, Inc. 2004C, 2005). During the 2004 surveys, San Emigdio blue butterfly was documented within the Specific Plan

area in the west-central edge of Potrero Canyon. During the 2005 surveys, five adult San Emigdio blue butterflies were again observed at this location. One San Emigdio blue butterfly was also observed in the High Country SMA at the northwestern edge of Salt Canyon during the 2005 surveys; however, no additional observations of the species were made at this location or other portions of Salt Canyon during the 2005 surveys (Compliance Biology, Inc. 2005).

Fish

Arroyo Chub (*Gila orcutti*). The arroyo chub is listed as a California Species of Special Concern, is considered imperiled regionally and globally under the Natural Heritage Program methodology, and is considered sensitive by the U.S. Forest Service. It occurs in slow-moving or backwater sections of warm to cool (10ºC to 24ºC) streams with mud or sand substrates (ENTRIX 2009). In their collections within the Specific Plan area of the RMDP Project site, ENTRIX (2009) found that the arroyo chub was common to abundant. ENTRIX (2009) describes the arroyo chub as the dominant species of the Santa Clara River within the Project area.

Santa Ana Sucker (*Catostomus santaanae*). The Santa Ana sucker is listed as a California Species of Special Concern throughout its range. Outside of the Newhall Ranch Specific Plan area, populations within the species' natural historic range, including the Los Angeles, San Gabriel, and Santa Ana River basins, are listed federally as threatened. It is also considered sensitive by the U.S. Forest Service, critically imperiled by the Natural Heritage Program, and vulnerable by the IUCN World Conservation Union. The fish are most abundant in cool, shallow streams with good water quality and with streamside riparian vegetation that can provide refuge during seasonal floods and repopulation after flooding (Buth and Crabtree 1982; NatureServe 2007). Santa Ana sucker has been documented within the Specific Plan area throughout the Santa Clara River. In their collections within the Specific Plan area of the RMDP Project site, ENTRIX (2009) found that the Santa Ana sucker was common. Surveys conducted on June 3 and July 14, 2000, found this species within 500 meters upstream and downstream of the I-5 Bridge over the Santa Clara River (Impact Sciences, Inc. 2003A, 2003B; Haglund and Baskin 2000). This species is not expected to occur in Salt Creek.

Unarmored Threespine Stickleback (*Gasterosteus aculeatus williamsoni*). The unarmored threespine stickleback is listed as both state and federally endangered and is a California Fully Protected species. The USFWS (1985) notes that the unarmored threespine stickleback can be found in all areas of streams; however,

they tend to gather in slow-moving and standing water or behind obstructions, at the edges of streams, or in vegetation in faster-moving water. The unarmored threespine stickleback was observed during surveys within the Santa Clara River portion of the Specific Plan in 1988, 1995, 2000, 2002–2005, and 2007 (Aquatic Consulting Services, Inc. 2002A–D; ENTRIX 2009; Haglund 1989; SMEA 1995, 2000; Impact Sciences, Inc. 2003A–C).

Reptiles and Amphibians

Low Mobility

Coast Horned Lizard (*Phrynosoma coronatum*). The coast horned lizard is listed as a California Species of Special Concern. The species is found in a wide variety of vegetation types with the requisite loose sandy soils, including California sagebrush scrub, annual grassland, chaparral, oak woodland, riparian woodland, and coniferous forest (Klauber 1939; Stebbins 1954). One coast horned lizard was captured during the 2006 pitfall trap surveys and five additional coast horned lizards were incidentally observed during the 2004 reptile surveys (Impact Sciences, Inc. 2006A). The coast horned lizard observed during the 2006 surveys was captured in the eastern portion of the Specific Plan area (in the vicinity of the Potrero Village development area) in an area described as containing sandy soils and riparian and non-native grassland vegetation (Impact Sciences, Inc. 2006A). No location or habitat association information was provided for the coast horned lizards incidentally observed during the 2004 surveys. Coast horned lizard was also observed along the Santa Clara River floodplain, approximately 500 feet south of The Old Road Bridge in 2006 (Chris Huntley, personal communication, October 2006).

Coastal Western Whiptail (*Aspidoscelis tigris*). The coastal western whiptail is designated by CDFG as a California Special Animal. The western whiptail is found in a variety of habitats, primarily in areas where plants are sparse and there are open areas for running. The species is also found in woodland and streamside growth and avoids dense grassland and thick shrub growth. While coastal western whiptails were not trapped or otherwise observed during the pitfall trap surveys, the subspecies was identified as having potential to occur in the Project area (Impact Sciences, Inc. 2006A). Because of observations in the High Country SMA and nearby locations (Compliance Biology, Inc. 2006; Dudek 2006B), the presence of suitable habitat, observance that the Project area is within the range of the subspecies as described by Stebbins (2003), and the fact that the entire Project area was not surveyed by Impact Sciences (2006A) at a level of detail necessary

to determine presence or absence of a particular reptile species, the coastal western whiptail is assumed to be present in the Project area.

Silvery Legless Lizard (*Anniella pulchra pulchra*). The silvery legless lizard is designated by CDFG as a California Species of Special Concern. This species may be found in sparsely vegetated areas in a variety of habitats, including beach dunes, chaparral, California sagebrush scrub, oak woodlands, pine forests, pine–oak woodland, sandy washes, and stream terraces with sycamores, cottonwoods, or oaks (Zeiner *et al.* 1988; Stebbins 2003; Holland and Goodman 1998). Silvery legless lizards were observed within the leaf litter of coast live oak woodlands in Chiquito Canyon. Overall, 23 individual silvery legless lizards were captured and released (Impact Sciences, Inc. 2006A). Silvery legless lizard was also observed at two locations in Long Canyon in 2005 (Chris Huntley, personal communication, October 2006).

Semi-Aquatic

Southwestern Pond Turtle (*Actinemys marmorata pallida*). The southwestern pond turtle is listed as a California Species of Special Concern. Western pond turtles use a variety of aquatic habitats, including lakes, natural ponds, rivers, oxbows, streams (perennial/ephemeral), marshes, vernal pools, freshwater and brackish estuaries, drainage ditches, reservoirs, mill ponds, ornamental park ponds, stock ponds, abandoned gravel pits, and sewage treatment plants (Buskirk 2002; NatureServe 2007). The southwestern pond turtle has been documented in the Project area at several locations along the Santa Clara River and in the Salt Creek tributary during various field surveys conducted between 1996 and 2006. Additional incidental observations of southwestern pond turtle in the RMDP area have been made by Impact Sciences (2002) and Compliance Biology (2004D).

Two-Striped Garter Snake (*Thamnophis hammondii*). The two-striped garter snake is a California Species of Special Concern. Two-striped garter snakes are found in a variety of perennial and intermittent freshwater streams within oak woodlands, shrublands, and sparse coniferous forests from sea level to 2,400 meters (7,874 feet) AMSL (Stebbins 2003; Zeiner *et al.* 1988). This species was observed in the reach of the Santa Clara River within and adjacent to the Specific Plan area (Aquatic Consulting Services, Inc. 2002C; Impact Sciences, Inc. 2002; Compliance Biology, Inc. 2004; ENTRIX 2006B).

Arroyo Toad (*Bufo californicus*). The arroyo toad is listed as a California Species of Special Concern and is federally endangered. The species utilizes aquatic, riparian, and upland habitats to different degrees depending on the individual's stage of development and the season. No adult or subadult arroyo toads have been

observed in the Project area. However, arroyo toad tadpoles were observed in the Specific Plan area during surveys conducted in 2000 (Aquatic Consulting Services, Inc. 2002A–D). Specifically, during the surveys conducted by Aquatic Consulting Services, arroyo toad tadpoles were observed in the Santa Clara River upstream and downstream of the proposed Commerce Center Drive Bridge site and near the Valencia Water Treatment Plant.

Western Spadefoot Toad (*Spea hammondii*). The western spadefoot toad is a listed California Species of Special Concern. The species prefers open areas with sandy or gravelly soils in a variety of habitats, including mixed woodlands, grasslands, coastal sage scrub, chaparral, sandy washes, river floodplains, alluvial fans, playas, and alkali flats (Stebbins 2003; Holland and Goodman 1998). In total, there have been four separate documented occurrences of the western spadefoot toad in the Project area based on the focused surveys and incidental observations. Two occurrences of tadpoles are known from the Mission Village development area (Compliance Biology, Inc. 2006C). A western spadefoot toad was also observed within an isolated pool along the Santa Clara River upstream of the Commerce Center Bridge (Aquatic Consulting Services 2002A). Western spadefoot toads were observed in the Potrero Village development area within a rain pool in winter 2005; this location is believed to be extant (Dave Crawford, Compliance Biology, pers. comm., 2007). As western spadefoot toads have been observed in various locations in the Project area, and because suitable conditions for the species are expected elsewhere in unsurveyed portions of the Project area, there is a high potential for this species to occur in additional areas that contain seasonal pools.

Mammals

Low Mobility

San Diego Desert Woodrat (*Neotoma lepida*). The San Diego desert woodrat is listed as a California Species of Special Concern. Desert woodrats are found in a variety of shrub and desert habitats and are primarily associated with rock outcroppings, boulders, cacti, or areas of dense undergrowth (Bleich 1973; Bleich and Schwartz 1975; Brown *et al.* 1972; Cameron and Rainey 1972; Thompson 1982). The mammal assessment conducted by Impact Sciences (2005) found that the San Diego desert woodrat is a relatively common rodent within the Specific Plan area of the RMDP site. Dudek observed a single midden in the High Country SMA (Dudek 2006B). San Diego desert woodrat was observed in Long and Potrero Canyons in 2005 (Chris Huntley, personal communication, October 2006).

Moderate Mobility

American Badger (*Taxidea taxus*). The American badger is listed as a California Species of Special Concern (CSC). Badgers are generally associated with dry, open, treeless regions, prairies and grasslands, low-intensity agriculture (*e.g.*, pasture and dryland crops), drier open shrublands and forest, parklands, and cold desert areas (Long 1973; Zeiner *et al.* 1990B). The badger, although not common on site, has been documented through systematic surveys and anecdotal observations of badger dens and tracks in three locations in the Project area, including the Specific Plan area (Impact Sciences, Inc. 2005), Potrero Creek in the Specific Plan area (Behrends, personal observation, 2006), and High Country SMA (Dudek 2006B).

San Diego Black-Tailed Jackrabbit (*Lepus californicus*). The San Diego black-tailed jackrabbit is listed as a California Species of Special Concern. The black-tailed jackrabbit occupies many diverse habitats, but is primarily found in arid regions supporting shortgrass habitats. Systematic surveys of the Project area have not been conducted, but the San Diego black-tailed jackrabbit has been anecdotally observed on site (Impact Sciences, Inc. 2005). Based on the Impact Sciences (2005) report of the San Diego black-tailed jackrabbit in the Project area, it is assumed that the species potentially occurs in suitable habitat throughout the site.

High Mobility

American Black Bear (*Ursus americanus*). The American black bear is considered special status as a trust resource by CDFG for the purposes of this report. The black bear is found in dense, mature stands of a variety of forest types. It can utilize valley foothill riparian forests, wet meadows, and brushy stands of forests. The black bear was anecdotally observed within High Country SMA in 2005 (Dudek 2006B). The specific location was not recorded, but it is assumed that black bears utilize portions of the High Country SMA due to its connection to the Santa Susana Mountains to the south.

Mountain Lion (*Puma concolor*). The mountain lion is designated by CDFG as a Specially Protected Mammal, which affords it some protections: it is unlawful to take, injure, possess, transport, import, or sell any species that are considered Specially Protected Mammals (except with a depredation permit for mountain lion). The mountain lion is considered a special-status species for the purposes of this analysis. Mountain lions prefer habitats that provide cover, such as thickets of brush and timber in woodland vegetation communities (Zeiner *et al.* 1990B). They also utilize caves and other natural cavities for cover and breeding.

Mountain lions have been documented within and adjacent to the Project area during focused surveys in 2004 for mammals by Impact Sciences (2005). Specific locations for mountain lions in the Project area were not provided, but it is assumed that mountain lions could occur anywhere in the Project area where deer also occur.

Mule Deer (*Odocoileus hemionus*). The mule deer is considered a CDFG trust resource and is considered a special-status species for the purposes of this analysis, because take of the species requires a game permit. Mule deer have been documented within and adjacent to the Project area during focused surveys in 2004 for mammals by Impact Sciences (2005). Mule deer were also observed in the High Country SMA in 2005 (Dudek and Associates, Inc. 2006B).

Mollusk

Undescribed Snail (*Pyrgulopsis* sp. *nova*). The undescribed snail has no current status; however, in 2006, it was observed on the Project site within portions of the Middle Canyon Spring. In addition, the snail's habitat requirements are unknown and a comprehensive distribution survey has not yet been attempted. The species was first observed within Middle Canyon Spring by USFWS biologists in 2006. In 2007, Dudek biologists observed over 100 of the undescribed snails in Middle Canyon Spring as well as in the lower reach of the Middle Canyon drainage (Dudek 2007C).

VCC

Birds

Raptors

Cooper's Hawk (*Accipiter cooperii*). The Cooper's hawk is on CDFG Watch List. Cooper's hawks are found in areas with dense stands of live oak, riparian, or other forest communities near water (Zeiner *et al.* 1990A). The Cooper's hawk frequents landscapes where wooded areas occur in patches and groves and often uses patchy woodlands and edges with snags for perching (Beebe 1974). The Cooper's hawk has been regularly observed within riparian and oak woodland habitats over multiple years during bird surveys conducted from 1988 through 2006 along the Santa Clara River (Guthrie 1988–1990, 1991A–B, 1992, 1993A–B, 1994A–B, 1995A–B, 1996A–B, 1997A–B, 1998A–B, 1999A–C, 2000B–C, 2000E–F, 2001A–B, 2002A, 2002C, 2003A–B, 2004F, 2004H–I, 2005A–B, 2006A–C; Labinger and Greaves 1995, 1996, 1997A–B; Labinger and Greaves

1999A). This species is known to be a year-round resident within the Project area (Bloom Biological, Inc. 2007A).

Loggerhead Shrike (*Lanius ludovicianus*). The loggerhead shrike is a Bird of Conservation Concern and has been designated by CDFG as a California Species of Special Concern. The species occurs most frequently in riparian areas along the woodland edge, grasslands with sufficient perching and butchering sites, scrublands, and open-canopied woodlands, although they can be quite common in agricultural and grazing areas and can sometimes be found in mowed roadsides, cemeteries, and golf courses. It has been observed within the VCC planning area (Guthrie 1995A, 2004B); however, no mapped locations were recorded**.**

Prairie Falcon (*Falco mexicanus*). North America's only endemic falcon, the prairie falcon is a Bird of Conservation Concern and is on CDFG Watch List. Additionally, the prairie falcon is a migratory bird protected under the Migratory Bird Treaty Act (16 U.S.C. § 703 *et seq.*) and the USFWS has identified it as a Bird of Conservation Concern (USFWS 2002B). Prairie falcons inhabit open habitats in North America, including arid plains and steppe habitats. In the western states they prefer chaparral, desert grasslands, and creosote bush habitats. Surveys conducted by Guthrie detected two individual prairie falcons foraging during various surveys. One prairie falcon was detected on July 2, 2001, near VCC along Castaic Creek between the confluence with the Santa Clara River and I-5 (Guthrie 2001A).

Turkey Vulture (*Cathartes aura*). The turkey vulture has no federal or state status, but it is being discussed, for purposes of this report, as a CDFG trust resource. Turkey vultures use a variety of habitats while foraging for both wild and domestic carrion. They prefer open stages of most habitats. In the western United States, they tend to occur regularly in areas of hilly pastured rangeland, nonintensive agriculture, and areas with rock outcrops suitable for nesting, although they are not generally found in high-elevation mountain areas (Kirk and Mossman 1998; Zeiner *et al.* 1990A). On site, this species has been observed over multiple years during bird surveys conducted from 1988 through 2007 along the by Guthrie (1991B, 2004B) and Dudek (2006D). However, there are no mapped locations for any of these observations.

White-Tailed Kite (*Elanus leucurus*). The white-tailed kite is a California Fully Protected species. The white-tailed kite is commonly associated with agriculture areas (Grinnell and Miller 1944). It also inhabits low-elevation grasslands, savannah-like habitats, open sage scrub, meadows, wetlands, and oak woodlands, particularly in areas with a dense population of voles (Waian and Stendell 1970).

On the Project site, white-tailed kite has been observed primarily along the Santa Clara River, where it nests in associated riparian woodlands and forages in adjacent grasslands, open sage scrub, and agricultural fields (Guthrie 2005C; Bloom Biological, Inc. 2007A). Guthrie noted a total of eight pairs nesting within the Santa Clara River corridor from The Old Road Bridge to the Castaic Creek confluence between the years of 1993 and 2005 and he observed a total of three pairs nesting within Castaic Creek between 1993 and 2005 (Guthrie 2005C). In the latest survey effort, at least 10 pairs were observed along the Santa Clara River within the Specific Plan and VCC areas and adjacent to the Project site in Castaic Junction and near the Ventura County line (Bloom Biological, Inc. 2007A).

Riparian

Black-Crowned Night-Heron (*Nycticorax nycticorax*). The black-crowned night heron is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range. Its habitat requirements are varied, including all types of wetland areas, including fresh, brackish, and saltwater ecosystems and even man-made ditches, canals, reservoirs, and wet agricultural fields (IHRMP 2001G). On site, this species was observed early in the year and is thought to be a wintering or migratory species within VCC planning area (Guthrie 1988, 1992, 1994A, 1995A, 1996A, 1997A, 1998B, 1999A, 2000E). There are no mapped occurrences of these observations. No roosts or rookeries (nesting colonies) have been detected during the surveys within or adjacent to the Project site during any of the surveys that have been conducted over the years.

Least Bell's Vireo (*Vireo bellii pusillus*). The least Bell's vireo was state listed as endangered in 1980 and federally listed as endangered by the USFWS in 1986 (51 FR 16474). The USFWS made a final critical habitat designation for the least Bell's vireo in 1994 (59 FR 4845). Least Bell's vireos primarily occupy riverine riparian habitats that typically feature dense cover within one to two meters of the ground and a dense, stratified canopy. The least Bell's vireo inhabits low, dense riparian growth along water or along dry parts of intermittent streams and is typically associated with southern willow scrub, cottonwood forest, mulefat scrub, sycamore alluvial woodland, southern coast live oak riparian forest, arroyo willow riparian forest, wild blackberry, or mesquite in desert localities. The least Bell's vireo has been observed over multiple years within the VCC planning area (Guthrie 1994A, 1995A, 1996A, 2003A, 2006C).

Nuttall's Woodpecker (*Picoides nuttallii*). The Nuttall's woodpecker is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range. The woodpecker is primarily found in oak woodlands, to a lesser extent in riparian woodlands, and rarely in conifer forests. Nuttall's woodpecker has been described as a species characteristic of, if not confined to, oak woodlands in California (Lowther 2000). It has been observed nearly every year along the Santa Clara River since surveys began in 1988. Bloom Biological recorded additional sightings along the Santa Clara River east of Castaic Creek in the VCC planning area (Bloom Biological, Inc. 2007).

Tricolored Blackbird (*Agelaius tricolor*). The tricolored blackbird is a California Species of Special Concern and a Bird of Conservation Concern with regard to its nesting colony status. It was petitioned for state and federal listing by the Center for Biological Diversity in 2004, but the USFWS made a decision not to warrant protection in December 2006. These birds prefer to breed in freshwater marshes with dense growths of emergent vegetation dominated by cattails or bulrushes, but have also established colonies in willows, blackberries, thistles, and nettles. This species has been observed on within the VCC planning area during focused bird surveys (Guthrie 1994A, Guthrie 1995A, and Guthrie 1996A, Guthrie 1999A, 2006C), and off site in Castaic Junction (Guthrie 1994A, 2000E, 2001A, 2006C; Dudek 2006E). No breeding colonies have been observed since 1994, despite annual surveys through 2007 as described above. Tricolored blackbird has not been observed to breed on site.

Western Yellow-Billed Cuckoo (*Coccyzus americanus occidentalis*). The western yellow-billed cuckoo is a candidate for listing under the federal ESA, is a CESA-listed endangered species, and is a Bird of Conservation Concern with regard to its nesting status. The eastern yellow-billed cuckoo prefers a diverse variety of habitats, including open woodland with clearings and low, dense, scrubby vegetation as well as abandoned farmland, overgrown fruit orchards, successional shrubland, dense thickets along streams and marshes, shade trees, and gardens (Hughes 1999). The habitat preference of the western yellow-billed cuckoo, in contrast, is much more restricted in both species composition and size of the patch of preferred habitat. The habitat of the western yellow-billed cuckoo primarily consists of large blocks of riparian habitat, particularly cottonwood–willow riparian woodlands (66 FR 38611–38626). The western yellow-billed cuckoo has occasionally been documented within the Santa Clara River corridor during focused bird surveys in the RMDP area, although the locations of these observations were not mapped. Single individuals (thought to be migrants) were observed along the Santa Clara River east of the Project site in 1997 and 1998

(Guthrie 1997A; Labinger *et al.* 1997B; Labinger and Greaves 1999A) and west of the Ventura county line in 1997 (Guthrie 1997B). However, none have been observed in the Project area since then.

Yellow Warbler (*Dendroica petechia brewsteri*). The yellow warbler has no federal or state sensitivity status but is designated as a California Species of Special Concern by CDFG. In general, the yellow warbler breeds most commonly in wet, deciduous thickets, especially those dominated by willows, and in disturbed and early successional habitats (Lowther *et al.* 1999). This species was observed in the VCC planning area (Guthrie 1988, 1989, 1991A, 1992, 1993A, 1994A, 1995A, 1996A, 1997A, 1998B, 1999A, 2000E, 2001A, 2002A, 2003A, 2004F, 2005A, 2006C); however, these observations were not mapped. Off site, one nest was mapped in 2000 (Guthrie 2000F) in the Castaic Junction area. With the exception of the nest mapped in 2000, this species was only mapped during the Bloom Biological surveys (Bloom Biological, Inc. 2007A). These mapped observations were located in Castaic Creek and Hasley Canyon.

Yellow-Breasted Chat (*Icteria virens*). The yellow-breasted chat is designated by CDFG as a California Species of Special Concern. This species is not federally listed as threatened or endangered, but has been listed as threatened, endangered, or of special concern in some states and provinces on the periphery of its range (*e.g.*, Connecticut, New Jersey, New York, Ontario, and British Columbia) (Eckerle and Thompson 2001). In southern California, the yellow-breasted chat is primarily found in dense, relatively wide riparian woodlands and thickets of willows, vine tangles, and dense brush with well-developed understories. On site, recent observations were made in Castaic Creek in the VCC planning area in 2006 (specific locations not mapped), where chats were observed calling from territories in the riparian woodland (Guthrie 2006A, 2006C).

Yellow-Headed Blackbird (*Xanthocephalus xanthocephalus*). The yellow-headed blackbird is designated by CDFG as a California Species of Special Concern. This species is not federally listed as threatened or endangered within any part of its range. It is found primarily within prairie wetlands, but it is also found commonly in wetlands associated with quaking aspen parks, mountain meadows, and arid regions. This species has been observed within the VCC planning area (Guthrie 1997A, 2006C). No nesting colonies have been observed within the Project site.

Upland Grassland

California Horned Lark (*Eremophila alpestris*). The California horned lark is on CDFG Watch List. California horned larks are common and abundant residents in a variety of open habitats, usually where trees and shrubs are absent. This species has been observed regularly foraging in plowed and graded fields near the Santa Clara River and Castaic Creek within the VCC planning area (Guthrie 1990, 1991B, 1992, 1996B, 1997B, 2000C, 2001A, 2002A, 2003A, 2004B, 2005A–B, 2006C; Dudek 2006D).

Upland Scrub and Chaparral

Allen's Hummingbird (*Selasphorus sasin*). The Allen's hummingbird is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range and according to Sauer *et al.* (1996) shows no statistically significant declines in population for the period from 1966 to 1996. The vegetation communities most commonly used by breeding Allen's hummingbirds are coastal scrub, valley foothill hardwood, and valley foothill riparian habitats. Allen's hummingbird has been documented numerous times within the VCC planning area. One individual was observed by Guthrie in late April in the VCC planning area (Guthrie 2004B). There are no mapped occurrences of these observations.

Chipping Sparrow (*Spizella passerina*). The chipping sparrow is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range and Sauer *et al.* (1997) have concluded that continental populations appear healthy. Chipping sparrows prefer open wooded habitats with a sparse or low herbaceous layer and few shrubs, if any (Zeiner *et al.* 1990A). On site, this species has been observed as a common migrant in the Project area, and one to 12 individuals were observed near edges of agricultural fields most days in early March (Bloom Biological, Inc. 2007A). The chipping sparrow has been observed over multiple years during bird surveys conducted from 1988 through 2007 along the Santa Clara River within riparian scrub and woodland habitat.

Coastal California Gnatcatcher (*Polioptila californica californica*). The coastal California gnatcatcher is a federally listed threatened species and a CDFG Species of Special Concern. It occurs in coastal southern California and Baja California year-round, where it depends on a variety of arid scrub habitats. While isolated occurrences of California gnatcatchers occur off site to the east and southwest, no California gnatcatchers have been observed during the course of the focused surveys conducted for this species within the Specific Plan or Entrada

areas. However, during the course of surveys conducted within the VCC planning area, an individual California gnatcatcher was observed on October 5, 2007, by Dudek biologist Jeff Priest and biologist Ron Francis, a subconsultant to Dave Crawford, Compliance Biology, Inc. (Priest 2007A).

Costa's Hummingbird (*Calypte costae*). The Costa's hummingbird is designated by CDFG as a California Special Animal. It is not federally listed as threatened or endangered within any part of its range. It has a CNDDB ranking of global: demonstrably widespread, abundant, and secure; subnational: vulnerable to extirpation or extinction. Primary habitats are desert wash, edges of desert riparian and valley foothill riparian areas, coastal scrub, desert scrub, desert succulent scrub, lower-elevation chaparral, and palm oasis (Zeiner *et al.* 1990A). The species has been observed over multiple years during bird surveys conducted from 1988 through 2006 along the Santa Clara River within riparian scrub and woodland habitat; however, no mapped locations were recorded.

Southern California Rufous-Crowned Sparrow (*Aimophila ruficeps canescens*). The southern California rufous-crowned sparrow is on CDFG Watch List. This species is not federally listed as threatened or endangered within any part of its range (Collins 1999B). The rufous-crowned sparrow occupies moderate to steep hillsides that are rocky, grassy, or covered by coastal sage scrub or chaparral. The southern California rufous-crowned sparrow has been observed over multiple years as a fairly common resident in the coastal scrub within the VCC planning area during annual bird surveys.

Upland Woodland

Lawrence's Goldfinch (*Carduelis lawrencei*). The Lawrence's goldfinch is designated by CDFG as a California Special Animal. Additionally, this species is recognized under the NatureServe system of Natural Heritage Programs as vulnerable at the state level within California and throughout its range and is listed as a Bird of Conservation Concern by the USFWS. Lawrence's goldfinches are found in cropland and hedgerows, shrubland and chaparral, and conifer, hardwood, and mixed woodlands (NatureServe 2007). Lawrence's goldfinch has been observed within the VCC planning area (Guthrie 1997A, 2000E, 2003A); however, no mapped locations were recorded.

Oak Titmouse (*Baeolophus inornatus*). The oak titmouse is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range. Oak titmice inhabit a variety of habitat types, but are primarily associated with oaks, especially those in warm, dry habitats (Cicero 2000). The oak titmouse is common and abundant in

the Project area, nesting on site in cottonwood riparian and coast live oak communities. It has been observed over multiple years along the Santa Clara River and its tributaries and in the VCC planning area. Most observations of this species were not mapped.

Fish

Arroyo Chub (*Gila orcutti*). The arroyo chub is listed as a California Species of Special Concern, considered imperiled regionally and globally under the Natural Heritage Program methodology, and considered sensitive by the U.S. Forest Service. It occurs in slow-moving or backwater sections of warm to cool (10ºC to 24ºC) streams with mud or sand substrates (ENTRIX 2009). Arroyo chub species were observed within the within the VCC planning area (Haglund 1989).

Reptiles and Amphibians

Low Mobility

Coastal Western Whiptail (*Aspidoscelis tigris*). The coastal western whiptail is designated by CDFG as a California Special Animal. The coastal western whiptail is found in a variety of habitats, primarily in areas where plants are sparse and there are open areas for running. The species is also found in woodland and streamside growth and avoids dense grassland and thick shrub growth. While coastal western whiptails were not trapped or otherwise observed during pitfall trap surveys, the subspecies was identified as having the potential to occur in the Project area (Impact Sciences, Inc. 2006A). Because of observations in the High Country SMA and nearby locations (Compliance Biology, Inc. 2006; Dudek and Associates, Inc. 2006B), the presence of suitable habitat, observance that the Project area is within the range of the subspecies as described by Stebbins (2003), and the fact that the entire Project area was not surveyed by Impact Sciences (2006A) at a level of detail necessary to determine presence or absence of a particular reptile species, the coastal western whiptail is assumed to be present in the Project area.

Semi-Aquatic

Two-Striped Garter Snake (*Thamnophis hammondii*). The two-striped garter snake is a California Species of Special Concern. Two-striped garter snakes are found in a variety of perennial and intermittent freshwater streams within oak woodlands, shrublands, and sparse coniferous forests from sea level to 2,400 meters (7,874 feet) AMSL (Stebbins 2003; Zeiner *et al.* 1988). This species was observed within the VCC planning area (Ecological Sciences, Inc. 2003A).

Western Spadefoot Toad (*Spea hammondii*). The western spadefoot toad is a listed California Species of Special Concern. The species prefers open areas with sandy or gravelly soils in a variety of habitats, including mixed woodlands, grasslands, coastal sage scrub, chaparral, sandy washes, river floodplains, alluvial fans, playas, and alkali flats (Stebbins 2003; Holland and Goodman 1998). Western spadefoot toads were observed in the VCC planning area in a location that has since been developed (Dave Crawford, Compliance Biology, pers. comm., 2007; Compliance Biology, Inc. 2004G). As western spadefoot toads have been observed in various locations in the Project area, and because suitable conditions for the species are expected elsewhere in unsurveyed portions of the Project area, there is a high potential for this species to occur in additional areas that contain seasonal pools.

Entrada

Birds

Raptors

Cooper's Hawk (*Accipiter cooperii*). The Cooper's hawk is on CDFG Watch List. Cooper's hawks are found in areas with dense stands of live oak, riparian, or other forest habitats near water (Zeiner *et al.* 1990A). The Cooper's hawk frequents landscapes where wooded areas occur in patches and groves and often uses patchy woodlands and edges with snags for perching (Beebe 1974). This species has been regularly observed foraging within the Entrada planning area adjacent to the Santa Clara River during annual bird surveys (Guthrie 1988–1990, 1991A–B, 1992, 1993A–B, 1994A–B, 1995A–B, 1996A–B, 1997A–B, 1998A–B, 1999A–C, 2000B–C, 2000E–F, 2001A–B, 2002A, 2002C, 2003A–B, 2004F, 2004H–I, 2005A–B, 2006A–C; Labinger and Greaves 1995, 1996, 1997A–B; Labinger and Greaves 1999A).

Golden Eagle (*Aquila chrysaetos*). The golden eagle is on CDFG Watch List and a Fully Protected species. The golden eagle requires rolling foothills, mountain terrain, and wide arid plateaus deeply cut by streams and canyons, open mountain slopes and cliffs, and rock outcrops (Zeiner *et al.* 1990A). On site, this species has occasionally been observed during annual bird surveys conducted from 1988 through 2007 along the Santa Clara River. A golden eagle was observed flying over the Santa Clara River in the vicinity of the Six Flags Magic Mountain Amusement Park within the Entrada planning area (Guthrie 1993A, 1993B).

Loggerhead Shrike (*Lanius ludovicianus*). The loggerhead shrike is a Bird of Conservation Concern and has been designated by CDFG as a California Species of Special Concern. The species occurs most frequently in riparian areas along the woodland edge, grasslands with sufficient perching and butchering sites, scrublands, and open-canopied woodlands, although they can be quite common in agricultural and grazing areas and can sometimes be found in mowed roadsides, cemeteries, and golf courses. The loggerhead shrike is a breeding resident on site (Bloom Biological, Inc. 2007A). It has been observed within the Entrada planning area (Guthrie 2000D, 2004G; Dudek 2006E); however, there are no mapped occurrences for these observations.

Turkey Vulture (*Cathartes aura*). The turkey vulture has no federal or state status, but it is being discussed, for purposes of this report, as a CDFG trust resource. Turkey vultures use a variety of habitats while foraging for both wild and domestic carrion. They prefer open stages of most habitats. In the western United States, they tend to occur regularly in areas of hilly pastured rangeland, nonintensive agriculture, and areas with rock outcrops suitable for nesting, although they are not generally found in high-elevation mountain areas (Kirk and Mossman 1998; Zeiner *et al.* 1990A). On site, this species has been observed by Guthrie (2000D, 2004G) and Dudek (2006E); however, there are no mapped locations for any of these observations.

White-Tailed Kite (*Elanus leucurus*). The white-tailed kite is a California Fully Protected species. The white-tailed kite is commonly associated with agriculture areas (Grinnell and Miller 1944). It also inhabits low-elevation grasslands, savannah-like habitats, open sage scrub, meadows, wetlands, and oak woodlands, particularly in areas with a dense population of voles (Waian and Stendell 1970). A single white-tailed kite was observed hunting within the Entrada planning area in 2004 (Guthrie 2004G).

Riparian

Black-Crowned Night-Heron (*Nycticorax nycticorax*). The black-crowned night-heron is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range. Its habitat requirements are varied, including all types of wetland areas, including fresh, brackish, and saltwater ecosystems and even man-made ditches, canals, reservoirs, and wet agricultural fields (IHRMP 2001G). On site, this species was observed early in the year and is thought to be a wintering or migratory species within the Project site. Observations of the species were mapped along the Santa Clara River in the Entrada planning area near the water reclamation plant west of

Old Road (Bloom Biological, Inc. 2007A). No roosts or rookeries (nesting colonies) have been detected during the surveys within or adjacent to the Project site during any of the surveys that have been conducted over the years.

Nuttall's Woodpecker (*Picoides nuttallii*). The Nuttall's woodpecker is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range. The Nuttall's woodpecker is primarily found in oak woodlands, to a lesser extent in riparian woodlands, and rarely in conifer forests. Nuttall's woodpecker has been described as a species characteristic of, if not confined to, oak woodlands in California (Lowther 2000). It has been observed in the Entrada planning area; however, no mapped locations were recorded.

Western Yellow-Billed Cuckoo (*Coccyzus americanus occidentalis*). The western yellow-billed cuckoo is a candidate for listing under the federal ESA, is a CESA-listed endangered species, and is a Bird of Conservation Concern with regard to its nesting status. The eastern yellow-billed cuckoo prefers a diverse variety of habitats, including open woodland with clearings and low, dense, scrubby vegetation as well as abandoned farmland, overgrown fruit orchards, successional shrubland, dense thickets along streams and marshes, shade trees, and gardens (Hughes 1999). The habitat preference of the western yellow-billed cuckoo, in contrast, is much more restricted in both species composition and size of the patch of preferred habitat. The habitat of the western yellow-billed cuckoo primarily consists of large blocks of riparian habitat, particularly cottonwood–willow riparian woodlands (66 FR 38611–38626). The western yellow-billed cuckoo has occasionally been documented within the Santa Clara River corridor during focused bird surveys in the Entrada planning area, although the locations of these observations were not mapped. However, none have been observed in the Project area since then.

Yellow Warbler (*Dendroica petechia brewsteri*). The yellow warbler has no federal or state sensitivity status but is designated as a California Species of Special Concern by CDFG. In general, the yellow warbler breeds most commonly in wet, deciduous thickets, especially those dominated by willows, and in disturbed and early successional habitats (Lowther *et al.* 1999). A single migrant was observed in the Entrada planning area in 2000 (Guthrie 2000D).

Upland Grassland

California Horned Lark (*Eremophila alpestris*). The California horned lark is on CDFG Watch List. Horned larks are common and abundant residents in a variety of open habitats, usually where trees and shrubs are absent. Horned larks

have been observed regularly foraging in plowed and graded fields adjacent to the Entrada planning area in Castaic Junction (Guthrie 1991B, 1993A, 1994A–B, 1995B, 2000F, 2003A, 2004, 2005A).

Upland Scrub and Chaparral

Allen's Hummingbird (*Selasphorus sasin*). The Allen's hummingbird is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range and according to Sauer *et al.* (1996) shows no statistically significant declines in population for the period from 1966 to 1996. The vegetation communities most commonly used by breeding Allen's hummingbirds are coastal scrub, valley foothill hardwood, and valley foothill riparian habitats. Allen's hummingbird has been documented numerous times within the Entrada planning area. Six observations were made in the Entrada planning area in mid- to late June in 2004 (Guthrie 2004C).

Costa's Hummingbird (*Calypte costae*). The Costa's hummingbird is designated by CDFG as a California Special Animal. It is not federally listed as threatened or endangered within any part of its range, and has a CNDDB ranking of global: demonstrably widespread, abundant, and secure; subnational: vulnerable to extirpation or extinction. Primary habitats are desert wash, edges of desert riparian and valley foothill riparian areas, coastal scrub, desert scrub, desert succulent scrub, lower-elevation chaparral, and palm oasis (Zeiner *et al.* 1990A). The species has been observed over multiple years during bird surveys conducted from 1988 through 2006 along the Santa Clara River within riparian scrub and woodland habitat; however, there are no mapped locations for observations.

Southern California Rufous-Crowned Sparrow (*Aimophila ruficeps canescens*). The southern California rufous-crowned sparrow is on CDFG Watch List. This species is not federally listed as threatened or endangered within any part of its range (Collins 1999B). The rufous-crowned sparrow occupies moderate to steep hillsides that are rocky, grassy, or covered by coastal sage scrub or chaparral. The southern California rufous-crowned sparrow has been observed over multiple years as a fairly common resident in the coastal scrub within the Entrada planning area during annual bird surveys. There are no mapped occurrences of these observations.

Upland Woodland

Oak Titmouse (*Baeolophus inornatus*). The oak titmouse is designated by CDFG as a California Special Animal. This species is not federally listed as threatened or endangered within any part of its range. Oak titmice inhabit a

variety of habitat types, but are primarily associated with oaks, especially those in warm, dry habitats (Cicero 2000). The oak titmouse is common and abundant in the Project area, nesting on site in cottonwood riparian and coast live oak communities. It has been observed over multiple years along the Santa Clara River and its tributaries and in the Entrada planning area. Most observations of this species were not mapped.

Bats

Western Red Bat (*Lasiurus blossevillii*). The western red bat is a listed California Species of Special Concern. There is little ecological information specifically for the western red bat; most studies are based on the red bat before it was separated into the western and eastern species. Red bats (*Lasiurus* spp.) typically roost in trees, occasionally in shrubs, and even on the ground (Shump and Shump 1982). Of the 135 total detections of bats in 2004 (Impact Sciences, Inc. 2005), there were only two detections of the western red bat.

Yuma Myotis (*Myotis yumanensis*). The Yuma myotis is a listed California Special Animal. Forests and woodlands are primary habitats and foraging usually occurs within open, uncluttered habitats and low over water sources, such as ponds, streams, and stock ponds (Brigham *et al.* 1992; Zeiner *et al.* 1990B). The presence of the Yuma myotis was confirmed in the Project area through capture at The Old Road and I-5 survey site in 2006.

Insects (Butterflies)

Monarch Butterfly (*Danaus plexippus*). The monarch butterfly has been designated by CDFG as a California Special Animal. The species' distribution is controlled by the distribution of its larval host plant (*i.e.*, various milkweeds, genus *Asclepias*). Individual monarch butterflies were observed during surveys conducted in April and May of 2004 and 2005 as well as during various other wildlife and plant surveys that have been conducted. However, no wintering sites have been observed, and, due to the site's distance from the coast, it is unlikely that the Project area would be used by large numbers of overwintering adults (Compliance Biology, Inc. 2004A).

Fish

Arroyo Chub (*Gila orcutti*). The arroyo chub is listed as a California Species of Special Concern, is considered imperiled regionally and globally under the Natural Heritage Program methodology, and is considered sensitive by the USFS. It occurs in slow-moving or backwater sections of warm to cool (10ºC to 24ºC)

streams with mud or sand substrates (ENTRIX 2009). Arroyo chub species have been observed within the Entrada planning area (Aquatic Consulting Services, Inc. 2002D; Haglund and Baskin 1995, 2000).

Reptiles and Amphibians

Semi-aquatic

Two-Striped Garter Snake (*Thamnophis hammondii*). The two-striped garter snake is a California Species of Special Concern. Two-striped garter snakes are found in a variety of perennial and intermittent freshwater streams within oak woodlands, shrublands, and sparse coniferous forests from sea level to 2,400 meters (7,874 feet) AMSL (Stebbins 2003; Zeiner *et al.* 1988). This species has been observed within the Entrada planning area (Impact Sciences, Inc. 2001).

Southwestern Pond Turtle (*Actinemys marmorata pallida*). The southwestern pond turtle is listed as a California Species of Special Concern. Western pond turtles use a variety of aquatic habitats, including lakes, natural ponds, rivers, oxbows, streams (perennial/ephemeral), marshes, vernal pools, freshwater and brackish estuaries, drainage ditches, reservoirs, mill ponds, ornamental park ponds, stock ponds, abandoned gravel pits, and sewage treatment plants (Buskirk 2002; NatureServe 2007). The southwestern pond turtle has been documented in the Project area at several locations along the Santa Clara River and in the Salt Creek tributary during various field surveys conducted between 1996 and 2006. There were additional incidental observations of southwestern pond turtle within the Santa Clara River in the Entrada planning area by Impact Sciences (2001), Ecological Sciences (2004A), and Dudek (Dudek and Associates, Inc. 2006E).

Mammals

Low Mobility

San Diego Desert Woodrat (*Neotoma lepida*). The San Diego desert woodrat is listed as a California Species of Special Concern. Desert woodrats are found in a variety of shrub and desert habitats and are primarily associated with rock outcroppings, boulders, cacti, or areas of dense undergrowth (Bleich 1973; Bleich and Schwartz 1975; Brown *et al.* 1972; Cameron and Rainey 1972; Thompson 1982). The mammal assessment conducted by Impact Sciences (2005) found that the San Diego desert woodrat is a relatively common rodent within the Specific Plan area of the RMDP site. Dudek observed a single midden in Entrada (Dudek 2006G). San Diego desert woodrat was observed in Long and Potrero Canyons in 2005 (Chris Huntley, personal communication, October 2006).

High Mobility

Mule Deer (*Odocoileus hemionus*). The mule deer is considered a CDFG Trust Resource and is considered a special-status species for the purposes of this analysis, because take of the species requires a game permit. Mule deer were observed in the Entrada planning area in 2000 and 2006 (Haglund and Baskin 2000; Dudek 2006E).

Special-Status Wildlife Species Not Observed within the Project Area

Birds

Raptors

Short-Eared Owl (*Asio flammeus*). The short-eared owl is a federally listed Bird of Conservation Concern as well as a CDFG-designated California Species of Special Concern. The short-eared owl is a resident of mixed and tall grass habitats. The species is usually found in open areas with few trees, such as annual and perennial grasslands, prairies, tundra, dunes, meadows, agricultural lands, and saline and fresh emergent wetlands (Zeiner *et al.* 1990A; Terres 1980). Short-eared owls have never been documented in the Project area. However, an individual was observed just outside the Project boundary in the Salt Creek area just west of the Ventura/Los Angeles County line in the fall of 2005 (Dudek 2006B).

Riparian

Willow Flycatcher (*Empidonax traillii*)/Southwestern Willow Flycatcher (*E. t. extimus*). The full species of willow flycatcher, including the southwestern willow flycatcher, little willow flycatcher (*E. t. brewsteri*), and *E. t. adastus* (no common name other than willow flycatcher) subspecies, was listed as state endangered by CDFG in 1991. The subspecies southwestern willow flycatcher was listed as federally endangered species by the USFWS in 1995. The willow flycatcher has been detected almost every year within the River corridor in the Project area during the focused bird surveys. However, because all observations were early in the breeding season and no observations occurred after June 22, indicating nesting on site, all individuals are assumed to have been migrants and were probably either the little willow flycatcher or *E. t. adastus*. No southwestern willow flycatchers have been observed to nest on site. Along the Santa Clara River in the RMDP, willow flycatchers were observed by Guthrie (1993B, 1997B, 1998A, 1999B, 2000C, 2001B, 2002C, 2004H, 2005B), Labinger *et al.* (1995), and Bloom Biological, Inc. (2007A); along Castaic Creek in VCC by Guthrie

(1988, 1990, 2000E, 2001A, 2002A, 2003A, 2004F, 2005A); and adjacent to Entrada in the Castaic Junction area by Guthrie (1990, 1997A, 1999A, 2000E, 2002A, 2003A, 2006C) and Dudek (2006E). No southwestern willow flycatchers exhibiting nesting, paired, or territorial behavior have been observed in the Project site or vicinity. The most recent observation of the southwestern willow flycatcher displaying territorial behavior is downstream approximately 18 miles, near Saticoy (Labinger and Greaves 1999A). The CNDDB (CDFG 2007A) lists one occurrence of nesting southwestern willow flycatchers in the Santa Clara River corridor upstream of the Project area, along Soledad Canyon Road near Agua Dulce, in 1997.

Summer Tanager (*Piranga rubra*). The summer tanager is not state or federally endangered, but is designated by CDFG as a California Species of Special Concern. Western populations of summer tanagers occupy riparian woodlands dominated by willows and cottonwoods (*Populus* spp.) at lower elevations (Robinson 1996; Rosenberg *et al.* 1982, 1991); and at higher elevations they utilize mesquite (*Prosopis* spp.) and salt cedar (*Tamarix* spp.) habitats (Robinson 1996). No individuals have been observed within the Project site during annual bird surveys. One individual was observed off site west of the Ventura County line in 1993 and 1994 (Guthrie 1993B, 1994B); within Castaic Junction in 1991 (Guthrie 1991A); in April, May, and July 1993 in dense cottonwoods downstream of the Valencia Wastewater Plant (Castaic Junction area) (Guthrie 1993A); and it has also been observed east of the project site in 2000 and 2003 (Guthrie 2000E, 2003A). These observations were not mapped.

Upland Grassland

Grasshopper Sparrow (*Ammodramus savannarum*). The grasshopper sparrow has been designated by CDFG as a California Species of Special Concern. The species frequents dense, dry or well-drained grassland, especially native grassland with a mix of grasses and forbs for foraging and nesting. Grasshopper sparrows require fairly continuous native grassland areas with occasional taller grasses, forbs, or shrubs for song perches (Garrett and Dunn 1981). No observations of the grasshopper sparrow have been made within the Project area, but potential habitat exists on site.

Upland Scrub and Chaparral

Bell's Sage Sparrow (*Amphispiza belli belli*). The Bell's sage sparrow is not state or federally endangered, but is on CDFG Watch List and is a USFWS Bird of Conservation Concern. The Bell's sage sparrow occupies semi-open habitats with evenly spaced shrubs that are one to two meters (3.3 to 6.6 feet) high

(IHRMP 2001A). At higher elevations in southern California, Bell's sage sparrow often occurs in big sagebrush (*Artemisia tridentata*) (IHRMP 2001A). Bell's sage sparrow has never been detected within the Project area or region. However, two individuals were observed in April 2004 during a focused bird survey in the Legacy Project site (Guthrie 2004C). This site is adjacent to the Specific Plan site, just south of Mission Village and east of Potrero Village.

Black-Chinned Sparrow (*Spizella atrogularis*). The black-chinned sparrow is designated by CDFG as a California Special Animal and is a USFWS Bird of Conservation Concern. This species is not federally listed as threatened or endangered within any part of its range. The black-chinned sparrow occupies arid brushlands and chaparral, although it occurs less commonly within coastal sage scrub (Unitt 2004; Garrett and Dunn 1981). The species may use open chaparral (Garrett and Dunn 1981) but usually favors moderately dense but not overgrown chaparral of mixed species and shows in lowest numbers in thick old chaparral on north-facing slopes (Tenney 1997; Unitt 2004). The black-chinned sparrow was not detected within the Project area or region. The species has not been detected in the area for over a dozen years; it is not believed to occur within the Project area.

Bats

Long-Legged Myotis (*Myotis volans*). The long-legged myotis has been designated by CDFG as a California Special Animal. The long-legged myotis is a year-long resident of California and primarily occurs in coniferous forests, but it also uses riparian and oak woodland habitats for roosting and foraging (Warner and Czaplewski 1984; Wilson and Ruff 1999; Zeiner *et al.* 1990B). The presence of the long-legged myotis was not confirmed in the Project area during the acoustic and mist netting surveys conducted in 2004 and 2006 (Impact Sciences, Inc. 2005, Johnson 2006). However, bats with acoustic signatures in the 40 kHz range, which is the range for the long-legged myotis, were detected on site in 2004 and 2006.

Western Small-Footed Myotis (*Myotis ciliolabrum*). The western small-footed myotis is designated by CDFG as a California Special Animal. The western small-footed myotis occurs in a wide variety of arid upland habitats at elevations ranging from sea level to 2,700 meters (8,860 feet) AMSL (Zeiner *et al.* 1990B). Habitats used by this species include riparian areas, woodlands, and brushy uplands (Holloway and Barclay 2001; Zeiner *et al.* 1990B). The presence of the western small-footed myotis was not confirmed in the Project area during the

acoustic and mist netting surveys conducted in 2004 and 2006 (Impact Sciences, Inc. 2005, Johnson 2006).

Townsend's Big-Eared Bat (*Corynorhinus townsendii*). The Townsend's big-eared bat is a designated California Species of Special Concern. The Townsend's big-eared bat is primarily associated with mesic habitats characterized by coniferous and deciduous forests, although it also occurs in xeric areas (Kunz and Martin 1982). This species was not detected during the 2004 and 2006 surveys (Impact Sciences, Inc. 2005, Johnson 2006).

Fish

Southern Steelhead (*Oncorhynchus mykiss*). The southern steelhead is listed as federally endangered and is listed as a California Species of Special Concern. Within the Santa Clara River drainage, southern steelhead historically inhabited Piru Creek, Sespe Creek, Santa Paula Creek, Hopper Creek, and possibly Pole Creek (Titus *et al.* n.d.). Presently, southern steelhead occur downstream of the proposed Project in the Santa Clara River watershed in Piru Creek, between the confluence with the Santa Clara River and Santa Felicia Dam, in Sespe Creek, in Santa Paula Creek, and possibly in Hopper Creek and Pole Creek (Stoeker and Kelly 2005). Habitat for juveniles and spawning adults is described as relatively cool freshwater streams, well-oxygenated water with adequate depth and cover in the way of gravel, cobble, boulder, undercut banks, large and small woody debris, and overhanging vegetation. As non-spawning adults, southern steelhead are found in the Pacific Ocean (McEwan and Jackson 1996; Moyle 2002). Reconnaissance surveys conducted along the Santa Clara River and tributary drainages within the Specific Plan area of the RMDP were negative in 2004 and 2005 (ENTRIX 2009).

Reptiles and Amphibians

Low Mobility

Coast Patch-Nosed Snake (*Salvadora hexalepis virgultea*). The coast patch-nosed snake is listed as a California Species of Special Concern. It occupies desert scrub, coastal chaparral, washes, sandy flats, and rocky areas. Coast patch-nosed snakes were not trapped or otherwise observed during surveys conducted on portions of the Specific Plan area in 2004 and 2006 (Impact Sciences, Inc. 2006A). The Project area is located towards the northern extent of the subspecies' range (Stebbins 2003), and based on the CNDDB, the coast patch-nosed snake has only been documented south of the Project area.

Rosy Boa (*Charina trivirgata*). The rosy boa is designated by CDFG as a California Special Animal. The rosy boa inhabits rocky shrubland and desert habitats and is attracted to oases and streams but does not require permanent water (Stebbins 2003). Rosy boas were not trapped or otherwise observed during surveys conducted on portions of the Specific Plan area in 2004 and 2006 (Impact Sciences, Inc. 2006A).

San Bernardino Ringneck Snake (*Diadophis punctatus*). The San Bernardino ringneck snake is designated by CDFG as a California Special Animal. The ringneck snake is found in moist habitats, including woodlands, hardwood and conifer forest, grassland, sage scrub, chaparral, croplands/hedgerows, and gardens (NatureServe 2007; Stebbins 2003). San Bernardino ringneck snakes were not trapped or otherwise observed during surveys conducted on portions of the Specific Plan area in 2004 and 2006 (Impact Sciences, Inc. 2006A).

Semi-Aquatic

California Red-Legged Frog (*Rana draytonii*). The California red-legged frog is a federally threatened species and is also designated by CDFG as a California Species of Special Concern. Breeding occurs in streams, deep pools, backwaters within streams and creeks, ponds, marshes, sag ponds, dune ponds, lagoons, and stock ponds. California red-legged frogs can occur in ephemeral ponds or permanent streams and ponds; however, populations probably cannot persist in ephemeral streams (Jennings and Hayes 1985). The California red-legged frog has not been observed in the Project area. While there are no records of California red-legged frog from the Project site in the numerous wildlife surveys conducted since 1992, the species is known from the Project region. The San Marino Environmental Associates (1995) report states that Thomas Haglund observed red-legged frogs in the mid-1970s in the Santa Clara River at Fillmore and that "this may represent the last sighting of this species in the Santa Clara River" (p. 37).

Aquatic

South Coast Garter Snake (*Thamnophis sirtalis*). The south coast garter snake is designated by CDFG as a California Species of Special Concern. They are restricted to marshlands, meadows, and upland habitats near permanent water with adjoining riparian vegetation (Jennings and Hays 1994). No focused surveys have been conducted for this species, and no observations have been noted in previous wildlife surveys for other riparian and aquatic species (SMEA 1995; Aquatic Consulting Services, Inc. 2002A, 2002B, 2002C, 2002D; Impact Sciences, Inc. 2002; Compliance Biology, Inc. 2004D; Impact Sciences, Inc.

2001; Ecological Sciences, Inc. 2004A). Natural history records for the south coast garter snake in California include sightings from Santa Clara River Valley (Ventura County), south to San Pasqual (San Diego County) (NatureServe 2007).

Mammals

Low Mobility

Southern Grasshopper Mouse (*Onychomys torridus*). The southern grasshopper mouse is designated by CDFG as a California Species of Special Concern. The southern grasshopper mouse is found rangewide in low arid scrub and semi-scrub vegetation (Frank and Heske 1992; McCarty 1975), and the subspecies *O. t. ramona* (which is the subspecies designated as a California Species of Special Concern) occurs in grasslands and sparse coastal scrub habitats. The mammal assessment conducted by Impact Sciences (2005) did not document the southern grasshopper mouse in the Project area. The species also was not captured in pitfall trapping studies in 2004 and 2006 that were conducted primarily to inventory the reptiles and amphibians in the Project area (Impact Sciences, Inc. 2006).

Moderate Mobility

Ringtail Cat (*Bassariscus astutus*). The ringtail cat (ringtail) is a California Fully Protected species. Suitable habitat for ringtails consists of broken semi-arid country with a mixture of hardwood forest and shrubland in close association with rocky areas or riparian habitats (Poglayen-Neuwall and Toweill 1988; Zeiner *et al.* 1990B). Although no ringtails were documented during the mammal survey, Impact Sciences (2005) concluded that the species has a moderate potential to occur on site in dense woodland or riparian areas. However, in addition to the negative Impact Sciences (2005) study findings, this species has never been observed in the numerous wildlife surveys conducted in the Specific Plan area, including recent wildlife surveys conducted by Dudek (2006A, 2006B, 2006C, 2006D).

4.5.3.4.7 Wildlife Habitat Connectivity and Buffers

The existing setting of the Project area includes large areas of natural undeveloped land and active land uses, including oil and natural gas production, cattle grazing, and agricultural operations that have been in operation for decades and are currently ongoing (see **Subsection 4.5.3.3.1** and **Figure 4.5-10**, RMDP/SCP – Ongoing Agricultural, Grazing Practices, and Oil Leases under No Action/No Project Alternative). SR-126 passes through the north-central portion of the Specific Plan area along the Santa Clara River. The River corridor also contains substantial areas of agriculture. Native and naturalized vegetation communities present are representative of those found in the region and include high-quality examples of the vegetation communities found in the ecosystems of the Santa Susana Mountains and the Santa Clara River. Upland vegetation communities dominate the landscape within the Specific Plan site, both north and south of the Santa Clara River. The dominant upland vegetation communities include coastal scrub (and associations and alliances), chaparral and associations, coast live oak woodland, mixed oak woodland valley oak/grass, and California annual grasslands. The Santa Clara River supports a variety of riparian vegetation communities, including southern cottonwood–willow riparian forest, southern willow scrub, mulefat scrub, arrow weed scrub, alluvial scrub, herbaceous wetlands, coastal and valley freshwater marsh, cismontane alkali marsh, and river wash. Intermittent and ephemeral drainages on site include cismontane alkali marsh, river wash, mulefat scrub, scalebroom scrub, big sagebrush scrub, and alluvial scrubs.

Although oil and natural gas production, cattle grazing, and agricultural operations have had an impact on overall wildlife habitat quality and likely affect the distribution of wildlife in the Project area, current wildlife use of the area probably is relatively unconstrained, compared to a post-build-out scenario. The discussion of wildlife corridors and buffers in the following subsections therefore focuses on the existing characteristics of the Project area that will be important for analyzing the impacts of the proposed Project to habitat connectivity and wildlife buffers.

For a literature review regarding wildlife habitat buffers see the Newhall Ranch Resource Management and Development Plan: Wildlife Habitat Buffers and Connectivity White Paper (Dudek 2008C) in **Appendix 4.5**.

4.5.3.4.7.1 *Wildlife Habitat Connectivity*

A fundamental concept and central tenet of conservation biology theory is that a lack of habitat connectivity and contiguity (usually referred to as habitat fragmentation and isolation) may cause extinction of local populations as a result of two processes: (1) reduction in total habitat area, which reduces effective population sizes; and (2) insularization of local populations, which affects dispersal and immigration rates (Wilcox and Murphy 1985; Wilcove *et al.* 1986). Wilcox and Murphy (1985) further point out that immigration may be impeded by conversion of natural

vegetation communities that provide habitat between occupied or potential habitat patches, thus increasing the probability of extinction. This latter point is the crux of the habitat linkage problem. That is, isolation of habitat patches accompanied by intervening inhospitable land cover (*e.g.*, urban development, roadways) is thought to increase the probability of permanent extinction of local populations. Because of complex community-level interactions (*e.g.*, mutualistic species, habitat guilds, keystone species), the loss of one or a few species from a habitat patch as a direct result of habitat fragmentation (primary extinctions) also may result in multiple "secondary" extinctions within the habitat patch (Wilcox and Murphy 1985).

Habitat fragmentation has been linked with reduced diversity in bird species, even on adjacent nonfragmented habitats (Rottenborn 1999). Several studies in coastal San Diego County have demonstrated species losses related to habitat fragmentation and isolation. Soulé *et al.* (1988) found very high rates of extinction in a study of the distribution of "chaparral-dependent" native birds (the analysis included coastal sage scrub species) in isolated canyon habitat fragments. Soulé *et al.* (1988) attributed this loss to the focal species' generally low vagility and inability to traverse urban environments. Similarly, Soulé *et al.* (1992) found that fragmentation caused rapid extinctions with predictable sequences of species loss in a suite of species including plants, birds, and rodents in coastal sage scrub habitat and Bolger, Alberts *et al.* (1997) found fewer rodent species in fragments isolated for longer periods of time and at greater isolation distances in coastal San Diego County. Lower arthropod diversity was also observed by Bolger *et al.* (2000) in older and smaller habitat fragments in the same region.

Wildlife connections also likely play a critical role in sustaining "metapopulations," which are characterized as local populations of the same species that are partially isolated but connected by pathways for dispersal (immigration/emigration) (Levins 1969). Local populations within a metapopulation are subject to stochastic events, and they fluctuate depending on the rate of dispersal between the local populations and the local rate of extinction. Patches subject to local extirpations may be recolonized by dispersal from other source patches, provided that habitat connectivity remains for the species. Truly or functionally isolated local populations risk permanent extinction by a variety of causes, including simple population dynamics, loss of genetic integrity, or stochastic environmental impacts.

Natural environments are typically heterogeneous and form a mosaic across a landscape. Plant community distributions, in particular, follow distinct patterns based on abiotic conditions (*e.g.*, soil, slope aspect, elevation) and biotic conditions (*e.g.*, competition, soil microbial ecology, parasitism). Terrestrial wildlife species typically occupy favorable patches within a landscape matrix and may move between patches through less favorable habitats. However, terrestrial wildlife species are more likely to follow pathways between habitat patches that contain elements of their preferred habitat (Rosenberg *et al.* 1997). Disjunct habitat patches that are used by terrestrial wildlife to negotiate through landscape mosaics have been likened to "stepping-stones," and some researchers (*e.g.*, Bennet 2003) have suggested that, in some cases

and for some species, stepping-stone habitat is as effective as continuous corridors are. However, such stepping-stone patches must be traversable and must not be behaviorally limiting to the species. Behavior has been shown to be a primary condition that determines the propensity of a particular species to utilize a habitat linkage or corridor. Such limitations include movement behavior, environmental cues (*e.g.*, olfactory cues), perceived risk of predation, susceptibility to disturbance, and human activity (*e.g.*, Aars and Ims 1999; Brinkerhoff *et al.* 2005; Fernandez-Juricic *et al.* 2005). For example, individuals may traverse relatively long distances across generally unsuitable but natural habitat, but behaviorally will avoid crossing paved and unpaved roads (see Trombulak and Frissell 2000 for a review of the ecological effects of roads). Therefore, for a habitat linkage or corridor to function properly, it must not pose physical or behavioral obstacles to the movement behavior of a particular species. Additionally, the rate of animal movement through a landscape matrix may depend on the quality of habitat for that species (Rosenberg *et al.* 1997). Terrestrial wildlife tend to move more slowly through areas with higher-quality habitat components than through those areas with lower-quality habitat components. Risk of predation, disturbance, and human activity are also limiting factors for species movement and dispersal.

There is a distinction between short-term individual movements (such as foraging within an organism's home range), long-term dispersal (one-time emigration and immigration events between populations), and migration (seasonal or periodic movements). Corridors and habitat linkages may allow for both long- or short-term movements, dispersal, and migration, depending on the life history requirements and the ability of a particular species to travel through a landscape (also called its vagility). The habitat requirements that allow for dispersal and migration likely are similar, the difference being that dispersal is usually a one-way movement related to emigration/immigration, and migration is a seasonal or periodic movement (Lincoln *et al.* 1998).

For the purpose of this discussion, two kinds of dispersal are defined, based on Pielou (1979): diffusion and jump dispersal. Diffusion is the gradual movement or expansion of populations (as opposed to individuals) across a landscape over several generations and may be applicable to, for instance, nonmigratory small mammals or birds re-occupying recovering burned sites. Jump dispersal (hereafter simply called dispersal) is a one-time, long-distance movement within the lifetime of an organism across otherwise relatively unsuitable landscapes or across suitable habitat already occupied by conspecifics (members of the same species). An example of jump dispersal is a juvenile mountain lion dispersing across other individuals' home ranges or rural developed areas to establish a new home range.

These two types of movement—diffusion and dispersal—are discussed in the context of three main types of habitat connections—habitat linkages, wildlife corridors, and wildlife crossings—in the following subsections to provide a framework for later applications to the Project area. These habitat connections thus decrease in scale from regional or landscape-level connections

(habitat linkages) to linear pathways between areas (wildlife corridors), and down to constrained wildlife movement pathways within development (wildlife crossings).

Wildlife Landscape Habitat Linkages. Landscape habitat linkages (or simply linkages) are relatively large open space areas that contain natural habitat and provide connection between at least two larger adjacent open spaces that can provide for both diffusion and dispersal of many species. Linkages can form contiguous tracts of habitat when adjacent to other open space areas. Large open space networks can be formed in this way to connect and conserve habitat through entire regions (Bennett 2003).

Linkages can form large tracts of natural open space, serving both as "live-in" or "resident" habitat and as connections to the larger landscape (*e.g.*, large core habitat areas). Linkages are capable of sustaining certain communities of species in self-contained, functioning ecosystems, thus supporting both plant and animal populations and allowing for gene flow through diffusion of populations over a period of generations, as well as allowing for jump dispersal between neighboring habitats. Linkages may vary in their function depending on the species, serving more as landscape-scale dispersal corridors than habitat for larger or more vagile species, particularly those with large home ranges such as mountain lions. Linkages are, nonetheless, capable of supporting at least a portion of the populations of these larger or more vagile species. Linkages may also serve as migratory routes for ungulates, for example, and thus provide a more natural and sustainable landscape environment for large predators and their prey compared to wildlife corridors through which species are expected to move quickly.

As used here, linkages are defined as large, open space areas that are large enough to support at least a natural habitat mosaic and viable populations of smaller terrestrial species, such as rodents, smaller carnivores (raccoons, skunks, foxes, and weasels), passerine birds, amphibians, reptiles, and invertebrates.

Figure 4.5-22 shows the conceptual regional open space connectivity identified by Penrod *et al.* (2006) that would provide for landscape-scale habitat connectivity between the Santa Susana Mountains to the south and the Los Padres National Forest to the north. These conceptual linkages encompass the High Country SMA and the Salt Creek area within the Project area and the Santa Clara River west of the Project area. Penrod *et al.* (2006) considered the High Country SMA and Salt Creek area, along with regional open space conservation areas and initiatives such as "SOAR,"[1] in recommending a linkage

[1] Save Open-Space and Agricultural Resources (SOAR) is a non-profit organization which seeks to maintain agricultural, open space, and rural lands within Ventura County and surrounding regions. Development activities within the SOAR boundaries are limited by County Ordinance.

design that would connect the Santa Monica Mountains, San Gabriel Mountains, and the Sierra Madre Mountains. This linkage design was also based on a "least cost analysis" that quantitatively models the most efficient routes that target animals could take to travel between these open space areas. The least cost analysis incorporates available information for movement-limiting variables such as elevation, vegetation, topography, and road density. The least cost analysis also considered designated and existing open space, including National Forest and designated Newhall Ranch Specific Plan open space such as the High Country SMA. The "least cost path" is the most direct or optimum route utilizing suitable habitat and minimizing costs (*e.g.*, energy costs, risk of mortality), but it does not represent all potential routes available to a species that may be more costly, but feasible, alternatives. Dispersing animals are often young adults, and behaviorally these animals may take routes that do not ensure the least cost or the highest rate of survivability, or they may be inhibited from using such routes by adults. However, these least cost analyses quantitatively identify idealized linkages and corridors that would allow for the most efficient long-range dispersal and migration movement for wildlife between larger conservation areas.

The High Country SMA and Salt Creek area within the Project area comprise an important part of the least cost path linkage design identified by Penrod *et al.* (2006). They provide a key part of the east–west linkage that crosses I-5 and connects to the Angeles National Forest in the San Gabriel Mountains to the east and to Ventura County SOAR open space to the southwest. They also provide a significant part of the north–south linkage between the Santa Susana Mountains and the "Fillmore Greenbelt" to the northwest that further links to the Los Padres National Forest and the Angeles National Forest to the north.

Wildlife Corridors. Rosenberg *et al.* (1995) distinguish between habitat and wildlife corridors. Habitat provides for the life history components of survivorship, reproduction, and movement. Wildlife corridors are linear landscape elements that provide for species movement and dispersal between two or more habitats but do not necessarily contain sufficient habitat for all life history requirements of a species, particularly reproduction (Rosenberg *et al.* 1995, 1997). For this reason, while corridors may provide for dispersal of most species, they may not provide for diffusion of populations over a longer time scale. The main prerequisite for corridors is that they increase animal movement between habitat patches. The mechanisms related to the efficacy of corridors are varied and species-specific (Soulé and Gilpin 1991; Beier and Loe 1992; Rosenberg *et al.* 1995; Haddad and Tewksbury 2005A). Additionally, even if the corridor itself does not provide habitat functions, it is expected to at least maintain plant and animal populations, gene flow between the constituent subpopulations, and biodiversity (Haddad 1999). This ebb and flow of genetic diversity should occur if organisms are traversing corridors that physically connect geographically patchy populations (Beier and Loe 1992). Corridors

thus provide physical conduits for maintaining specific genetic diversity, species richness, and community integrity. However, corridors may also connect population sources to "sink habitat" that can result in the net reduction of a population; in other words, the sink habitat either does not support the full life history of the species, or populations are more vulnerable to risk factors.

As noted above, under existing conditions, wildlife have a relatively unconstrained landscape for habitat use and movement throughout the Project area. In a relatively undeveloped landscape, high and moderate mobility wildlife such as mule deer, mountain lion, American badger, black-tailed jackrabbit, and virtually all bird species can be expected to travel relatively freely throughout an area, because no significant obstacles to movement exist. However, even in an unconstrained landscape, there are likely favored areas for habitat use and movement related to existing conditions, such as vegetation cover, topography, and existing land uses. For example, mule deer prefer rugged terrain and slopes, and mountain lions prefer canyon bottoms and gently sloping terrain.

Potentially important wildlife corridors in the Project area include linear landscape elements that connect larger habitat patches. Potential corridors should allow high mobility ground-dwelling species (*e.g.*, mule deer, mountain lion, black bear) to move through areas in a single generation and should also contain sufficient habitat components for occupation by low and moderate mobility species. Less vagile species that are unable to move through a corridor in a lifetime require sufficient habitat to allow diffusion of the species over more than one generation (intergenerationally) through the area. High mobility aerial species were not considered in the identification of corridors because of their relative independence of wildlife corridors.

These potential wildlife corridors were identified primarily from scent/track station data collected in 2004 by Impact Sciences, Inc. (2005), topographic analysis, incidental field observations (Dudek and Associates 2006B), and professional judgments based on known habitat associations of wildlife species in the Project area. The Impact Sciences, Inc. (2005) scent/track stations were located throughout the Specific Plan area, including locations along Salt Creek Canyon from the eastern portion toward the Ventura County line, north above Potrero Mesa, throughout Long Canyon and around the agriculture field north of Long Canyon, south of Lion Canyon and Grapevine Mesa, dispersed throughout Exxon Canyon and Middle Canyon, and in a few portions of Chiquito Canyon, San Martinez Grande, and the Entrada planning area. Impact Sciences, Inc. (2005) also conducted nighttime spotlight surveys along roadways throughout the Project area for five nights a week between July 28 and September 30, 2004.

Thirteen potential wildlife corridors within the Project area were identified in this analysis (**Figure 4.5-31**):

1. Santa Clara River Corridor
2. Salt Creek Confluence
3. Salt Creek–High Country
4. East Fork Salt Creek
5. Potrero Canyon–Salt Creek
6. Potrero Canyon
7. Long Canyon
8. Short Canyons–River Corridor
    a. Humble Canyon
    b. Lion Canyon
    c. Exxon Canyon
    d. Dead End Canyon
    e. Middle Canyon
    f. Magic Mountain Canyon
9. Chiquito Canyon
10. San Martinez Grande Canyon
11. Off-Haul Canyon
12. Homestead Canyon
13. Castaic/Hasley Corridor

These corridors provide habitat connections among the larger open space areas—High Country SMA, Salt Creek area, and River Corridor SMA—and provide connections to habitat areas beyond the Project area, as discussed above in the context of the regional landscape-level habitat connections.

The Santa Clara River is a critical wildlife corridor in the Project area because it provides both significant habitat connectivity and resident habitat for many wildlife species. The River corridor connects downstream and upstream areas, including tributary drainages such as Salt Creek and Castaic Creek that allow wildlife access to uplands from the River.

The Salt Creek–High Country, East Fork Salt Creek, and Salt Creek Confluence corridors provide the most direct, non-disturbed connections between the River corridor habitat and large upland habitat areas south of the River. As noted above, the least cost analyses conducted by Penrod *et al.* (2006) identified these areas as important components of

regional habitat connectivity. Based on the Impact Sciences, Inc. (2005) mammal study and incidental observations (Dudek and Associates 2006B), there is frequent wildlife activity in these areas despite agricultural and grazing activities. It is likely that wildlife move from the River corridor to upland areas through the Salt Creek Confluence corridor.

The Castaic/Hasley Corridor was not identified by Penrod *et al.* (2006) as a regional linkage, but it allows for movement of many species such as coyote, mule deer, and possibly mountain lion, and functions as live-in habitat for many other species. Although the vicinity of Castaic Creek north of the Project area is becoming increasingly developed, it will continue to have connectivity value between the Santa Clara River and upland habitats to the northeast of the Project area extending to Castaic Lake and the Angeles National Forest.

Figure 4.5-31 also shows several tributary corridors in the Project area: No. 5: Potrero Canyon–Salt Creek; No. 6: Potrero Canyon; No. 7: Long Canyon; No. 8a: Humble Canyon; No. 8b: Lion Canyon; No. 8c: Exxon Canyon; 8d: Dead End Canyon; 8e: Middle Canyon; 8f: Magic Mountain Canyon; No. 9: Chiquito Canyon; No. 10: San Martinez Grande Canyon; No. 11: Off-Haul Canyon; and No. 12 Homestead Canyon. Under existing conditions, these corridors likely are used by most of the high and moderate mobility species for movement throughout the Project area, perhaps except for black bear, but they are subject to greater anthropogenic disturbances, such as cattle grazing, agriculture, and film production activities. They also have more remote and indirect connections to the regional habitat linkages identified by Penrod *et al.* (2006).

Wildlife Crossings. Wildlife crossings are locations where wildlife must pass through physically constrained environments (*e.g.*, roads, development) during movement within home ranges or during dispersal or migration between core areas of suitable habitat. Development and roads may transect or interrupt an existing natural crossing, creating dangerous or impassible barriers that impede the natural movement of a species and possibly expose it to higher risks of injury and mortality from adverse human interactions, such as increased vehicle collisions at roadways where no safe wildlife passage is provided (Meese *et al.* 2007).

When designing wildlife crossings, it is important to identify the natural passageways that target animals use to locate crossings. Often, artificial crossings are seldom used by wildlife when a more natural alternative or previously used crossings still exist. For example, Tull and Krausman (2001) found that, while 22% of radio-collared mule deer locations were in a designed crossing of a canal, there were indications that the deer crossed at other points along the canal. Tull and Krausman (2001) attributed the other crossings to the absence of significant urbanization along the canal and suggested that, as development encroached along the canal, the designed crossing would become more important.

Post-development drainages are typical pathways for wildlife movement across roads, although they are not the only pathways used. Structures where roads and drainages intersect are often constricted or confined in some way and provide funnel points for movement, such as road undercrossings, space beneath bridges, or pathways through large culverts. Wildlife crossings are used differently or at different frequencies, depending on the species and the conditions at the crossing. Although most existing structures, such as culverts or bridges under roads, were not originally designed to accommodate wildlife passage, they can be retrofit or redesigned to encourage wildlife use by restoring or maintaining native vegetation and "soft-bottom" natural substrates within the crossing, allowing natural lighting, using fences to guide larger species toward the crossing, locating crossings at pre-existing animal passages, and improving habitat adjacent to the crossing to provide cover and protection for wildlife (Carr *et al.* 2003; Meese *et al.* 2007). Some recommended design standards for different kinds of wildlife crossings are available from Ruediger and DiGiorgio (2007), as summarized in **Table 4.5-22**.

Table 4.5-22
Crossing Structure Type and Size: Recommendations for Different Species[1]

Crossing Structure	Round Culvert	Concrete Box Culvert	Multi-Plate Steel Arch	Open-Space Bridge, Bridge Extension	Overpass
Black bear	10'+	10'+ h × 20'+ w	10'+ h × 20'+ w	10'+ h × 20'+ w	75'+ w
Mountain lion	10'+	10'+ h × 20'+ w	10'+ h × 20'+ w	10'+ h × 20'+ w	75'+ w
Bobcat	48"+	48"+ h × 48"+ w	structures for larger animals will be adequate for smaller animals		
Coyote	48"+	48"+ h × 48"+ w	structures for larger animals will be adequate for smaller animals		
Small carnivores: badger, raccoon, skunk, weasel, and fox. Also accommodates smaller mammals, reptiles, and amphibians	36"+	36"+	structures for larger animals will be adequate for smaller animals		
Deer	10'+	10'+ h × 20'+ w	10'+ h × 20'+ w	10'+ h × 20'+ w	75'+ w
Key:					
Adequate for Passage					
Best for Passage					

[1] Adapted from Ruediger and DiGiorgio (2007). "Information in this table was established from current studies, including recommendations from biologists and engineers with extensive wildlife crossing experience. This table is a general guide to designing and choosing appropriate structures for many target species. Other factors, such as terrain, engineering feasibility, cost, and site-specific conditions are always a consideration. The table is meant only as a broad guideline to assist in the selection of wildlife crossings" (Ruediger and DiGiorgio 2007).

Although there are some general recommendations for the dimensions of crossing structures, as shown in **Table 4.5-22**, the specific factors that contribute most to the effectiveness and design criteria of structures used as wildlife crossings, such as bridges and box culverts, are still under debate. Among these factors, in addition to structural dimensions, are the use of fencing, existing landscapes, proximity to natural habitat edges and water features, the probability of human disturbance, and the intended species. Views differ regarding the most effective placement of wildlife crossings and whether structural features or location and landscape features are more important in determining ultimate success.

Several studies have shown that structural dimensions beyond the height and width of the crossing and related factors play primary roles in the success of providing adequate wildlife crossings between habitat fragmented by roads and highways. Reed *et al.* (1975) found openness to be a significant factor in determining relative effectiveness of structures in terms of use by deer and other species. In this study, the openness factor (or index) was a structural variable used as a measurement of ambient light in a structure and was calculated by the following equation: width times height divided by length (in meters) (Reed *et al.* 1975). Later studies also applied the openness index as one measurement for the effectiveness of wildlife movement at highway underpasses. For example, Donaldson (2005) found that the length of a structure should be short enough to result in an openness factor of at least 0.25 to discourage white-tailed deer from turning around at structure crossings. This study also determined that effective underpasses were easily accessible with level approaches and had clear lines of site to habitats on the far side (Donaldson 2005). Another study determined that use of crossing structures by raccoons and domestic cats and dogs was positively correlated with passage length, while use by mule deer was negatively correlated with the same factor (Ng *et al.* 2004). The importance of structural dimensions has been illustrated for both large predator and prey species. In Banff National Park, structural dimensions, including openness and width, were determined to be most significant only for ungulates while playing a less significant attribute for carnivores (Clevenger and Waltho 2000). However, later studies indicated structural passage by grizzly bears, wolves, elk, and deer to be strongly influenced by wildlife crossings that were high, wide, and short in length, and that black bears and cougars favored more constricted crossing structures (Clevenger and Waltho 2003).

Others have argued against the ultimate value that structural dimensions hold with respect to wildlife crossings. Many studies have identified several other factors as the most significant in contributing to the effectiveness of crossing structures. Beier and Loe (1992) have emphasized that the critical features of a wildlife corridor are not physical traits, such as its length or width or vegetation, but rather how well a particular piece of land fulfills several functions, including allowing wide-ranging animals to travel, migrate, and meet mates; plant propagation; genetic interchange; movement of

populations due to environmental changes and natural disasters; and allowing recolonization of habitats from which populations have been locally extirpated. Beier and Loe (1992) argue that these functions (rather than some minimum width) should be used to evaluate the suitability of land as a wildlife corridor. The Ng *et al.* (2004) study, discussed above, also identified correlations with several other factors. Coyote use of wildlife crossings showed a significant positive correlation with human activity and a negative correlation with developed habitat. For bobcats, the relationship between passage use and percentage of natural habitat was positive (Ng *et al.* 2004). Riley *et al.* (2006) contend that, to counteract genetic isolation, corridors across freeways could conceivably include more natural habitat so that home ranges could extend across freeways and rates of genetic exchange might be increased. Several studies have also indicated that fencing plays a significant factor in determining success. Although some species may use underpass or overpass systems without fences, some form of fencing does appear to be necessary for most species (Jackson and Griffin 2000). Ungulates commonly seek to avoid underpasses and will generally use them only if other access across the highway is barred (Ward 1982).

While the debate about the efficacy of wildlife crossings continues, at least three concepts are clear: (1) Protecting suitable habitat in the vicinity of crossing points is especially important; (2) consideration must be given to passage dimensions (Ng *et al.* 2004); and (3), if fence and passage systems are not designed for use by a broad range of wildlife, a project that facilitates passage for one species might constitute an absolute barrier for another (Jackson and Griffin 2000).

Existing man-made wildlife crossings in the Project vicinity are primarily located under SR-126, which, with high current traffic volume, is the main existing impediment to wildlife movement perpendicular to the Santa Clara River. **Figure 4.5-32** shows six of the largest existing crossings that can be accessed by wildlife coming directly from adjacent uplands or by moving along the Santa Clara River. Three of the crossings shown in **Figure 4.5-32** are in Ventura County west of the Project area. These six crossings are associated with current agricultural operations and are bridges or culverts large enough for vehicle passage, as illustrated in **Figure 4.5-32**. The large culverts in Ventura County are about 4.4 meters (14 feet, 7 inches) in height, 7.5 meters (25 feet) in width, and 51.8 meters (170 feet) in length, resulting in an openness factor of 0.65, which well exceeds the openness factor of 0.25 found by Donaldson (2005) to be adequate for white-tailed deer. They are therefore expected to provide adequate passage for high mobility ground-dwelling species such as mule deer, mountain lion, and black bear. The easternmost of the Ventura County crossings serve wildlife passing through the Project area *via* the Salt Creek corridors discussed above as well as Tapo Canyon in Ventura County. Within the Project area, there are existing crossings at San Martinez Grande Canyon, Chiquito Canyon, and at the Castaic Creek confluence with the Santa Clara

River. These crossings are short and open and include soft-bottom overpasses at the San Martinez Grande Canyon and Castaic Creek crossings and a large parallel set of box culverts at the Chiquito Creek crossing (**Figure 4.5-32**). These crossings should not significantly constrain current wildlife movement in the area.

Wildlife Buffers. The term "buffer" as used here refers to the area or zone between the urban development edge and an important biological resource, which is necessary to protect the resource from adverse edge effects such as habitat degradation, increased occurrence of non-native and urban-related species, increased predation from domestic animals and mesopredators, and other edge effects. (see **Subsection 4.5.5.1** for detailed discussion of secondary edge effects). Buffers typically are described as some minimum width between the development edge or disturbance source and the resource, and, all things being equal, the larger the buffer width is, the more protection a resource is provided. However, buffers usually also include different vegetation types, topographic features, or structures (such as fences) that provide some level of protection for the resource. For example, a strip of dense cactus in a relatively narrow buffer zone may effectively protect native wildlife from disturbance by humans or pets. Various combinations of width, dense vegetation, extreme terrain, artificial features (such as fencing), and management may interact in various ways to improve the buffer function and compensate for narrower intrinsic buffer zones (see CBI 2000). That is, where buffers are necessarily smaller in width, other environmental or project design features or management may be needed to offset the increased risk of disturbance. Because of the interactive and compensatory nature of buffer features, each edge/buffer situation needs to be evaluated separately to determine its effectiveness.

Although the more common understanding of buffer function refers to the protective functions discussed above, the buffer zone itself may provide important ecological functions beyond just protecting core habitat areas. For example, a buffer may both protect aquatic habitat and provide transitional and/or terrestrial habitat that supports the nonaquatic life history aspects of semi-aquatic reptiles and amphibians, such as foraging, nesting, aestivation, and hibernation (Semlitsch and Bodie 2003). Also, buffers may provide adjunct habitat that may be used and may be beneficial to a species but is not critical for a species. For example, least Bell's vireos have been documented foraging in upland shrub habitats adjacent to riparian nesting areas late in the breeding season (Kus and Miner 1989), but it is unknown whether this adjacent upland habitat is critical in their life history. Such foraging may be opportunistic and may only provide marginal benefits over foraging limited to riparian areas. However, providing upland shrub habitat adjacent to vireo nesting habitat should be considered a benefit for this species and incorporated in the open space design where feasible.

Because buffers are defined by the relationship between wildlands and the urban development edge, they do not strictly constitute an existing biological resource or condition prior to development; in other words, buffers cannot be defined without reference to an explicit project footprint. However, existing conditions and the documented distribution of special-status and sensitive biological resources in the Project area do allow for a description of where buffers will be important to consider in the environmental impact analysis.

Several special-status fish species in the Santa Clara River within the Project area (unarmored threespine stickleback, arroyo chub, and Santa Ana sucker) depend on the aquatic system to meet all of their life history requirements (*e.g.*, shelter, food, reproduction). Buffers can provide several functions that protect these species from adverse edge effects, such as increased stream temperatures due to reduced canopy cover. (Note: It is assumed that issues such as water quality and sedimentation are not strictly edge impacts because the point source can be anywhere in the watershed; therefore, these issues are addressed through project design features). Increased stream temperatures associated with a reduced canopy may directly affect habitat suitability for these species and may allow some exotic fish species that prefer warmer water to become established. Maintaining a riparian buffer zone along the River channel, therefore, is important for these three fish species.

Terrestrial habitat buffers along the Santa Clara River (including riparian habitat on terraces, upland vegetation communities (such as shrublands and grasslands), and agricultural areas) may provide essential habitat for meeting the life history needs of semi-aquatic special-status species, such as western spadefoot toad, arroyo toad, two-striped garter snakes, and southwestern pond turtle. Substantial data have been collected for movements of the southwestern pond turtle and the arroyo toad, providing some guidance for identifying adequate terrestrial buffers.

Southwestern pond turtles are known to utilize terrestrial habitats adjacent to aquatic environments in the summer for nesting and for over-wintering. Nests typically are located along stream or pond margins, but the movement of southwestern pond turtles probably is related to the availability of suitable nesting and over-wintering sites in relation to aquatic habitat and, thus, is likely to be very site-specific (Goodman (1997A; Rathbun *et al.* (1992). Although Rathbun *et al.* (1992) documented movements for nesting over 330 feet, over-wintering turtles may travel farther than for nesting, with a mean distance over 600 feet and a maximum of 1,640 feet observed by Reese and Welsh (1998) in northern California.

Similar to the southwestern pond turtle, the arroyo toad uses terrestrial habitats adjacent to aquatic areas for foraging, aestivation, and hibernation. Subadults and adults may

range widely into the surrounding uplands, commonly within 650 to 3,280 feet, but up to 1.2 miles (69 FR 23254–23328). Radiotelemetry studies by Ramirez demonstrated that arroyo toads typically burrow no farther than about 121 feet to 1,062 feet from the edge of a stream, with an average distance of about 52 feet (69 FR 23254–23328). A radiotelemetry study of arroyo toads in San Juan Creek in southern Orange County, which has a similar structure to the Santa Clara River (*i.e.*, a fairly wide active floodplain and relatively narrow wet channel, with agricultural operations adjacent to much of the creek), found that virtually all of the toad activity was limited to the active floodplain (Ramirez 2003).

Studies of the southwestern pond turtle and the arroyo toad indicate that, at minimum, the entire floodplain of the Santa Clara River, which ranges from 1,000 feet to 2,000 feet wide, may be used by these species. Given the long-distance movements made at least occasionally by these species, they potentially also use upland areas, including agriculture, next to the River corridor that are accessible and have suitable friable soils for burrowing.

The terrestrial buffer zone along the Santa Clara River also provides valuable habitat for native species that are attracted to ecotones that have high habitat diversity. Impact Sciences, Inc. (1997), for example, analyzed small mammal populations in upland habitats next to riparian areas along the Santa Clara River and found that home ranges tended to be smaller and more compact in high-quality habitat (*e.g.*, higher native shrub cover) compared to low-quality habitats (*e.g.*, disturbed or agricultural areas with little cover), and that the highest densities and diversity of small mammals occurred in high-quality upland habitat. These results suggest that high-quality habitats provide greater resources for small mammals and reduce the need to travel longer distances, thus reducing predation risk and other behavioral costs. High-quality habitats, such as those with higher native shrub cover, also provide greater protection from predators than low-quality habitat.

Impact Sciences, Inc. (1997) also conducted surveys in riparian areas and adjacent upland edges on the Santa Clara River and San Francisquito Creek immediately east of the Project area to characterize riparian bird diversity, abundance, and habitat use in these areas prior to development. These surveys were conducted prior to residential development adjacent to San Francisquito Creek; adjacent land use typically included agricultural and light industrial uses. Bird species (including both resident and migrant species) characterized in the scientific literature as highly "riparian-dependent" were observed within adjacent upland habitat. As noted above, the least Bell's vireo, for example, may forage in upland shrub habitats adjacent to riparian breeding habitat late in

the breeding season (Kus and Miner 1989). Where upland habitat was of high quality,[2] 99% of observations of riparian-dependent birds by Impact Sciences, Inc. (1997) were within 100 feet of the riparian edge; in low-quality upland habitat, 90% of such observations were within 100 feet of the riparian edge. All observations of these species in adjacent uplands occurred within 150 feet of the riparian edge. For species that are known to be riparian associates but not riparian dependents, 84% of birds were observed within 100 feet of the riparian edge in high-quality upland habitat and 93% of birds were observed within 100 feet of the riparian edge in low-quality upland habitat. As with riparian-dependent species, riparian associates were not observed beyond 150 feet from the riparian edge where high-quality upland habitat was present. The Impact Sciences, Inc. (1997) study indicates that riparian buffers along the Santa Clara River should range from a minimum of 100 to 150 feet in width for riparian-dependent birds and riparian associates, depending on the quality of the upland habitat; a larger buffer width would be required if the upland habitat were of low quality. If existing upland habitat quality is low, habitat enhancement in areas where the buffer is narrower could compensate for the smaller buffer.

While most of the focus of this subsection is on the buffer function along the Santa Clara River because of the high number of special-status species in the River corridor (including several listed species), buffers along the protected upland open space–urban development interface in the High Country SMA and Salt Creek area also are an important consideration. In particular, Potrero Village is bounded on the south and west by the High Country SMA and Salt Creek area. However, most of the planned development along this boundary is estate residential, which would have less potential for adverse edge effects than higher-density uses, assuming that project design features (*e.g.*, lighting) and other restrictions (*e.g.*, on landscape plants, irrigation, and runoff) are implemented. Likewise, the planned development at the boundary between open space and the Homestead West development is estate residential. In addition, because these interface areas are in fairly rugged terrain and are occupied by wildlife species that are generally widespread in the upland open space areas (*i.e.*, these areas do not support specific microhabitats or features that are a key resource for the upland species), buffers are not as critical in these areas as they are along the Santa Clara River corridor.

[2] Habitat quality was determined by evaluating seven variables: (1) shrub/tree cover variability; (2) percentage of shrub/tree cover; (3) percentage of ground cover; (4) average shrub/tree height; (5) percentage of herbaceous cover; (6) herbaceous cover variability; and (7) shrub/tree height variability.

INTENTIONALLY LEFT BLANK

4.5.4 IMPACT SIGNIFICANCE CRITERIA

The significance criteria listed below derive from Appendix G of the State CEQA Guidelines (Cal. Code Regs., tit. 14, § 15000 *et seq.*) but have been modified to better suit the proposed Project. The lead agencies have applied these criteria when determining the significance of the Project's impacts on biological resources. Biological impacts would be significant if implementation of the proposed Project or its alternatives would:

(1) Have a substantial adverse effect, either directly or *via* habitat modifications, on any "special-status species" as such species are defined in **Subsection 4.5.3.4.5** and **Subsection 4.5.3.4.6**, and listed in **Subsection 4.5.3.1** of this EIS/EIR; or violate any federal, state, or local law which protects biological resources;

(2) Have a substantial adverse effect on any riparian habitat or other special-status natural community identified by federal, local, or state agencies;

(3) Have a substantial adverse effect on federally protected wetlands or substantial change to state-protected streambeds through direct removal, filling, hydrological interruption, loss of functions or services, or other means (evaluated in **Section 4.6**, Jurisdictional Waters and Streams, of this EIS/EIR);

(4) Interfere substantially with the movement of any native resident or migratory fish or wildlife species, or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites;

(5) Conflict with any local plans, policies, or ordinances protecting biological resources, such as a tree preservation policy or ordinance;

(6) Cause scouring of the riverbed to the point of removing a substantial amount of aquatic, wetland, or riparian habitats from the river channel (evaluated in **Section 4.2**, Geomorphology and Riparian Resources, of this EIS/EIR); and

(7) Have the potential to substantially reduce the habitat of a fish or wildlife species; cause a fish or wildlife population to drop below self-sustaining levels; threaten to eliminate a plant or animal community; or substantially reduce the number or restrict the range of an endangered, rare, or threatened species**.**

Appendix G of the State CEQA Guidelines also includes the criterion of whether the project would conflict with the provisions of an adopted Habitat Conservation Plan; Natural Community Conservation Plan; or other approved local, regional, or state habitat conservation plan. This criterion is not used in this EIS/EIR in the analysis of impacts to biological resources because there are no Habitat Conservation Plans; Natural Community Conservation Plans; or other approved local, regional, or state habitat conservation plans in the Project area or nearby vicinity.

In order to maintain consistency in the impacts analysis, the Corps has agreed to use these CEQA-based criteria for purposes of the EIS/EIR. However, the Corps will not formally adopt these CEQA-based criteria for general application; nor will the Corps rely solely on these CEQA-based criteria when assessing the impacts of *this* Project. Instead, the Corps will augment these criteria by applying additional federal criteria, as appropriate.

It should be noted that impacts deemed "significant" under these criteria may be significant on a local level only and may not be significant on a regional, state-wide, or national level.

4.5.5 IMPACTS OF THE PROPOSED PROJECT AND ALTERNATIVES

4.5.5.1 Impact Analysis Approach and Methods

This subsection describes the impact analysis approach and methods for Alternatives 2 through 7. Impacts are categorized as direct, indirect, and secondary for each alternative. See also **Section 1.0**, Introduction, for a discussion of direct, indirect, and secondary impacts. Direct and indirect impacts differ in regard to the Project component resulting in the impacts. As used here, direct impacts would occur as a result of implementation of the RMDP and SCP and include temporary disturbance and/or permanent loss of vegetation communities, including sensitive vegetation communities, general wildlife, and special-status plant and animal species. For the purposes of the impact analysis, the total loss of habitat for direct and indirect effects is evaluated in its entirety. However, Project impacts would be phased over 20 years (depending on market and economic conditions) such that not all permanent and temporary direct impacts would occur at the same time. The permanent impacts reported in this EIS/EIR would occur at different times and generally would be from east to west (*i.e.*, starting from the edge of existing developed areas and gradually proceed toward the more remote areas), allowing wildlife to adjust to the loss of habitat in increments (*e.g.*, by shifting foraging and breeding activities, movement, and dispersal). As RMDP associated temporary impacts are completed, restoration and revegetation of those areas would be implemented. This would provide ongoing replacement of the biological functions of the temporarily impacted areas. Where applicable for the wildlife species addressed in this EIS/EIR, the temporal phasing of the Project is considered in the analysis of impacts on the species. For example, a raptor species that forages in a wide variety of habitats will be able to forage in portions of the Project area not yet under construction or area designated for open space preservation. Depending on the species analyzed, and the extent of the ultimate amount of habitat loss, findings of less than significant, with or without mitigation, may be appropriate for species that will successfully adjust their activities and be able to meet their life history requirements (*i.e.*, foraging, breeding, movement, dispersal, and refuge) in the permanently preserved open space.

Direct permanent loss of vegetation communities and land covers would result from proposed RMDP improvements, including:

- Construction of bridges and associated piers and abutments;
- Road crossing culverts;
- Bank stabilization/protection that includes ungrouted rock riprap, turf reinforcement mats, and exposed gunite slope-lining protection under bridge crossings and their abutments;
- Drainage facilities that include partially lined open channels;

- Grade controls and other channel improvements, including grade control structures in tributaries; engineered natural channels in Potrero, Long, and Lion canyons; grouted sloping boulder drops; non-grouted boulder step-pools; soil-cement grade control structures; sculpted concrete drop structures; and check structures;
- Water reclamation plant outfall;
- Water quality control features, such as water quality basins, debris basins, detention basins, catch basin inserts, and biorention features;
- Various roadway improvements to SR-126; and
- Recreation facilities.

Permanent loss of non-native vegetation communities (California annual grassland and giant reed) and artificial land covers (agriculture, disturbed land, and developed areas) will also occur as a result of habitat restoration and enhancement activities.

Temporary loss of vegetation communities and land covers includes vegetation and land cover clearing, grading, and other Project-related disturbances (*e.g.*, temporary haul routes) in the Project area that temporarily displace the vegetation community or land cover that was present prior to construction. Temporary impacts would occur where grading or soil disturbance would occur for a short period of time (*e.g.*, along the edges of proposed facilities), but where no permanent structures would be constructed and no disturbance would occur.

Implementation of the proposed Project would also result in impacts to wildlife movement corridors and unique landscape features, such as the River Corridor SMA, High Country SMA, and Middle Canyon Spring.

Indirect impacts would occur as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. Indirect impacts also include permanent loss of vegetation communities, including sensitive vegetation communities, general wildlife, and special-status plant and animal species. For purposes of analyzing indirect impacts, any temporary disturbance areas are included in the permanent footprint. (There are no temporary impacts identified for build-out of the Specific Plan, VCC, and Entrada planning areas.)

Secondary impacts are those reasonably foreseeable effects caused by Project implementation on remaining or adjacent biological resources outside the construction disturbance zone. Secondary impacts may affect areas within the defined Project area, but outside the construction disturbance zone, including open space, and areas outside the Project area, such as downstream effects. Secondary impacts include short-term effects immediately related to construction activities and long-term or chronic effects related to the human occupation of developed areas. Both implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada

planning areas would result in short-term construction-related secondary impacts and long-term secondary impacts.

Each of these types of impacts (direct, indirect, and secondary) is discussed in greater detail below.

4.5.5.1.1 Direct Impacts of RMDP/SCP

Direct impacts represent the absolute physical loss of a biological resource due to clearing and grading associated with implementation of the RMDP and SCP under Alternatives 2 through 7 and are analyzed in six ways: (1) permanent loss of vegetation communities, land covers, and general wildlife and their habitat; (2) permanent loss of or harm to individuals of special-status plant and wildlife species; (3) permanent loss of suitable habitat for special-status species; (4) permanent loss of wildlife movement and habitat connectivity in the Project area; (5) temporary loss of vegetation communities, land covers, and general wildlife and their habitat; and (6) temporary loss of suitable habitat for special-status species.

4.5.5.1.1.1 *Permanent Impacts*

Permanent Loss of Vegetation Communities, Land Covers, and General Wildlife and Their Habitat. A distinction is made between vegetation communities, land covers, and habitat for the purpose of the analysis in this section. Vegetation communities correspond to the Vegetation Classification and Mapping Program "List of California Terrestrial Natural Communities Recognized by the California Natural Diversity Database" (CDFG 2003). "Land cover" refers to artificial or human-altered areas, including active agriculture, disturbed land, and developed land. "Habitat" is defined by Lincoln *et al.* (1998) as "the locality, site and particular type of local environment occupied by an organism." "Habitat," as used in this EIS/EIR, refers to vegetation communities and land covers specifically used by plant and wildlife species in the Project area, and is often some combination of vegetation communities and land covers. Habitats are defined for each special-status species, as applicable for the species and the Project area. Modeled suitable habitat represents vegetation communities and land covers in the Project area with characteristics such as vegetation constituents and structure and other physical features that support the life history requirements of the particular species. The identified species are not documented to occur within all of the modeled suitable habitat within the Project site; however, for purposes of analysis of the species, it is assumed that all modeled suitable habitat for a particular species could support the species for all or some part of its life history, including foraging, breeding, refuge, aestivation/hibernation, wintering, *etc.* (For suitable habitat models, see RMDP (Dudek 2008D) *Appendix C – Species Preserve Report*, which provides a list of suitable habitats for most of the special-status species known or expected to occur within the RMDP preserve area in

Appendix 1.0.) For example, suitable breeding and foraging habitat for the southern California rufous-crowned sparrow (*Aimophila ruficeps canescens*) in the Project area is defined as California sagebrush scrub (including all associations, such as California sagebrush–black sage, as well as burned and disturbed areas), and California sagebrush scrub/undifferentiated chaparral. For other species, breeding and foraging habitats are analyzed separately because they are distinctly different and impacts may be proportionally different. For example, for the long-eared owl (*Asio otus*), breeding habitat is defined as southern coast live oak riparian forest, southern cottonwood–willow riparian forest, southern willow scrub, coast live oak woodland, mixed oak woodland/grassland, and valley oak woodland. Long-eared owl foraging habitat is defined as agriculture, California annual grassland, purple needlegrass grassland, mixed oak woodland/grassland, and valley oak/grassland. Even if very little breeding habitat was lost, a large loss of foraging habitat could significantly affect the long-eared owl in the Project area.

Several species rely on specific microhabitats rather than broad landscapes, such as the western spadefoot toad (*Spea hammondii*) that breeds in seasonal aquatic habitat, such as ephemeral pools filled by rain or agricultural runoff in the lower and flatter portions of the Project area, and within seasonal drainages and existing ponds. Suitable habitat was quantified for some species that use discrete microhabitats (*e.g.*, undescribed snail, undescribed sunflower), but not all, as appropriate for each species. For those species for which suitable habitat was not quantified, discrete microhabitats and habitat impacts are discussed qualitatively.

Permanent loss of vegetation communities and land covers includes vegetation and land cover clearing and/or grading in the Project footprint for Alternatives 2 through 7, designated by final grading plans for construction of physical facilities that permanently displace the vegetation communities or land covers that were present prior to construction. Permanent loss of vegetation communities and land covers is reported as acres removed and percentage of total acres in Project area removed as a result of implementation of Alternatives 2 through 7. Direct permanent loss of vegetation communities would result from proposed RMDP improvements. Permanent loss of artificial landcovers will also occur as a result of habitat restoration and enhancement activities.

Permanent loss of common wildlife and their habitat are addressed qualitatively for Alternatives 2 through 7 by describing the general effects of the permanent loss of individuals and habitat resulting from the RMDP and SCP, including loss and displacement of species during and following construction, and the long-term effect of the Project on the status and distribution of common wildlife species on site.

Section 2.0 contains the complete Project description of the RMDP improvements.

Permanent Loss of or Harm to Individuals of Special-Status Plant and Wildlife Species. Loss of or harm to individuals of special-status species includes impacts that result in mortality or injury of individuals (including removal of or damage to plants) that can be immediately attributed to Project construction activities such as vegetation clearing and/or grading. How loss or harm to individuals can occur for different species may vary, but the result is a net permanent loss of a portion of a species population. For example, for fossorial (burrowing) species, such as small rodents, as well as reptiles and amphibians in certain phases of their life cycles (*e.g.*, hibernation or aestivation), equipment used for excavation or grading can cause direct mortality, or injure or entomb individuals, resulting in their eventual death. Vegetation clearing and/or grading can also result in destruction of birds' nests, resulting in the loss of eggs and young. For special-status plant species, loss of or harm to individuals is reported as the loss of individuals or loss of acreage of mapped plant population polygons or acreage of habitat in which the species occurs, as applicable. For most special-status wildlife species, loss of or harm to individuals is not quantified as the number of individuals lost or harmed, but rather is based on the proportion of suitable habitat that would be lost, because data on species abundance (*e.g.*, number of individuals per acre) generally are not available. If only documented locations for a species were to be used for the impact analysis, the amount of impacts to individuals could be severely underestimated because of the relative lack of abundance data for wildlife compared to plants. For example, for the San Diego desert woodrat (*Neotoma lepida intermedia*), a relatively common rodent in upland shrub habitats on site, the RMDP would permanently impact about 80 acres suitable habitat, and it can be inferred that some individuals would be lost or harmed during clearing and/or grading activities.

Permanent Loss of Suitable Habitat for Special-Status Species. Similar to vegetation communities and land covers, permanent loss of suitable habitat for special-status species includes clearing and/or grading in the Project footprint under Alternatives 2 through 7, designated for construction of physical facilities that permanently displace the suitable habitat that was present prior to construction. Permanent loss of suitable habitat is reported as the acres removed and the percentage of total acres in the Project area removed as a result of the Project construction activities for Alternatives 2 through 7. Direct permanent loss of suitable habitat for special-status species would result from proposed RMDP activities, as described above for permanent loss of vegetation communities and landcovers.

Permanent Loss of Wildlife Movement and Habitat Connectivity in the Project Area. As described in **Subsection 4.5.1**, the impact analysis for special-status wildlife

species is organized by wildlife "guilds," which are groups of species that have similar ecological resource requirements and similar roles in the ecological community. Species within a particular guild also are likely to be affected in similar ways by Project impacts to wildlife movement and habitat connectivity. For example, semi-aquatic species, such as the arroyo toad (*Bufo californicus*) and the southwestern pond turtle (*Actinemys marmorata pallida*), rely both on aquatic and adjacent terrestrial habitat to meet their life history requirements. Neotropical migrants that nest in riparian habitats on site also will be affected in similar ways. Thus, grouping species by guilds allows for a more efficient and ecologically meaningful way of analyzing Project impacts to wildlife movement and habitat connectivity under Alternatives 2 through 7.

4.5.5.1.1.2 *Temporary Impacts*

Temporary Loss of Vegetation Communities, Land Covers and General Wildlife and Their Habitat. Temporary loss of vegetation communities and land covers includes vegetation and land cover clearing and grading associated with construction of proposed temporary haul roads and construction of proposed permanent new access roads, grade control structures, buried bank protection, installation of culverts, and other improvements required for Alternatives 2 through 7. The temporary loss of vegetation communities and landcovers would occur where grading or soil disturbance would occur for a short period of time (*e.g.,* along the edges of proposed facilities), but where no permanent structures would be constructed and no disturbance would occur. Areas temporarily disturbed by construction activities would be restored and revegetated with a native species mix similar to that which existed prior to disturbance following completion of work in the area. Native plant material would be crushed and stockpiled for later use in revegetation. After the construction work is completed, the area would be restored to its original contours and elevation, with salvaged native vegetative debris spread out over the disturbed area to allow seeds and propagules to become established naturally.

Temporary loss of vegetation communities and land covers is reported as acres removed as a result of Alternatives 2 through 7. Direct temporary loss of vegetation communities and land covers would result from proposed RMDP improvements that do not day light above the natural contours of the ground surface, including buried bank stabilization, buried storm drains, utility crossings, and temporary haul routes for grading equipment across the Santa Clara River. Temporary impacts may also occur in construction areas for access and haul roads, and on-site staging and storage areas where these activities cannot be sited in designated grading areas.

Temporary loss of common wildlife and their habitat is addressed qualitatively by describing the general effects of the temporary loss of individuals and habitat resulting

from the RMDP and SCP, including loss and displacement of species during and following construction, and the long-term effect of the Project under Alternatives 2 through 7 on the status and distribution of common wildlife species on site.

Temporary Loss of Suitable Habitat for Special-Status Species. Also similar to vegetation communities and land covers, temporary loss of suitable habitat for special-status species includes clearing, grading, and other Project-related disturbances (*e.g.*, temporary haul routes) in the Project area that temporarily displace the suitable habitat that was present prior to construction. Temporary loss of suitable habitat is reported as acres removed as a result of the Project. Direct temporary loss of suitable habitat would result from proposed RMDP activities under Alternatives 2 through 7, as described above for permanent loss of vegetation communities and land covers.

4.5.5.1.2 Indirect Impacts

Indirect impacts represent the absolute physical loss of a biological resource due to build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 2 through 7 and are analyzed in four ways: (1) permanent loss of vegetation communities, land covers, and general wildlife and their habitat; (2) permanent loss of or harm to individuals of special-status plant and wildlife species; (3) permanent loss of suitable habitat for special-status species; and (4) permanent loss of wildlife movement and habitat connectivity in the Project area.

For the purpose of analyzing indirect impacts to vegetation communities and land covers and suitable habitat due to clearing and grading associated with build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 2 through 7, it is assumed that all of the designated Project footprints will be graded. For purposes of analyzing indirect impacts, any temporary disturbance areas are included in the permanent footprint for each alternative (there are no temporary impacts identified for build-out of the Specific Plan, VCC, and Entrada planning areas).

4.5.5.1.2.1 *Permanent Impacts*

Potential permanent impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 2 through 7, analyzed in **Subsection 4.5.5.2**, are listed below and described in detail above in **Subsection 4.5.5.1.1**.

- Permanent loss of vegetation communities, land covers, and general wildlife and their habitat;
- Permanent loss of or harm to individuals of special-status plant and wildlife species;
- Permanent loss of suitable habitat for special-status species; and
- Permanent loss of wildlife movement and habitat connectivity in the Project area.

4.5.5.1.3 Secondary Impacts

Secondary impacts, as used in **Section 4.5** of this EIS/EIR, are those reasonably foreseeable effects caused by Project implementation on remaining or adjacent biological resources outside the construction disturbance zone (*i.e.*, secondary impacts may affect areas within the defined Project area but outside the construction disturbance zone, including open space, and areas outside the Project area, such as downstream effects). Secondary impacts would occur as a result of implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 2 through 7. Secondary impacts are characterized as resulting from two main different sources: (1) short-term construction-related impacts and (2) long-term impacts related to implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas. The long-term secondary impacts are further categorized as landscape-level impacts and open space–urban interface (or "edge") impacts. **Subsection 4.5.5.2** analyzes each of these potential secondary impacts on vegetation communities and land covers, unique landscape features, general wildlife, and generally for special-status plant species. The impact analysis for general wildlife (which includes special-status species) is organized by guilds that are based on common ecological requirements and/or responses to secondary impacts by groups of species (*e.g.*, riparian birds, raptors, low mobility reptiles and amphibians). Individual impact analyses for each special-status wildlife and plant species are presented in **Subsection 4.5.5.3**.

4.5.5.1.3.1 *Short-Term Construction-Related Secondary Impacts*

Hydrological Alterations and Water Quality Impacts. Construction of RMDP facilities, including bank stabilization, construction of bridges and associated piers and abutments, and construction of drainage culverts, as well as mass grading associated with build-out of the Specific Plan, VCC, and Entrada planning areas, could result in short-term hydrologic and water-quality-related impacts adjacent to and downstream of the impact areas. Short-term hydrological alterations primarily associated with the RMDP include changes in flow rates and patterns in streams and rivers, and dewatering that may affect adjacent and downstream aquatic, wetland, and riparian vegetation communities, and aquatic species (*e.g.*, fish), semi-aquatic species (*e.g.*, frogs, toads, and some reptiles), and riparian nesting birds. Water temperature changes also may occur due to

short-term changes to the active channel morphology, thus affecting aquatic habitat suitability for aquatic and semi-aquatic species that have specific thermal tolerances. Short-term water quality impacts potentially occurring from the RMDP and Project area build-out include chemical and toxic compound pollution (fuel, oil, lubricants, paints, release agents, and other construction materials), erosion, increased turbidity, and excessive sedimentation.

Erosion and Chemical and Toxic Compound Pollution in Uplands. Erosion and chemical and toxic compound pollution (fuel, oil, lubricants, paints, release agents, and other construction materials) may also affect upland vegetation communities, wildlife habitats, and wildlife species.

Dust. Excessive dust can decrease the vigor and productivity of plant communities through effects on light and penetration as well as photosynthesis, respiration, transpiration; increased penetration of phytotoxic gaseous pollutants; and increased incidence of pests and diseases.

Construction Noise. Construction noise may affect essential behavioral activities of wildlife in several ways. Excessive noise may affect birds, for example, in at least four ways: (1) Noise may be annoying and cause birds to abandon nests that are otherwise perfectly suitable; (2) noise can be stressful and may raise the level of stress hormones, interfering with sleep and other activities; (3) intense noise can cause permanent injury to the auditory system; and (4) noise can interfere with acoustic communication by masking important sounds or sound components (Dooling 2006). Similar effects may occur in other taxa. Noise may interfere with communication in toads and frogs that use calls to advertise their location and attract mates (*e.g.*, Barrass and Cohn 1984). Loud noise, such as off-road vehicles, may damage the hearing of some terrestrial species (Berry 1980; Brattstrom and Bondello 1983).

Vibration. Vibration caused by construction equipment may affect essential behavioral activities and the habitat of wildlife in several ways. Vibration from equipment operating in creeks and other aquatic habitats may affect fish and semi-aquatic species, causing them to abandon areas. Vibration may also directly disturb terrestrial species that occupy burrows, dens, and depressions, such as rodents, coyotes (*Canis latrans*), badgers (*Taxidea taxus*), and lagomorphs (rabbits and hares), causing them to abandon these areas. Excessive vibration might cause the collapse of burrow systems and dens in areas with highly friable soils.

Lighting. Lighting may affect essential behavioral activities, physiology, population ecology, and ecosystems of both diurnal and nocturnal wildlife. Longcore and Rich (2004) call these effects "ecological light pollution" and identify three types of effects:

(1) chronic or periodically increased illumination; (2) unexpected changes in lighting; and (3) direct glare. Chronic increased illumination includes skyglow, lighted buildings and towers, streetlights, and security lights. Unexpected changes may occur from vehicle lights or other discrete events such as flares or spotlighting by law enforcement helicopters. Direct glare may be chronic or unexpected.

Longcore and Rich (2004) address the ecological effects of ecological light pollution at three levels: (1) behavioral and population ecology; (2) community ecology; and (3) large-scale ecosystem functions. Effects at the behavioral and population ecology level include orientation/disorientation and attraction/repulsion, reproduction, and communication.

Orientation and disorientation are responses to ambient light levels, while attraction and repulsion are responses to the source of light (*e.g.*, moths attracted to a light bulb). Orientation includes artificially expanding behavioral repertoires of normally diurnal or crepuscular species, such as foraging or territorial advertisement or mate attraction (*e.g.*, singing birds), into nighttime periods. Disorientation may occur in nocturnal species that normally orient during dark periods and whose visual systems are adapted to low light levels. Attraction to lights affects birds that may suffer injury or mortality due to collisions with lighted structures. Many insects are attracted to light sources, resulting in high numbers of prey being taken by nocturnal insectivores, such as bats. Repulsion of nocturnal wildlife by lights is probably quite common and may cause them to avoid lighted areas in their normal home ranges.

Wildlife reproduction may be affected by lighting in various ways. Movement to breeding areas, chorus behavior, and mate selection by some amphibians may be affected (Longcore and Rich 2004). Lighting may disturb the nighttime rest and sleep periods of diurnal species, including most passerine (perching) birds, having similar effects as noise, including annoying individuals and causing them to abandon nests that are otherwise perfectly suitable. Nest site selection by some birds may be affected by light, with nests being established farther from light sources (Longcore and Rich 2004). Artificial light may simulate increased day length, affecting reproductive cycles by triggering premature reproductive activity at a time when environmental conditions are not conducive to successful reproduction (*e.g.*, cold temperatures and/or poor food resources). Because light may interfere with sleep, it can be stressful and may disrupt normal biological rhythms and raise the level of stress hormones, which may in turn affect reproductive capacity.

At the level of community ecology, ecological light pollution may affect competition and predation (Longcore and Rich 2004). Behavioral interactions by groups of species may

be affected by lighting, as species move into the "light niche" (Longcore and Rich 2004). Species groups that normally partition foraging periods in relation to ambient light levels may be in direct competition under artificial light conditions. Likewise, species that are adapted to higher light levels (*e.g.*, crepuscular species) may outcompete strictly nocturnal species that normally forage in the darkest part of the night.

Lighting may increase the risk of predation of both nocturnal and diurnal species because they may be more detectable to nocturnal predators. Some species, such as amphibians, may be attracted to light because insect prey may congregate around light sources, which may in turn increase the risk of the amphibians being preyed upon. Longcore and Rich (2004) characterize this as a tradeoff in the benefit of foraging longer (or at richer sources) with the cost of higher predation risk. Many small species, such as rodents, rabbits, snakes, and bats, actually forage at lower rates at high illumination levels (Longcore and Rich 2004), which may be a biological adaptation to high levels of moonlight. Overall, chronic ecological light pollution may favor light-tolerant species over those that are dark-adapted (Longcore and Rich 2004).

The various levels of ecological light pollution ultimately may affect large-scale ecosystem functions in ways not yet understood, as effects at the behavioral and population ecology and community ecology levels reverberate through the system (Longcore and Rich 2004).

Ecological light pollution directly associated with construction ultimately would be temporary, but it may be considered chronic to some extent in terms of effects on wildlife. For example, lighting for security and public safety in some construction areas may extend for several months or more, thus potentially disrupting critical phases of species' life cycles, such as reproduction, or causing animals to abandon lighted areas. Other lighting impacts may be short-term or unexpected. Lighting for nighttime construction or maintenance of construction equipment typically involves high-intensity lighting systems that may have very wide light sheds and high glare values. Vehicle ingress and egress at construction sites may occur during twilight or nighttime hours (especially during winter months), resulting in unexpected changes.

Increased Human Activity. Increased human activity in construction areas could affect essential behavioral activities and physiology of wildlife. Similar to noise and lighting effects, increased human activity could disturb nocturnal animals during their rest or sleep periods, annoying them and causing them to abandon nests or den sites, as well as disrupting their normal biological rhythms and raising the level of stress hormones. Abandonment (even temporary) of active nests or dens increases the risk to eggs, nestlings, fledglings, and other dependent young. Flushing animals from nests, dens, and

other refuges also increases their risk of injury or mortality from collisions with construction equipment and other vehicles, as well as predation. Human presence may also alter the spatial behavior of animals, causing them to avoid certain parts of their home range, which may prevent them from using critical resources, such as water.

Temporary Fencing. Temporary fencing, such as snow fencing, may provide some protection for wildlife by keeping them out of construction zones, but also may inhibit the movement of some species that have large home ranges, such as coyotes and mule deer (*Odocoileus hemionus*). Disrupting the ability of these species to move freely throughout their ranges may alter their foraging and social behavior, and may expose them to greater risks in other areas they may normally avoid or use less frequently due to lower habitat suitability, greater risks of predation, or greater risks of vehicle collisions.

Accidental Clearing, Trampling, or Grading. Accidental clearing, trampling, or grading of vegetation communities and wildlife habitat outside designated construction zones may occur during construction activities for various reasons, including incorrect construction grading plans, human error in interpreting grading plans, human error or accidents in operating construction equipment, and misunderstandings or disregard by construction personnel in adhering to construction plan requirements, including avoidance of natural resources.

Oak Tree Root Impacts. Oak tree root systems may be affected during construction due to soil compaction, pollutants, or toxic compounds.

Trash and Other Debris. Trash and other non-toxic debris associated with construction activities can degrade vegetation communities and wildlife habitat, and can attract nuisance and pest species. Trash and debris include discarded construction-related materials, such as packaging materials and plastic sheeting, that may be dispersed into natural areas by wind or along creeks and streams. Trash generated by construction personnel, such as food packaging and cigarette butts, also can be dispersed by wind and water into natural areas. Pest and predatory species, such as crows and ravens, seagulls, skunks, and raccoons, may be attracted to discarded food.

4.5.5.1.3.2 *Long-term Secondary Impacts Related to Implementation of the RMDP and SCP, and Build-Out of the Specific Plan, VCC, and Entrada Planning Areas*

Long-term secondary impacts resulting from implementation of the RMDP and the build-out of the Specific Plan, VCC, and Entrada planning areas generally can be categorized as (1) landscape level impacts or (2) "edge" effects that generally occur along the open space–urban interface. These potential impacts are listed here with a brief summary of their effects on biological resources. **Appendix 4.5** (Newhall Ranch Resource

Management and Development Plan: Wildlife Habitat Buffers and Connectivity White Paper (Dudek 2008C)) contains a more complete treatment of long-term secondary impacts. The SCP is a preservation plan and would not have long-term adverse secondary impacts.

Landscape-Level Secondary Impacts. Landscape-level secondary impacts under Alternatives 2 through 7 include foreseeable impacts that can result in large-scale habitat degradation in open areas and an associated reduction in effective total habitat area, which, in turn, reduces effective population sizes of plant and wildlife species and increases the risk of local population extinctions. Landscape-level secondary impacts also include habitat fragmentation and isolation effects resulting from interposing urban development between large, core habitat areas and decreasing effective biological connections between the fragmented habitat areas.

Bridge/Road Crossing, Traffic Noise, and Lighting. Traffic noise and lighting are typically discussed in the context of edge effects, but they can also affect wildlife at the landscape level if they interfere with movement and dispersal; *i.e.*, they can functionally isolate populations if they inhibit wildlife movement. Depending on the ultimate Project approved, up to three bridges would be constructed over the Santa Clara River corridor at Commerce Center Drive, Long Canyon Road, and Potrero Canyon Road. Also depending on ultimate Project approval, bridges or culverted road crossings would also be constructed over major tributaries such as Chiquito Canyon, Long Canyon, San Martinez Grande Canyon, Potrero Canyon, Lion Canyon, and Ayers Canyon. Chronic traffic noise from the bridges could have the same effects on wildlife as those discussed above for construction noise, although many species may adapt to chronic noise or avoid noisy areas altogether (see discussion in Dudek 2008C, included in **Appendix 4.5**). Chronic traffic noise could also interfere with the ability of small mammals to hear predators such as hawks and owls (although noise may also interfere with the ability of nocturnal predators such as owls to detect prey). Likewise, lighting for bridges may have the same effect on wildlife as discussed above for construction-related impacts.

Downstream Effects of Drainage and Control Facilities and Water Reclamation Plant (WRP) Outfall. Potential downstream effects of drainage, flood control, and WRP facilities may occur, including altered flow rates and timing (*e.g.*, peak flows from storm events and perennial flows from urban sources, such as landscape irrigation and other forms of runoff). These effects could alter downstream aquatic and riparian vegetation and wildlife habitat for many species, including aquatic and semi-aquatic species and riparian birds. For example, excessive and/or perennial runoff could increase downstream ponding, converting riparian communities to marsh, and thus, altering species' communities. Water thermal regimes may also be altered and potentially exclude

species with narrow thermal tolerances. It should be noted, however, that flood control facilities would be designed pursuant to adopted Best Management Practices (BMPs) and NPDES permitting requirements. The Newhall Ranch Subregional Stormwater Mitigation Plan prescribes the post-development stormwater management facilities to treat or detain runoff to ensure compliance with the Basin Plan and other policies such as hydromodification. Further, drainage structures would focus on managing the amount of debris that would enter the drainage system, balancing the amount of sedimentation or erosion that would occur, and maintaining the quality of water in the drainage system at a level consistent with the Clean Water Act and the Porter-Cologne Water Quality Control Act.

The WRP outfall would be constructed from the WRP through the bank stabilization to the bed of the Santa Clara River. An earthen channel and adjacent walkway would be constructed to reach the actual flow path of the River. The walkway would be used to obtain water samples, as required in the NPDES permit for the WRP. The channel and walkway would be maintained periodically due to storm damage, vegetative cover, and water erosion. Depending on the extent of maintenance and repair activities (*e.g.*, type of equipment, duration, and timing), secondary impacts resulting from these activities could be similar to the construction-related secondary impacts discussed above, including hydrologic and water quality alterations, erosion, chemical and toxic compounds pollution, dust, noise, vibration, lighting, increased human activity, temporary fencing, accidental clearing, trampling, grading, oak tree root impacts, and trash and other debris.

Downstream Effects of Water Quality Control Facilities. Water quality control facilities are required to comply with Clean Water Act section 402(p), which regulates construction, municipal, and industrial stormwater discharges under the NPDES program. The Stormwater Pollution Prevention Plan is required to implement BMPs to reduce or eliminate pollutants in stormwater discharges. Proposed facilities include water quality basins, detention basins, catch basin inserts, bioretention (vegetated swales), and solids separator units. Although these facilities are designed to prevent degradation of downstream resources, they could affect downstream hydrology, such as peak flow volume and timing, and geomorphology (*e.g.*, sediment transport) that could have secondary impacts on vegetation communities, wildlife habitat, and species composition.

Monitoring and Maintenance of RMDP Facilities. Ongoing monitoring maintenance of RMDP facilities will be conducted by the Los Angeles County Department of Public Works (DPW), and may include removal of vegetation from facilities to protect their function and structural integrity, clearing of storm drain outlets to ensure proper drainage, removal of ponded water to control odors and mosquitoes, as-needed repairs and maintenance of bridges, as-needed repairs of bank protection, as-needed clearing of

detention and debris basins and removal of deposits per approved maintenance procedures, and emergency maintenance activities. These activities generally would require the use of a backhoe, or similar construction equipment, to excavate areas to remove vegetation, debris, sediment, *etc.* On-highway trucks would be used to remove excavated materials from sites. Potential secondary impacts from these activities would be similar to several of the construction-related secondary impacts discussed above, including hydrologic and water quality alterations, erosion, chemical and toxic compounds pollution, dust, noise, vibration, lighting (*e.g.*, during emergency operations), increased human activity, accidental clearing, trampling, and grading, and trash and other debris.

Maintenance of Utility Crossings. Various electrical, sewer, water, gas, and communication lines would be installed across the Santa Clara River, Chiquito Canyon, San Martinez Canyon, Potrero Canyon, and Long Canyon. Periodic maintenance and repair of these utilities will be required, resulting in potential for temporary secondary impacts associated with these activities. These impacts would similar to the construction-related secondary impacts discussed above, including hydrologic and water quality alterations, erosion, chemical and toxic compounds pollution, dust, noise, vibration, lighting, increased human activity, temporary fencing, accidental clearing, trampling, grading, oak tree root impacts, and trash and other debris.

Recreational Facilities. A key component of the Specific Plan is a comprehensive system of bicycle, pedestrian, and equestrian trails throughout the Specific Plan area that provides public access to open space in the Specific Plan area. Several trail crossings would be required in or adjacent to the Santa Clara River corridor and drainages in the Specific Plan area. In addition to the trail elements adopted in the Master Trails Plan, the RMDP proposes to construct three to five nature viewing platforms that would be located in CDFG/Corp jurisdictional areas. Use of the trails and viewing platforms could result in secondary impacts to vegetation communities, wildlife habitats, and wildlife species, including trampling of vegetation, creation of unauthorized trails, increased human presence around, and potential harassment of or harm to, wildlife (*e.g.*, causing abandonment of nest sites, collection of animals, crushing by bicycles and horses, *etc.*), potential harassment of or harm to wildlife by pets, contact with pet fecal material, and potential for transmission of diseases and parasites as well as trash and debris.

Improvements to SR-126. Improvements to SR-126 include expansion of the existing two-lane bridges over Chiquito and San Martinez Grande canyons to four-lane bridges, and the existing six-lane bridge over Castaic Creek would be expanded to eight lanes. The additional lanes would provide for increased vehicle trips as build-out of the Project area, and in the region, occurs. Traffic noise along SR-126 is expected to increase and

potentially have increased noise effects on wildlife, as discussed above. Increased traffic on SR-126 also could increase polluted runoff from the roadway into the Santa Clara River and tributaries during rain events.

Stream Restoration and Enhancement Activities. Riparian resources along the Santa Clara River that are impacted by the RMDP will require restoration, with the objective of providing habitat quality and values similar to pre-Project conditions. Associated habitat enhancement activities include rehabilitation of native areas that have been disturbed by past activities (*e.g.*, grazing, roads, oils and gas operations, *etc.*) or invaded by non-native plant species such as giant reed (*Arundo donax*) and tamarisk (*Tamarix* spp.). Secondary effects of restoration and enhancement activities may include altered hydrology and geomorphology, as well as altered vegetative structure in the Santa Clara River corridor that may favor some wildlife species, but not others. For example, increased riparian habitat cover benefitting riparian birds may reduce open stream channels used by fish, reptiles, and amphibians. However, the River is a dynamic system subject to "resetting" events that generally govern long-term habitat cycles. The net increase in riverine habitat achieved by rehabilitating currently disturbed areas will provide additional long-term value to the system. Therefore, it is anticipated that the net long-term result of restoration and enhancement activities on habitat quality and values in the Santa Clara River system will be positive.

Habitat Fragmentation and Isolation. Habitat fragmentation and isolation of plant and wildlife populations, including impacts on wildlife movement and dispersal as well as impacts on plant pollinators and seed dispersal, may cause extinction of local populations as a result of two processes: (1) reduction in total habitat area, which reduces effective population sizes; and (2) insularization of local populations, which affects dispersal and immigration rates (Wilcox and Murphy 1985; Wilcove *et al.* 1986). Because of complex community-level interactions (*e.g.*, mutualistic species, habitat guilds, and keystone species), the loss of one or a few species from a habitat patch as a direct result of habitat fragmentation (primary extinctions) also may result in multiple "secondary" extinctions within the habitat patch (Wilcox and Murphy 1985).

The build-out of the Specific Plan, VCC, and Entrada planning areas will result in potential habitat fragmentation and isolation effects as a result of large-scale development of uplands and associated roads adjacent to the Santa Clara River corridor and within and adjacent to major tributary drainages, including Chiquito Canyon, San Martinez Grande Canyon, and Castaic Creek north of the Santa Clara River, and Potrero Canyon, Long Canyon, Lion Canyon, and Middle Canyon south of the River. This build-out will alter the spatial relationships of on-site vegetation communities and species populations and will potentially affect the connectivity among important resource areas. Movement and

dispersal of resident low-mobility species (*e.g.*, rodents and terrestrial reptiles) may be impeded by urban development and roadways that cross open space areas, resulting in potential connectivity "bottlenecks." Build-out will also alter the movement behavior of high-mobility wildlife species such as the mule deer, the mountain lion (*Puma concolor*), and the black bear (*Ursus americanus*) that probably use the Project area for dispersal movements among large habitat areas in the region.

These potential impacts are analyzed in the context of known and presumed species distributions and movement patterns in the Project area and the future proposed open space system designed to reduce and mitigate habitat fragmentation and isolation effects.

Altered Natural Wildfire Regimes. Urbanization alters natural wildfire regimes in terms of the frequency of fires, but also in regard to the strategic and tactical approaches to preventing and fighting wildfires. Wildfire in Mediterranean-type ecosystems affects the structure and function of vegetation communities. In most cases, fires are quickly suppressed for public safety and to protect property, but in some cases fires become uncontrollable and catastrophic, in part because past fire suppression has resulted in much greater fuel loads in urbanized environments than would occur under natural regimes. These types of fire regime alteration (suppression and catastrophic and/or frequent fires) can drastically affect plant and animal communities, such as California sagebrush scrub, through increases or decreases in the natural fire interval to which the plant and animal communities have adapted. Longer-than-natural fire intervals can result in excessive buildup of fuel loads, so that when fires do occur, they are catastrophic. Unnaturally long fire intervals can also result in senescence of plant communities, such as chaparral that rely on shorter intervals for rejuvenation. Shorter-than-natural fire return intervals can preclude recovery of the native vegetation between fires, weaken the ecological system, allow for invasion of exotic species, and, in some cases, result in permanent transitions of the vegetation to non-native communities, such as annual grassland and weedy communities (*e.g.*, Malanson and O'Leary 1982; Keeley 1987; O'Leary *et al.* 1992). The alteration of vegetation communities consequently has profound effects on the wildlife species communities.

Altered wildfire regime, and particularly increased incidence of fires in urbanizing areas, may also be considered an edge effect because often these fires are a result of human activities at the open space–urban interface, such as accidental ignitions from sparks from equipment, such as mowers striking rocks, cigarettes, children playing with matches, *etc.*, as well as intentional ignitions, such as arson. However, fires may be ignited by downed or arcing powerlines or cars catching on fire along roadways in fairly remote areas. More importantly, the effect of large wildfires is at the landscape level, especially when fires are quickly spread by strong winds.

Increased Traffic and Vehicle Collisions. The increased density and capacity of roads associated with development results in increased risk of vehicle collisions where wildlife use or attempt to cross roadways, particularly in areas that were frequently used by wildlife before roads and other development were built. Factors related to the number and types of species affected include vehicle speeds, traffic volume, traffic pulses, accessibility of cover, structure of the road (*e.g.*, whether the road is raised or at grade level with the surrounding environment), barrier walls to prevent access to a roadway, and availability of alternative crossing, such as bridges and culverts (Dodd *et al.* 2004).

SR-126 is a high-volume, high-speed arterial highway that runs east–west through the Project area and parallel to the Santa Clara River corridor. Wildlife that attempt to cross SR-126 are currently at high risk of vehicle collisions under existing conditions. Build-out of the Project area will increase traffic volume on SR-126 and increase the risk to wildlife attempting to cross the roadway. Depending on the final Project design, build-out of the Project area includes the construction of up to three new roads that will connect to SR-126: Potrero Canyon Road/Valencia Boulevard, Long Canyon Road, and Commerce Center Drive. Magic Mountain Parkway would connect to Potrero Canyon Road/Valencia Boulevard in the southeastern portion of the Project area. For the most part, these connecting roads will be constructed within development areas and have very little direct contact with open space, and thus relatively little risk of vehicle collisions with wildlife.

Altered Hydrology. Increased urban and stormwater runoff due to the increase in impervious surfaces from build-out of the Project area may result in long-term hydrological alterations, including increased runoff volume, increased peak flow rates, increased duration of flows, and altered patterns in streams and rivers. Groundwater levels may be affected as a result of interference with groundwater recharge that could cause a deficit in aquifer volumes or lowering of the local groundwater table. These hydrological alterations may affect adjacent and downstream aquatic and riparian vegetation and wildlife habitat for many species, including aquatic and semi-aquatic species and riparian birds. For example, excessive and/or perennial runoff could increase downstream ponding, converting riparian communities to marsh, and, thus, altering species' communities. Water thermal regimes may also be altered and potentially exclude species with narrow thermal tolerances.

It should be noted, however, that flood control facilities would be designed pursuant to adopted Best Management Practices (BMPs) and NPDES permitting requirements. The Newhall Ranch Subregional Stormwater Mitigation Plan prescribes the post-development stormwater management facilities to treat or detain runoff to ensure compliance with the Basin Plan and other policies, such as hydromodification. Further, drainage structures

would focus on managing the amount of debris that would enter the drainage system, balancing the amount of sedimentation or erosion that would occur, and maintaining the quality of water in the drainage system at a level consistent with the Clean Water Act and Porter-Cologne.

Watershed-Level Water Quality Impacts. Watershed-level water quality impacts may occur as a result of runoff from development areas and roadways. Potential pollutants include fertilizers (containing nutrients such as nitrogen and phosphorus), pesticides, herbicides, estrogenic chemicals, and petroleum products (fuel, oil, and lubricants). These water quality impacts are of particular concern in the Santa Clara River, which provides aquatic, riparian, and terrestrial habitats for many species, including federally and state-listed endangered and threatened species such as the least Bell's vireo (*Vireo bellii pusillus*) and the unarmored threespine stickleback (*Gasterosteus aculeatus williamsoni*). Amphibians are susceptible to changes or degradation of water quality because of integument (skin) permeability. There is clear evidence that chemical contamination such as pesticides and herbicides can affect amphibian development, reproduction, and survival (*e.g.*, Hayes *et al.* 2003; Bridges and Semlitsch 2000). Increased nutrients, such as nitrogen and phosphorus, can cause eutrophication effects, such as algae blooms that deplete oxygen concentration and degrade habitat for aquatic, semi-aquatic species, and riparian species, including vegetation structure and prey composition and abundance.

Air Pollution. Air pollution in the Project area will increase as a result of the increased population, vehicles, *etc.* One effect of air pollution is increased nitrogen deposition (N-deposition), which, in turn, facilitates the growth of non-native plants species and degrades habitat for native plant and wildlife species. N-deposition is recognized as a statewide phenomenon in California. Sources of nitrogenous air pollutants include transportation, agriculture, industry, electricity generation, wildfire, and emissions from natural and semi-natural ecosystems (Weiss 1999). Future development in the Project area will likely increase local sources of nitrogenous air pollutants, primarily due to transportation and demand for electricity generation. The major documented impact on of N-deposition in California is an increase of invasive annual grasses in low-biomass ecosystems. Coastal scrub is one of seven California ecosystems known to be susceptible to N-deposition. In coastal scrub communities, N-deposition has been identified as one of the main drivers of the conversion of shrublands to grasslands by the invasion of annual grasses (Allen *et al.* 1998; Cione *et al.* 2002; Padgett and Allen 1999). Increased abundance of non-native plants and invasive annual grasses, in particular, represents a potentially significant impact to native vegetation communities and wildlife habitat.

Increased Human Activity. Increased human activity in open space areas associated with the RMDP and build-out of the Project area will include permitted recreational use of trails by humans and their pets, and potential unauthorized impacts, including trespass, vandalism, illegal shooting and hunting, motorized and non-motorized off-road vehicles, trampling of vegetation, soil compaction, and trash dumping. These unauthorized activities would cause secondary impacts to vegetation communities, wildlife habitats, and wildlife species, including trampling of vegetation, creation of unauthorized trails, increased human presence around, and potential harassment of or harm to, wildlife (*e.g.*, causing abandonment of nest sites, collection of animals, crushing by bicycles and motorized off-road vehicles), potential harassment of or harm to wildlife by pets, contact with pet fecal material and potential for transmission of diseases and parasites, and trash and debris.

Increased Mesopredators. Habitat fragmentation and isolation is associated with increases in urban-adapted mesopredators, such as the raccoon, skunk, opossum, and fox in small habitat fragments where top predators, such as coyotes, are not present (*i.e.*, the "mesopredator release" effect) (Crooks and Soulé 1999). Non-native mesopredators also may include stray and feral cats and dogs that can have the same effects as native mesopredators. These species can outcompete smaller native species for available resources, and increase predation rates, thus reducing the distribution and populations of vulnerable native species (Crooks and Soulé 1999). The increase in mesopredators in fragmented habitats is often considered an edge effect, but because some of these species can penetrate long distances in natural habitats in the absence of top predators, resulting in landscape-level effects.

Increased Invasive Plants. According to Invasive Plants of California's Wildlands (Bossard *et al.* 2000), non-native invasive plant species can alter ecosystem processes, such as nutrient cycling, hydrological cycles, and frequencies of wildfires, erosion and sediment deposition. Invasive plants interfere in ecosystem functions by outcompeting and displacing native plants and animals, by providing refuge for non-native animals, and by hybridizing with native species (Bossard *et al.* 2000). Several organizations, such as the California Native Plant Society (CNPS) and the California Invasive Plant Council (Cal-IPC) (formerly known as the California Exotic Pest Plant Council (Cal EPPC)), have provided detailed documentation regarding invasive plant species that threaten California's native flora and fauna.

Invasive plant species, and especially upland species, are often treated as an edge effect because they generally colonize modified or otherwise disturbed zones between development and natural open space areas. However, invasive species can colonize virtually any upland natural area that is subject to some kind of disturbance, such as road

shoulders, cleared zones along railroad lines, clearing along utility easements, excessive fire, fire breaks, and grazing. The air pollution discussion above also demonstrates that N-deposition favors non-native annual grasses over low-biomass ecosystems, such as coastal scrub. Many species, like black mustard (*Brassica nigra*) and non-native annual grasses of Mediterranean origin (*e.g.*, *Bromus* spp., *Hordeum* spp., and *Avena* spp.), have become naturalized to the point that they are beyond realistic control measures at a landscape level. Currently, the main risk to upland areas by these species is the high frequency of fires in the region that could result in permanent transitions of coastal scrub and chaparral to annual grassland.

Riparian and wetland systems are also extremely vulnerable to invasive plants such as giant reed, tamarisk, and pampas grass (*Cortaderia* sp.) because of the highly effective transport of these along rivers and streams. These species can dominate the biomass of riparian and wetlands communities where they become established, virtually choking out the native vegetation. Giant reed is perhaps the most pernicious invasive species in river systems in southern California. The stems of giant reed root at the nodes along the stalk and can span of up to 40 feet in diameter allowing the species to grow as much as 10 inches a day (Bossard *et al.* 2000). This growth rate produces a large amount of aboveground biomass that can quickly monopolize local resources and restrict native species. Effects on native environments by giant reed include exclusion of riparian species and subsequent reduction in wildlife habitat and species diversity. Giant reed also reduces soil moisture through evapotranspiration rates three times that of native riparian species, converts channel morphology through trapping large amounts of sediment, and increases water temperature by providing little shade (Jackson 1998). Furthermore, giant reed has a shallow rooting system that is often uprooted by large precipitation events causing increased erosion. Finally, the massive amounts of biomass associated with giant reed are increasing fire frequency and intensity in riparian systems, which, in turn, facilitate the process of conversion to monocultural stands of giant reed (Jackson 1998). The main risk areas for invasive riparian and wetland species are the Santa Clara River corridor and Salt Creek, which will remain undeveloped.

Increased Invasive Aquatic and Semi-Aquatic Species. Invasive aquatic and semi-aquatic species known to occur, or having the potential to occur, in the Santa Clara River and other wetland and riparian areas include bullfrog (*Rana catesbeiana*), African clawed frog (*Xenopus laevis*), and crayfish (*Cambarus clarkii*) as well as non-native fishes, such as mosquito fish (*Gambusia affinis*) and largemouth bass (*Micropterus psalmodies*) (ENTRIX 2009). Several amphibian declines in the western United States have been associated with introduced aquatic predators (Doubledee *et al.* 2003). For example, experiments, field studies, and observations have found California red-legged

frog abundance to be negatively correlated with the presence of bullfrogs (Doubledee *et al.* 2003).

Alterations of the hydrology and thermal regimes in the Santa Clara River could favor establishment of mosquitofish and largemouth bass. For example, ENTRIX, Inc. (2009) found that mosquitofish were relatively rare in the Santa Clara River, except schools where schools of mosquito fish were collected in watercress-choked habitats in the downstream side of the Humble Crossing located downstream of Castaic Creek. ENTRIX, Inc. (2009) also found that road crossings of the River with several broad lateral backwaters (sometimes spring fed) appeared to provide good unarmored threespine stickleback habitat; however, no stickleback were found. ENTRIX, Inc. (2009) suggests that such marginal pools are also potentially preferred by, and encourage, exotic species like largemouth bass, African clawed frogs, green sunfish (*Lepomis cyanellus*), and mosquitofish.

Utility Transmission Lines. Powerlines, transmission towers, and utility poles can cause entanglements and electrocution of large birds, such as the California condor (*Gymnogyps californianus*), the golden eagle (*Aquila chrysaetos*), and other raptors (Lehman *et al.* 2007; Franson *et al.* 1995). Other potential secondary impacts associated with maintenance and repair of utility transmission lines were discussed above in relation to long-term RMDP secondary effects, including hydrologic and water quality alterations, erosion, chemical and toxic compounds pollution, dust, noise, vibration, lighting, increased human activity, temporary fencing, accidental clearing, trampling, grading, oak tree root impacts, and trash and other debris.

Microtrash. Microtrash, such as glass, bottle caps, wires, and screws, that may be ingested by young California condors is expected to increase with increases in the population resulting from build-out of the Project area.

Increased Risk of Disease. The increased human and associated pet population can increase of the risk of disease transmission to native wildlife in the Project area. For example, free-ranging domestic cats and dogs can transmit new diseases to wild animals. Mountain lions and other native wildlife, such as the raccoon, skunk, and fox, may be at risk to a variety of diseases from domestic cats, including feline immunodeficiency virus, feline leukemia virus, feline infectious peritonitis, feline and canine distemper, panleukopenia, and rabies (Foley 1996; Florida Fish and Wildlife Conservation Commission 2003).

The increased prevalence of non-native amphibians, such as the African clawed frog, which occurs in the Project area, increases the risk of disease transmission to native amphibians. Based on epidemiological evidence, the African clawed frog has been

proposed as the origin of spread of the amphibian chytrid fungus (*Batrachochytrium dendrobatidis*), which infects amphibians with the disease chytridiomycosis that is considered one of the main causes of amphibian die-offs worldwide (Weldon *et al.* 2004; Lefcort and Blaustein 1995). The African clawed frog was an international trade species beginning in the mid-1930s, and prior to that time, the amphibian chytrid fungus appeared to be limited to southern Africa (Weldon *et al.* 2004).

Diseases transmitted from humans and pets also may affect raptors, such as Cooper's hawk (*Accipiter cooperii*). Boal and Mannan (1999) found that mortality of nestling Cooper's hawks in urban settings primarily was from trichomoniasis, which is caused by the parasitic protozoan *Trichomonas gallinae* that occurs in the digestive and urogenital tracts of many animals and humans. This parasite causes lesions in the mouth, throat, and crop of birds and prevents infected individuals from eating. An important vector of trichomoniasis in urban areas may be domestic pigeons (*Columba livia*) and potentially wild doves (Columbidae), which are preyed upon by hawks and falcons. Stabler (1941) found that of 242 pigeons originating from Pennsylvania, Maryland, and New Jersey, 64.5% were infected with *Trichomonas gallinae*.

Some plant communities may be more vulnerable to diseases in urban settings. For example, overwatering resulting from urban runoff and summer irrigation or very wet precipitation cycles (or some combination of the two) can make oaks (*Quercus* spp.) more susceptible to various oak root diseases resulting from water mold fungi such as *Phytophthora* (Raabe 1990). The pathogen (*Phytophthora ramorum*) also infects the leaves and twigs of common ornamental nursery plants, such as rhododendrons and camellias, which serve as vectors for pathogen dispersal (COMTF 2008). Surveys in 2004 in southern California counties, including Los Angeles County, failed to detect this pathogen however, and the current documented southern extent of this pathogen is Monterey County (COMTF 2008). The risk of this pathogen spreading to southern California counties currently is considered to be low (COMTF 2008).

Open Space–Urban Interface Secondary Impacts. Secondary impacts under Alternatives 2 through 7 along the open space–urban interface, also called "edge" effects, are foreseeable impacts resulting from development and increased human populations that can result in chronic habitat degradation and decline or loss of species along the boundaries of open space areas. Similar to habitat fragmentation and isolation, edge effects reduce the effective total habitat area preserved in open space, which, in turn reduces effective population sizes of plant and wildlife species and increases the risk of local population extinctions. The sources and mechanisms of many of the edge effects discussed below are the same as described above for short-term construction-related impacts, but may have long-term chronic impacts rather than temporary impacts, and

thus, may permanently affect habitat conditions and species distributions at the boundary area between open space and development.

Increased Noise. Chronic increases in noise related to development primarily result from increased traffic volumes at all hours. Other sources of development-related increases in noise that may affect native wildlife include operation of landscape maintenance equipment and tools (*e.g.*, mowers, blowers, trimmers, wood chippers), active recreation at parks (particularly at night), loud music from vehicles and residences, and on-site heavy equipment and machinery use by commercial and industrial businesses.

Some of these noise sources, such as traffic noise, are relatively constant (although with daily cycles related to peak traffic periods), and some wildlife species may habituate and adapt to the chronic ambient noise levels, while others may avoid noisy areas. Other noise sources are more occasional or discrete and are more likely to startle wildlife and at least temporarily disrupt their behavior at the time. As described above for construction activities, noise may affect wildlife in several ways that disrupts both their behavior and physiology in complex and interactive ways, including startling or annoying, raising stress levels, interrupting sleep and rest, interfering with acoustic communications, interfering with prey detection, and in the case of loud abrupt noises, causing permanent injury to the auditory system (Dooling 2006; Barrass and Cohn 1984; Brattstrom and Bondello 1983).

Lighting. As reviewed above, ecological light pollution can have effects at the behavioral and population ecology level, the community ecology level, and the ecosystem level (Longcore and Rich 2004). These effects generally include orientation/disorientation and attraction/repulsion, reproduction, and communication at the behavioral and population ecology level, and competition and predation at the community ecology level, the effects of which would be expected to reverberate to the ecosystem level (Longcore and Rich 2004).

Ecological light pollution associated with build-out of the Project area generally would be chronic as a result of increased ambient light and direct glare from sky glare, lighted buildings, streetlights, and security lights. Lighting from vehicles will be both chronic and unexpected.

Pet, Stray, and Feral Animals. Development of the Project area will increase the number of pet cats and dogs, and increase the potential for stray and feral animals. Unconstrained pets at the interface between open space and residential development can have significant predation effects on native wildlife, including birds, rodents, reptiles, and amphibians (*e.g.*, Churcher and Lawton 1987; Kelly and Rotenberry 1993). Lost or abandoned pets may penetrate even further into open space areas in search of food or

refugia. Feral populations of dogs and cats are a particular problem because most of their food resources may be native prey.

Also, as noted above in the discussion of disease, domestic cats and dogs may be vectors for diseases that affect native wildlife, such as feline immunodeficiency virus, feline leukemia virus, feline infectious peritonitis, feline and canine distemper, panleukopenia, and rabies (Foley 1996; Florida Fish and Wildlife Conservation Commission 2003).

Microclimate Changes. Development may introduce microclimate changes at the open space–urban edge, such as alterations in wind, solar radiation and light exposure, and water that may have substantial effects on native vegetation and wildlife species (Saunders *et al.* 1991).

Increased wind exposure at the open space–urban interface may result in direct physical damage to vegetation (*e.g.*, windpruning and/or loosening of bark) or increase evapotranspiration, reduce humidity, and increase desiccation of plants that require adequate soil moisture for regeneration (Saunders *et al.* 1991). Increased wind also may increase dust levels and seed transport at edges, potentially interfering with photosynthesis and introducing non-native species (Saunders *et al.* 1991).

Alterations in solar radiation and light exposure can have numerous effects along edges. Daytime temperatures can be higher and nighttime temperatures lower than areas within intact natural vegetation patches, resulting in greater temperature ranges of the soil and increased chance of frost (Saunders *et al.* 1991). Soil nutrient cycling, soil moisture retention, invertebrate communities, and predator–prey relations at habitat edges also may be affected by altered soil temperatures (Saunders *et al.* 1991). Temperature alterations may also occur at the edge of aquatic habitats that exceed species' (*e.g.*, fish and amphibian) tolerances due to vegetation changes and sedimentation within streams.

Water alterations and related effects at habitat edges include change the rates of rainfall interception and evapotranspiration, soil moisture, water penetration pathways, surface flows, erosion, movement of salts, nutrients, pesticides, altered seedbed characteristics, and habitat alterations for ground-dwelling species (Saunders *et al.* 1991). Irrigation in fuel modifications zones, overspray from landscaped areas, and urban runoff may create edge areas with artificially high moisture, attracting invasive species such as Argentine ants (*Linepithema humile*) (Menke and Holway 2006). The Argentine ant has demonstrated negative impacts on native wildlife, such as coast horned lizard (*Phrynosoma coronatum*), which predominantly feeds on native harvester ants that are displaced by Argentine ants (Suarez and Case 2002), and may affect seed dispersers and pollinators of native plants due to its impact on the native invertebrate community.

All of these microclimate effects have the potential to alter habitats and microhabitats for a variety of native plant and wildlife species along the open space–urban interface.

Invasive Plant Species. Invasive plant species that thrive in edge habitats are a well-documented problem along the open space–urban interface in southern California, as well as throughout the United States. The California Invasive Plant Council (Cal-IPC 2008) lists several adverse effects of non-native species in natural open space areas: non-native plants degrade wildlife habitat value (*e.g.*, by forming monocultures that displace native communities that provide food and shelter for native wildlife) and are considered to be the greatest threat to threatened and endangered species after habitat destruction; certain invasive plants can increase fuel loads compared to native plants and facilitate more frequent and catastrophic fires; and some invasive plants (*e.g.*, giant reed and tamarisk) consume enormous amounts of water that is lost to native plants and wildlife.

The Project area already supports a number of non-native species, such as annual grasses (*Bromus* spp., *Avena* spp.), Mediterranean mustard (*Hirschfeldia incana*), black mustard, tocalote (*Centaurea melitensis*), and Russian thistle (*Salsola tragus*) at a landscape level as a result of historic disturbances such as grazing, oils and natural gas production, agricultural operations, and increasingly frequent wildfires. These species have essentially become naturalized and large-scale control or eradication is not feasible. However, development has the potential to increase the spread of these species due to widespread surface soil alterations, especially along roadsides and in fuel modification zones. Mustards, for example, are common invasive species that can quickly invade disturbed areas adjacent to development and along roadsides. Development also has the potential to increase non-native invasive species used in landscaping, such as pampas grass.

Wildlife Community Alterations. Wildlife community alterations may occur along the open space–urban interface due to development-induced habitat degradation. One well-documented effect is an increase in brown-headed cowbirds (*Molothrus ater*), which parasitize the nests of several native birds, including least Bell's vireo (*e.g.*, Sharp and Kus 2006). Rottenborn (1999), for example, characterized wildlife species as being "tolerant" or "sensitive" to urbanization. The "tolerant" species include several birds that are commonly thought of as urban-related, such as the rock dove (*Columbia livia*), the mourning dove (*Zenaida macroura*), the western scrub-jay (*Aphelocoma californica*), the American crow (*Corvus brachyrhynchos*), the northern mockingbird (*Mimus polyglottos*), and the bushtit (*Psaltriparus minimus*). Urban "sensitive" species included both year-long resident species, such as the California quail (*Callipepla californica*), the acorn woodpecker (*Melanerpes formicivorus*), the Bewick's wren (*Thryomanes bewickii*), and

the California thrasher (*Toxostoma redivivum*), as well as migrants, such as the willow flycatcher (*Empidonax traillii*) and the yellow warbler (*Dendroica petechia*). Permeability to invasive species such as the cowbird, or urban-tolerant species may be increased through reductions in plant structure and cover related to increased human activity in the area, and especially related to fuel modification activities along habitat edges. These species may outcompete resident native species for resources (*e.g.*, habitat, food, nesting locations) or directly prey on or parasitize the native residents. European starlings (*Sturnus vulgaris*), for example, may directly compete with native cavity nesters for nest sites in urban settings.

Longcore (2003) documented adverse edge effects within fuel modification thinning zones in coastal sage scrub, including the loss of arthropod diversity and increases in exotic species, such as Argentine ants, European earwigs (*Forficula auricularia*), pillbugs (*Armadillidium vulgare*), sowbugs (*Porcellio* sp.), and sowbug killers (*Dysdera crocata*), which, in turn, negatively affect predator species, such as the coast horned lizard and arachnids, such as scorpions and trap-door spiders.

Trampling of Vegetation and Compaction of Soils. Increases in human activity along the open space–urban interface may result in trampling of vegetation and compaction of soils, affecting the viability of plant communities, wildlife habitat quality, and species that are sensitive to habitat structure, such as shrub and herbaceous vegetation integrity, soil friability, and burrowing substrate quality (*e.g.*, rodents, reptiles, amphibians, and invertebrates). Trampling of vegetation and compaction of soils probably also interacts with the microclimate/microhabitat alterations discussed above, and especially water alterations and related effects at habitat edges such as changes in the rate of rainfall interception and evapotranspiration, soil moisture, water penetration pathways, surface flows, and erosion.

Pesticides, Fertilizers, Fungicides, Herbicides, and Rodenticides. Pesticides, fertilizers, fungicides, herbicides, and rodenticides may directly affect vegetation communities and habitat quality, be directly toxic to species, indirectly toxic through prey vectors, or reduce prey abundance. These substances may penetrate the open space–urban interface through urban runoff from residential and commercial landscape areas and golf courses, overspray, wind, direct applications in interface areas, soil penetration, and wildlife vectors.

Pesticides, for example, can act in several ways. The original pesticide can be toxic, its decomposed elements can be even more toxic, and it can "bio-accumulate," whereby the contaminant concentrates in each link of the food chain, and thus reaches high concentrations at each higher level of the food chain. DDT and other chlorinated

hydrocarbon pesticides have been used worldwide to control crop pests and disease-carrying insects since the 1940s. DDT was banned in the United States by the EPA in 1972 because of unacceptable risks to the environment and potential harm to human health (EPA 1972). Long-term ecological exposure and accumulation resulted in eggshell thinning and loss of young in many raptorial bird species, resulting in serious declines in reproductive success (Terres 1980; Henny and Wight 1972). Negative impacts on survival and reproductive success of burrowing owls (*Athene cunicularia*) may occur due to direct toxicity, and was observed when Carbofuran, a carbamate insecticide, was sprayed over nest burrows (County of Riverside 2008). Indirect mortality due to contaminated prey may also be significant, but this is unknown to date. The weights of breeding western burrowing owls (*A. c. hypugaea*) on pastures where strychnine-coated grain is used to control ground squirrels are significantly lower than on control pastures, suggesting a sublethal effect or less food available. Organochlorine residues were found in adult and juvenile western burrowing owls in Saskatchewan, but the effect on reproduction was not documented (County of Riverside 2008).

Fertilizers, as discussed above, can enter wetland and riparian systems and cause algae blooms and eutrophication. They also can enhance growth of non-native species in edge areas.

Rodenticides may also affect wildlife in various ways. Rodenticides are directly toxic to rodents, but may also indirectly affect rodent predators, such as hawks and owls, coyotes, snakes, *etc.* either through loss or contamination of prey. Eradication of rodents also can affect habitat quality for other species, such as burrowing owls that use ground squirrel burrows and many species of reptiles, amphibians, and insects that use rodent burrow as refugia, aestivation, and hibernation.

Human Collection and Harassment of Native Species. Increased human populations increase the risk of collection of certain species for the pet trade (*e.g.*, rare snakes, such as the rosy boa (*Charina trivirgata*) and the coast horned lizard) or incidentally by children (*e.g.*, slow-moving, non-aggressive snakes, the coast horned lizard, and the southwestern pond turtle as well as most frogs and toads) because of easier access to open space areas. Commercial collecting of the coast horned lizard was banned in 1981, but, prior to this time, the lizard was extensively exploited by the pet and curio trade (Nafis 2008). Similarly, the rosy boa has increased in its popularity in the pet trade (Fisher 2003).

4.5.5.2 Impacts to Vegetation Communities, Land Covers, Unique Landscape Features, and Wildlife, Including Impact Analysis for Alternative 1 (No Action/No Project)

4.5.5.2.1 Summary Descriptions of the EIS/EIR Alternatives

In general, the six alternatives other than the No Action/No Project alternative were designed in an attempt to provide a gradation in the levels of environmental impacts that would result from the Project. Specifically, alternatives were designed to provide a broad range of options for avoiding impacts to jurisdictional waters and impacts to the San Fernando Valley spineflower. As impacts to jurisdictional waters would be primarily associated with the construction of bridges and the grading and realigning of drainages, alternative configurations for these facilities were evaluated in depth. Similarly, because the Project would potentially impact all San Fernando Valley spineflower areas not designated as spineflower preserves, a broad range of possible preserve designs were evaluated. The alternatives are generally designed to further reduce impacts when compared to the proposed Project (Alternative 2). For example, Alternative 3 modifies the proposed Spineflower Conservation Plan (SCP) by adding additional spineflower preserve acreage at the Airport Mesa and Entrada populations. The preserve design under Alternative 4 retains these additional acreages, and further adds spineflower preserve acreage at the Potrero Canyon and Grapevine Mesa populations. This subsection provides a brief narrative summary of the key features of each of the alternatives considered in this EIS/EIR in order to provide the context for the impact analyses that follow. **Table 4.5-23**, Key Components of Alternatives, provides a summary of the key components for each of the Project alternatives.

4.5.5.2.1.1 *Alternative 1 (No Action/No Project)*

- The proposed RMDP and SCP would not be approved, and the requested comprehensive state and federal authorizations would not be granted.
- No change in existing land use practices; oil and gas, grazing, and cultivated agriculture would continue on site.
- No preserves or natural open space set-asides would be dedicated.
- The previously approved Specific Plan and VCC developments would not go forward.
- The planned development within the Entrada planning area would not go forward.

The impact analysis for the effects of Alternative 1 (No Action/No Project) is provided below in **Subsection 4.5.5.2.2**, including for general vegetation communities and land covers; unique landscape features; special-status vegetation communities; general wildlife; special-status wildlife; wildlife habitat linkages, corridors, and crossings; and special-status plants. This analysis is presented in summary fashion in this section for special-status wildlife and plant

species in order to avoid repeating the same analysis for each of the 92 special-status species in **Subsection 4.5.5.3**.

Table 4.5-23
Key Components of Alternatives

Project Component	Alternative 1	Alternative 2	Alternative 3	Alternative 4	Alternative 5	Alternative 6	Alternative 7
Santa Clara River bridges	0	3 (Potrero Canyon Road, Long Canyon Road, Commerce Center Drive)	2 (No bridge at Potrero Canyon Road)	2 (No bridge at Potrero Canyon Road)	3, with a long span at Potrero Canyon Road	2 (No bridge at Commerce Center Drive)	1 (No bridge at Commerce Center Drive or Potrero Canyon Road)
Santa Clara River bank stabilization	None	Installed	Installed	Installed	Installed	Installed	Installed outside 100-year floodplain
Tributaries converted to storm drain	None	Minor drainages except for those in Humble and Ayers canyons	Minor drainages except for those in Humble and Ayers canyons	Minor drainages except for those in Humble and Ayers canyons	Minor drainages except for those in Humble and Ayers canyons	Minor drainages except for those in Humble, Ayers, and upper Middle canyons	Minor drainages except for those in Humble, Ayers, Magic Mountain, and Middle canyons
Tributaries realigned	None	Major tributaries, narrowest channels	Major tributaries, somewhat widened channels	Major tributaries, narrowest channels, lower Potrero canyon avoided	Major tributaries, Potrero, Chiquito, San Martinez Grande canyons greatly widened	Major tributaries, all channels greatly widened	None. Major tributaries preserved in place
Tributary road crossings	0 bridges 0 culverts	0 bridges 19 culverts	3 bridges 16 culverts	2 bridges 17 culverts	7 bridges 12 culverts	9 bridges 12 culverts	18 bridges 4 culverts
Spineflower preserve acres	0	167.5	221.2	259.4	338.4	891.9	659.2
Percent preservation of cumulative spineflower habitat	N/A	68.6%	76.6%	81.6%	83.3%	87.5%	96.9%
Dwelling units facilitated	0	22,610	21,558	21,864	21,155	20,212	17,323
Commercial and industrial total square feet facilitated	0	10,220	10,153	5,933	5,865	5,784	3,815

4.5.5.2.1.2 *Alternative 2 (Proposed Project)*

- The RMDP and SCP would be approved as proposed by the Project applicant and the requested comprehensive state and federal authorizations would be granted.
- Three major roadway bridges across the Santa Clara River would be authorized, including the Commerce Center Drive Bridge (previously approved by the Corps and CDFG in 1999),[1] the Potrero Canyon Road Bridge, and the Long Canyon Road Bridge.
- Major tributaries would be re-graded and realigned to facilitate and protect urban development.
- Nearly all minor tributaries would be graded and converted to buried storm drain systems.
- Five spineflower preserves would be established within the Specific Plan and Entrada planning areas, totaling 168 acres and preserving 68.6% of the cumulative habitat occupied by spineflower; no spineflower preservation would occur within the VCC planning area.
- This alternative would facilitate urban development, including 22,610 residential units and 10,220 thousand square feet of commercial and industrial floor space.

4.5.5.2.1.3 *Alternative 3 (Elimination of Potrero Canyon Road Bridge and Addition of Additional Spineflower Preserves)*

- The RMDP and SCP would be modified from those proposed by the Project applicant, and the requested comprehensive state and federal authorizations would be granted consistent with said modifications.
- Two major roadway bridges across the Santa Clara River would be authorized, including the Commerce Center Driver Bridge (previously approved by the Corps and CDFG in 1999) and the Long Canyon Road Bridge. The Potrero Canyon Road Bridge would not be constructed under this alternative.
- Although major tributaries would be re-graded and realigned under this alternative, the channels would be wider than those of the proposed Project (Alternative 2). The cismontane alkali marsh in lower Potrero Canyon would be avoided.
- Additional spineflower preserve acreage would be dedicated at the sites of the Airport Mesa and Entrada populations. Alternative 3 would provide a total of 222 acres of

[1] The Commerce Center Drive Bridge was previously analyzed in the Final EIS/EIR (CDFG and Corps 1998) prepared and approved by the Corps and CDFG in connection with the previously adopted NRMP.

spineflower preserves and would protect 77.2% of the cumulative habitat occupied by spineflower on site.

- This alternative would facilitate urban development within the Specific Plan, VCC, and Entrada planning areas, including 21,558 residential units and 10,153 thousand square feet of commercial and industrial floor space.

4.5.5.2.1.4 *Alternative 4 (Inclusion of VCC Preserve Area and Elimination of Potrero Canyon Road Bridge)*

- The RMDP and SCP would be modified from those proposed by the Project applicant, and the requested comprehensive state and federal authorizations would be granted consistent with said modifications.
- Two major roadway bridges across the Santa Clara River would be authorized, including the Commerce Center Driver Bridge (previously approved by the Corps and CDFG in 1999) and the Long Canyon Road Bridge. The Potrero Canyon Road Bridge would not be constructed under this alternative.
- Major tributaries would be re-graded and realigned under this alternative, but cismontane alkali marsh in lower Potrero Canyon would be avoided.
- Additional spineflower preserve acreage would be dedicated at the sites of the Airport Mesa, Potrero Canyon, Grapevine Mesa, and Entrada populations. A spineflower preserve would also be established within the VCC planning area. Alternative 4 would provide a total of 260 acres of spineflower preserves and would protect 82.2% of the cumulative habitat occupied by spineflower on site.
- This alternative would facilitate urban development within the Specific Plan and Entrada planning areas, including 21,864 residential units and 5,933 thousand square feet of commercial and industrial floor space. No development would be facilitated within the VCC planning area.

4.5.5.2.1.5 *Alternative 5 (Widened Tributary Channels)*

- The RMDP and SCP would be modified from those proposed by the Project applicant, and the requested comprehensive state and federal authorizations would be granted consistent with said modifications.
- Three major roadway bridges across the Santa Clara River would be authorized, including the Commerce Center Driver Bridge (previously approved by the Corps and CDFG in 1999), the Potrero Canyon Road Bridge, and the Long Canyon Road Bridge. The Potrero Canyon Road Bridge would have a longer span under this alternative than under the proposed Project (Alternative 2), and the northern abutment would be pulled back to lessen impacts to the Santa Clara River.

- Major tributaries would be re-graded and realigned under this alternative. This alternative would result in substantial impact reductions in the Chiquito Canyon, San Martinez Grande Canyon, and Potrero Canyon drainages compared to the proposed Project (Alternative 2).
- Additional spineflower preserve acreage would be dedicated at the sites of the Airport Mesa, Potrero Canyon, Grapevine Mesa, San Martinez Grande, and Entrada populations. A spineflower preserve would also be established within the VCC planning area. Alternative 5 would provide a total of 339 acres of spineflower preserves and would protect 84.0% of the cumulative habitat occupied by spineflower on site.
- This alternative would facilitate urban development within the Specific Plan and Entrada planning areas, including 21,155 residential units and 5,865 thousand square feet of commercial and industrial floor space. No development would be facilitated within the VCC planning area.

4.5.5.2.1.6 *Alternative 6 (Maximum Spineflower Expansion/Connectivity)*

- The RMDP and SCP would be modified from those proposed by the Project applicant, and the requested comprehensive state and federal authorizations would be granted consistent with said modifications.
- Two major roadway bridges across the Santa Clara River would be authorized, including the Potrero Canyon Road Bridge—with an extended span similar to that proposed under Alternative 5—and the Long Canyon Road Bridge. The previously approved Commerce Center Drive Bridge would not be constructed under this alternative.
- Major tributaries would be re-graded and realigned under this alternative. However, all realigned channels would be many times wider under this alternative than under the proposed Project (Alternative 2), and the majority of proposed road crossings along the channels would be bridges as opposed to culverts.
- This alternative would designate spineflower preserves at the sites of all six spineflower populations, but would designate one large preserve per population rather than several smaller preserves as proposed under the other alternatives. Alternative 6 would substantially increase spineflower preserve acreage on site and would provide a total of 891 acres of spineflower preserves, protecting 88.3% of the cumulative habitat occupied by spineflower on site.
- This alternative would facilitate urban development within the Specific Plan and Entrada planning areas, including 20,212 residential units and 5,784 thousand square feet of commercial and industrial floor space. No development would be facilitated within the VCC planning area.

4.5.5.2.1.7 *Alternative 7 (Avoidance of 100-Year Floodplains and Spineflower)*

- The RMDP and the SCP would be modified from those proposed by the Project applicant, and the requested comprehensive state and federal authorizations would be granted consistent with said modifications.
- Only one roadway bridge across the Santa Clara River would be authorized, located at Long Canyon Road. The Potrero Canyon Road Bridge and the previously approved Commerce Center Drive Bridge would not be constructed under this alternative. Bank stabilization along the River would be constructed outside the 100-year floodplain.
- Under this alternative, major tributaries would not be re-graded or realigned. Bank stabilization would be constructed to protect development but would be located outside the 100-year floodplains of these drainages. In addition, the Middle Canyon and Magic Mountain Canyon drainages, which are proposed for conversion to buried storm drains under the proposed Project (Alternative 2), would be preserved.
- Alternative 7 was designed to achieve maximal avoidance of cumulative habitat occupied by spineflower. This alternative would designate spineflower preserves with 300 feet of buffer areas surrounding all cumulative habitat occupied by spineflower. Alternative 7 would provide a total of 661 acres of spineflower preserves, protecting 98.2% of the cumulative habitat occupied by spineflower on site.
- This alternative would facilitate urban development within the Specific Plan and Entrada planning areas, including 17,323 residential units and 3,815 thousand square feet of commercial and industrial floor space. No development would be facilitated within the VCC planning area.

4.5.5.2.2 Comparative General Impacts of EIS/EIR Alternatives, Including Alternative 1 (No Action/No Project)

4.5.5.2.2.1 *Alternative 1 (No Action/No Project)*

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. No preserves or natural open space set-asides would be dedicated or managed. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. The long-term effects of Alternative 1 are that adverse anthropogenic (human-related) disturbances evident in the Project area would continue for the foreseeable future. As described in more detail in **Subsection 4.5.3.3**, Existing Conditions by Project Area, existing disturbances that result in habitat loss and degradation include road construction and maintenance, grazing lots, oil pad construction, and agricultural activities. Cattle grazing, in particular, has broad-ranging effects on habitat conditions, including direct impacts on native vegetation (including preventing

recovery of shrub communities from wildfires), erosion, and impaired water quality. During warm, dry periods cattle often congregate in riparian and wetland areas, causing additional localized damage to these areas. For example, in Middle and Potrero canyons, cattle are the dominant foragers in portions of the remaining riparian communities. Extensive grazing may also "powder out" soft soils that quickly become denuded of vegetation, reducing habitat quality and increasing erosion.

4.5.5.2.2.2 *Vegetation Communities and Land Covers*

Existing land uses are described in more detail below in relation to the five general vegetation community types and one man-made land cover type organized by the general physiognomic and physical locations and human-dominated cover types identified in the Project area and listed in **Table 4.5-17.**

Grass and Herb Dominated Communities. This category includes California annual grassland and purple needlegrass. Because only 0.6 acre of purple needlegrass was mapped on site, this discussion addresses the effect of existing land use practices on California annual grassland.

As a non-native community, California annual grassland generally is a consequence of past land use practices in the Project area that have disturbed the native vegetation communities, including cattle grazing and mechanical disturbances such as mowing, scraping, disking and spraying. Frequent, repetitive fire also results in type conversion to California annual grasslands as native shrub communities are less able to recover. Existing land use practices under Alternative 1, and especially grazing, would be expected to facilitate continued type conversion of native communities to California annual grassland and prevent or inhibit recovery of native shrub communities. However, cattle grazing, which disturbs soils and helps distribute non-native species, would also facilitate "disturbance" of California annual grassland by spreading weedy non-native species such as black mustard and tocalote that degrade habitat value for native forbs that can co-exist with non-native grasses (bromes and wild oats), as well as grassland wildlife species. Such areas become more disturbed or ruderal than California annual grassland and generally have less resource value for native plant and wildlife species. Dirt roads and other mechanical disturbances within California annual grassland related to agricultural and oil and gas production can also facilitate colonization of non-native weedy species. Irrigation and runoff from agricultural fields, including fertilizers, can also promote the growth and dispersal of non-native weedy species, especially along the interface between agriculture and California annual grassland.

Scrub and Chaparral. This category includes several general habitat types, including coastal scrub, undifferentiated chaparral scrubs, chamise chaparral, scrub oak chaparral, and *Eriodictyon* scrub. Most of the effects of existing land use practices on scrub and

chaparral are related to cattle grazing. Cattle wander through and browse on shrub vegetation, particularly in areas that have been previously disturbed by fire or occur on gentle slopes. This activity results in trampling of native vegetation and soils and facilitates type conversion to California annual grassland and weedy communities, as well as erosion. Dense, intact stands of scrub and chaparral in steep rugged terrain probably are not substantially affected by cattle.

Apart from direct habitat loss, agriculture and oil and gas production have fewer direct effects on scrub and chaparral, but may still have adverse edge effects. Irrigation and runoff, including fertilizers and other chemical pollutants, may affect scrub and chaparral vegetation along the interface between fields and native vegetation, resulting in potential decreased productivity of the native vegetation and increased non-native invasive species. Maintenance of oil and gas production facilities and access roads such as mechanical clearing and grading also facilitates colonization by non-native invasive species. Dust from disking, vehicles, movement of farm equipment, and other operations also may reduce the vigor and productivity of adjacent scrub and chaparral through effects on light and penetration as well as photosynthesis, respiration, transpiration; increased penetration of phytotoxic gaseous pollutants; and increased incidence of pests and diseases.

Broad Leafed Upland Tree Dominated. This category includes two general habitat types: oak woodland and forest and California walnut woodland and forest, of which oak woodlands comprise approximately 98%. Because walnut woodland and forest is such a small component of this category, this discussion is focused on oak woodland and forest. Similar to scrub and chaparral, most of the effects of existing land use practices on oak woodland and forest are related to cattle grazing. Woodland and forest areas accessible to cattle in the High Country SMA and Salt Creek area exhibit grazing pressure, with the understory of woodland areas dominated by non-native grasses such as wild oat, slender oat, and bromes. In oak/grass areas there appears to be low recruitment of oaks, possibly due to cattle foraging on and trampling seedlings and saplings and impacts on acorn viability. Oak seedlings may also have to compete for water and other soil nutrients with the non-native grasses associated with grazing. Under Alternative 1, cattle grazing would continue in the High Country SMA/Salt Creek area, whereas under Alternatives 2 through 7, grazing would be terminated, with exception of the long-term management of resources.

Apart from direct habitat loss, agriculture and oil and gas production have fewer direct effects on oak woodlands and forests, but may still have adverse edge effects. Irrigation and runoff, including fertilizers and other chemical pollutants, may affect oak woodlands. A variety of oak diseases and blights are associated with modified water regimes, especially from irrigation (Swiecki and Bernhardt 1996). Root rot can result from overwatering and oaks can also suffer from dewatering if groundwater is pumped out for

agriculture. Weakened oaks are also more vulnerable to bark beetles. Maintenance of oil and gas production facilities and access roads, including activities such as mechanical clearing and grading, also facilitates colonization by non-native invasive species that may compete for water and nutrients. Dust from disking, vehicles, movement of farm equipment, and other operations also may reduce the vigor and productivity of oaks, as noted above for scrub and chaparral.

Because existing land use practices, and associated adverse impacts, have been in place for many decades and because of the longevity of oak trees, it is expected that the extent and distribution of oak woodlands and forests in the Project would remain essentially the same for the foreseeable future under Alternative 1.

Bog and Marsh. This category includes three general types: cismontane alkali marsh, bulrush-cattail wetland, and coastal and valley freshwater marsh. The cismontane alkali marsh is the dominant of the three types, accounting for 85% of the total. It is located mainly in middle and lower Potrero Canyon and at the confluence of the East Fork and mainstem of Salt Creek. Cismontane alkali marsh on site has low vegetative diversity and appears to be tolerant of cattle grazing and other existing land use practices. Its extent and distribution on site would not be expected to substantially change under Alternative 1. Bulrush-cattail wetland only occurs in two small locations along lower Salt Creek. Because of its limited distribution and extent on site, it probably has relatively low resource value. It is currently subject to cattle grazing and congregating and its status on site would likely remain the same under Alternative 1. Freshwater marsh is limited to the lower to middle reach of Potrero Creek and is relatively intact and undisturbed. With existing land use practices, it is expected that the extent and status of freshwater marsh would remain the same under Alternative 1.

Riparian and Bottomland Habitat. This category includes a variety of riparian, scrub, and wetland types associated with the Santa Clara River, Castaic Creek, and tributaries (see **Table 4.5-17**). A number of these habitat types are also special-status vegetation communities and are discussed in more detail in **Subsection 4.5.3.4.4**. This discussion provides a broader analysis of the effects of Alternative on these habitat types.

The common disturbances resulting from existing land use practices for the riparian and bottomland habitats on site are cattle grazing within and agricultural operations adjacent to the Santa Clara River, creeks, and tributaries. Cattle grazing can substantially affect these habitat types, and particularly the riparian communities. Cattle, grazing and congregating in riparian habitat, result in damage to the riparian understory, which affects the vigor and productivity of the community and prevents or inhibits recruitment of important constituents such as willows and cottonwood trees. Damage to the horizontal and vertical structure of the habitat, as well as altering hydrology and impairing water

quality, can also facilitate colonization by non-native invasive plants and animals (such as brown-headed cowbirds) and reduces habitat quality for many native wildlife species such a nesting birds, amphibians and semi-aquatic reptiles such as southwestern pond turtle and two-striped garter snake. Damage to riparian habitat structure by cattle can also alter wind and solar exposures along the edges of the habitats, thus altering soil moisture, nutrient conditions, and species relationships in these edge areas. Cattle impacts to riparian-associated scrub habitats, such as arrow weed scrub, mulefat scrub, big sagebrush scrub, and Mexican elderberry scrub, as well as river wash, are probably less adverse, and these disturbance-maintained and early successional or seral habitats may in fact be partly maintained by cattle disturbance. Cattle impacts to riparian and bottomland habitats are most prevalent in the mainstem Salt Creek, the East Fork of Salt Creek, and in Potrero Creek.

Riparian and bottomland habitats are also highly vulnerable to edge effects from agricultural practices, primarily irrigation runoff including fertilizers and other chemical pollutants that can impair water quality and the vigor of plants, and can facilitate the dispersion and growth of non-native invasive species. Perennialized stream flows resulting from irrigation also may substantially alter the hydrology (*e.g.*, surface and subsurface flows, natural infiltration, and ground water) and geomorphology (coarse sediment transport and deposition) of riparian and bottomland systems that are adapted to seasonal ephemeral and intermittent flow patterns (timing and magnitude of peak flows). Perennialized flows may result in type conversion to habitats better adapted to wetter conditions, such as marshes, ponds, and backwater areas with emergent vegetation and algae blooms as opposed to more natural riparian systems such as southern willow scrub, southern cottonwood–willow riparian forest, and coast live oak riparian forest.

Dust from disking, vehicles, movement of farm equipment, and other operations also may reduce the vigor and productivity of riparian and bottomland habitats, as noted above for scrub and chaparral.

Under Alternative 1, these existing land use practices would continue for the foreseeable future. The native riparian and bottomland habitats would not be restored, enhanced, or managed, including removal of cattle (except for long-term resource management) as they would under Alternatives 2 through 7.

Man-Made Land Cover Types. This category includes agriculture, developed land, and disturbed land, which are the result of existing land use practices. These land uses would remain the same for the foreseeable future under Alternative 1. However, conversion of agriculture or disturbed land to development (for oil and gas production, for example) could reduce habitat value in these areas for some wildlife species such as foraging

raptors and other species that forage or nest in agricultural areas such as California horned lark.

4.5.5.2.2.3 *Unique Landscape Features*

River Corridor SMA. Under Alternative 1, the River Corridor SMA would continue to provide resident habitat for wildlife and function as a regional east-west wildlife habitat linkage and wildlife corridor. However, under Alternative 1, specific protection, restoration and enhancement, and management of the River Corridor SMA would not occur. Along with the existing benefit of the River Corridor SMA to the watershed and wildlife, the negative impacts of existing land use practices would continue. Agricultural operations immediately adjacent to the River corridor would continue and temporary road crossings and associated culverts would be constructed and used. The oxbows and lateral ponding that occur at these crossings provide potential habitat for native species such as southwestern pond turtle and unarmored threespine stickleback, but also provide habitat for exotic predators such as African clawed frog, largemouth bass, green sunfish, mosquitofish, and crayfish. These potential conditions would continue and monitoring and management of African clawed frogs and crayfish would not occur. Runoff from agricultural fields would continue, contributing to perennial high velocity flows in the River that are detrimental to the unarmored threespine stickleback.

Water quality and hydrology in the River Corridor SMA would be expected to generally remain the same under Alternative 1. Existing pollutant concentrations, for example, generally are higher compared to predicted levels for build-out of the Project area. **Section 4.4**, Water Quality, concluded that while total runoff ammonia, total nitrogen, trace metals, and chloride loads and dissolved copper concentration would be higher with build-out compared to existing conditions, concentrations of all modeled constituents (except for dissolved copper) would decrease when compared to existing conditions.

Concentrations of hydrocarbons and Methylene Blue Activated Substances (MBAS), which is related to the presence of detergents in runoff, and concentrations of pathogens, pesticides, trash and debris, and cyanide may increase with build-out compared to existing conditions.

High Country SMA and Salt Creek Area. Under Alternative 1, the High Country SMA and Salt Creek area would continue to provide wildlife habitat value and regional wildlife habitat connectivity function. However, specific protection, restoration and enhancement, and management, including removal of cattle grazing (except for long-term resource management), would not occur under Alternative 1. Therefore, an increase in wildlife habitat value resulting from riparian and oak woodland restoration and enhancement, for example, would not occur. The adverse effects of cattle grazing, including the trampling of native vegetation and soils, and facilitating colonization by

invasive species and type conversion of coastal scrub and chaparral to annual grassland would continue under Alternative 1.

Middle Canyon Spring. Under Alternative 1, the Middle Canyon Spring would remain intact, but would not be specifically protected, monitored, or managed.

4.5.5.2.2.4 *Special-Status Vegetation Communities*

Purple Needlegrass. Because there is only a very small area of purple needlegrass (less than 1.0 acre) in the High Country SMA, existing land use practices under Alternative 1 are not expected to substantially affect this special-status vegetation community on site.

California Walnut Woodland. California walnut woodland comprises approximately 27 acres, locally distributed on the south-facing slopes in the Salt Creek area and in the southern portion of the High Country SMA. The existing land use practice most likely to affect this community is cattle grazing, which can result in browsing of seedlings and saplings and trampling of soils, and facilitate invasion by non-native grasses and weeds. Non-native species may affect walnut seed bank characteristics and seedlings by competing for moisture and nutrients. Under Alternative 1, areas supporting California walnut woodland would not be protected, restored and enhanced, or managed, including removal of cattle grazing (except for long-term resource management).

Valley Oak Woodland and Valley Oak/Grass. Valley oak woodland and valley oak/grass on site comprise approximately 541 acres. Valley oak woodland occurs in relatively small patches in the southern portions of Salt Creek, the High Country SMA, and the East Fork of Salt Creek and in other smaller, scattered patches in the Windy Gap area and along the Santa Clara River north of Airport Mesa. Much larger patches of valley oak/grass occur on site in the southern portion of the Salt Creek area and High Country SMA, as well as smaller patches between the East Fork of Salt Creek and Potrero Canyon and the Magic Mountain Canyon area. The existing land use practice most likely to affect these communities is cattle grazing, which can result in browsing of seedlings and saplings and trampling of acorns and soils, and facilitate invasion by non-native grasses and weeds. Non-native species may affect oak seedlings by competing for moisture and nutrients. Under Alternative 1, areas supporting valley oak woodland and valley oak/grass would not be protected, restored and enhanced, or managed, including removal of cattle grazing (except for long-term resource management).

Herbaceous Wetlands. Special-status herbaceous wetlands on site include bulrush-cattail wetland, cismontane alkali marsh, coastal and valley freshwater marsh, herbaceous wetland, and river wash.

Bulrush-cattail wetland only occurs in two small locations along lower Salt Creek. Because of its limited distribution and extent on site, it probably has relatively low resource value. It is currently subject to cattle grazing and congregating, and its status on site would likely remain the same under Alternative 1.

Cismontane alkali marsh is located mainly in middle and lower Potrero Canyon and at the confluence of the East Fork and mainstem of Salt Creek. Cismontane alkali marsh on site has low vegetative diversity and appears to be tolerant of cattle grazing and other existing land use practices. Its extent and distribution on site would not be expected to substantially change under Alternative 1.

Freshwater marsh is limited to the lower to middle reach of Potrero Creek and is relatively intact and undisturbed. With existing land use practices, it is expected that the extent and status of freshwater marsh would remain the same under Alternative 1.

Herbaceous wetland on site appears to be an early seral form of riparian vegetation where past flooding (particularly during the winter of 2004/2005) has severely altered the bed of the Santa Clara River by scouring and deposition. It also appears to be highly susceptible to non-native riparian species such as giant reed and tamarisk. Under Alternative 1, these conditions would continue because the Santa Clara River corridor would not be specifically protected and restoration and enhancement, and management would not occur.

River wash is common in the Santa Clara River. It is a naturally dynamic habitat with unvegetated and sparsely vegetated areas that are subject to scouring by typical seasonal storm flows and major resetting events. However, river wash has also probably become more prevalent in the River in the recent past due to alterations of upstream flows, which exacerbate conditions. Under Alternative 1, existing conditions, including perennial flows in the River, would continue, likely maintaining or increasing the amount of the river wash in the Santa Clara River system.

Riparian Scrub. Special-status riparian scrub on site includes alluvial scrub, arrow weed scrub, big sagebrush scrub, giant reed, Mexican elderberry, mulefat scrub, southern willow scrub, and shrub tamarisk.

Alluvial scrub and big sagebrush scrub are similar in that both occur in alluvial areas along washes and are more tolerant to xeric conditions than other riparian scrubs and include a mixture of wetland species and transitional sage scrub species where alluvial processes and other disturbance factors affect the pattern of vegetation. Cattle grazing is probably the main existing land use practice that affects these two communities where they occur in tributaries to the Santa Clara River, such as the East Fork of Salt Creek,

resulting in trampling of vegetation and soils, and facilitation of invasive non-native species.

Arrow weed scrub and mulefat scrub are also similar in that both are disturbance-maintained or seral communities. Cattle grazing probably affects both communities through trampling and soils disturbances and facilitation of invasive non-native species such as horehound and short-podded mustard, tocalote, and tree tobacco.

Mexican elderberry scrub occurs in several small patches on site, including upper and lower Salt Creek, tributaries to the East Fork of Salt Creek, between middle Potrero Canyon and the East Fork of Salt Creek, lower Homestead Canyon, San Martinez Grande Canyon, south and west of middle Long Canyon, and along Middle Canyon. Overall, this community is relatively intact and undisturbed on site, although a small area was mapped as disturbed west of Long Canyon. Under Alternative 1, this community would be expected to remain essentially the same as existing conditions. However, continued cattle grazing in this community may facilitate the invasion of non-native species such as nettle-leaved goosefoot, horehound, milk thistle, Italian thistle, short-podded mustard, and tree tobacco.

Southern willow scrub is fairly common on site, with occurrences along the Santa Clara River, upper and lower Potrero Creek, upper and lower Salt Creek, and the East Fork of Salt Creek. This community is successional and is intact and relatively undisturbed on site, except for the stands in Potrero Creek, which have experienced greater disturbance associated with grazing activities. Grazing (including cattle congregating and resting in riparian zones), which would continue under Alternative 1, disturbs the understory and structure of southern willow scrub, facilitating invasion by non-native species on site such as yellow sweet-clover, white sweet-clover, tumble mustard, hedge mustard, milk thistle, tamarisk, short-podded mustard, and cheeseweed, reducing it value as nesting habitat for species such as the least Bell's vireo and other riparian bird species. Cattle grazing and congregating in southern willow scrub also impairs water quality. Agricultural operations adjacent to the River Corridor SMA also would continue and potential edge effects from these operations; such as irrigation runoff, including fertilizers, and dust from disking and vehicles; could affect the vigor and vitality of southern willow scrub. Fertilizers may facilitate the distribution and growth of weedy species at the edges of this community. Under Alternative 1, specific protection, restoration and enhancement, and management, including removal of cattle (except for long-term resource management) of southern willow scrub would not occur.

Giant reed and shrub tamarisk are both non-native invasive species in riparian and wetlands systems. Large stands of giant reed occur along flood-scoured portions of the main channel of the Santa Clara River, as well as in occasional smaller clumps that were

too small to be mapped as a separate vegetation community. Tamarisk occurs in small, fairly monotypic patches at the lower end of Salt Creek, in middle and lower Potrero Canyon, in Castaic Creek near the confluence with Santa Clara River, and just upstream of this confluence in the River. Under Alternative 1, restoration, enhancement, and management of the riparian system, including removal and control of giant reed and tamarisk, would not occur.

Riparian Forest and Woodland. Special-status riparian forest and woodland on site includes southern coast live oak riparian forest and southern cottonwood–willow riparian. Southern coast live oak riparian forest only occurs in a small patch (less than 1 acre) at the confluence of Ayers Canyon and the Santa Clara River. Southern cottonwood–willow riparian forest comprises approximately 358 acres, primarily occurring in dense swaths along the main channel of the Santa Clara River and in Castaic Creek, in the portion of the floodplain beyond the effects of flood scour. Small reaches and/or patches of southern cottonwood–willow riparian also occur in upper Chiquito Canyon, upper Mid-Martinez Canyon, Potrero Canyon, and lower Middle Canyon. This community is relatively intact and undisturbed in the Santa Clara River, but the edges of the community are susceptible to exotic invasive species, such as giant reed and tamarisk. Edge areas that have undergone scouring or sedimentation disturbance have a much higher susceptibility to invasive colonization, primarily by giant reed. This type of disturbance also creates colonization sites for the slow-growing tamarisk, but to a more limited degree. Under Alternative 1, no specific protection, restoration and enhancement of southern coast live oak riparian forest and southern cottonwood–willow riparian would occur in the River Corridor SMA. Agricultural operations adjacent to the River Corridor SMA would continue and potential edge effects from these operations such as irrigation runoff, including fertilizers, and dust from disking and vehicles could affect the vigor and vitality of these communities. Fertilizers may facilitate the distribution and growth of weedy species at the edges of these communities. Grazing would continue in tributaries to the Santa Clara River that support southern cottonwood–willow riparian forest, disrupting the understory of this community by trampling vegetation and soils, facilitating invasion by non-native species, and impairing water quality.

4.5.5.2.2.5 *Common Wildlife*

Although the Project area still supports a rich and diverse wildlife community, indicating that existing land use practices have been generally compatible with maintaining the wildlife community, these land use practices also likely have had a negative impact on many species that occupy and use the area. These potential impacts are described by wildlife taxonomic groups below.

Birds. Birds are particularly sensitive to habitat degradation and other anthropogenic disturbances. Riparian and shrubland (coastal scrub and chaparral) birds likely are the most affected groups due to habitat loss and degradation from existing land uses. Even if vegetation communities generally remain, the disturbance of their horizontal and vertical structure and strata can significantly degrade their value as nesting and foraging habitat. Reducing the functional width of riparian habitat, for example, increases adverse edge effects such as invasion by exotic species and predation, as well as altering wind and solar exposures. Cattle grazing damages important riparian nesting and foraging habitat and may attract brown-headed cowbirds that parasitize nests of native passerine species, including least Bell's vireo and southwestern willow flycatcher. Agriculture adjacent to the Santa Clara River may reduce upland foraging areas for some riparian species such as least Bell's vireo that uses adjacent upland habitats for foraging in the latter part of the breeding season. Pesticides used on agricultural crops may reduce insect prey availability and/or cause secondary poisoning as a result of foraging on contaminated food items, including insects, forbs, and seeds. Some species also may suffer reproductive impairment or failure from pesticides. Human activities associated with agriculture and oils and gas production also may attract predators and competitors of less common nesting species, such as common ravens, American crow, European starling, as well as mesopredators such as raccoons, opossum, and striped skunk.

The ongoing impact of existing land use practices on raptors is probably mixed. Riparian and woodland nesting species such as Cooper's hawk, white-tailed kite, and long-eared owl likely have been negatively affected by existing practices because of degradation of nesting habitat and potential disturbances of nest sites due to human activity. The long-eared owl in particular is sensitive to human activities (Bloom 1994). On the other hand, raptors that forage in open areas, such as turkey vulture, red-tailed hawk, merlin, prairie falcon, and ferruginous hawk probably benefit from existing land uses (especially agriculture) because suitable foraging habitat conditions are maintained and prey that are often associated with human activities, such as California ground squirrels, cottontail rabbits, and pocket gophers, are plentiful and easily captured. However, intensive or monoculture agriculture, such as row crops, is less suitable for raptors because of a relative lack of prey using these areas. In addition, pesticides (*e.g.*, rodenticides, insecticides) may be harmful to raptors due to a reduced abundance of prey and/or secondary poisoning.

Insects. Although the overall Project area still supports a high number and diversity of insects associated with the large variety of habitats on site, agricultural areas disked and treated with pesticides have lower a abundance and diversity of insects compared to riparian, woodland, grassland, and shrublands. Cattle grazing, which causes general habitat degradation and loss of vegetative diversity, also likely reduces the abundance and diversity of insects. Insects that forage or reproduce in vegetation browsed by cattle

would be directly affected. Ground-dwelling insects, including many beetles, ants and spiders, likely are directly impacted by cattle grazing as a result of trampling of individuals and their nests and refuge areas. The loss and reduction of insects in disturbed areas also has an effect on vertebrate species that prey on these insects, including amphibians, reptiles, and small mammals, including bats.

Fish. The Santa Clara River supports a variety of fish, including arroyo chub, Santa Ana sucker, and unarmored threespine stickleback. Existing agricultural operations bordering the Santa Clara River and agriculture and cattle grazing in tributaries and associated side canyons likely have had an effect on habitat quality in the River for the native fish species, but the effect is complex and probably is both positive and negative. For example, ENTRIX (2009) identified agricultural runoff as contributing to high velocity flows in the Santa Clara River. The unarmored threespine stickleback prefers low flow backwater areas, while the arroyo chub and Santa Ana sucker can tolerate higher flows and were detected more frequently in high flow areas of the River (ENTRIX 2009). Culverts associated with temporary road crossings for agricultural operations create oxbows and lateral ponded areas that may provide suitable habitat for the unarmored threespine stickleback, but at the same time may provide suitable habitat for exotic species expected to prey on sticklebacks, such as African clawed frogs, largemouth bass, green sunfish, mosquitofish, and crayfish. The culverts also tend to increase local flow velocities that are detrimental to the unarmored threespine stickleback.

Although under existing land use practices, the Santa Clara River provides suitable habitat for native fish, without the preservation and management associated with the RMDP, including habitat restoration and enhancement in the River corridor and monitoring and management of exotic species such as African clawed frog and crayfish, the long-term suitability of the River corridor for native fishes is uncertain.

Amphibians. Populations of common and highly adaptable amphibians such as California treefrog, Pacific treefrog, and western toad are unlikely to be significantly affected on existing land uses, with the exception of the occasional loss of individuals due to crushing by vehicles and farm equipment and destruction of refugia by disking and cattle trampling (especially western toad, which uses uplands), as well as loss of insect prey resulting from the use of pesticides.

The western spadefoot toad could be directly affected by agricultural operations and cattle grazing, which could destroy or degrade ephemeral breeding locations, as well as aestivation/hibernation habitat adjacent to breeding locations. For example, this species has been detected in middle Potrero Canyon, which supports cattle grazing and agriculture, as well as oil pads and access roads.

Adult arroyo toads have not been documented in the Project area, it potentially could occur in the Santa Clara River and uplands adjacent to the River. The effects on existing land uses on the River corridor discussed above for fish, including increased flows and creation of temporary ponded areas at River crossings and the presence of exotic species such as mosquitofish, African clawed frog, and crayfish, could adversely affect habitat quality for the arroyo toad and preclude it from successfully breeding in the River corridor. Impairment of water quality from agricultural runoff, including pesticides and fertilizers, may affect their reproduction and development. Existing agricultural practices, such as disking, adjacent to the River adversely affect upland habitats potentially used by the arroyo toad for aestivation/hibernation.

Reptiles. Reptiles known from the Project include semi-aquatic species, such as southwestern pond turtle and two-striped garter snake and terrestrial species such as western whiptail, western fence lizard, side-blotched lizard, western rattlesnake, and gopher snake, among others.

The southwestern pond turtle primarily occurs in the Santa Clara River and likely is affected in a similar way as the fish and amphibian species by existing land use practices. The temporary culverts that create oxbows and lateral ponds at crossings of the River sometimes create suitable, but temporary, deepwater habitat for this species. On the other hand, agricultural uses adjacent to the River corridor may limit the pond turtle's use of the adjacent uplands for nesting and overwintering. Exotic and native predators of pond turtle hatchlings on site may include species currently known from the Project area such as largemouth bass, common ravens, and American crows.

Terrestrial reptiles would be affected by existing land use practices that result in habitat loss and degradation. Many of the lizards and/or snakes use rodent burrows for refuge and hunting, which may be trampled by cattle or disturbed by agricultural operations such as disking. Slow-moving diurnal species such as coast horned lizard, western rattlesnake, and gopher snake are also directly vulnerable to trampling by cattle, vehicle collisions, and farm equipment. Pesticides, including rodenticides, may result in prey reduction and loss of burrows used as for refuge, aestivation, and hibernation.

Mammals. The effect of existing land use practices on many common mammals known from the Project area is considered to be relatively benign. Urban-adapted species such as raccoon, cottontail rabbit, striped skunk, pocket gopher, California ground squirrel, and many small native rodents, such as deer mouse (*Peromyscus maniculatus*) and western harvest mouse (*Reithrodontomys megalotis*), actually thrive in disturbed habitats. The rodent species also provide primary prey for several raptor species, including most hawks and owls. The long-tailed weasel, American badger, and coyote, which prey on rodents and rabbits, also occur frequently in agricultural settings and are unlikely to be

significantly affected, although breeding dens and general activity of badgers may be relatively more affected and this species is vulnerable to vehicle collisions and farm equipment. The use of rodenticides may affect these three species due to loss of prey and/or secondary poisoning. Habitat loss and degradation due to existing land uses, however, does affect other mammals that rely on native habitat and vegetation cover, including larger species such as mule deer, mountain lion, and bobcat. These species tend to shy away from human activity and are also vulnerable to vehicle collisions. Smaller mammal species that use riparian and/or shrublands that may be degraded by existing land uses, and particularly cattle grazing, include gray fox, California pocket mouse, kangaroo rats (*Dipodomys* spp.), woodrats (*Neotoma* spp.), California mouse (*Peromyscus californicus*), brush mouse (*Peromyscus boylii*), cactus mouse (*Peromyscus eremicus*), and California vole (*Microtus californicus*). These species are also vulnerable to vehicle collisions between dusk and dawn when they attempt to cross roads.

Bats, as a group, are most likely to be affected by the loss of prey and/or secondary poisoning as a result of the use of pesticides associated with agricultural operations. Otherwise, because most bat species occurring in the Project area are generalist insectivores (insect eating) and many forage over agricultural areas in addition to most natural habitats, existing land uses probably have relatively little adverse affect on their overall foraging behavior. With regard to roosting sites, only one species—pallid bat—is known to have a maternity roost in the Project area: a building in middle Potrero Canyon. Other species use night roosts in the Santa Clara River and at the I-5 Bridge over the River, but no day roosts for the other species have been detected in the Project area. It is unknown whether existing land use practices have adversely affected the use of the potential day roosts on site.

Mollusks. The undescribed snail (genus *Pyrgulopsis*) is restricted to portions of the Middle Canyon Spring and the lower reach of the adjacent Middle Canyon drainage where surface water is present due to agricultural operations. This species may persist under existing land use practices because the Middle Canyon Spring will remain and agricultural runoff would continue to supply the Middle Canyon drainage under existing operations. However, under Alternative 1, preservation, monitoring, and management of habitat for snail would not occur. Changes in water quantity or quality in the spring or flow speed of water through the spring could result in multiple negative side affects, including elevated water temperatures, lower dissolved oxygen availability, and the accumulation of fine sediments which could smother preferred substrates and impair egg-laying or survivorship of eggs or young (Cordeiro 2002). Because 90% of the population turns over annually, any condition that impairs egg-laying or survivorship of eggs or young (*e.g.*, excessive smothering sedimentation) may result in extirpation (Furnish and Monthey 1998). The unchecked spread of non-native, invasive plant species into the spring could also threaten the snail population.

4.5.5.2.2.6 *Special-Status Wildlife*

Bird – Raptor. The special-status species in this guild observed on site include American peregrine falcon, California condor, Cooper's hawk, ferruginous hawk, golden eagle, loggerhead shrike, long-eared owl, merlin, northern harrier, prairie falcon, sharp-shinned hawk, turkey vulture, western burrowing owl, and white-tailed kite.

Existing land use practices probably have both positive and negative effects on these special-status raptors. Agriculture, disturbed land, and grazed grassland and pastures are beneficial to raptors that forage in open, sparsely vegetated habitats, such as American peregrine falcon, California condor, ferruginous hawk, golden eagle, loggerhead shrike, merlin, northern harrier, prairie falcon, sharp-shinned hawk, turkey vulture, western burrowing owl, and white-tailed kite. These raptors forage on small prey that commonly occur in these open habitats such as California ground squirrels, cottontail rabbits, pocket gophers, and other small rodents that are plentiful and easily captured. However, intensive or monoculture agriculture, such as row crops, is less suitable for these raptors because of a relative lack of prey using these areas. On the other hand, the Cooper's hawk that nests and forages in riparian and woodland habitats on site and the white-tailed kite that nests in riparian and woodland habitats likely have been negatively affected by existing practices such as grazing because of degradation of nesting habitat and potential disturbances of nest sites due to human activity. Grazing in particular reduces habitat quality in riparian and woodland communities as a result of congregating and trampling, facilitation of invasive annual grasses and weeds, and interference with recruitment in the case of oaks. In addition, pesticides associated with agriculture (*e.g.*, rodenticides and insecticides) may be harmful to raptors due to a reduced abundance of prey and/or secondary poisoning.

Bird – Riparian. The special-status species in this guild observed on site include black-crowned night heron, least Bell's vireo, Nuttall's woodpecker, tricolored blackbird, vermilion flycatcher, western yellow-billed cuckoo, willow flycatcher, yellow-headed blackbird, yellow warbler, and yellow-breasted chat.

Riparian birds generally are sensitive to habitat degradation that occurs from activities such as cattle grazing and invasive plant and animal species. Disturbance of horizontal and vertical structure and strata can significantly degrade nesting and foraging habitat for riparian birds. Reducing the functional width of riparian habitat, for example, increases adverse edge effects, such as invasion by exotic species and predation, as well as altering wind and solar exposures in the riparian zone. Cattle grazing damages important riparian nesting and foraging habitat and may attract brown-headed cowbirds, which can penetrate narrow riparian corridors and parasitize nests. Agriculture adjacent to the Santa Clara River may reduce upland foraging areas for some riparian species, such as least Bell's

vireo that uses adjacent upland habitats for foraging in the latter part of the breeding season. Pesticides used on agricultural crops may reduce insect prey availability and/or cause secondary poisoning as a result of birds foraging on contaminated food items, including insects, forbs, and seeds. Some species, such as black-crowned night heron, also may suffer reproductive impairment or failure from pesticides (County of Riverside 2008). Human activities associated with agriculture adjacent to riparian areas may attract predators and competitors of less common nesting species, such as common ravens, American crow, European starling, as well as mesopredators such as raccoons, opossum, and striped skunk.

Bird – Upland Grassland. The only special-status species in this guild observed on site is the California horned lark. The grasshopper sparrow has potential to occur on site, but has not been observed in the numerous surveys conducted between 1988 and 2007. The California horned lark commonly forages in agricultural areas and grazed lands and has been commonly observed on site in plowed and graded fields near the Santa Clara River. Existing land use practices are unlikely to have a significant negative effect on this species, although it could be susceptible to secondary poisoning from food items (insects, snails, spiders, seeds and forbs) contaminated by pesticides. In addition, this species, as an open ground nester, may attempt to nest in areas subject to disturbances associated with agricultural operations and oil and gas production, although it has not been observed to nest on site in the past.

Bird – Upland Scrub and Chaparral. The special-status species in this guild observed on site include Allen's hummingbird, chipping sparrow, coastal California gnatcatcher, Costa's hummingbird, rufous hummingbird, and southern California rufous-crowned sparrow.

Similar to riparian birds, scrub and chaparral birds are sensitive to land use practices that result in the loss and degradation of habitat. Existing agricultural operations and gas and oil production probably are not significant impacts on these species on site because areas that are periodically disturbed or disked, for example, would recover too slowly to provide habitat for these species. On site, most of the scrub and chaparral species occur in rugged areas that are not suitable for agricultural uses. However, the use of pesticides for agriculture may reduce insect prey and/or cause secondary poisoning through contaminated food items. Cattle grazing probably has had a substantial impact on scrub and chaparral species on site because cattle may wander through and browse on shrub vegetation. Cattle may also inhibit the recovery of scrub and chaparral communities after wildfires because they forage in recovering areas dominated by annual grasslands, trampling soils and new sprouts, and facilitating type conversion of the scrub and chaparral to annual grassland and weedy communities.

Bird – Upland Woodland. The special-status species in this guild observed on site include hermit warbler, Lawrence's goldfinch, and oak titmouse.

These species are also sensitive to land use practices that result in the loss and degradation of habitat. Existing agricultural operations and gas and oil production probably are not significant impacts on these species on site because oak woodlands generally are not directly affected by these activities. However, the use of pesticides may reduce insect prey and/or cause secondary poisoning through contaminated food items. Cattle grazing probably has had a substantial impact on upland woodlands on site because they browse on and may trample seedlings and saplings. Grazing disturbs soils and also promotes invasion by annual grasses, which compete with oak seedlings for soil moisture, adversely affecting recruitment of new oak individuals. Some areas of the High Country SMA that support grazing, for example, show little oak recruitment.

Bat. The special-status species in this guild directly confirmed or determined to have potential to occur on site based on acoustic signals include fringed myotis, long-legged myotis, pallid bat, pocketed free-tailed bat, western small-footed myotis, western mastiff bat, western red bat, and Yuma myotis.

Bats are most likely to be affected by the loss of prey and/or secondary poisoning as a result of the use of pesticides associated with agricultural operations. Otherwise, because most bat species occurring in the Project area are generalist insectivores (insect eating) and many forage at night over agricultural areas in addition to most natural habitats, existing land uses probably have relatively little adverse affect on their overall foraging behavior. Artificial lighting of existing facilities on site may attract bats because of the high abundance of insect prey and may alter competitive foraging relationships among the different species. With regard to roosting sites, only one species—pallid bat—is known to have a maternity roost in the Project area: a building in middle Potrero Canyon. Other species use night roosts in the Santa Clara River and at the I-5 Bridge over the River, but no day roosts for the other species have been detected in the Project area. It is unknown whether existing land use practices have adversely affected the use of the potential day roosts on site.

Insect. The two special-status species in this guild observed on site are the monarch butterfly and San Emigdio blue butterfly. Individual monarch butterflies have been observed, but no wintering sites are present. Existing land use practices are not expected to significantly affect the monarch butterfly. The San Emigdio blue butterfly is locally abundant at the west-central edge of Potrero Canyon in association with its primary host plant four-wing saltbush, as well as quail brush. Pesticide use associated with existing agricultural operations on Potrero Mesa just east of the San Emigdio blue butterfly colony could have an adverse effect on this species.

Fish. The special-status species in this guild occurring in the Santa Clara River reach within the Project area include the arroyo chub, Santa Ana sucker, and unarmored threespine stickleback.

As described generally for fish in **Subsection 4.5.3.4.3**, General Wildlife, agricultural runoff has contributed to high velocity flows in the Santa Clara River (ENTRIX 2009), which limits the distribution of unarmored threespine stickleback, but is generally tolerated by arroyo chub and Santa Ana sucker. Culverts associated with temporary crossings of the River create oxbows and lateral ponding that could be suitable for the unarmored threespine stickleback, but which are also suitable for assumed exotic predators of the stickleback, such as African clawed frogs, largemouth bass, green sunfish, mosquitofish, and crayfish. The culverts also tend to increase local flow velocities that are detrimental to the unarmored threespine stickleback.

Although under existing land use practices, the Santa Clara River provides suitable habitat for special-status fish, without the preservation and management associated with the RMDP, including habitat restoration and enhancement in the River corridor and monitoring and management of exotic species such as African clawed frog and crayfish, the long-term suitability of the River corridor for these fish is uncertain.

Reptile – Low Mobility. The special-status species in this guild observed on site include coast horned lizard, coastal western whiptail, and silvery legless lizard.

These species generally are sensitive to land use practices that result in habitat loss and degradation. The coast horned lizard and silvery legless lizard are particularly vulnerable to agriculture and cattle grazing. Cattle grazing degrades habitat quality by disturbing soils and facilitating invasion by annual grass and weedy species. Silvery legless lizards, which inhabit loose soils, are vulnerable because these disturbances reduce soil moisture and alter the conformation of the substrate. These activities thus may limit the food base or make the substrate physically unsuitable for silvery legless lizards (Jennings and Hayes 1994). Irrigation of crops increases moisture along the edges of fields, attracting Argentine ants which compete with and displace native harvester ants that are primary prey (up to 90%) for coast horned lizards. Coast horned lizards are also relatively sedentary and are vulnerable to trampling and crushing by cattle, as well as to vehicle collisions on dirt roads and to farm equipment on dirt roads and along the edges of habitat. Coastal western whiptail probably is more tolerant of habitat disturbances that open up habitats because as "runners" they prefer open ground and sparsely vegetated habitats, but type conversion of coastal scrub and chaparral to annual grassland as a result of grazing adversely affects this species. Whiptails are more mobile than horned lizards, but are also vulnerable to vehicles collisions and farm equipment. Pesticide use

associated with agriculture could also reduce insect prey for these species and/or cause secondary poisoning.

Reptile and Amphibian – Semi-Aquatic. The special-status species in this guild observed on site include southwestern pond turtle, two-striped garter snake, arroyo toad, and western spadefoot toad. These species generally are sensitive to land use practices that result in habitat loss and degradation.

The southwestern pond turtle primarily occurs in the Santa Clara River and likely is affected in a similar way as the special-status fish by existing land use practices. The temporary culverts that create oxbows and lateral ponds at crossings of the River sometimes create suitable, but temporary, deepwater habitat for this species. On the other hand, agricultural uses adjacent to the River corridor may limit the pond turtle's use of the adjacent uplands for nesting and overwintering. Exotic and native predators of pond turtle hatchlings on site may include species currently known from the Project area such as largemouth bass, common ravens, and American crows.

Adult arroyo toads have not been documented in the Project area, but it potentially could occur in the Santa Clara River and uplands adjacent to the River. The effects on existing land uses on the River corridor discussed above for special-status fish, including increased flows and creation of temporary ponded areas at River crossings and the presence of exotic species such as mosquitofish, African clawed frog, and crayfish, could adversely affect habitat quality for the arroyo toad and preclude it from successfully breeding in the River corridor. Impairment of water quality from agricultural runoff, including pesticides and fertilizers, may affect its reproduction and development. Existing agricultural practices, such as disking, adjacent to the River adversely affect upland habitats potentially used by the arroyo toad for aestivation/hibernation. Arroyo toads using these areas could be injured, killed, or buried by these activities.

The western spadefoot toad could be directly affected by agricultural operations and cattle grazing, which could destroy or degrade ephemeral breeding locations, as well as aestivation/hibernation habitat adjacent to breeding locations. For example, this species has been detected in middle Potrero Canyon, which supports cattle grazing and agriculture, as well as oil pads and access roads.

The two-striped garter snake probably is less affected by existing land use practices than the other semi-aquatic special-status species, but it may be secondarily affected by exotic species such as mosquitofish that prey on treefrogs and newts (Goodsell and Kats 1999) that are, in turn, prey for the two-striped garter snake.

Mammal – Low Mobility. The only special-status species in this guild observed on site is the San Diego desert woodrat. This species is relatively common in coastal scrub and

chaparral on site. Similar to scrub and chaparral birds, the San Diego desert woodrat is sensitive to land use practices that result in the loss and degradation of habitat. Existing agricultural operations and gas and oil production probably are not significant impacts on this species because areas that are periodically disturbed or disked would recover too slowly to provide habitat for this species. On site, most of the scrub and chaparral is in rugged areas that are not suitable for agricultural uses. Cattle grazing probably has had a substantial impact on the San Diego desert woodrat on site because cattle may wander through and browse on shrub vegetation. Cattle may also inhibit the recovery of scrub and chaparral communities after wildfires because they forage in recovering areas dominated by annual grasslands, trampling soils and new sprouts, and facilitating type conversion of the scrub and chaparral to annual grassland and weedy communities. The San Diego desert woodrat also is vulnerable to vehicle collisions and farm equipment between dusk and dawn, although this species tends to confine its activities to areas around dens or middens. It would be at highest risk of collisions during dispersal.

Mammal – Moderate Mobility. The special-status species in this guild observed on site include the American badger and San Diego black-tailed jackrabbit. The ringtail cat is also in this guild but has not been observed on site.

Both the American badger and San Diego black-tailed jackrabbit generally are tolerant of the existing land use practices. As open habitat species, both may occur in relatively high densities in low-intensity agricultural areas, grazed lands, and other disturbed areas such as oil and gas production sites. The main risk for both species is vehicle collisions and farm equipment, as well as human activity; both species are shy of humans and will leave areas when disturbed. In addition, both species may attempt to breed in areas subject to disturbances. The badger is especially vulnerable to breeding den disturbances from agricultural operations because young may remain in the natal den for up to six weeks. Black-tailed jackrabbits are less vulnerable to nest impacts because nests are usually small depressions and the young are independent of the nest within about 24 hours. The badger is also vulnerable to the use of rodenticides due to loss of prey and/or secondary poisoning.

Mammal – High Mobility. The special-status species in this guild observed on site include American black bear, mountain lion, and mule deer. The American black bear does not typically occur in the lower elevations the Project area subject to most of the existing land use practices and probably only uses these areas when moving between suitable habitat areas north and south of the site. This species is addressed in more detail in **Subsection 4.5.3.4.7**, Wildlife Habitat Connectivity and Buffers. The mule deer is common on site and the mountain lion is uncommon, but occasionally observed.

Both the mule deer and mountain lion are sensitive to existing land use practices that result in habitat loss and degradation because both rely on riparian, woodland, and shrubby vegetation for cover and refuge. As noted above for other guilds, cattle grazing degrades these habitats. Mule deer also may compete with cattle for food resources ((NatureServe 2007; Zeiner *et al.* 1990B). Both species tend to shy away from human activity and may alter their behavior patterns to avoid humans. Mountain lions, for example, shift their natural foraging activities to after sunset in areas with higher human activity (Van Dyke *et al*. 1986). Both species are vulnerable to vehicle collisions.

Mollusk. The undescribed snail (genus *Pyrgulopsis*) is the only special-status species in this guild observed on site. It is restricted to portions of the Middle Canyon Spring and the lower reach of the adjacent Middle Canyon drainage where surface water is present due to agricultural operations. This species may persist under existing land use practices because the Middle Canyon Spring will remain and agricultural runoff would continue to supply the Middle Canyon drainage under existing operations. However, under Alternative 1, preservation, monitoring, and management of habitat for snail would not occur. Changes in water quantity or quality in the spring or flow speed of water through the spring could result in multiple negative side affects, including elevated water temperatures, lower dissolved oxygen availability, and the accumulation of fine sediments which could smother preferred substrates and impair egg-laying or survivorship of eggs or young (Cordeiro 2002). Because 90% of the population turns over annually, any condition that impairs egg-laying or survivorship of eggs or young (*e.g.*, excessive smothering sedimentation) may result in extirpation (Furnish and Monthey 1998). The unchecked spread of non-native, invasive plant species into the spring could also threaten the snail population.

4.5.5.2.2.7 *Wildlife Habitat Linkages, Corridors, and Buffers*

As noted above, current wildlife use of the Project area is probably relatively unconstrained by existing land use practices. This subsection describes the potential impacts of Alternative 1 on wildlife landscape linkages, wildlife corridors, wildlife crossings, and wildlife buffers.

Wildlife Habitat Linkages. Under Alternative 1, RMDP facilities would not be constructed and build-out of the Specific Plan, VCC, and the Entrada planning areas would not occur. The Project area would remain undeveloped and wildlife would continue to use the area. **Figure 4.5-21** shows the conceptual regional open space connectivity identified by Penrod *et al.* (2006). This habitat linkage would remain intact and relatively undisturbed. However, the High Country SMA and Salt Creek area would not be preserved as public open space and existing activities such as cattle grazing and agriculture would continue. Activities anticipated under management, including creation,

restoration, and/or enhancement of native vegetation communities (including riparian, oak woodland, and coastal scrub) and removal of grazing (except for long-term resource management activities) would not occur. Nonetheless, with existing land use practices it is expected that mule deer and mountain lion, as well as American black bear, will continue to use these areas for movement across the landscape and to access large habitat areas such as the Santa Susana Mountains, the Fillmore Greenbelt, and the Los Padres and Angeles National Forests.

Wildlife Corridors. **Figure 4.5-31** shows thirteen potential wildlife corridors in the Project area. These corridors currently provide relatively unconstrained habitat connections throughout the Project area. Under Alternative 1, RMDP facilities would not be constructed and build-out of the Specific Plan, VCC, and the Entrada planning areas would not occur. These wildlife corridors would remain intact and generally unconstrained and wildlife would continue to use the area. Wildlife would remain subject to ongoing activities, such as cattle grazing, oil production, and agriculture. Under Alternative 1, the main east-west corridor along the Santa Clara River SMA would not be conserved and managed as an SMA. Restoration and enhancement of riparian vegetation, removal of cattle, and monitoring and control of invasive species such as African clawed frog and crayfish that prey on native amphibians and fish that use the River corridor would not occur under Alternative 1. Temporary road crossings of the River and associated culverts would continue to be constructed, creating oxbows and lateral ponding, which may benefit some species such as southwestern pond turtle and unarmored threespine stickleback, but which also may create habitat for exotic predators such as largemouth bass, African clawed frog, green sunfish, mosquitofish, and crayfish.

Wildlife Crossings. **Figure 4.5-32** shows six of the largest existing crossings that can be accessed by wildlife coming directly from adjacent uplands or by moving along the Santa Clara River. These crossings would all remain for the foreseeable future in their present form and will function as they do now under Alternative 1. The Chiquito Creek crossing is currently a triple box culvert that may have limited function because it is filling with sediments.

Wildlife Buffers. Under Alternative 1, RMDP facilities would not be constructed and build-out of the Specific Plan, VCC, and the Entrada planning areas would not occur. Under Alternative 1, wildlife would be subject the same activities as existing conditions, including disturbances from ongoing agriculture, oil field production, and cattle grazing. These ongoing effects include pesticides, irrigation, lighting, noise, and dust, which have adverse effects on species occurring in the Project area in areas adjacent to these activities.

Pesticides used on crops may extend into adjacent habitat, resulting in direct impacts on native species or secondarily by reducing insect prey or contaminating prey and other food items such as seeds, causing secondary poisoning. Herbicides may have direct effects on native plants at the interface between the fields and the native vegetation communities, reducing wildlife habitat value along the interface.

Irrigation of crops may increase soil moisture along the edges of fields, attracting Argentine ants, which adversely affect native species such as coast horned lizard, as well as other native birds and reptiles. Irrigation and/or soil disturbances along the edges of agricultural fields, oil and gas production facilities, and access roads may also facilitate the invasion of natural habitat by exotic invasive species, thus reducing wildlife habitat value. Fertilizers, for example, can enter wetland and riparian systems and cause algae blooms and eutrophication. They also can enhance growth of non-native species in upland edge areas. Over-irrigation can result in erosion and release of sediments, as well as chemical pollutants, into adjacent habitats, and particularly riparian and wetland areas.

Artificial lighting associated with agricultural and oil and gas production facilities may attract mesopredators and increase the detectability of prey, including rodents, nocturnal amphibians and reptiles, and nesting birds. Artificial lighting can also adversely affect behavioral activities, daily rhythms, hormonal regulation, and increase stress on wildlife. Artificial lighting also attracts insects, which, in turn, attract predators such as bats and nocturnal wildlife, potentially altering foraging competitive relationships among these species.

Noise and vibration from farm equipment, oil and gas production equipment, and occasional vehicle passage can disrupt behavioral activities of activities. Unlike chronic traffic noise to which many wildlife species can habituate or adapt, noises that are discrete, sudden, or surprising tend to be more startling and more disruptive of behavior; *e.g.*, causing freezing, flight responses, and increasing stress. Such noises also may mask noises made by predators (*e.g.*, during stalking) and increase predation rates. Excessive vibration may directly disturb terrestrial species that occupy burrows, dens, and depressions, such as rodents, coyotes, badgers, and rabbits, and causing them to abandon these areas or actual collapse of burrows and dens.

Excessive dust from disking and other agricultural operations and vehicles on dirt roads use can decrease the vigor and productivity of adjacent plant communities through effects on light and penetration as well as photosynthesis, respiration, transpiration; increased penetration of phytotoxic gaseous pollutants; and increased incidence of pests and diseases.

4.5.5.2.2.8 *Special-Status Plants*

Most of the special-status plants species are subject to one or more disturbances that would continue as a result of existing land use practices, including cattle grazing, agricultural operations, and gas and oil production.

Cattle grazing can result in direct impacts on these special-status plants from trampling and browsing. Cattle also trample soils and facilitate colonization by non-native grasses and other weedy species that compete with native species for space, light, nutrients, and water. Special-status plant species that are vulnerable to cattle grazing because they may occur in grasslands and coastal scrub subject to grazing impacts are San Fernando Valley spineflower, slender mariposa lily, California black walnut, island mountain-mahogany, late-flowered mariposa lily, oak-leaved nemophila, Parish's sagebrush, Peirson's morning-glory, Plummer's mariposa lily, Ojai navarretia, and oak trees.

Several of the San Fernando Valley Spineflower and slender mariposa lily occurrences are adjacent to agricultural fields, including Grapevine Mesa, Airport Mesa, and Potrero Mesa. Surface and subsurface hydrology may be altered at the interface between agriculture and habitat areas supporting these species as a result of irrigation and runoff, including herbicides, insecticides, and fertilizers that may adversely affect special-status plants. Fertilizers, for example, may facilitate the dispersion and growth of non-native species that outcompete and/or displace special-status plants. Irrigation and runoff from agricultural fields may chronically increase moisture levels at the interface between the fields and special-status plant populations, attracting non-native Argentine ants that may displace or compete with native insect pollinators, such as native ants. Airborne herbicides and pesticides may also directly affect special-status plants near agricultural areas by directly killing plants or reducing their vigor and long-term productivity, as well as secondarily affecting these plants through impacts on insect pollinators and insect and vertebrate seed dispersers (*e.g.*, native ants and small rodents). Disking, vehicles, and the moving of farm equipment generates dust which may affect the vigor and vitality of adjacent populations of San Fernando Valley Spineflower and slender mariposa lily. Additional clearing of vegetation related to agriculture and oil and gas production may change solar and wind conditions at the edges of habitat that supports these populations, also affecting their vigor and long-term productivity.

Although other special-status plant species on site currently are not as vulnerable to the secondary effects of agriculture, they would be subject to similar impacts if areas adjacent to existing populations were converted to agriculture in the future.

The undescribed everlasting is not as vulnerable to cattle grazing, agriculture, and oil and gas production because it is limited to three areas: in the Santa Clara River near the mouth of Long Canyon, in Castaic Creek south of SR-126, and in Castaic Creek west of I-5 and east of Commerce Center Drive.

Mainland cherry is not as vulnerable to grazing impacts as the species listed above because it is large shrub. It is an occasional component of undifferentiated chaparral, big sagebrush scrub, and river wash and does occur in areas where cattle graze. Therefore, it is possible that seedlings could be browsed.

The undescribed sunflower occurs in association with the Middle Canyon Spring. Under Alternative 1, the Middle Canyon Spring would remain intact, but would not be specifically protected, monitored, or managed. The present characteristics of the spring area probably are influenced to a large extent by the position of the berms and outflow channels. Without these berms and channels, the spring would likely naturally have a more diffuse sheeting outflow and extend its margins toward the edge of the Santa Clara River terrace. Under Alternative 1, measures to restore a more natural flow west of the current spring area would not be implemented. In addition, the loose bank material associated with the adjacent road cut into the steep hill above the entire south margin of the spring area may not be stabilized and/or closed to control erosion and sedimentation.

Southwestern spiny rush only occurs in the Santa Clara River within the Specific Plan area where grazing is excluded. However, under Alternative 1, the Santa Clara River corridor would not be specifically protected and restoration and enhancement and management would not occur. Therefore, southwestern spiny rush in these areas could be affected by invasive species that occur in the River corridor, such as giant reed.

4.5.5.2.2.9 *Comparison of Alternatives 2 through 7*

This subsection provides a general comparison of Alternatives 2 through 7 with regard to direct impacts due to implementation of the RMDP and SCP. Direct permanent loss of vegetation communities and land covers would result from proposed RMDP improvements for all six alternatives, including construction of bridges and associated piers and abutments; road crossing culverts; bank stabilization/protection that includes ungrouted rock riprap, turf reinforcement mats, and exposed gunite slope-lining protection under bridge crossings and their abutments; drainage facilities that include partially lined open channels; grade controls and other channel improvements, including grade control structures in tributaries, engineered natural channels in Potrero, Long, and Lion canyons, grouted sloping boulder drops, non-grouted boulder step-pools, soil-cement grade control structures, sculpted concrete drop structures, and check structures; water reclamation plant outfall; water quality control features, such as water quality basins, debris basins, detention basins, catch basin inserts, and biorention features; various roadway improvements to SR-126; and recreation facilities (see **Section 2.0**, Project Description, for full details). Permanent loss of artificial land covers will also occur as a result of habitat restoration and enhancement activities for all six alternatives.

While all six alternatives include similar RMDP facilities and spineflower preserves, they differ in the details and extent of these facilities (see **Section 3.0**, Description of Alternatives, for a

complete treatment of the alternatives). **Table 4.5-24**, Comparison of RMDP Infrastructure Impacts and Spineflower Preserves for Alternatives 2 through 7, summarizes key differences in RMDP facilities and the spineflower preserves among the six alternatives.

Table 4.5-24
Comparison of RMDP Infrastructure Impacts and Spineflower Preserves for Alternatives 2 through 7

RMDP Infrastructure Facilities	Alternative					
	2	**3**	**4**	**5**	**6**	**7**

[1]Bridges:
CCD – Commerce Center Drive
LCR – Long Canyon Road
PCR – Potrero Canyon Road

The combined total RMDP direct permanent and temporary impacts are similar among the alternatives, with a range of 582 acres for Alternative 4 to 744 acres for Alternative 7. However, unlike Alternatives 2 through 6 where permanent impacts account for 57.6% to 66.2% of the total impacts, for Alternative 7, permanent impacts account for about 76.8% of the impacts. Alternative 7 would have the least amount of permanent impacts resulting from construction of RMDP facilities.

Along the Santa Clara River, the major RMDP facilities include bank stabilization, outlets, and bridges. Generally, the linear feet of bank stabilization constructed along the Santa Clara River is greatest with Alternative 2 and the least with Alternative 7. The differences in the amount of bank stabilization among the Alternatives 2 through 6 generally relate to the number and size of bridge crossings, and for Alternative 7, the number of bridge crossings and the amount of interface between the Specific Plan development area and the Santa Clara River. Alternatives 3, 4, and 5 have intermediate amounts of bank stabilization, and Alternative 6 has the second least amount. Alternatives 3 and 4 have substantially less bank stabilization compared to Alternative 2 because Potrero Canyon Road Bridge would not be constructed under these alternatives. Alternative 5 would include Potrero Canyon Road Bridge, but bank stabilization is configured differently from Alternative 2 because the bridge in Alternative 5 would be almost 1,000 feet longer compared to Alternative 2. The Commerce Center Drive Bridge would not be constructed under Alternatives 6 and 7. Under Alternative 6, the Potrero Canyon Bridge would be more than 1,000 feet longer than under Alternative 2 and 100 feet longer than under Alternative 5. Under Alternative 7, only the Long Canyon Road Bridge would be constructed and development in the Landmark Village and Homestead East Village areas would be pulled back from the Santa Clara River corridor.

The number of drainage outlets along the Santa Clara River would be the same for all alternatives.

Impacts in tributary drainages include modification of drainages, buried storm drains, bank stabilization, bridge crossings, and culverts. Alternatives 2 through 7 would have varying amounts of modified drainages in the tributaries to the Santa Clara River, with a range of 21,177 linear feet for Alternative 7 to 60,041 linear feet for Alternative 3. The vast majority of these modifications would occur in the major drainages of Chiquito, Lion, Long, Potrero, and San Martinez Grande canyons. For drainages converted to buried storm drains, Alternatives 2 through 5 would have similar amounts of conversion, ranging from 59,845 linear feet to 60,683 linear feet. Alternative 7 would have the least amount of buried storm drains at 19,330 linear feet, and Alternative 6 would have an intermediate amount at 43,335 linear feet. West bank stabilization related to tributary drainages would be similar for Alternatives 2, 3, 4, 6, and 7, ranging from 32,981 to 39,692 linear feet, but would be substantially greater Alternative 5 (60,715 linear feet). East bank stabilization related to tributary drainages would be similar for Alternatives 2, 3, 4, 6, and 7, ranging from 33,546 to 46,281 linear feet, but would be zero for Alternative 5.

The amount of preserved tributary drainage would be generally similar under Alternatives 2 through 6, ranging from 122,050 linear feet for Alternative 3 to 138,887 linear feet for Alternative 6. Alternative 7 would have substantially higher preserved tributaries (201, 593 linear feet) compared to the other alternatives.

The number of bridge crossings of tributary drainages would increase for each of the alternatives sequentially and the number of culverts would decrease, reflecting a tradeoff in the construction of bridges versus culverts among the different alternatives.

As the total impacts decrease with each of the alternatives sequentially, the spineflower preserves would be larger, with the smallest cumulative spineflower preserve area under Alternative 2 (168 acres) and the largest under Alternative 6 (891 acres). Similarly, the amount of preserved habitat occupied by spineflower would generally increase with each alternative, ranging from 14 acres for Alternative 2 to 20 acres for Alternative 7.

4.5.5.2.3 Impacts to Vegetation Communities and Land Covers

As described in detail in **Subsection 4.5.5.1**, Impact Analysis Approach and Methods, direct and indirect impacts represent the absolute physical loss of a biological resource due to implementation of the RMDP and SCP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas, respectively, and are analyzed in six ways: (1) permanent loss of vegetation communities, land covers, and general wildlife and their habitat; (2) permanent loss of or harm to individuals of special-status plant and wildlife species; (3) permanent loss of suitable habitat for special-status species; (4) permanent loss of wildlife movement and habitat connectivity in the Project area; (5) temporary loss of vegetation communities, land covers, and general wildlife and their habitat; and (6) temporary loss of suitable habitat for special-status species.

Secondary impacts are those reasonably foreseeable effects caused by Project implementation on remaining or adjacent biological resources outside the construction disturbance zone. Secondary impacts include short-term effects immediately related to construction activities and long-term or chronic effects related to the human occupation of developed areas.

Subsection 4.5.5.2.3.1, Summary Descriptions of Impacts to Vegetation Communities and Land Covers of the EIS/EIR Alternatives, provides a general description of impacts to general vegetation and land covers. Vegetation and land cover types are organized at the CNDDB (CDFG 2003) general physiognomic and physical location level for the purpose of this summary description.

This general discussion of impacts to vegetation communities and land covers is organized as follows:

- Permanent and temporary losses of vegetation communities and land covers under the Alternatives 2 through 7 resulting from implementation of the RMDP and SCP;
- Permanent losses of vegetation communities and land covers under the six alternatives resulting from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas; and

- Secondary impacts to vegetation communities and land covers under the six alternatives resulting from construction activities and long-term occupation of the Project area.

Subsection 4.5.5.2.3.2, Detailed Descriptions of Impacts to Vegetation Communities and Land Covers, provides a much more comprehensive analysis of direct impacts to vegetation communities and land covers resulting from implementation of the RMDP and SCP; indirect impacts resulting from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas; and secondary impacts resulting from implementation of the RMDP and SCP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only) and Entrada planning areas. This subsection breaks out each vegetation community (*e.g.*, alluvial scrub and arrow weed scrub), analyzes the removal of the vegetation community or land cover and secondary impacts resulting from implementation of the RMDP and SCP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under each of the alternatives, and evaluates the significance of the vegetation removal in accordance with impact significance criteria established in **Subsection 4.5.4**, Impact Significance Criteria. For impacts found to be significant, absent mitigation, applicable mitigation measures are summarized that would reduce the impact to a level that is adverse but not significant.

4.5.5.2.3.1 *Summary Descriptions of Impacts to Vegetation Communities and Land Covers of the EIS/EIR Alternatives*

Direct Impacts. A summary of the general vegetation and land cover types that would be permanently and temporarily lost as a result of the RMDP and SCP for Alternatives 2 through 7 can be found in **Table 4.5-25**, Permanent and Temporary Loss of General Vegetation and Land Cover Types for Alternatives 2 through 7 Resulting from Implementation of RMDP and SCP. The main difference between the six alternatives is substantially less reduction of bog and marsh and riparian and bottomland habitat under Alternative 7 when compared to the other alternatives. Alternative 7 would result in the permanent loss of 0.7 acre of bog and marsh and 17 acres of riparian and bottomland habitats, compared to a range of 7.8 acres to 13 acres of permanent loss of bog and marsh and a range of 66 acres to 104 acres of permanent loss of riparian and bottomland habitat by the other alternatives. Temporary loss of bog and marsh and riparian and bottomland habitats would be similar under all six alternatives, with a range of 4.3 to 5.8 acres for bog and marsh, and a range of 95 acres to 111 acres for riparian and bottomland habitats. Similar amounts of native upland vegetation types (chaparral, scrub, and broad leaf upland tree dominated) would be permanently and temporarily lost under Alternatives 2 through 6, and Alternative 7 would have somewhat less permanent loss and more temporary loss of these upland vegetation types. Also, similar amounts of annual grassland, agriculture, developed or disturbed would be permanently and temporarily lost under Alternatives 2 through 6, and Alternative 7 would have substantially less permanent loss and substantially more temporary loss of these non-native and manmade land covers.

Indirect Impacts. Indirect impacts represent the absolute physical loss of a biological resource due to build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas. Alternatives 2 and 3 include build-out of the Specific Plan, VCC, and the Entrada planning areas, while Alternatives 4, 5, 6, and 7 only include build-out of the Specific Plan and the Entrada planning areas.

Table 4.5-25
Direct Permanent and Temporary Loss of General Vegetation and Land Cover Types for Alternatives 2 through 7 Resulting from Implementation of RMDP and SCP

General Physiognomic and Physical Location[1]	Total in Project Area (acres)	Alternative											
		2		3		4		5		6		7	
		Perm. (acres)	Temp. (acres)	Perm. (acres)	Temp. (acres)	Perm. (acres)	Temp. (acres)	Perm. (acres)	Temp. (acres)	Perm. (acres)	Temp. (acres)	Perm. (acres)	Temp. (acres)
Chaparral	2,146.0	26.2	1.5	25.4	1.8	26.9	1.5	26.9	1.8	24.0	1.8	20.8	9.1
Scrub	4,336.1	30.8	2.3	28.5	4.5	28.9	2.0	33.0	6.0	28.5	7.6	18.7	12.5
Native grassland	0.6	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
Bog and marsh	205.9	12.5	4.3	8.3	4.8	7.8	4.6	8.7	5.8	8.4	4.6	0.7	4.3
Riparian and bottomland habitat	982.8	103.5	98.3	81.3	105.2	83.4	95.5	88.2	110.7	65.8	102.0	16.9	95.3
Broad leafed upland tree dominated	1,467.5	9.3	1.4	9.5	1.4	8.9	1.4	13.1	1.4	18.3	1.4	5.6	13.2
California walnut woodland	27.2	0.1	0.0	0.1	0.0	0.1	0.0	0.1	0.0	0.1	0.0	0.1	0.0
California annual grassland, agriculture, developed, or disturbed	5,121.9	211.6	93.6	196.8	132.2	179.1	142.0	233.8	118.1	237.5	131.7	112.2	437.6
Total	**14,288.0**	**393.9**	**201.4**	**349.9**	**249.9**	**335.2**	**247.0**	**403.8**	**243.7**	**382.6**	**248.9**	**175.0**	**572.0**

[1]General physiognomic and physical location classifications are from the "List of California Terrestrial Natural Communities Recognized by the California Natural Diversity Database" (CDFG 2003).

As shown in **Table 4.5-26,** Loss of General Vegetation and Land Cover Types for Alternatives 2 through 7 Resulting from Build-Out of Specific Plan, VCC, and Entrada Areas, the total loss of vegetation communities and land cover types associated with Alternatives 2 and 3 is similar. The percent loss of vegetation communities and land cover types under the six alternatives ranges from a low of 24% for Alternative 7 to a high of 36% for Alternative 2. The loss associated with Alternatives 4, 5, and 6 is generally lower compared to Alternatives 2 and 3 because the approximately 206-acre VCC would not be constructed. The total vegetation community and land cover loss for Alternative 7 is more than 1,440 acres lower than Alternatives 2 and 3 because VCC would not be constructed and large areas of agriculture in Landmark Village and Homestead Village East adjacent to the Santa Clara River would not be developed. This difference is mostly reflected in the category California annual grassland, agriculture, developed, or disturbed where the difference is more than 860 acres between Alternative 7 and Alternatives 2 and 3. Permanent loss of vegetation and land covers under Alternative 7 would also be substantially lower than Alternatives 4, 5, and 6 because of the avoidance of the agricultural areas in Landmark Village and Homestead Village East. For example, there is a 217-acre reduction in the loss of agriculture for Alternative 7 compared to Alternative 6, which would have the lowest impact to agriculture of the other alternatives.

Table 4.5-26
Indirect Permanent Loss of General Vegetation and Land Cover Types for Alternatives 2 through 7 Resulting from Build-Out of Specific Plan, VCC, and Entrada Areas

General Physiognomic and Physical Location[1]	Total in Project Area (acres)	Alternative (acres)					
		2	3	4	5	6	7
Chaparral	2,145.9	430.7	417.3	407.9	409.0	406.5	326.9
Scrub	4,336.2	1,493.3	1,415.5	1,373.8	1,322.3	1,094.1	1,012.8
Native grassland	0.6	0.0	0.0	0.0	0.0	0.0	0.0
Bog and marsh	205.9	2.5	0.6	0.8	0.0	0.0	0.0
Riparian and bottomland habitat	982.8	106.4	84.5	66.6	64.2	35.6	21.8
Broad leafed upland tree dominated	1,467.5	85.4	66.2	64.8	65.9	40.5	44.4
California walnut woodland	27.2	0.0	0.0	0.0	0.0	0.0	0.0
California annual grassland, agriculture, developed, or disturbed	5,121.9	3,081.2	2,957.5	2,821.9	2,767.6	2,548.5	2,088.3
Total	**14,288.0**	**5,199.5**	**4,940.6**	**4,735.9**	**4,629.0**	**4,125.2**	**3,494.2**

[1] General physiognomic and physical location classifications are from the "List of California Terrestrial Natural Communities Recognized by the California Natural Diversity Database" (CDFG 2003).

The general trend of reduction in loss, successively from Alternative 2 to Alternative 7, is also generally true for each of the different vegetation and land cover types. Alternative 2 would have the largest loss of each of the different vegetation and land cover types and Alternative 7 would have the smallest loss for each. However, Alternative 7 would result in a relatively lower loss of riparian and bottomland habitat when compared to the other alternatives in relation to the comparative loss of upland vegetation and land cover. For example, a comparison of Alternative 7 with Alternative 2 shows that Alternative 7 has 67% of the loss of Alternative 2 overall (*i.e.*, 3,494 acres under Alternative 7 versus 5,200 acres under Alternative 2), 76% of the loss of chaparral, 68% of the loss of scrub, 52% of the loss for broad leaf upland tree dominated, and 68% of the loss of California annual grassland, agriculture, developed, or disturbed land cover types. In contrast, Alternative 7 has 20% of the loss of riparian and bottomland habitat compared to Alternative 2 and 61% of the loss under Alternative 6, which has the next lowest loss of riparian and bottomland habitat of the other alternatives.

Secondary Impacts. Secondary impacts on vegetation communities and land covers are foreseeable impacts that could occur under all of the alternatives and that could reduce the vigor and quality of native and naturalized (*e.g.*, California annual grassland) vegetation communities as a result of short-term construction-related impacts and long-term impacts related to development. Secondary impacts on manmade land cover types are considered to be minimal. This section describes each of the potential secondary impacts and how they compare among the different alternatives.

Short-Term Construction-Related Secondary Impacts. Short-term construction-related secondary impacts are discussed in detail in **Subsection 4.5.5.1**, Impact Analysis Approach. The relative level of these secondary impacts for the different alternatives is briefly summarized here. Short-term construction-related impacts generally would be similar for implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas and would be common to all six alternatives, but would differ in degree among the alternatives. For example, with fewer total indirect impacts, these secondary impacts would be somewhat less under Alternative 7 compared to the other alternatives, because there would be less edge between open space and development areas.

Hydrologic Alterations and Water Quality Impacts. Construction of RMDP facilities, including bank stabilization; construction of bridges, associated piers, and abutments; and construction of drainage culverts, could result in hydrologic and water-quality-related impacts adjacent to and downstream of the impact area. Hydrologic alterations include changes in flow rates and patterns in streams and rivers as well as dewatering that may affect adjacent and downstream aquatic, wetland, and riparian vegetation communities. Water quality impacts include chemical and toxic compound pollution (fuel, oil,

lubricants, paints, release agents, and other construction materials), erosion, increased turbidity, and excessive sedimentation. Water temperature changes also may occur due to short-term changes to the active channel morphology, thus affecting vegetation communities in these areas.

All of the alternatives would have similar short-term construction-related impacts on hydrology and water quality because the facilities are relatively the same among the alternatives and only differ in the relative amount and duration of the impact. For example, for bank stabilization, if it is assumed that on average 100 linear feet can be completed per week, then bank stabilization for 29,844 linear feet along the Santa Clara River under Alternative 2 would take 299 weeks while bank stabilization for 25,561 linear feet along the Santa Clara River under Alternative 7 would take 256 weeks, all things being equal. Similarly, short-term hydrology and water quality impacts from construction of piers and abutments would be proportional to the number of bridges constructed under the six alternatives. Alternatives 2 and 5 would construct three bridges over the Santa Clara River; Alternatives 3, 4, and 6 would construct two bridges; and Alternative 7 would construct one bridge (as seen in **Table 4.5-24**, Comparison of RMDP Infrastructure Impacts and Spineflower Preserves for Alternatives 2 through 7). The combined potential impacts to hydrology and water quality of modified drainages and buried storm drains in the tributaries would be similar for Alternatives 2 through 5, ranging from 106,954 linear feet for Alternative 2 to 103,535 linear feet for Alternative 4. Alternative 6 has substantially less modification to tributaries at 94,336 linear feet, and Alternative 7 has relatively little modification, with 19,247 feet of buried storm drain and no drainage modification. Also, the potential risk of impacts to hydrology and water quality in the tributaries is relatively low because most of the tributaries lack perennial flows that would convey local impacts (ENTRIX 2009).

Dust. Dust impacts that could decrease the vigor of plant communities would be similar for the different alternatives, with progressively fewer impacts with succeeding alternatives due to a general reduction of construction activities.

Oak Tree Root Systems. Impacts to oak tree root systems may occur due to soil compaction, pollutants, or toxic compounds. Although potential secondary impacts to oak tree root systems were not quantified, the relative secondary impacts under the different alternatives are expected to be proportional to the permanent and temporary impacts on oak trees. All of the alternatives have similar levels of permanent or temporary impacts on regulated oak trees resulting from implementation of the RMDP and SCP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas; ranging from 1,198 trees (5%) for Alternative 7 to 1,363 trees (6%) for Alternative 2. Therefore, potential secondary impacts to oak tree root systems are anticipated to be relatively similar among all of the alternatives.

Accidental Clearing, Trampling, or Grading. The risk of accidental clearing, trampling, or grading of vegetation communities outside designated construction zones would be similar under the different alternatives and proportional to the size of the grading footprints and the amount of interface with natural vegetation communities. Alternatives 2 and 3, which include construction of VCC (Alternatives 2 and 3 only), would have the greatest relative risk of accidental clearing, trampling, or grading, although much of VCC is already bordered by existing development. Alternatives 6 and 7 would have the least relative risk of accidental clearing, trampling, or grading because of reduced impacts, and Alternative 6 probably has the least risk because of reduced impacts in Potrero Village and Mission Village due to larger spineflower preserve areas.

Trash and Other Debris. The risk of trash and other debris that degrade habitat would be similar under the different alternatives and generally would be a function of the duration of construction activities. Presumably the alternatives with the greatest impacts (*i.e.*, Alternatives 2 and 3) would have the greatest relative risk and the alternatives with the least impacts (*i.e.*, Alternatives 6 and 7) would have the least relative risk, given the gradational reduction in urban land use and construction activities needed for build-out.

Long-Term Secondary Impacts. Potential long-term development-related secondary impacts may operate at both the broader landscape scale and locally along the open space–development interface, or "edge" areas. As with short-term construction-related impacts, long-term development-related secondary impacts generally would be similar for implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and the Entrada planning areas and would be common to all six alternatives, but would differ in degree among the alternatives.

Habitat Fragmentation and Isolation. Habitat fragmentation and some level of isolation of plant communities, including related potential impacts on seed and plant material dispersal (*e.g.*, wind-borne, water-transported, or animal vectors) and plant pollinators, as a result of implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would occur under all of the alternatives.

Habitat fragmentation and isolation resulting from the Project can be evaluated on two scales: (1) the larger regional landscape level that extends beyond the Project boundaries; and (2) the local Project-level scale relating to open space within the Project's outer boundaries (which includes non-preserve natural open space and manufactured open space). From a regional landscape level, build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under the different alternatives would have a similar effect on habitat fragmentation and isolation because the outer boundary or perimeter of the Project development area is essentially the same (see

Figures 4.14-2 through **4.14-7** in **Section 4.14**, Land Use). Under all of the alternatives, the same areas of the High Country SMA, Salt Creek area, and River Corridor SMA would be preserved and would contribute to landscape level habitat connectivity that connects large areas of habitat such as the Santa Susana Mountains to the south, SOAR open space to the west, and the Los Padres National Forest to the north. At the local project-level scale, the different alternatives would result in similar levels of habitat fragmentation and isolation, even though there are some differences in the amount and location of non-preserve natural and manufactured open space areas (see **Figures 4.14-2** through **4.14-7** in **Section 4.14**, Land Use). For example, the relative amount of development and open space for Potrero Village is somewhat different for each of the alternatives. Overall, Alternatives 2 and 3 would result in the greatest level of habitat fragmentation and isolation because they include the development of the VCC planning area, which would constrain the reach of Castaic Creek east of Commerce Center Drive more than under existing conditions. Alternative 7 would have the least amount of habitat fragmentation and isolation within the general boundaries of the Project area. Although the alternatives differ somewhat in the relative amounts of internal development and open space within the broader development boundary, only the size of the spineflower preserves are considered to be significantly different under the different alternatives, with the total spineflower preserve area being progressively larger with each successive alternative (as seen in **Table 4.5-24**, Comparison of RMDP Infrastructure Impacts and Spineflower Preserves for Alternatives 2 through 7).

Although the overall pattern of development within the Project area is similar for the different alternatives, dispersal of plant species by wind and water transport or wildlife vectors along existing drainages within the Project area, such as along the Santa Clara River, Potrero Canyon, Long Canyon, San Martinez Grande Canyon, Chiquito Canyon, and Castaic Creek, is expected to continue after development, albeit in a constrained setting. Implementation of the RMDP includes the construction of bridge crossings over the Santa Clara River and bridge crossings and culverts along tributaries to the River (see **Table 4.5-24**, Comparison of RMDP Infrastructure Impacts and Spineflower Preserves for Alternatives 2 through 7). In principle, bridges and culverts are potential physical obstacles to wind and water transport and wildlife vectors for seed and plant material dispersal and movement of plant pollinators. Because culverts tend to be smaller and more confining than bridges, they are more likely to alter normal wind and water flow patterns and to disrupt movement by wildlife vectors and pollinators. For example, some wildlife, such as mule deer, are hesitant to enter dark culverts, but will readily cross under bridges. Also, culverts are more likely to disrupt wind-borne plant dispersal along drainages than bridge structures because of the more confined space. If culverts result in grade separations in the drainage at the inlet and outlets of the culvert, natural low water flows can be disrupted. Therefore, all things being equal, alternatives with relatively more culverts and fewer bridges are likely to have greater long-term effects on vegetation

communities than alternatives with more bridges and correspondingly fewer culverts. As shown in **Table 4.5-24**, Comparison of RMDP Infrastructure Impacts and Spineflower Preserves for Alternatives 2 through 7, all of the alternatives would include bridge crossings of the Santa Clara River, ranging from one crossing under Alternative 7 to three crossings under Alternatives 2 and 5. However, because all of the bridges across the Santa Clara River would have large spans and adequate heights for plant and wildlife movement and dispersal, the differences in habitat fragmentation and isolation among the alternatives for these bridges is minimal. **Table 4.5-24**, Comparison of RMDP Infrastructure Impacts and Spineflower Preserves for Alternatives 2 through 7, also shows the proposed number of bridges and culverts along the tributaries. Generally, progressing from Alternative 2 to Alternative 7, the number of bridges increases and the number of culverts decreases. From the perspective of maintaining continuous habitat connections along the tributary drainages, Alternative 2 would have the greatest habitat fragmenting and isolating effect and Alternative 7 would have the least effect. Also related to habitat fragmentation and isolation is the linear feet of preserved tributary drainage. **Table 4.5-24**, Comparison of RMDP Infrastructure Impacts and Spineflower Preserves for Alternatives 2 through 7, shows that from Alternative 2 to Alternative 7 there is a progressive increase in the linear feet of preserved drainage within the entire RMDP planning area. Alternatives 2 through 6 are fairly similar, ranging from 125,802 linear feet of preserved drainage for Alternative 2 to 139,659 linear feet for Alternative 6, an 11% increase. Alternative 7 would preserve 214,747 linear feet of drainage, a 71% increase over Alternative 2 and a 54% increase over Alternative 6.

An important factor contributing to internal habitat fragmentation and isolation is the circulation system associated with each build-out scenario under the different alternatives. Apart from the constraining effects of culverts under roads, the roads themselves may preclude or inhibit the movement of wildlife vectors and pollinators. The main roads that could contribute to habitat fragmentation and isolation where they cross movement corridors are Commerce Center Drive, Potrero Canyon Road, Long Canyon Road, and Magic Mountain Parkway. These four roads would all be constructed to varying design requirements under all of the alternatives.

Potrero Canyon Road to some extent would be constructed under all of the alternatives, but only under Alternatives 2, 5, and 6 would the road extend north to cross the Santa Clara River *via* a large bridge. Under these alternatives, Potrero Canyon Road could isolate pollinators near the Potrero Preserve Area and potentially affect upland movement of wildlife vectors between Potrero Canyon and Salt Creek (although the River corridor would also allow for such movement). Under Alternatives 3, 4, and 7, Potrero Canyon Road would terminate well south of the Potrero Preserve Area and wetlands mitigation areas and not cause habitat fragmentation and isolation in this area.

Long Canyon Road would be constructed under all of the alternatives. Although the road primarily would be bordered by manufactured open space, it would cross Long Canyon, which would continue to have habitat connectivity function, albeit constrained. The crossing of Long Canyon under all of the alternatives would be a soft bottomed arched culvert, except for Alternative 7, which would have a bridge crossing. The culvert design would likely result in a greater risk of disrupting water flows, wind-borne seed and plant material dispersal, wildlife vector movement, and pollinator movement.

Magic Mountain Parkway also would be constructed under all of the alternatives and would cross Long Canyon and Lion Canyon, which provide a habitat connection to open space south of the Specific Plan area. Although the road primarily would be bordered by residential development, it potentially could affect habitat connectivity along Long Canyon and Lion Canyon. The crossing of Long Canyon by Magic Mountain Parkway under all of the alternatives would be a 400-foot-long road fill with a soft bottomed arched culvert, except for Alternative 7, which would have a bridge crossing. The culvert design alternative would result in a greater risk of disrupting water flows, wind-borne seed and plant material dispersal, wildlife vector movement, and pollinator movement.

Commerce Center Drive would be constructed under Alternatives 2, 3, 4, and 5. The most important biological resource east of Commerce Center Drive is the Airport Mesa Preserve Area. Under Alternative 2, one large core area of spineflower would be in the preserve east of the road. Under Alternatives 3 and 4, two patches (the large core area and a smaller patch) would be in the preserve east of the road. Under Alternative 5, the two patches east of the road would be in the preserve, as would an additional two small patches west of the road. Under Alternative 5, Commerce Center Drive would isolate the two westerly patches from the two easterly patches, resulting in a risk of disrupting wind-borne seed and plant material dispersal, wildlife vector movement, and pollinator movement. Under Alternative 6 (without Commerce Center Drive) these four patches would all be combined into a single non-fragmented preserve area. Under Alternative 7 all the patches would be preserved but not as a single, integrated spineflower preserve area.

Hydrologic Alterations. Long-term hydrologic alterations, such as flow rates and patterns in streams and rivers due to increased urban and storm runoff, dewatering, or other causes, may affect aquatic, wetland, and riparian vegetation communities and habitats under all of the alternatives. These hydrologic alterations could also affect aquatic-dependent fish and wildlife resources during episodic flooding events where the depth and rate of flow could impact their ability to access suitable high-water refugia. ENTRIX (2009) evaluated the impacts of these hydrologic alterations to special-status fish species, discussed in greater detail in **Subsection 4.5.5.3**.

Section 4.1, Surface Water Hydrology and Flood Control, provides a description of the surface water hydrology within the Project area and evaluates the potential secondary surface water hydrology and flood control impacts resulting from the different alternatives. The different alternatives were evaluated in the context of two significance criteria related to hydrologic alterations. Impacts to hydrology would be significant if implementation of the proposed Project or its alternatives would:

- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on or off site; and/or
- Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff.

In comparison to existing conditions, all alternatives would result in some reduction in floodplain acreages at the different interval flow events (*e.g.*, 2-, 5-, 10-year storm events) (see **Section 4.1**, Surface Water Hydrology and Flood Control, for details). River flows would be impacted by proposed improvements that would reduce the area of the estimated floodplain during less frequent, larger flood events. To prevent flooding, all alternatives include bank stabilization that is designed to contain and convey the FEMA 100-year flood event and the DPW capital flood event. Based on the hydrologic model results (PACE 2009), the Project improvements under all alternatives would not be subjected to significant flooding impacts. Under all alternatives the proposed improvements do not impact storm flows in the Santa Clara River because these improvements are designed to accommodate the flows associated with the 2-, 5-, 10-, 20-, 50-, and 100-year flood events under the proposed conditions for each alternative. In addition, no storm flows are diverted from or to the River as a result of the Project under any alternative, and no drainage tributary to the River will be prevented from flowing to the River in the proposed Project condition under any alternative.

Under all alternatives, runoff within the major tributaries would be conveyed through both engineered, soft-bottom channels and underground stormwater conveyance infrastructure. The engineered channels would be designed to convey both the 100-year and capital flood events in accordance with DPW requirements. Regarding the underground stormwater conveyance infrastructure, the design of these storm drains would comply with DPW requirements for "Storm Drains and Urban Flood Protection" and would incorporate project design features (PDFs) specified in the Newhall Ranch Specific Plan Sub-Regional Stormwater Mitigation Plan (Geosyntec 2008) to minimize flood hazards. The final design of storm drains would be evaluated and approved by

DPW during Village-level review. Final design would be compliant with DPW requirements for storm drains and urban flood protection (County of Los Angeles 1993).

Increases in the volume of debris from the Project area on downstream areas could result in secondary flood hazards downstream of the Project area under all of the alternatives. However, the planned debris basins would be designed to comply with DPW requirements and would incorporate project design features outlined in the Newhall Ranch Specific Plan Sub-Regional Stormwater Mitigation Plan (Geosyntec 2008) to balance runoff and sediment loading to Project tributaries and the Santa Clara River. The adequacy of final designs for the debris basins would be assessed by DPW during Village-level review.

The analysis presented in **Section 4.1**, Surface Water Hydrology and Flood Control, determined that the potential secondary surface water hydrology and flood control impacts on the Santa Clara River and tributaries resulting from all of the alternatives were adverse but not significant (see summary in **Table 4.1-18** for the Santa Clara River and **Table 4.1-19** for tributaries).

Geomorphic Alterations. **Section 4.2**, Geomorphology and Riparian Resources, provides an overview of the existing conditions for geomorphic and riparian resources and evaluates the potential direct, indirect, and secondary hydraulic impacts on sensitive aquatic/riparian resources in the Santa Clara River corridor and tributaries due to implementation of the proposed Project. Geomorphic processes include sediment production, transport, and storage through the River corridor. River geomorphology includes the changes (natural or otherwise) to the landscape and within the floodplain that can cause a variety of adverse or beneficial outcomes. These geomorphic alterations could also affect aquatic-dependent fish and wildlife resources during episodic flooding events where the depth and rate of flow could impact their ability to access suitable high-water refugia. ENTRIX (2009) evaluated the impacts of these geomorphic alterations on special-status fish species, discussed in greater detail in **Subsection 4.5.5.3**.

The different alternatives were evaluated in the context of significance criteria derived from Appendix G of the State CEQA Guidelines (Cal. Code Regs., tit. 14, § 15000 *et seq*). Generally, geomorphic impacts would be significant if implementation of the proposed Project or its alternatives would:

- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on site or off site.

In order to evaluate the impacts relative to the above significance criterion, the following sub-categories for direct and indirect impacts were used in the analysis presented in **Section 4.2:**

Significance Criterion 1: Project would result in short-term impacts from construction activities that would temporarily change the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on- or off-site;

Significance Criterion 2: Project would result excessive long-term erosion and/or downstream deposition post-Project implementation;

Significance Criterion 3: Project would result in a substantial adverse impact to geomorphic function (*i.e.*, channel stability); and

Significance Criterion 4: Project would result in excessive scouring of established or revegetated riparian vegetation.

In addition, the following sub-category was used for the analysis of secondary impacts resulting from the implementation of the Project:

Significance Criterion 5: Project would result in a substantial reduction of sand transported to Ventura County beaches.

The analysis presented in **Section 4.2** made the following conclusions for the Santa Clara River and its tributaries relative to these significance criteria for Alternatives 2 through 7:

1. Installation of bank stabilization features and bridge piers and abutments would directly impact geomorphic elements of the Santa Clara River and its tributaries, including alterations of the River and tributaries in a way that would cause substantial erosion, resulting in significant impacts, absent mitigation, under Alternatives 2 through 7 (significance criterion 1).

   Construction of the Specific Plan, VCC, and Entrada planning areas (particularly site clearing and grading operations) would have the potential for discharging sediment downstream during storm events, resulting in significant impacts, absent mitigation, under Alternatives 2 through 7 (significance criterion 1).

2. Implementation of the RMDP improvements and facilities would have the potential for discharging sediment downstream during storm events, which may result in substantial erosion and deposition and could result in significant impacts

downstream, absent mitigation, under Alternatives 2 through 7 (significance criterion 2).

The drainage areas in which the Specific Plan, VCC, and Entrada planning areas occur would not be completely developed; therefore, storm flows from the upper reaches would contain sediment and vegetative debris. The amount of sediment and debris contained in the storm flows would be dependent upon the size of the area being drained and whether or not the area had been subject to recent burning. If this debris enters and clogs on-site drainages, upstream flooding could occur, which would be a significant impact, absent mitigation, under Alternatives 2 through 7 (significance criterion 2).

3. The proposed RMDP improvements and facilities would have limited and localized hydromodification impacts to the Santa Clara River. Under moderate storm runoff events, localized increases in flow quantity and velocity would be present at drainage outlet facilities along the banks of the Santa Clara River. These events, however, would be of short duration (temporary) and limited in comparison to periodic channel disturbances caused by Santa Clara River flows from upstream, as described by Balance Hydrologics (2005). The estimated change in hydraulic characteristics under the proposed RMDP to the Santa Clara River would be relatively minor, and, thus, these impacts are considered to be adverse but not significant under Alternatives 2 through 7 (significance criterion 3).

   The proposed tributary drainage treatments incorporate hydromodification controls that lessen potential stormwater-related impacts (intensity and duration) to the River, including buried storm drains, partially open channels, and relocated stream alignments. These impacts are considered to be significant, absent mitigation under Alternatives 2 and 4 and adverse but not significant under Alternatives 3, 5, 6, and 7 (significance criterion 3).

   Potential indirect hydromodification impacts to the Santa Clara River and tributaries include stream corridor disturbances from build-out of the Project area and associated increased runoff intensity, and the sediment transport regime from the urbanized tributary drainages. These impacts are considered to be significant, absent mitigation, under Alternatives 2 through 7 (significance criterion 3).

4. Installation of bank stabilization features, bridges, and turf-reinforced mats would not cause significant scouring, and, therefore, would not alter the amount and pattern of riparian habitats in the River in the Project area. The current pattern of scouring due to high velocities would remain intact. These impacts were considered to be adverse but not significant under Alternatives 2 through 7 (significance criterion 4).

Impacts to riparian vegetation within the tributaries located within the RMDP boundary are primarily associated with the physical alterations to the stream channels and are considered to be significant, absent mitigation, for Alternatives 2, 4, and 5, and adverse but not significant for Alternatives 3, 6, and 7 (significance criterion 4).

5. The effects of the implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas on beach replenishment are a function of the sediment load delivered through the Project reach. The Santa Clara River contributes approximately 60% of beach sand within Ventura County. The reduction of area subject to erosion could result in a relative reduction of floodwater sediment, which could negatively impact beaches, as incrementally less sediment would be available for their replenishment. The geomorphic analysis estimated an approximately 0.02% decrease from the current sediment supply as a result of the Project and concluded that this impact would be adverse but not significant (significance criterion 5).

All of the impacts considered to be significant, absent mitigation, are mitigable to a level that is adverse but not significant. **Subsection 4.2.6** describes the mitigation measures that will be implemented to reduce the significant impacts to geomorphic processes, including measures from the Specific Plan EIR (County of Los Angeles 2003A) and additional measures proposed by this EIS/EIR.

Water Quality. **Section 4.4**, Water Quality, provides an overview of the existing conditions for surface water and groundwater quality and evaluates the potential direct, indirect, and secondary impacts to surface water in the Santa Clara River corridor and tributaries and groundwater quality under the different alternatives. Surface water pollutants of concern identified for the Project area include sediments (total suspended solids (TSS) and turbidity), nutrients (ammonia, nitrite, nitrate, total nitrogen, and total phosphorus), trace metals (aluminum, copper, lead, and zinc), chloride, pathogens (fecal coliform, viruses, and protozoa), petroleum hydrocarbons (oil and grease and Polycyclic Aromatic Hydrocarbons (PAHs), pesticides, trash and debris, Methylene blue activated substances (MBAS), cyanide, and bioaccumulation (see **Table 4.4-11** in **Section 4.4**, Water Quality, for details).

The different alternatives were evaluated in the context of three significance criteria related to water quality. Impacts to water quality would be significant if implementation of the proposed Project or its alternatives would:

- Violate any water quality standards or waste discharge requirements;
- Create or contribute runoff water, which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff; or
- Otherwise substantially degrade water quality.

The Newhall Ranch Specific Plan Sub-Regional Stormwater Mitigation Plan (Geosyntec 2008) summarizes the water quality PDFs that would be incorporated into the Project under all of the alternatives to meet all relevant federal, state, and local regulations and policies (see **Subsection 4.4.3.1**, Regulatory Setting). These PDFs include site design, source control, and treatment control BMPs incorporated into the Project to effectively manage wet-weather and dry-weather water quality by limiting or managing pollutant sources. Site design and source control BMPs are practices implemented to minimize runoff and the introduction of pollutants in stormwater runoff. Treatment controls are implemented to remove pollutants once they have been mobilized by runoff (see **Table 4.4-12** in **Section 4.4**, Water Quality, for details).

A comprehensive water quality analysis for Alternative 2 is presented in **Section 4.4** (see **Subsection 4.4.5.2.7**, Total Impacts—Alternative 2). This analysis concluded that comprehensive site design, source control, and treatment control strategy, and full compliance with regulatory requirements would assure that potential long-term direct and indirect impacts from RMDP and SCP maintenance activities and Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada areas build-out on receiving water quality would not be significant after this mitigation under the significance criteria listed above. This analysis also found that the long-term secondary impacts to water quality in the Santa Clara River and groundwater would be reduced to an adverse but not significant level. All of the other alternatives would have reduced RMDP improvements and reduced levels of build-out in the Project area compared to Alternative 2, and, therefore, potential water quality impact under Alternatives 3 through 7 would also be adverse but not significant.

Other Landscape-Scale Long-Term Secondary Impacts. There are several additional landscape-scale long-term secondary impacts on vegetation communities that would be common to all of the alternatives and would likely have a similar level of impact.

- Alterations in wildfire regimes, including shorter fire intervals in some areas due to accidental and intentional ignitions, and long fire intervals where wildfires are suppressed are likely to occur as a result of build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and the Entrada planning areas. The long-term effect of shorter fire intervals could be the permanent transition of shrublands (scrubs and chaparral) to annual grasslands. This transition may be facilitated by habitat

fragmentation of small habitat patches in natural open space areas within the general Project boundaries as discussed above because colonization of the sites by native plant species may be precluded or inhibited.

- Air pollution resulting in increased nitrogen deposition, which, in turn, facilitates the growth of non-native plants would be similar for all of the alternatives.
- Increased human activity in open space areas, including permitted recreational use of trails by humans and their pets, and unauthorized impacts, including trespass, vandalism, illegal shooting and hunting, motorized and non-motorized off-road vehicles, trampling of vegetation, soil compaction, and trash dumping would be similar for all of the alternatives.
- The potential for invasive plant species that affect streams and rivers, including giant reed, tamarisk, and pampas grass would be similar for all of the alternatives.

Edge Effects. Potential long-term development-related secondary impacts operating at the open space–development interface, or edge, include:

- Microhabitat changes along habitat edges due to increased wind and solar exposure or vegetation thinning and/or irrigation in fuel modifications zones;
- Invasive plant species that thrive in edge habitats;
- Increased moisture regimes at habitat edges that attract invasive animal species, such as Argentine ant, and subsequent impacts on native species, including seed dispersers and pollinators of native plants;
- Trampling of vegetation and compaction of soils, affecting the viability of plant communities and certain species; and
- Herbicides that may be directly toxic to native plant species.

Long-term development-related impacts at both the landscape scale and along the open space–development interface generally would be similar for implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and the Entrada planning areas under the six alternatives, but would differ in degree among the alternatives. Alternative 7, in particular, would have fewer secondary edge effects along the Santa Clara River Corridor SMA because of the reduced impacts to agricultural areas adjacent to the River in Landmark Village and Homestead Village East. Because VCC would not be constructed under Alternatives 4, 5, 6, and 7, those alternatives would not have edge effects along Castaic Creek compared to Alternatives 2 and 3. All of the alternatives have the same planned development land use plan along the interface of Potrero Village and the High Country SMA and Salt Creek area.

4.5.5.2.3.2 *Impacts to Vegetation Communities and Land Covers*

Implementation of the proposed Project would result in the direct permanent and temporary loss of, indirect permanent loss of, and secondary impacts to, both common and special-status plant communities (see **Subsection 4.5.5.1**, Impact Analysis Approach and Methods, for a discussion of direct, indirect, and secondary impacts). Some of the plant communities in the RMDP and SCP study areas have widespread distributions, are common, and are both locally and regionally abundant. As described in **Subsection 4.5.3.3**, Existing Conditions by Project Planning Area, the vegetation communities present in the RMDP and Specific Plan area vary in quality from high biological value riparian and upland habitat to highly disturbed land, such as agricultural areas and graded oil well pads (**Figures 4.5-11-A1** through **4.5-11-C2**, RMDP/SCP – Vegetation Communities and Land Covers).

Upland vegetation communities dominate the landscape within the RMDP and SCP study areas, both north and south of the Santa Clara River, and would be the largest area subject to project disturbance. The dominant upland vegetation communities in these areas include coastal scrub (and alliances and associations), chaparral and associations, coast live oak woodland, mixed oak woodland and valley oak/grass, and California annual grasslands. Man-made land covers agriculture and disturbed land also occur in many upland areas and are bordered by various coastal scrub communities.

Riparian communities are equally well represented in the proposed Project area. For example, southern cottonwood–willow riparian forest, river wash, and herbaceous wetlands vegetation communities comprise the majority of the land in the Santa Clara River Corridor. Many of the tributaries that occur in the project area also support riparian and scrub communities.

Direct permanent and temporary impacts to existing vegetation communities and land covers resulting from implementation of the proposed RMDP, along with indirect permanent impacts caused by the build-out of the Specific Plan, VCC, and Entrada planning areas are presented in **Table 4.5-27**. **Figures 4.5-33-A1** through **4.5-38-D2** depict the vegetation communities that would be subject to project disturbance for Alternatives 2 through 7.

Although each riparian and upland vegetation community and land cover is analyzed separately below in order to be comprehensive, the impact analysis review is organized by category: Riparian Communities; California Annual Grasslands, Agriculture, Disturbed Land, and Developed Land; Coastal Scrub Communities; Chaparral Communities; Oak Woodland and Forest Communities; Purple Needlegrass; and California Walnut Woodland. As part of the significance finding, the value of each vegetation community or land cover as wildlife habitat for special-status species is also considered, and the mitigation strategy is discussed. The full text for proposed mitigation measures is provided in **Subsection 4.5.6**, Mitigation Measures. Illustrative lists of special-status species using the different vegetation communities and land covers are provided where relevant; these lists are not intended to be comprehensive or

exhaustive. Special-status species impacts under Alternatives 2 through 7 are analyzed in **Subsection 4.5.5.3**, Impacts to Special-Status Species.

Construction effects to vegetation communities may occur in a variety of ways, including the direct removal of plants during the course of construction or from secondary effects including the spread or colonization of exotic species, increased fire frequency, or human trampling in edge areas. Clearing and grading associated with the construction of RMDP facilities or the build-out of the Specific Plan, VCC or Entrada planning areas may also result in the alteration of soil conditions, including the loss of native seed banks and changes to the topography and drainage of a site such that the capability of the habitat to support native vegetation is impaired. Construction may also result in the creation of conditions that are favorable for the invasion of weedy exotic species that prevent the establishment of desirable vegetation and may adversely affect wildlife. Some ecosystems are especially sensitive to ground disturbance and can take decades to recover, if at all. For example, clearing or substantial pruning of oak woodlands may take decades to functionally recover to pre-construction conditions.

For the purposes of this analysis it is important to note that the implementation of the RMDP and the build-out of the Specific Plan, VCC, and Entrada planning areas would result in the large scale land use conversion from existing uses to developed parcels. This would involve the permanent removal of vegetation to accommodate the proposed development. While one component of the development would include designated open areas and buffers, the implementation of the Project would ultimately result in the loss of existing vegetation communities in many areas. To mitigate for the loss of existing land uses and conversion to developed land, a series of mitigation measures would be implemented to reduce the effects of the permanent loss of vegetation communities. In addition, a series of mitigation measures would be implemented to reduce the effects of temporary and secondary impacts to remaining vegetation communities. The specific measures to be employed and the rationale for their success are described below.

Permanent loss of non-native vegetation communities (California annual grassland and giant reed) and man-made land covers (agriculture, disturbed land, and developed areas) would also occur as a result of habitat restoration and enhancement activities associated with implementation of the SCP and with proposed mitigation measures.

A detailed description of the specific types of effects that may occur to vegetation is located in **Section 4.5.5.1**, Impact Analysis Approach and Methods.

Implementation of the proposed Project would require construction to occur within a broad array of vegetation communities and land covers. **Subsection 4.5.3.4.1**, Vegetation Communities and Land Cover Types, contains a detailed description of the various vegetation present in the proposed Project area.

Significance Criteria. The effects of a project to any given vegetation community may differ depending on a variety of factors. These include, but are not limited to, the sensitivity of the community (*i.e.*, is the community designated as sensitive by CDFG or other resource agency); the ability of the community to support special-status plants or wildlife; the total acreage lost or affected by the proposed Project; and the physical amount of habitat that remains in the project area at the conclusion of construction. For projects where large scale land conversion occurs the effects of the project must consider how the loss of specific vegetation communities affect both local and regional populations of species that occupy those areas lost through development. **Subsection 4.5.4**, Impact Significance Criteria, contains a detailed discussion of the significance criteria developed for this project.

As described in **Subsection 4.5.4**, Impact Significance Criteria, the consideration of impacts to vegetation communities and land covers falls under the following significance criteria. Biological impacts would be significant if implementation of the proposed Project or its alternatives would (1) Have a substantial adverse effect, either directly or via habitat modifications, on any species designated as candidate or special status by federal, state, or local agencies; (2) Have a substantial adverse effect on any riparian habitat or other special-status natural community identified by federal, local, or state agencies; (5) Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance; and (7) Have the potential to substantially reduce the habitat of a fish or wildlife species; cause a fish or wildlife population to drop below self-sustaining levels; threaten to eliminate a plant or animal community; or substantially reduce the number or restrict the range of an endangered, rare, or threatened species.

4.5.5.2.3.2.1 Impacts to Vegetation Communities and Land Covers—Alternative 2

Impacts to Riparian Communities

Existing Conditions. Riparian forests are structurally and floristically complex vegetation communities (Roberts *et al.*, 1977). Under ideal conditions, these forests consist of several layers with dense undergrowth (Warner *et al.*, 1984) and are often difficult to characterize as different communities often merge into each other as specific sites undergo succession. The Santa Clara River and its tributaries and portions of the RMDP contain a broad array of early to late successional riparian communities ranging from sand and gravel bars dominated by sandbar willow saplings and cattails to mature

galleries of Fremont cottonwood with complex understories of woody and herbaceous vegetation.

Riparian communities in the proposed Project area are of high sensitivity and biological value. As described in **Subsection 4.5.3.3**, Existing Conditions by Planning Area, the Santa Clara River Corridor and its tributaries supports a variety of special-status plant and wildlife species. Some of the special-status wildlife known to occur includes the arroyo toad, black crowned night-heron, Cooper's hawk, and least Bell's vireo. Northern harrier, white tailed kite, willow flycatcher, yellow warbler, yellow breasted chat, and yellow headed blackbird have also been identified. As many portions of the RMDP support perennial water, several aquatic or semi-aquatic species have been observed including arroyo chub, Santa Ana sucker, unarmored threespine stickleback, southwestern pond turtle, and two striped garter snake. Three special-status plants have been recorded in the River Corridor SMA, and include an undescribed everlasting, an undescribed sunflower, and slender mariposa lily.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

Subsection 4.5.5.1, Impact Analysis Approach and Methods, of this EIS/EIR contains a detailed description of the different direct, indirect, and secondary effects that could occur from the implementation of the proposed RMDP and the SCP. **Subsection 4.5.5.1** also provides the reader with a comprehensive description for each of the different impact types and how the impact may affect the vegetation community.

The primary direct effect of the RMDP is the permanent land use conversion of riparian vegetation communities. As described above, construction activities would result in the permanent removal of approximately 116 acres of riparian vegetation communities on site. Implementation of the RMDP would also result in the temporary removal of 103 acres of riparian vegetation communities.

Both permanent and temporary disturbance to vegetation and landcovers would occur from clearing and grading associated with the construction of proposed permanent and temporary haul or access roads, grade control structures, buried bank protection, installation of culverts and other improvements. The temporary loss of riparian vegetation communities would occur where grading or soil disturbance would occur for a short period of time (*e.g.*, along the edges of proposed facilities), but where no permanent structures would be constructed.

Construction within riparian vegetation communities may result in a series of effects including the loss of vegetation and native seed banks; changes to the topography and drainage of a site such that the capability of the habitat to support native vegetation is impaired; and the alteration of existing soils. Temporary impacts to riparian vegetation can also result in the displacement of wildlife and increase the potential for exotic plant propagation. Although areas temporarily disturbed by construction would be restored at the conclusion of construction; sediment and vegetation removal in riparian communities would reduce the seed bank and could adversely affect hydric soils. Soils would be impacted during vegetation removal by the direct removal of litter and organic matter along with vegetation, and would result in a reduction of the biomass available as new input to the soil. The removal of sediments would also eliminate soil microbes essential to the reestablishment of wetland plants.

Depending on the type of riparian communities that would be affected by project construction, the restoration time required to restore the functional values of the habitat may take several years to replace. For example, temporary impacts to early successional riparian communities including marsh and river wash communities can respond fairly quickly after a disturbance as these areas are dominated by rapidly colonizing plant species. Some willow scrub communities may also reach habitat functions and services/values in a short period of time as these areas are often subject to annual storm flows and scour events. Conversely, disturbance of southern-cottonwood willow riparian forest or alluvial scrub communities could take several years to functionally recover.

Construction activities that remove native vegetation may also result in the creation of conditions that are favorable for the invasion or spread of weedy exotic species that thrive in riparian areas, such as giant reed and tamarisk. Non-native plants pose a threat to the natural processes of plant community succession, fire frequency, biological diversity and species composition. The survival of some populations of special-status species could be adversely affected by the success of an introduced plant species.

Exotic vegetation has been demonstrated to be more abundant in riparian habitats that are in close proximity to urbanized areas. Studies have shown that riparian bird species richness and density tend to be negatively correlated with exotic vegetation abundance, presumably because exotic plant assemblages fail to provide the necessary structural and nutritional resources that native plant communities provide (Rottenborn 1997 and 1999; Mills *et al.* 1989; Anderson *et al.* 1977). Urbanized areas also tend to support higher concentrations of common disturbance-following species that often displace local species dependent on

riparian habitats. The introduction and spread of non-native plant species normally occurs when vehicles or equipment exposed to populations of noxious weeds in one geographic area inadvertently transport the seeds to another area where lands have been disturbed. Although the region currently supports wide populations of noxious weeds, the introduction of new species not currently present in the region or the spread of noxious plant species across the project area would be considered a significant impact absent mitigation.

Construction activities associated with the development of RMDP facilities (*e.g.*, buried bank protection, levees, bridges, and ancillary structures) would result in the permanent removal of 116 acres and temporary removal of 103 acres of riparian communities on site. These impacts would occur to both woody and herbaceous wetland communities. For example, direct impacts to woody riparian communities would include the permanent/temporary loss of 36/40 acres of southern cottonwood–willow riparian forest; the permanent/temporary loss of 2.7/4.9 acres of southern willow scrub; the permanent/temporary loss of 16/8.2 acres of mulefat scrub; the permanent/temporary loss of 2.8/2.3 acres of arrow weed scrub; the permanent/temporary loss of 24/5.2 acres of big sagebrush scrub; the permanent/temporary loss of 21/38 acres of river wash; the permanent/temporary loss of 0.3/0.0 shrub tamarisk; and the permanent/temporary loss of 1.5/0.0 acres of Mexican elderberry scrub. Permanent and temporary impacts would not occur to alluvial scrub, big sagebrush scrub – California buckwheat, disturbed Mexican elderberry scrub, giant reed, or southern coast live oak riparian forest from implementation of the proposed RMDP. However, because giant reed is an invasive nonnative plant community it is expected that these areas would be revegetated with other native vegetation communities as a result of enhancement and restoration opportunities associated with the River Corridor SMA. In addition, the reestablishment of giant reed would be controlled through the mitigation monitoring period.

Direct losses from implementation of the RMDP to herbaceous communities would include the permanent/temporary loss of 9.7/0.0 acres of cismontane alkali marsh; permanent/temporary loss of 1.6/0.0 of coastal and valley freshwater marsh; permanent/temporary impacts to 1.1/4.3 acres of herbaceous wetland on site. Implementation of the proposed RMDP and SCP would not result in the permanent or temporary removal of bulrush–cattail wetland. Implementation of the SCP would not directly impact any riparian vegetation community. **Table 4.5-27**, Impacts of the Proposed Project to Vegetation Communities and Land Covers, provides a detailed analysis of the vegetation acreage affected by each project component.

As a relative index of the habitat availability on site, approximately 1,189 acres of riparian communities occur in the proposed RMDP project area. Thus, the relative loss of these vegetation communities from direct impacts is approximately 10.0% of the existing riparian communities present in the project area. However, the total percentage of any given community may range from a low of 0% for southern oak riparian forest and giant reed to 51.1% for cismontane alkali marsh. What is important to recognize for all vegetation percentages identified in this report is the total percentage of a vegetation community lost only reflects the percent of the habitat that occurs in the project area. That is, while the total percentage of cismontane alkali marsh affected by the proposed project is high, the total acreage lost is 9.7 acres out of approximately 19 acres that occur on site. Conversely, southern cottonwood-willow riparian forest would be subject to a loss of 8.5% of the existing habitat (a total of 36 acres lost) of the 422 acres of this community that is present in the project area. Further, while there are 754 acres of riparian habitat along the Santa Clara River on site, 11.2% of that habitat will be impacted. By contrast, there are 435 acres of riparian habitat along the tributaries on site, 55.8% of which will be impacted by the proposed Project.

For riparian communities that are present in the Project area the majority of the habitat removal would result from the construction of buried bank protection and the associated RMDP infrastructure. Implementation of the SCP would not result in impacts to riparian vegetation communities.

Significance Finding: Significant absent mitigation for Alternative 2. In California more than 95.0% of riparian habitats that were present prior to European settlement have been severely degraded or destroyed (Smith 1977; Katibah 1984). Although riparian zones naturally account for a low percentage of the total landscape (often less than 1.0%), they typically accommodate a disproportionately high number of species and provide a larger degree of ecological function than surrounding upland areas (Fischer and Fischenich 2000).

Riparian communities support some of the most diverse assemblages of wildlife and provide access to water, shade, and protection from predation. These areas also provide foraging habitat and are used for nesting and breeding by both common and special-status species. The diverse riparian community types that occur in the Santa Clara River and its tributaries provide habitat for a variety of resident and migratory wildlife species including several special status species such as least Bell's vireo, white tailed kite, unarmored three-spine stickleback, and southwestern pond turtle. The broad multi-structured riparian canopy in the Santa Clara River, including dense galleries of cottonwoods, is an important stopover for many migratory birds including the willow flycatcher. In addition, the wide

river channel and adjacent riparian communities function as a movement corridor for a number of wildlife species and provide connectivity from the Simi Hills to areas in both the Los Padres and Angeles National Forests. The tributaries function as movement corridors between the Santa Clara River and upland habitats and provide connectivity between the Los Padres National Forest and the Santa Susana Mountains.

With the exception of exotic plant communities such as shrub tamarisk or giant reed thickets, most riparian communities are considered sensitive by CDFG and are regulated by state and federal laws. However, due to the location of many exotic plant communities in the Santa Clara River or its tributaries (*e.g.*, within state or federal jurisdictional limits) even the loss of those communities would require compensatory mitigation in the form of creation and/or restoration with native vegetation. In addition, in some locations (*e.g.*, the Ventura River and Colorado River) exotic plant communities have been documented to support special-status wildlife including least Bell's vireo and southwestern willow flycatcher. Depending on the location within the Santa Clara River these same species could occupy habitat immediately adjacent to or within the mosaic of riparian communities that are present in the project area.

Based on the presence of special-status plants and wildlife in the Santa Clara River and its tributaries, the implementation of the proposed RMDP has the potential to result in substantial adverse effects on special-status species and habitat that occur in riparian communities. The permanent impacts associated with the construction of infrastructure associated with the RMDP facilities would constitute a substantial adverse effect on the vegetation communities present and would have the potential to substantially reduce the number or restrict the range of special-status species known to occur in the planning area (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2.

Mitigation Strategy for Direct Permanent and Temporary Impacts

In order to reduce direct impacts to riparian communities resulting from the implementation of the RMDP, a series of mitigation measures approved for the Specific Plan EIR and additional measures that would be implemented for this project would avoid and/or minimize the effects of Project construction on these resources.

The primary mechanism for mitigating the permanent loss of riparian vegetation communities in the RMDP and SCP study areas is the implementation of mitigation measures designed to replace the habitat functions and services/values

of riparian vegetation communities that were lost through construction and the dedication and maintenance of existing natural lands in the River Corridor SMA, High Country SMA, and Salt Creek area. These mitigation measures would off-set the direct removal of riparian vegetation communities in the project area.

For riparian vegetation communities this includes the direct replacement of riparian communities at a minimum 1:1 ratio for all permanently affected habitats in order to achieve the same habitat functions and services/values that were lost through implementation of the proposed Project. Restoration shall be in kind and at a 1:1 replacement ratio for new vegetation communities if the replacement vegetation is installed two years in advance of the removal of existing vegetation communities. If the replacement vegetation communities cannot be installed prior to the two year period the restoration ratios would increase to ensure the replacement of lost riparian functions and services/values. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

Mitigation designed to restore, enhance, or replace temporarily disturbed riparian vegetation communities focuses on achieving the required percent coverage and tree growth performance criteria for the proposed target species, as well as native species recruitment and reproduction. The intent of the restoration is to facilitate the reestablishment of native riparian habitat with a diverse profile (*e.g.*, structure and stratification, and plant species composition) of native plants necessary to provide wildlife nesting, sheltering, and foraging opportunities. General habitat structure and stratification will include the reestablishment of structured riparian strata including an understory composed of native herbaceous species, grass species, and small shrub species; a midstory (or midstories) composed of larger native shrubs and small trees of varying sizes; and an overstory or canopy composed of larger native trees of varying sizes. This should result in the establishment of suitable habitat for a diverse range of wildlife species typical of riparian habitats within the area. Suitable habitat includes opportunities for nesting, sheltering, and foraging by providing a broad diversity in plant species composition and age/size structure with layers of detritus/leaf litter, and dead/fallen wood and vegetative matter.

In order to reduce direct impacts to this vegetation community due to the removal of vegetation, the Project applicant would implement a series of mitigation measures designed to restore the functions and services/values provided by

riparian vegetation communities lost as a result of development. These measures include previously incorporated measures SP-4.6-1 through SP-4.6-16 and SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA; 1:1 riparian resource replacement), SP-4.6-26a (riparian revegetation and oak tree replacement opportunities in the High Country SMA), SP-4.6-28 (mitigation banking for various habitat types in the High Country SMA), SP-4.6-43 (Open Area use for mitigation of riparian or oak resources or elderberry scrub), SP-4.6-47a (allowing mitigation banking for riparian habitats, oak resources, and Mexican elderberry within the River Corridor SMA, High Country SMA, and Open Area). These impacts would also be reduced through the implementation of Mitigation Measures BIO-1 through BIO-16 (wetlands mitigation plan and riparian restoration activities on the Project site). CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

Further protection of vegetation communities would be achieved through the creation of buffers and biologically monitored perimeters during construction periods. Biologically monitored perimeters would limit the potential for the contractor to disturb vegetation outside the proposed construction footprint. The use of these measures would identify the limits of construction and provide a biological monitor to review the construction area in the field with the contractor and be present during initial vegetation clearing and grading. To further reduce the impacts of the proposed RMDP from accidental clearing or trampling of vegetation the applicant would implement previously incorporated Mitigation Measures SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA); SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the River Corridor SMA and the High Country SMA); and BIO-52 (pre- construction educational meetings, construction limit staking, and biological monitoring during vegetation clearing and grading activities). Implementation of these measures would reduce these effects to less-than-significant levels.

Following development, continued preservation of the dedicated areas would be accomplished through restricted access and long-term management of the River Corridor SMA, High Country SMA, and Salt Creek area. The use of buffers would limit the potential for the spread of exotic weeds and limit the potential for the spread of wildfires (buffers are described in detail under Secondary Impacts of the Proposed Project). To further reduce the impacts of the proposed Project, the

applicant would implement previously incorporated Mitigation Measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA); and BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas) and BIO-73 (permanent fencing along trails in the River Corridor SMA). Implementation of these measures would reduce these effects to less-than-significant levels.

Long-term management activities would include the establishment of native vegetation communities in currently disturbed habitat, a reduction in cattle grazing except where grazing may be used as a management tool to control exotics, and the management of exotic species. The specific mitigation measures that would provide for the dedication of open space and management of these areas includes previously incorporated Mitigation Measures SP-4.6-21 through SP-4.6-26 (Open space dedication of the River Corridor SMA), SP-4.6-36 through SP-4.6-42 (Open space dedication of the River Corridor SMA and the High Country SMA), and SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA). In addition, some of the new measures presented in this document include Mitigation Measures BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) and BIO-62 (dedication to the public of at least 1,900 acres of Open Area to an NLMO). These measures provide additional mechanisms to ensure the dedication and management of natural lands and open space to mitigate the effects of the proposed project to riparian communities. These areas support the same types of habitat that would be lost through construction and would be further enhanced through ongoing restoration and management activities.

In addition, previously adopted mitigation measures from the Specific Plan EIR and mitigation measures proposed for this Project provide mechanisms to restore temporarily disturbed habitat and enhance the habitat within the proposed mitigation lands. **Tables 4.5-13**, **4.5-14**, and **4.5-15** in **Subsection 4.5.3.3**, Existing Conditions by Project Planning Area, provide a breakdown of the vegetation communities and land covers present in the River Corridor SMA, High Country SMA, and Salt Creek area, respectively, that would be used to provide mitigation lands for the proposed RMDP. For this Project, over 169 mitigation measures have been presented to reduce or minimize the effects of the proposed Project on biological resources. **Subsection 4.5.6**, Mitigation Measures, contains the entire list of mitigation measures that would be used to reduce the effects of the proposed Project.

The goal of the mitigation program is to restore the floodplain functions and services/values lost during Project construction as described above by reestablishing riparian and upland (upper terrace) habitat, and to enhance the quality of the Santa Clara River ecosystem. Implementation of the restoration measures described below would restore functional habitat services/values and reduce the effects of the RMDP to less-than-significant levels.

The specific mitigation measures that would be utilized to reduce the direct impacts of the proposed RMDP to a level that is adverse but not significant are identified below in **Table 4.5-28**.

Table 4.5-28
Applicable Mitigation Measures for Direct Impacts to Riparian Vegetation Communities

Mitigation Measure(s)	Issue Mitigating
SP-4.6-1 through SP-4.6-16 (habitat restoration/enhancement in the River Corridor SMA)	Vegetation Removal
SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA)	Vegetation Removal
SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA)	Vegetation Removal
SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA)	Vegetation Removal
SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA)	Vegetation Removal
SP-4.6-26a (riparian revegetation and oak tree replacement opportunities in the High Country SMA)	Vegetation Removal
SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA)	Vegetation Removal
SP-4.6-28 (mitigation banking for various habitat types in the High Country SMA)	Vegetation Removal
SP-4.6-34 (marking and inspection of grading perimeters prior to impacts within or adjacent to the High Country SMA)	Vegetation Removal
SP-4.6-35 (avoidance of inadvertent impacts to biological resources within or adjacent to the High Country SMA)	Vegetation Removal
SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA)	Vegetation Removal
SP-4.6-43 (Open Area use for mitigation of riparian or oak resources or elderberry scrub)	Vegetation Removal
SP-4.6-47a (allowing mitigation banking for riparian habitats, oak resources and Mexican elderberry within the River Corridor SMA, High Country SMA, and Open Area)	Vegetation Removal
SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA; 1:1 riparian resource replacement)	Vegetation Removal
BIO-1 through BIO-16 (wetlands mitigation plan and riparian restoration activities on the Project site)	Vegetation Removal
BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126)	Vegetation Removal
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Vegetation Removal

Table 4.5-28
Applicable Mitigation Measures for Direct Impacts to Riparian Vegetation Communities

Mitigation Measure(s)	Issue Mitigating
BIO-62 (dedication to the public of at least 21,900 acres of Open Area to an NLMO)	Vegetation Removal
BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas)	Vegetation Removal
BIO-73 (permanent fencing along trails in the River Corridor SMA)	Vegetation Removal

Indirect Permanent Impacts

Most of the effects to riparian habitat would occur from construction activities associated with the RMDP. Only small areas of riparian vegetation would be affected by the build-out of the Specific Plan, VCC, and Entrada planning areas. The loss of riparian vegetation communities would occur through construction-related activities and the development of residential housing, commercial properties, and infrastructure.

Construction activities associated with the build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent removal of approximately 109 acres of riparian vegetation communities. Similar to direct effects, these impacts would occur to both woody and herbaceous wetland communities. Most of the permanent effects would occur to big sagebrush scrub (47 acres), followed by river wash (35 acres), southern cottonwood–willow riparian forest (6.8 acres), mulefat (6.4 acres), Mexican elderberry (6.1 acres), and arrow weed scrub (4.0 acres). Small impacts would also occur to herbaceous wetlands (0.7 acres), cismontane alkali marsh (1.4 acres), southern willow scrub (1.0 acre), shrub tamarisk (0.1 acre), alluvial scrub (0.5 acre), and coastal and valley freshwater marsh (0.3 acre). Indirect permanent impacts would not occur to southern coast live oak riparian forest, giant reed, or bulrush-cattail wetland from the build-out of the Specific Plan, VCC, and Entrada planning areas. However, because giant reed is an invasive nonnative plant community it is expected that these areas would be revegetated with other native vegetation communities as a result of enhancement and restoration opportunities associated with the River Corridor SMA. In addition, the reestablishment of giant reed would be controlled through the mitigation monitoring period.

As described in **Subsection 4.5.5.1**, Impact Analysis Approach and Methods, there are no temporary impacts associated with the build-out of the Specific Plan, VCC, and Entrada planning areas as all construction-related activities would occur within the proposed development footprint.

Significance Finding: Significant absent mitigation for Alternative 2. In Southern California, only 3.0% to 5.0% of the pre-settlement riparian forest remains intact, the rest having been converted primarily to farming or urban uses (Warner, *et al.* 1984). As described for direct impacts, the loss of even small acreages of riparian communities would result in substantial adverse impacts to these communities and the wildlife that occur in riparian habitats. In arid regions such as Southern California, riparian habitats play a particularly crucial role in maintaining biodiversity because up to 80.0% of vertebrate species rely on them for at least part of their lifecycle (Knopf *et al.* 1988) and because of the central role riparian habitats play in a variety of ecological functions (Fischer and Fischenich 2000; Rottenborn 1999).

The permanent impacts associated with the build-out of the Specific Plan, VCC, and Entrada planning areas, although less than the RMDP development, would constitute a substantial adverse effect on the riparian vegetation communities and would threaten to eliminate this land cover type in the planning area. Construction activities would also have the potential to substantially reduce the number or restrict the range of special-status species known to occur in the planning area (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2.

Mitigation Strategy for Indirect Permanent Impacts

The removal of riparian vegetation communities from the build-out of the Specific Plan, VCC, and Entrada planning areas and the applicable mitigation measures would be the same as described for direct impacts associated with implementation of the RMDP (see Significance Finding, Mitigation Strategy for Direct Permanent and Temporary Impacts, and **Table 4.5-28**, Applicable Mitigation Measures for Direct Impacts to Riparian Vegetation Communities, above). The implementation of these mitigation measures would reduce this impact to a level that is adverse but not significant for Alternative 2.

Secondary Impacts

Subsection 4.5.5.1, Impact Analysis Approach and Methods, of this EIS/EIR contains a detailed description of the different secondary effects that could occur from the implementation of the proposed RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas. **Subsection 4.5.5.1** also provides the reader with a comprehensive description of how secondary impacts may affect vegetation communities.

Secondary impacts are expected to occur both from the implementation of the RMDP and the SCP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas. Project-related construction impacts associated with the proposed RMDP, the SCP, Specific Plan, VCC, and Entrada developments would potentially result in impacts due to fugitive dust; runoff, sedimentation, chemical pollution, and erosion; litter; and accidental clearing, grading, and trampling. Long-term development-related impacts include increased risk of non-native, invasive plant and animal species, litter, hydrological alterations, human disturbance, and modified fire frequency. Long-term secondary impacts resulting from implementation of the RMDP and the build-out of the Specific Plan, VCC, and Entrada planning generally can be categorized as landscape level impacts and "edge" effects that generally occur along the open space urban interface.

Native vegetation located adjacent to the proposed development areas can be adversely affected by a number of secondary effects. Excessive dust from short-term construction-related secondary impacts can decrease or limit plant survivorship by decreasing photosynthetic output, reducing transpiration, and adversely affecting reproductive success. Construction of RMDP facilities or other infrastructure upgrades including mass grading can also severely or permanently alter the surface hydrology in an area and affect plant communities by reducing access to sheet flow during rain events. Vegetation can also be crushed through the inadvertent clearing of vegetation located outside the designated project footprint. Increases in human activity along the open space-urban interface may also result in the trampling of vegetation and compaction of soils. This can affect the long-term viability of plant communities and degrade wildlife habitat quality. Trampling of vegetation and compaction of soils also interacts with the soil chemistry and can affect soil moisture, water penetration, surface flows, and erosion.

Fertilizer and herbicide use may adversely affect vegetation communities and habitat quality by killing native species or allowing the establishment of non-native species in edge areas. These substances may penetrate the open space-urban interface through urban runoff from residential and commercial landscape areas and golf courses, and from overspray. Increased urban and stormwater runoff from impervious surfaces such as roads or structures may result in long-term hydrological alterations including increased runoff volume; increased peak flow rates; increased duration of flows; and altered patterns in streams and rivers. Groundwater levels may be affected as a result of interference with groundwater recharge that could cause a deficit in aquifer volumes or lowering of the local groundwater table.

Invasive plant species that thrive in edge habitats are a well documented problem along the open space-urban interface in Southern California, as well as through the U.S. riparian communities are highly susceptible to invasion from exotic plant species as these

areas are typically subject to routine scour from storm events and provide ample water to support weedy species. These nonnative species degrade habitat values by forming monocultures that displace native communities that provide food and shelter for native wildlife. Highly invasive species including giant reed and tamarisk are also known to dramatically affect the water balance of an area and can change the soil chemistry of a site. Giant reed can take over large areas of natural habitat and unlike native riparian vegetation, giant reed lacks the canopy structure that provides riverine environments with shading, thereby contributing to increased water temperatures and reduced habitat quality for aquatic species (Bell 1997). In some areas exotic plants are considered to be the greatest threat to threatened and endangered species after habitat destruction. Invasive plant species can colonize virtually any area that is subject to some kind of disturbance, such as the banks of stream channels and adjacent upland areas including road shoulders, cleared zones along housing developments, and fire breaks.

The spread of exotic species to riparian communities may dramatically alter the fire ecology of the area. The height and density of established stands of giant cane presents a fire hazard by providing large quantities of readily combustible fuels within riparian communities. During wildfires these fuels can result in excessive temperature extremes that kill native riparian species that may have otherwise survived natural wildfires. Where these and other weedy species such as tamarisk and eucalyptus invade riparian areas, the altered fire regimes can lead to type changes in habitat and further facilitate the expansion of exotic species. The alteration of vegetation communities consequently has profound effects on the wildlife species communities.

Altered wildfire regime, and particularly increased incidence of fires in urbanizing areas, may also be considered an edge effect because often these fires are a result of human activities at the open space urban interface, such as accidental ignitions from sparks from equipment such as mowers striking rocks, cigarettes, children playing with matches, and intentional ignitions such as arson. However, fires may be ignited by downed or arcing power lines or cars catching on fire along roadways in vegetated areas. More importantly, the effect of large wildfires is at the landscape level, especially when fires are quickly spread by strong winds.

Secondary effects of the proposed Project may also result in modifications to the existing hydrology of the area. One of the primary concerns to riparian ecosystems is the maintenance of a natural hydrologic regime (Busch and Smith 1995). Secondary effects from either construction or urbanization that alter the natural stream hydrology have the potential to significantly alter the existing communities in both the project area and portions of the Santa Clara River. This can occur from the attenuation of flows in tributary channels such as Middle Canyon, Long Canyon, or Potrero Canyon due to flood control structures or detention basins; or from increases in impervious surfaces that allow

large quantities of surface water to flow into the channels during storm events. Large scale grading which is planned for the proposed Specific Plan, VCC, and Entrada Planning areas can also dramatically alter the existing topography. Alterations of land forms can significantly alter the natural run-off patterns in an area and result in highly modified flow regimes to local creeks and drainages. Nuisance water from over watering or landscape irrigation can also greatly alter existing riparian communities.

The imposition of artificial stream flows by the attenuation of storm events may affect seedling recruitment at appropriate stream bank elevations, exaggerate drought stress, and increase mortality of seedlings (Mahoney and Rood 1998). In addition, the attenuation of flood events may prevent the essential geomorphic disturbance required to create new nursery sites for seedling recruitment while maintaining other areas relatively clear of vegetation within the scour zone, which provides critical habitat for a number of plant and animal species (Johnson *et al.* 1976).

Conversely, increases in storm flow and scour from un-constrained water sheds can lead to the elimination of late seral stage vegetation communities such as southern cottonwood-willow riparian forest and result in a more disturbance tolerant community such as river wash or scrub communities. Increases in summer flows from irrigation or nuisance water, coupled with periods of reduced disturbance, can result in the establishment of narrow, heavily vegetated riparian corridors in systems that would otherwise not, and historically did not, support such habitats. Encroachment of riparian vegetation on the banks of streams with augmented summer flows and attenuated storm releases can also lead to the development of monotypic stands of vegetation, channel constriction, and increased water velocities. Adverse affects on habitat are then created as sediment-starved water removes fine particulate material from the stream course resulting in stream narrowing, erosion of the streambed and banks, and development of a coarse, boulder-dominated, streambed (Mount 1995). In some circumstances these actions have resulted in the decadence and loss of riparian vegetation communities (Howe and Knopf 1991). Episodes of erosion, deposition, and inundation shape fluvial landforms and associated vegetation communities. Alteration of the channel cross-section resulting from variations from natural flow characteristics can strongly affect species distribution, which is strongly tied to height above the channel bed (Hupp and Osterkamp 1985).

To evaluate the potential downstream effects of the project on the Santa Clara River from the proposed Project the applicant completed a detailed hydrological analysis of the project area. While a number of studies provide insight to the effects of flow regulation on riparian habitats, current ecological theory suggests that a hydrologic regime that reflects a natural or nearly natural hydrologic cycle is necessary to maintain the complete native biodiversity and integrity of an aquatic ecosystem (Richter *et al.* 1997).

The Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area over the long term as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue, and as a result, the mosaic of habitats in the River that support various special-status species would be maintained, and the population of the species within and immediately adjacent to the River corridor would not be significantly affected.

Significance Finding: Significant absent mitigation for Alternative 2. The short-term (fugitive dust; runoff, sedimentation, chemical pollution, and erosion; litter; and accidental clearing, grading, and trampling) and long-term (increased risk of non-native, invasive plant and animal species; litter; human disturbance; and modified fire frequency) secondary impacts described above would constitute a substantial adverse effect on the riparian vegetation communities that are present, would threaten to eliminate riparian vegetation communities on site, and would threaten to substantially reduce the number or restrict the range of special-status species known to occur on site (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2.

Mitigation Strategy for Secondary Impacts

In order to reduce short-term and long-term secondary impacts to riparian plant communities resulting from the implementation of the RMDP and the build-out of the Specific Plan, VCC, and Entrada planning areas, the Project applicant will implement a series of existing mitigation measures approved for the Specific Plan EIR and additional measures that are designed to reduce or minimize the effects of the Project on these resources. Similar to the effects described for Direct and Indirect Impacts, many of the existing and proposed mitigation measures address the effects of several impacts. For example, the creation and maintenance of buffer areas can reduce the spread of wildfires, limit herbicide or fertilizer transport to native plant communities, inhibit the spread of exotic species, and attenuate the effects of human trampling on vegetation. Best management practices that reduce off-site sediment transport or nuisance water would also effectively mitigate the effects of both construction and secondary effects including irrigation or fertilizer use. Specific mitigation measures are described below.

Mitigation measures have been designed to limit the amount of particulate matter (dust) that leaves the construction area control dust and include actions such as daily watering

of disturbed areas and the use of chemical tackifiers. Best management practices (BMPs) would also be employed to reduce the off-site transport of sediment or sediment laden water during storm events. The applicable mitigation measures to reduce impacts from fugitive dust, runoff, erosion, sedimentation, and chemical pollutants include the previously incorporated measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA), SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), and SP-4.6-44 and SP-4.6-45 (drainage guidelines); as well as Mitigation Measures BIO-45 (pre-construction diversion of all stream flows within a work zone), BIO-46 (requiring the presence of a qualified biologist during stream diversion), BIO-47 (slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area), BIO-49 (prevention of mud and pollutants from entering streams and storm flows), BIO-52 (pre-construction educational meetings, construction limit staking, and biological monitoring during vegetation clearing and grading activities), BIO-70 (project design features, construction notes, and SWPPP BMPs (erosion and dust control, staging/storage area restrictions, equipment maintenance restrictions, trash restrictions) to ensure protection of vegetation communities and special status species), and BIO-71 (dust control measures to protect vegetation communities and special status aquatic wildlife species).

The applicant would also develop and construct a storm drain system that would match the existing hydrology to preserve the integrity of vegetated areas. This would prevent stormwater from collecting in vegetated areas and increasing soil moisture. In some cases increases in soil moisture can alter the vegetation community present at a site where plants have adapted to specific hydrology conditions. Flood control facilities would be designed pursuant to adopted BMPs and NPDES permitting requirements. The Newhall Ranch Sub-regional Stormwater Mitigation Plan prescribes the post-development stormwater management facilities to treat or detain runoff to ensure compliance with the Basin Plan and other policies such as hydromodification. Further, drainage structures would focus on managing the amount of debris that would enter the drainage system, balancing the amount of sedimentation or erosion that would occur, and maintaining the quality of water in the drainage system at a level consistent with the Clean Water Act and Porter Cologne Act. As previously described the possibility of herbicides or fertilizers accessing adjacent habitat may occur in a number of ways. Applicators could inadvertently apply the material to the vegetation; the chemicals can be associated with soil that washes off treated sites; or through drift from treated areas to adjacent habitat. To reduce these effects the applicant would ensure that the use of herbicides would take place over short periods of time, and would be applied either by or under the supervision

of a licensed professional to ensure that specific safety measures are followed. To reduce the potential for spills, the refueling of portable equipment shall occur within a contained area and applications would not occur during the wet season. These measures, coupled with the use of buffer areas including detention basins and naturally vegetated areas, would decrease the potential for wind blown or surface transported herbicides or fertilizers from reaching adjacent vegetation. The mitigation measures described above for short-term water quality impacts would also reduce the potential effects of changes in hydrology and use of herbicides and fertilizers. Additional applicable mitigation measures to reduce impacts from changes in hydrology and use of herbicides and fertilizers include the previously incorporated Mitigation Measures SP-4.6-44 and SP-4.6-45 (drainage guidelines), SP-4.6-58 (conformance with NPDES and RWQCB permit provisions), SP-4.6-64 (golf course maintenance plan).

The effects of invasive and noxious plants on natural communities are well documented. Invasive plants interfere in ecosystem functions by out-competing and displacing native plants and in some cases by hybridizing with native species (Bossard *et al.* 2000). Urbanization can adversely affect native vegetation communities by increasing the potential spread of exotics from landscaping or the release of seed packets into adjoining habitat by homeowners. Some of the measures identified in this EIS/EIR that would reduce the secondary effects of the proposed Project include the education of homeowners regarding the sensitivity of natural lands, the use of landscape species that have a limited potential to spread or are considered non-invasive, routine weeding of restored habitat, and the use of buffer areas that physically separate residential landscaping from natural areas. Some of the specific measures include previously incorporated Mitigation Measures SP-4.6-7 (revegetation plans for the River Corridor SMA to include guidelines for maintenance of the mitigation site during plant establishment), SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA), SP-4.6-26a (riparian revegetation and oak tree replacement opportunities in the High Country SMA), and SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs), and SP-4.6-43 (Open Area use for mitigation of riparian or oak resources or elderberry scrub); as well as Mitigation Measure BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation).

The spread of invasive plants can also result in altered fire ecology. Wildfires can be more common in urbanized areas where vehicles and equipment are operated in close association with vegetated areas. Sparks from vehicles, charcoal grills, or negligently discarded cigarettes can also result in fires. Similar to the measures described above, the applicant has proposed the development of transitional buffers adjacent to the proposed development. In addition, Fuel Management Zones (FMZ) would be located adjacent to

structures such as residential and commercial properties. Within these areas excess fuels and dead vegetation would be periodically removed and fire retardant plant species would be planted. These areas would provide the buffer requirements identified by the Los Angeles County Fire Department and would limit the potential for the spread of wildfires into adjacent habitat. To reduce accidental wildfires the applicant would implement a series of measures including the restriction of motorized vehicles in the High Country and River Corridor SMA, authorize the use of designated trails only, and restrict smoking in natural areas. During construction, the applicant would develop and implement a fuel modification plan that specifically addresses the use of welding equipment and designated fire watches in vegetated areas, ensures vehicles are equipped with spark arrestors, and identifies approved smoking areas. Applicable mitigation measures to reduce the potential for increased fire frequency include the previously incorporated measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-31 (prohibition of hunting, fishing, or motor or trail bikes within the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs), and SP-4.6-49 through SP-4.6-52 (wildfire fuel modification plan and standards for FMZs).

Short-term impacts resulting from accidental clearing, grading, and trampling would be minimized through the use of clearly identified construction areas and full-time biological monitoring to reduce the potential for equipment to stray into adjacent vegetation. The applicable mitigation measures to reduce impacts from trampling and clearing of vegetation outside of the construction zone include the previously incorporated measures SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA), SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA), as well as Mitigation Measures BIO-45 (pre-construction diversion of all stream flows within a work zone) and BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities).

Long-term effects of trampling and littering would be reduced through the preservation of mitigation lands, the education of homeowners regarding the sensitivity of natural lands, signage, and fencing. These include Mitigation Measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-29 through SP-4.6-32 (recreational usage and access restrictions within the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), and SP-4.6-39 (High Country SMA grazing and recreational use restrictions); as well as Mitigation Measures BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas)

and BIO-73 (permanent fencing along trails in the River Corridor SMA). While it is inevitable that some human disturbance will occur in natural lands; the applicant will provide designated trails within open areas and natural lands that are intended to provide recreational opportunities in a manner consistent with resource protection and recreational usage.

Implementation of these mitigation measures would reduce this impact to a level that is adverse but not significant for Alternative 2.

A concise summary of the specific mitigation measures that reduce the secondary impacts of the proposed Project are described in **Table 4.5-29** below.

Table 4.5-29
Applicable Mitigation Measures for Secondary Impacts to Riparian Vegetation Communities

Mitigation Measure(s)	Issue Mitigating
SP-4.6-7 (revegetation plans for the River Corridor SMA to include guidelines for maintenance of the mitigation site during plant establishment)	Invasive plants
SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA)	Dust, runoff, erosion, sedimentation, and chemical pollutants; fire frequency; trampling and littering
SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA)	Invasive plants
SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA)	Dust, runoff, erosion, sedimentation, and chemical pollutants; accidental clearing, grading, and trampling
SP-4.6-26a (riparian revegetation and oak tree replacement opportunities in the High Country SMA)	Invasive plants
SP-4.6-29 through SP-4.6-32 (recreational usage and access restrictions within the High Country SMA)	Trampling and littering
SP-4.6-31 (prohibition of hunting, fishing, motor or trail bikes within the High Country SMA)	Fire frequency
SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA)	Dust, runoff, erosion, sedimentation, and chemical pollutants; fire frequency; trampling and littering
SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs)	Invasive plants; fire frequency
SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA)	Dust, runoff, erosion, sedimentation, and chemical pollutants; accidental clearing, grading, and trampling
SP-4.6-39 (High Country SMA grazing and recreational use restrictions)	Trampling and littering
SP-4.6-43 (Open Area use for mitigation of riparian or oak resources or elderberry scrub)	Invasive plants
SP-4.6-44 and SP-4.6-45 (drainage guidelines)	Hydrology and water quality; fertilizers and herbicides; runoff, erosion,

Table 4.5-29
Applicable Mitigation Measures for Secondary Impacts to Riparian Vegetation Communities

	sedimentation, and chemical pollutants
SP-4.6-49 through SP-4.6-52 (wildfire fuel modification plan and standards for FMZs)	Fire frequency
SP-4.6-58 (conformance with NPDES and RWQCB permit provisions)	Hydrology and water quality; fertilizers and herbicides
SP-4.6-64 (golf course maintenance plan)	Fertilizers and herbicides
BIO-45 (pre-construction diversion of all stream flows within a work zone)	Runoff, erosion, sedimentation, and chemical pollutants; accidental clearing, grading, and trampling
BIO-46 (requiring the presence of a qualified biologist during stream diversion)	Hydrology, water quality
BIO-47 (slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area)	Runoff, erosion, sedimentation, and chemical pollutants
BIO-49 (prevention of mud and pollutants from entering streams and storm flows)	Runoff, erosion, sedimentation, and chemical pollutants
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Runoff, erosion, sedimentation, and chemical pollutants; accidental clearing, grading, and trampling
BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas)	Trampling and littering
BIO-70 (project design features, construction notes, erosion and dust control, and SWPPP BMPs to ensure protection of vegetation communities and special-status species)	Dust, runoff, erosion, sedimentation, and chemical pollutants
BIO-71 (dust control measures to protect vegetation communities and special-status aquatic wildlife species)	Dust
BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation)	Invasive plants
BIO-73 (permanent fencing along trails in the River Corridor SMA)	Trampling and littering

Summary of Impacts and Mitigation Strategy for Riparian Communities. Construction of RMDP facilities and build-out of the proposed development would both result in the permanent removal of riparian vegetation communities from the planning area. Implementation of the RMDP facilities would also result in the temporary loss of riparian vegetation communities. In total, implementation of the proposed RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent loss of 116 acres and the temporary removal of 98 acres of the total 1,189 acres of riparian communities that occur on site. Implementation of the SCP would not directly impact any riparian vegetation community.

As described above riparian ecosystems have undergone extensive changes as a result of urbanization, water diversion, agriculture, and river channelization. In southern

California, the loss of even small portions of riparian vegetation has the potential to result in significant adverse effects to both riparian plant communities and the wildlife that are dependent on them. Construction activities that remove habitat or urbanization related secondary effects such as the spread of exotic weeds or altered fire regimes would also adversely affect these communities. Therefore, the direct and indirect impacts associated with the proposed project would result in significant impacts absent mitigation.

Implementation of the mitigation measures described for Direct, Indirect, and Secondary Impacts above would reduce the effects of the proposed Project on riparian vegetation communities to less-than-significant levels. These measures include creation, enhancement, and/or restoration of riparian vegetation communities, as well as the dedication and preservation of large areas of natural lands intended to off-set the permanent removal of riparian vegetation. The dedicated areas described in Direct and Indirect Impacts would also be managed for the preservation and enhancement of natural communities. These measures would ultimately be designed to replace impacted riparian communities; restore, enhance, and maintain natural riparian communities; and create new riparian communities after development.

Secondary impacts from short term construction include fugitive dust, runoff, accidental clearing, grading, and trampling; or long-term development-related impacts from urbanization or "edge" effects that generally occur along the open space urban interface would also be reduced or mitigated through the implementation of the previously adopted measures from the Specific Plan EIR and the comprehensive mitigation measures described above.

Both the previously adopted measures from the Specific Plan EIR and the mitigation measures described for this Project would be implemented to reduce the effects of the proposed Project on riparian vegetation communities. Implementation of these measures would reduce direct, indirect, and secondary impacts to this vegetation class to a level that is adverse but not significant.

Impacts to California Annual Grasslands, Agriculture, Disturbed Land, and Developed Land

Existing Conditions. Most of the RMDP and Specific Plan study area has been subject to various forms of disturbances for decades. These include the construction of utilities and access roads, oil and natural gas production, cattle grazing, and agricultural operations. These ongoing activities have resulted in the degradation or elimination of habitat within portions of the RMDP and lead to the establishment of exotic plant communities. These include California annual grasslands, agriculture, disturbed land, and developed land.

California annual grassland, agriculture, and disturbed land are not considered special status by any federal, state, or local regulatory agencies within the project area. These habitats are common within the local and regional landscape, and the relative quality of these habitat types is low in many sections of the Specific Plan area due to ongoing anthropogenic disturbances including oil production and grazing. The loss of prime farmland which may occur as a result of the proposed Project is discussed in **Section 4.12**, Agricultural Resources.

As described in **Subsection 4.5.3.3**, Existing Conditions by Planning Area, while these communities and land covers are not typically protected, California annual grassland, agriculture, and disturbed lands in the project area are known to support a variety of special-status plants and wildlife. California annual grasslands in the project area support special-status plants including San Fernando Valley spineflower, Peirson's morning glory and slender mariposa lily; and provide open foraging habitat for raptors (birds of prey) such as white-tailed kite, and American kestrel. Other wildlife may include sharp shinned hawk, prairie falcon, merlin, northern harrier, coastal western whiptail, and coast horned lizard.

Agriculture practices, such as sowing of cereal crop fields (*e.g.*, oats and barley) and pasture areas (*e.g.*, alfalfa) are known to support large numbers of small mammals and rodents (*e.g.*, rabbits, mice, and squirrels). These species provide foraging opportunities for species such as California horned lark, loggerhead shrike, sharp-shinned hawk, northern harrier, merlin, golden eagle, turkey vulture, prairie falcon, and tricolored blackbird, and sometimes contain denning habitat for American badger. Disturbed land typically provides lower habitat quality when compared to more naturally vegetated areas; however, this land cover can also provide important foraging opportunities for many species. In the project area, disturbed land is known to support many of the same species that occur in California annual grasslands: California horned lark, tricolored blackbird, merlin, golden eagle, turkey vulture, prairie falcon, and sharp-shinned hawk.

Developed land typically provides only limited opportunities for wildlife; however, some species including nesting birds, bats, and rodents may occur in close proximity to structures that support limited human activity.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

Implementation of the proposed RMDP and the SCP would result in both permanent and temporary impacts to California annual grassland, agriculture, and

disturbed land. Developed lands would not be directly affected by the implementation of the RMDP and the SCP. **Table 4.5-27**, Impacts of the Proposed Project to Vegetation Communities and Land Covers, provides a detailed analysis of the vegetation acreage affected by each project component.

The sources of direct impacts (*i.e.*, clearing and grading) to California annual grassland, agriculture, and disturbed/developed vegetation communities and land covers would be the same as for riparian vegetation communities.

Construction activities associated with the development of RMDP facilities (*e.g.*, buried bank protection, levees, bridges, and ancillary structures) would result in the permanent removal of approximately 24 acres and the temporary disturbance of 9.7 acres of California annual grassland habitat; the permanent removal of 116 acres and the temporary disturbance of 68 acres of agriculture; and the permanent removal of 71 acres and the temporary disturbance of 16 acres of disturbed areas**.** These temporary disturbance areas would not be restored to grassland, agriculture, or disturbed areas, but would be restored as part of channel reconstruction and would be converted to other native riparian and upland vegetation communities. As a relative index of the habitat availability on site, approximately 2,300 acres of California annual grassland habitat; 1,617 acres of agriculture; and 1,201 acres of disturbed land occur within the proposed Project area. Thus, the approximate loss of these habitats relative to their availability from direct impacts is less than 1.0% of the existing vegetation communities present in the Project area. Most of the habitat removal that would occur under the proposed Project would result from the effects of the build-out of the Specific Plan, VCC, and Entrada planning areas. These effects are described fully below under Indirect Effects.

Implementation of the proposed SCP would result in native vegetation restoration of up to 55 acres of California annual grassland, 11 acres of agriculture, and 14 acres of disturbed land within the proposed spineflower preserves.

Significance Finding: Significant absent mitigation for Alternative 2. The permanent land use conversion of relatively small amounts of California annual grassland, agriculture, and disturbed/developed areas do not typically result in adverse effects to biological resources. However, these communities provide habitat for several special-status wildlife species that are known to occur in the project area. Although most grasslands within the state and the proposed RMDP study area have been heavily colonized by exotic grasses and are highly affected by grazing; with the exception of developed parcels, these communities (*e.g.*, annual grasslands, agriculture, and disturbed land) remain important foraging areas for raptors and other special-status wildlife. In addition, much of these

areas occur adjacent to existing riparian corridors or native upland habitats and are utilized by several sensitive species including white tailed kite. The permanent conversion of these areas can have dramatic effects on plant and wildlife species that require these areas for nesting or foraging.

Implementation of the RMDP would also result in the temporary loss of vegetation communities and land covers. Temporary disturbance to vegetation and land covers would occur from clearing and grading associated with construction of proposed temporary haul roads and construction of proposed permanent new access roads, grade control structures, buried bank protection, installation of culverts, and other improvements. The temporary disturbance of vegetation communities and land covers would occur where grading or soil disturbance would occur for a short period of time (*e.g.*, along the edges of proposed facilities), but where no permanent structures would be constructed. These temporary disturbance areas would not be restored to grassland, agriculture, or disturbed areas, but would be restored as part of channel reconstruction and would be converted to other native riparian and upland vegetation communities.

Temporary effects to California annual grassland, agriculture, and disturbed land in the RMDP study area are low compared to the acreage of these communities in the planning area. With the exception of agriculture or disturbed/developed land, which already support large non-native forb plant populations in the planning area, construction activities that result in disturbance to California annual grasslands could lead to the further spread or colonization of exotic weeds and could result in type changes to more non-native forb-dominated or disturbed habitats. The spread of existing invasive populations or the establishment of new noxious weed populations in previously native areas as a result of Project activities would be considered a significant impact without mitigation. Due to the intense effects of noxious weed establishment and spread within California, and the difficulty in controlling existing infestations or restoring arid habitats, Project-related activities that result in the increase in noxious weed populations would have long-lasting consequences for habitats adjacent to the RMDP and Specific Plan area.

The spread or colonization of invasive weeds can also result in increased fire frequency. Project areas subject to temporary disturbance would require restoration after construction to ensure stormwater runoff does not lead to off-site sediment transport, and to reduce or limit the effects of wildfire on adjacent communities. These temporary disturbance areas would be restored as part of channel reconstruction and would be converted to other native riparian and upland vegetation communities.

Typically, the loss of non-sensitive plant communities including California annual grassland, agriculture, and disturbed/developed vegetation communities and land covers would not be considered a significant impact. These communities are not sensitive, are locally and regionally abundant, and are typically dominated by exotics. Generally additional mitigation would not be required unless these communities occur within designated critical habitat for a federally listed species (*i.e.*, only critical habitat with constituent elements of the species' habitat, and not developed land, for example) or are known to support special-status plant species or wildlife that utilize these areas for foraging or nesting. Because California annual grassland, agriculture, and disturbed land are considered important foraging, nesting, and movement areas for sensitive plants and wildlife, the permanent land conversion of even small areas of these communities would be considered significant. Therefore, the permanent and temporary impacts associated with the implementation of the RMDP would constitute a substantial adverse effect on the vegetation community and would threaten to eliminate the land cover type in the planning area. Construction activities would also have the potential to substantially reduce the number or restrict the range of special-status species known to occur in the planning area (see **Subsection 4.5.5.3**, Impacts to Special-Status Species), (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2. Impacts to developed land would not be significant.

Mitigation Strategy for Direct Permanent and Temporary Impacts

The primary mechanism for mitigating the permanent loss of California annual grassland, agriculture, and disturbed land in the RMDP and Specific Plan area is the implementation of measures designed to mitigate vegetation communities that were lost through construction by the dedication of existing natural lands in the River Corridor SMA, High Country SMA, and Salt Creek area. The specific mitigation measures that would provide for the dedication of open space and management of these areas include previously incorporated Mitigation Measures SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA), and SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA). In addition, some of the new measures presented in this document include Mitigation Measures BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) and BIO-62 (dedication to the public of at least 1,900 acres of Open Area to an NLMO).

These areas support the same types of habitat that would be lost through construction and some areas would be further enhanced through ongoing

management activities. These activities would include a reduction in cattle grazing except where grazing may be used as a management tool to maintain foraging value within annual grassland areas and control invasive plant species and the removal of agricultural practices within Open Area. These measures provide mechanisms to ensure the dedication and management of natural lands and open space to mitigate the effects of the proposed project to California annual grassland, agriculture, and disturbed land.

Further protection of vegetation communities would be achieved through the creation of buffers and biologically monitored perimeters during construction periods. Biologically monitored perimeters would limit the potential for the contractor to disturb vegetation outside the proposed construction footprint. The use of these measures would identify the limits of construction and provide a biological monitor to review the construction area in the field with the contractor and be present during initial vegetation clearing and grading. To further reduce the impacts of the proposed RMDP from accidental clearing or trampling of vegetation the applicant would implement previously incorporated Mitigation Measures SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA); SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the River Corridor SMA and the High Country SMA); and BIO-52 (pre-construction educational meetings, construction limit staking, and biological monitoring during vegetation clearing and grading activities). Implementation of these measures would reduce these effects to less-than-significant levels.

Following development, continued preservation of the dedicated areas would be accomplished through restricted access and long-term management of the River Corridor SMA, High Country SMA, and Salt Creek area. To further reduce the impacts of the proposed Project, the applicant would implement previously incorporated Mitigation Measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA); and BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas) and BIO-73 (permanent fencing along trails in the River Corridor SMA). Implementation of these measures would reduce these effects to less-than-significant levels.

Long-term management activities would include a reduction in cattle grazing except where grazing may be used as a management tool to control exotics. The specific mitigation measures that would provide for the dedication of open space and management of these areas includes previously incorporated Mitigation

Measures SP-4.6-21 through SP-4.6-26 (Open space dedication of the River Corridor SMA), SP-4.6-36 through SP-4.6-42 (Open space dedication of the River Corridor SMA and the High Country SMA), and SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA). In addition, some of the new measures presented in this document include Mitigation Measures BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) and BIO-62 (dedication to the public of at least 1,900 acres of Open Area to an NLMO). These measures provide additional mechanisms to ensure the dedication and management of natural lands and open space to mitigate the effects of the proposed project to California annual grassland, agriculture, and disturbed land. These areas support the same types of habitat that would be lost through construction and would be further enhanced through ongoing management activities.

The specific mitigation measures that would be utilized to reduce the direct impacts of the proposed RMDP to a level that is adverse but not significant are identified below in **Table 4.5-30**.

Table 4.5-30
Applicable Mitigation Measures for Direct Impacts to California Annual Grassland, Agriculture, and Disturbed Land

Mitigation Measure(s)	Issue Mitigating
SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA)	Vegetation Removal
SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA)	Vegetation Removal
SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA)	Vegetation Removal
SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA)	Vegetation Removal
SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA)	Vegetation Removal
SP-4.6-34 (marking and inspection of grading perimeters prior to impacts within or adjacent to the High Country SMA)	Vegetation Removal
SP-4.6-35 (avoidance of inadvertent impacts to biological resources within or adjacent to the High Country SMA)	Vegetation Removal
SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA)	Vegetation Removal
BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126)	Vegetation Removal
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Vegetation Removal
BIO-62 (dedication to the public of at least 1,900 acres of Open Area to an NLMO)	Vegetation Removal
BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas)	Vegetation Removal
BIO-73 (permanent fencing along trails in the River Corridor SMA)	Vegetation Removal

Indirect Permanent Impacts

Most of the effects to California annual grassland, agriculture, and disturbed land would occur from the build-out of the Specific Plan, VCC, and Entrada planning areas. Each of these communities is present in the Specific Plan, VCC, and Entrada planning areas (see **Figures 4.5-11-A1** through **4.5-11-C2**). The loss of these communities would occur through construction-related activities and the development of residential housing, commercial properties, and infrastructure.

Construction activities associated with the build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent removal of approximately 1,042 acres of California annual grassland; 1,148 acres of agriculture; 889 acres of disturbed land; and 2.3 acres of developed land. In relation to each planning area approximately 955 acres of California annual grassland would be removed from the Specific Plan planning area, 64 acres would be removed from the VCC development, and 23 acres from the Entrada site (**Table 4.5-27**). Permanent impacts to disturbed and developed land would include 780/0.3 acres in the Specific Plan planning area, 60/1.6 acres from the VCC development, and 49/0.4 acres from the Entrada site respectively. The approximate loss of these habitats relative to their availability on site from indirect impacts is 45.3% for California annual grassland, 71.0% for agriculture, 74.0% for disturbed land, and 48.9% for developed land.

As described in **Subsection 4.5.5.1**, Impact Analysis Approach and Methods, there are no temporary impacts associated with the build-out of the Specific Plan, VCC, and Entrada planning areas as all construction-related activities would occur within the proposed development footprint.

Significance Finding: Significant absent mitigation for Alternative 2. The build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent land conversion of large areas of contiguous wildlife habitat within the Project area. California annual grassland, agriculture, and disturbed land are considered important live-in, foraging, nesting, and movement areas for special-status plants and wildlife in the project area and the permanent land conversion of these communities would be significant.

As described for direct impacts, while these communities are not sensitive, are locally and regionally abundant, and are typically dominated by exotics, they provide important habitat for several special-status plant and wildlife species in the project area including San Fernando Valley spineflower, Peirson's morning glory, slender mariposa lily, white-tailed kite, American kestrel, sharp shinned

hawk, prairie falcon, merlin, northern harrier, coastal western whiptail, and coast horned lizard, and sometimes contain denning habitat for American badger.

The permanent impacts associated with the build-out of the Specific Plan, VCC, and Entrada planning areas would constitute a substantial adverse effect on the vegetation community and would threaten to eliminate the land cover type in the planning area. Construction activities would also have the potential to substantially reduce the number or restrict the range of special-status species known to occur in the planning area (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2.

Mitigation Strategy for Indirect Permanent Impacts

The removal of California annual grassland, agriculture, and disturbed land from the build-out of the Specific Plan, VCC, and Entrada planning areas and the applicable mitigation measures would be the same as described for direct impacts associated with implementation of the RMDP (see Significance Finding, Mitigation Strategy for Direct Permanent and Temporary Impacts, and **Table 4.5-30**, Applicable Mitigation Measures for Direct Impacts to California Annual Grassland, Agriculture, and Disturbed Land, above). To reduce or minimize the large scale removal of vegetation the applicant has proposed the dedication and enhancement of lands in the High Country SMA, River Corridor SMA, and Salt Creek area, and Open Area. These areas would mitigate the lost vegetation community/land covers by preserving at a 0.5:1 mitigation ratio lands supporting the same types of plants and wildlife lost through the implementation of the proposed Project. The implementation of these mitigation measures would reduce this impact to a level that is adverse but not significant for Alternative 2.

Secondary Impacts

Secondary impacts are expected to occur both from the implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas. Secondary impacts to California annual grassland, agriculture, and disturbed land located adjacent to the proposed development areas would be subject to the same types of secondary effects as riparian vegetation communities. This can include impacts due to fugitive dust; runoff, sedimentation, chemical pollution, and erosion; hydrological alterations; litter; and accidental clearing, grading, and trampling. Long-term development-related effects including landscape-level impacts and "edge" effects include the increased risk of non-native, invasive plant and animal species, litter, hydrological alterations, human disturbance, and modified fire frequency.

Significance Finding: Significant absent mitigation for Alternative 2. The secondary effects of the proposed Project would be the same as described for riparian communities. The only difference is the magnitude of the effect. Since California annual grassland, agriculture, and disturbed land consist primarily of exotic non-native species the overall effects to these communities are attenuated. However, because in some areas these communities support sensitive plants and wildlife secondary impacts of the project may still result in significant impacts absent mitigation.

As described for riparian communities fertilizer and herbicide use in adjacent areas may effect these communities; however as these areas are dominated by non-native grasses and forbs the effects of chemical use are typically less pronounced. Fertilizer and herbicide use may adversely affect California annual grassland, agriculture, and disturbed land that has been subject to some form of restoration or enhancement. Nonetheless excessive fertilizer use or run-off may lead to type changes in grassland habitats and the result in the spread of more exotic and invasive species into California annual grasslands.

Increases in human activity along the open space-urban interface would also be the same. California annual grassland, agriculture, and disturbed land typically support a vegetation structure that is more open and less dense than many other plant communities. These areas also support attractive native and non-native annual flowers which tend to attract human visitors. Open areas with light vegetative cover may also attract pet owners, hikers, and other recreationists. This may result in the trampling of vegetation and compaction of soils. This can affect the long-term viability of plant communities and further degrade wildlife habitat. Trampling of vegetation and compaction of soils also interacts with the soil chemistry and can affect soil moisture, water penetration, surface flows, and erosion. Ultimately, this may lead to the further establishment of exotic plants.

The spread of invasive plants coupled with urbanization and increased public access may also result in altered fire ecology. Wildfires can be more common in urbanized areas where vehicles and equipment are operated in close association with vegetated areas. Sparks from vehicles, or from equipment such as mowers striking rocks, children playing with matches, charcoal grills, or negligently discarded cigarettes can result in fires. Fires may also be ignited by downed or arcing power lines or cars catching on fire along roadways in vegetated areas. More importantly, the effect of large wildfires is at the landscape level, especially when fires are quickly spread by strong winds.

While the effects of wildfires on disturbed or developed habitat are less likely to effect sensitive plants or wildlife these fires can quickly spread to adjacent communities. California annual grasslands which are dominated by exotic grasses quickly recover after

periodic fires. However, these communities can transition or degrade to more disturbed plant communities depending on the frequency of wildfires.

These short-term and long-term secondary impacts would constitute a substantial adverse effect on the vegetation communities and would threaten to eliminate the land cover type in the planning area. Construction activities would also have the potential to substantially reduce the number or restrict the range of special-status species known to occur in the planning area (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2.

Mitigation Strategy for Secondary Impacts

In order to reduce short-term and long-term secondary impacts to California annual grassland, agriculture, and disturbed land resulting from implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas, the Project applicant would implement the same general mitigation measures as described for Riparian Plant Communities (**Mitigation Strategy for Secondary Impacts**). This would include the existing mitigation measures approved for the Specific Plan EIR and additional measures that are designed to reduce or minimize the effects of the Project on these resources. The primary difference in the application of mitigation measures is that specific measures related only to riparian plant communities would not apply in upland areas. Otherwise the measures would be utilized.

Secondary effects associated with dust, runoff, erosion, sedimentation, and chemical pollutants would be the same as those described for riparian vegetation communities. Mitigation measures have been designed to limit the amount of particulate matter (dust) that leaves the construction area control dust and include actions such as daily watering of disturbed areas and the use of chemical tackifiers. BMPs would also be employed to reduce secondary impacts associated with runoff, erosion, sedimentation, and chemical pollutants. The applicable mitigation measures to reduce impacts from fugitive dust, runoff, erosion, sedimentation, and chemical pollutants include the previously incorporated measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA), SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), and SP-4.6-44 and SP-4.6-45 (drainage guidelines); as well as Mitigation Measures BIO-45 (pre-construction diversion of all stream flows within a work zone), BIO-46 (requiring the presence of a qualified biologist during stream diversion), BIO-47 (slow moving water habitats shall be constructed upstream and

downstream of any river crossing or bridge construction area), BIO-49 (prevention of mud and pollutants from entering streams and storm flows), BIO-52 (pre-construction educational meetings, construction limit staking, and biological monitoring during vegetation clearing and grading activities), BIO-70 (project design features, construction notes, erosion and dust control, and SWPPP BMPs (erosion and dust control, staging/storage area restrictions, equipment maintenance restrictions, trash restrictions) to ensure protection of vegetation communities and special status species), and BIO-71 (dust control measures to protect vegetation communities and special status aquatic wildlife species).

While the effects of invasive and noxious plants or altered fire ecology would be minimal on more disturbed habitats the applicant would still require the implementation of mitigation measures that include the education of homeowners regarding the sensitivity of natural lands, the use of landscape species that have a limited potential to spread or are considered non-invasive, routine weeding of restored habitat, and the use of buffer areas that physically separate residential landscaping from natural areas. Some of the specific measures include previously incorporated Mitigation Measures SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) and SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs; as well as Mitigation Measure BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation).

In addition, FMZs would be located adjacent to structures such as residential and commercial properties. Measures to control the use of motorized vehicles in the High Country and River Corridor SMA, authorize the use of designated trails only, and restrict smoking in natural areas would also be the same as for riparian communities. During construction, the applicant would develop and implement a fuel modification plan that specifically addresses the use of welding equipment and designated fire watches in vegetated areas, ensures vehicles are equipped with spark arrestors, and identifies approved smoking areas. Applicable mitigation measures to reduce the potential for increased fire frequency include the previously incorporated measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-31 (prohibition of hunting, fishing, or motor or trail bikes within the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs), and SP-4.6-49 through SP-4.6-52 (wildfire fuel modification plan and standards for FMZs).

Short-term impacts resulting from accidental clearing, and grading, and long-term effects of trampling and litter would be the same as those described for riparian communities.

These impacts would be minimized through the use of clearly identified construction areas, full-time biological monitoring, the preservation of mitigation lands, and the education of homeowners regarding the sensitivity of natural lands. These include Mitigation Measures SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA), SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA), as well as BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities).

Long-term effects of trampling and littering would be reduced through the preservation of mitigation lands, the education of homeowners regarding the sensitivity of natural lands, signage, and fencing. These include Mitigation Measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-29 through SP-4.6-32 (recreational usage and access restrictions within the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), and SP-4.6-39 (High Country SMA grazing and recreational use restrictions); as well as Mitigation Measures BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas) and BIO-73 (permanent fencing along trails in the River Corridor SMA). While it is inevitable that some human disturbance will occur in natural lands; the applicant will provide designated trails within open areas and natural lands that are intended to provide recreational opportunities in a manner consistent with resource protection and recreational usage.

The implementation of these mitigation measures will reduce this impact to a level that is adverse but not significant for Alternative 2. A concise summary of the specific mitigation measures that reduce the secondary impacts of the proposed Project are described below in **Table 4.5-31**, Applicable Mitigation Measures for Secondary Impacts to California Annual Grassland, Agriculture, and Disturbed Land.

Table 4.5-31
Applicable Mitigation Measures for Secondary Impacts to California Annual Grassland, Agriculture, and Disturbed Land

Mitigation Measure(s)	Issue Mitigating
SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA)	Dust, runoff, erosion, sedimentation, and chemical pollutants; fire frequency; trampling and littering
SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA)	Invasive plants
SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA)	Dust, runoff, erosion, sedimentation, and chemical pollutants; accidental clearing, grading, and trampling

Table 4.5-31
Applicable Mitigation Measures for Secondary Impacts to California Annual Grassland, Agriculture, and Disturbed Land

Mitigation Measure(s)	Issue Mitigating
SP-4.6-29 through SP-4.6-32 (recreational usage and access restrictions within the High Country SMA)	Trampling and littering
SP-4.6-31 (prohibition of hunting, fishing, motor or trail bikes within the High Country SMA)	Fire frequency
SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA)	Dust, runoff, erosion, sedimentation, and chemical pollutants; fire frequency; trampling and littering
SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs)	Invasive plants; fire frequency
SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA)	Dust, runoff, erosion, sedimentation, and chemical pollutants; accidental clearing, grading, and trampling
SP-4.6-39 (High Country SMA grazing and recreational use restrictions)	Trampling and littering
SP-4.6-44 and SP-4.6-45 (drainage guidelines)	Hydrology and water quality; fertilizers and herbicides; runoff, erosion, sedimentation, and chemical pollutants
SP-4.6-49 through SP-4.6-52 (wildfire fuel modification plan and standards for FMZs)	Fire frequency
SP-4.6-58 (conformance with NPDES and RWQCB permit provisions)	Hydrology and water quality; fertilizers and herbicides
BIO-45 (pre-construction diversion of all stream flows within a work zone)	Runoff, erosion, sedimentation, and chemical pollutants; accidental clearing, grading, and trampling
BIO-46 (requiring the presence of a qualified biologist during stream diversion)	Hydrology, water quality
BIO-47 (slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area)	Runoff, erosion, sedimentation, and chemical pollutants
BIO-49 (prevention of mud and pollutants from entering streams and storm flows)	Runoff, erosion, sedimentation, and chemical pollutants
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Runoff, erosion, sedimentation, and chemical pollutants; accidental clearing, grading, and trampling
BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas)	Trampling and littering
BIO-70 (project design features, construction notes, erosion and dust control, and SWPPP BMPs to ensure protection of vegetation communities and special-status species)	Dust, runoff, erosion, sedimentation, and chemical pollutants
BIO-71 (dust control measures to protect vegetation communities and special-status aquatic wildlife species)	Dust
BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation)	Invasive plants

Summary of Impacts and Mitigation Strategy for California Annual Grasslands, Agriculture, Disturbed Land, and Developed Land. Construction of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent removal of California annual grassland, agriculture, and disturbed land. Implementation of the RMDP facilities would also result in the temporary disturbance of these vegetation communities/land covers. These temporary disturbance areas would not be restored to grassland, agriculture, or disturbed areas, but would be restored as part of channel reconstruction and would be converted to other native riparian and upland vegetation communities. In total, implementation of the proposed RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent loss of 3,293 acres and the temporary removal of 94 acres of the total 5,122 acres of these three vegetation communities/land covers that occur on site. Implementation of the proposed SCP would result in native vegetation restoration of up to 55 acres of California annual grassland, 11 acres of agriculture, and 14 acres of disturbed land within the proposed spineflower preserves.

Typically, the loss of non-sensitive plant communities including California annual grassland, agriculture, and disturbed/developed vegetation communities and land covers would not be considered a significant impact. These communities are not sensitive, are locally and regionally abundant, and are typically dominated by exotics. Generally additional mitigation would not be required unless these communities occur within designated critical habitat for a federally listed species (*i.e.*, only critical habitat with constituent elements of the species' habitat, and not developed land, for example) or are known to support special-status plant species or wildlife that utilize these areas for foraging or nesting. Because California annual grassland, agriculture, and disturbed land are considered important foraging, nesting, and movement areas for sensitive plants and wildlife, the permanent land conversion of even small areas of these communities would be considered significant. Impacts to developed land would not be significant.

Implementation of the mitigation measures described for Direct, Indirect, and Secondary Impacts above would reduce the effects of the proposed Project on California annual grassland, agriculture, and disturbed land to less-than-significant levels. These measures include restoration of temporary impact areas, as well as the dedication and preservation

of large areas of natural lands intended to off-set the permanent removal of these vegetation communities/land covers. The dedicated areas described in Direct and Indirect Impacts would also be managed for the preservation and enhancement of natural communities.

Secondary impacts from short-term construction include fugitive dust, runoff, accidental clearing, grading, and trampling; or long-term development-related impacts from urbanization or "edge" effects that generally occur along the open space urban interface would also be reduced or mitigated through the implementation of the previously adopted measures from the Specific Plan EIR and the comprehensive mitigation measures described above.

Both the previously adopted measures from the Specific Plan EIR and the mitigation measures described for this project would be implemented to reduce the effects of the proposed Project on California annual grassland, agriculture, and disturbed land. Implementation of these measures would reduce direct, indirect, and secondary impacts to California annual grassland, agriculture, and disturbed land to a level that is adverse but not significant.

Impacts to Coastal Scrub Communities

Existing Conditions. Coastal scrub communities (including alliances and associations) are characterized by a variety of soft, low, aromatic, drought-deciduous shrubs, such as California sagebrush (*Artemisia californica*), California buckwheat (*Eriogonum fasciculatum*), California bush sunflower (*Encelia californica*), and sages (*Salvia* spp.), with scattered evergreen shrubs, including lemonadeberry (*Rhus integrifolia*). It typically develops on south-facing slopes and other xeric situations.

This vegetation category includes alliances of coastal scrub (California sagebrush scrub, California sagebrush–black sage scrub, California sagebrush–California buckwheat scrub, California sagebrush scrub–undifferentiated chaparral, coyote brush scrub) and their associations (burned California sagebrush scrub, California sagebrush–*Artemisia*, California sagebrush–purple sagebrush, disturbed California sagebrush scrub–purple sage, California sagebrush–black sage, burned California sagebrush scrub–undifferentiated chaparral). For the purposes of this document big sagebrush scrub and big sagebrush scrub-California buckwheat communities have been included in the riparian community discussion.

Coastal scrub exists primarily in wide areas on the central portion of the RMDP study area, as well as in the VCC and Entrada planning areas. Primary disturbance in this community consisted of dirt roads and utility tower footprints in the VCC planning area; however, overall, this community was relatively intact. Although the Entrada planning

area is influenced by adjacent disturbance and development, the community appeared to be relatively intact. This vegetation community provides potential habitat for the special-status plant species, including Peirson's morning-glory and southern California black walnut, and several special-status wildlife species, including southern California rufous-crowned sparrow, Bell's sage sparrow, black-chinned sparrow, Costa's hummingbird, sharp-shinned hawk, northern harrier, loggerhead shrike, golden eagle, turkey vulture, San Bernardino ringneck snake, silvery legless lizard, coast horned lizard, coastal western whiptail, and mountain lion.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

Implementation of the proposed RMDP and the SCP would result in both permanent and temporary impacts to coastal scrub vegetation communities. **Table 4.5-27**, Impacts of the Proposed Project to Vegetation Communities and Land Covers, provides a detailed analysis of the vegetation acreage affected by each project component.

The sources of direct impacts (*i.e.*, clearing and grading) to coastal scrub vegetation communities would be the same as for riparian vegetation communities.

Construction activities associated with the development of RMDP facilities (*e.g.*, buried bank protection, levees, bridges, and ancillary structures) would result in the permanent removal of 31 acres and temporary removal of 2.3 acres of coastal scrub communities on site. These impacts would occur to coastal scrub vegetation communities, including California sagebrush scrub and coyote bush scrub alliances and associations. Direct impacts to coastal scrub communities include the permanent/temporary loss of 5.5/0.6 acres of burned California sagebrush scrub; the permanent/temporary loss of 11/1.1 acres of California sagebrush scrub; the permanent/temporary loss of 3.3/0.2 acres of California sagebrush – *Artemisia*; the permanent/temporary loss of 1.8/0.2 acres of California sagebrush – black sage; the permanent/temporary loss of 3.9/0.2 acres of California sagebrush – California buckwheat scrub; the permanent/temporary loss of 1.9/0.1 acres of California sagebrush scrub – undifferentiated chaparral; the permanent/temporary loss of 2.9/0.0 acres of California sagebrush – purple sage; and the permanent/temporary loss of 0.6/0.0 acre of coyote brush scrub. Permanent and temporary impacts from implementation of the proposed RMDP would not occur to burned California sagebrush scrub/undifferentiated chaparral

or disturbed California sagebrush – purple sage. These temporary disturbance areas would not all be restored to the same coastal scrub associations and alliances as currently present, but would be restored as part of channel reconstruction and would be converted to native riparian and upland vegetation communities, which may include coastal scrub at higher elevations along the channel banks. **Table 4.5-27**, Impacts of the Proposed Project to Vegetation Communities and Land Covers, provides a detailed analysis of the vegetation acreage affected by each project component.

As a relative index of the habitat availability on site, approximately 4,336 acres of scrub communities occur in the proposed RMDP project area. Thus, the approximate loss of these habitats relative to their availability from direct impacts is 1.0% of the existing scrub communities present in the Project area. However, the total percentage of any given community may range from a low of 0% for disturbed California sagebrush – purple sage to 4.0% for California sagebrush scrub– *Artemisia*. What is important to recognize is the total percentage of a vegetation community lost only reflects the percent of the habitat that occurs in the project area.

Significance Finding: Significant absent mitigation for Alternative 2. In Southern California coastal scrub communities are locally and regionally abundant. In the Project area these communities form large blocks of habitat and dominate many of the hillsides in the RMDP planning area. Although widespread, scrub communities provide a unique vegetation structure and set of foraging resources that supports a broad array of special-status plants and wildlife. In addition, these communities have experienced rapid decline in the past decade from increasing development of coastal areas within southern California.

Although the other coastal scrub communities are not considered sensitive by federal, state, or local regulatory agencies, these communities provide live-in, nesting and foraging habitat for numerous special-status plant and wildlife species within the Project area. The loss of these communities associated within the RMDP and SCP study area would constitute a substantial adverse effect on the vegetation community and would threaten to eliminate the land cover type in the project area. The Project would also have the potential to substantially reduce the number or restrict the range of special-status species (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2.

Scrub communities would be subject to the same construction related impacts as described for Riparian Vegetation Communities and California annual grassland,

agriculture, and disturbed land (described above). These effects result from the permanent removal of these vegetation communities from the RMDP and SCP planning area. Temporary disturbance to these vegetation communities will also occur from clearing and grading associated with the construction of access roads, grade control structures, buried bank protection, installation of culverts and other improvements. These temporary disturbance areas would not all be restored to the same coastal scrub associations and alliances as currently present, but would be restored as part of channel reconstruction and would be converted to native riparian and upland vegetation communities, which may include coastal scrub at higher elevations along the channel banks. **Subsection 4.5.5.1**, Impact Analysis Approach and Methods of this EIS/EIR contains a detailed description of the different direct, indirect, and secondary effects that could occur from the implementation of the proposed RMDP.

As described above scrub communities would be subject the same types of impacts as riparian communities. The primary difference is how scrub communities respond to temporary disturbance and the colonization of exotic species. Similar to riparian communities coastal scrub vegetation is highly susceptible to damage from clearing and grading activities. These types of disturbances can result in the expansion or colonization of exotic weeds. Coastal scrub appears to be an easily invaded vegetation type, due in part to its open canopy (Allen 1998; Cox and Allen 2008). Exotic weeds can then result in the alteration of soil conditions and the disruption of native seed banks. Because coastal scrub communities are often in varying states of succession disturbance and colonization of weeds can quickly alter the community structure.

Mitigation Strategy for Direct Permanent and Temporary Impacts

The primary mechanism for mitigating the permanent loss of coastal scrub in the RMDP and Specific Plan area is the implementation of measures designed to mitigate vegetation communities that were lost through construction by the dedication of existing natural lands in the River Corridor SMA, High Country SMA, and Salt Creek area. The specific mitigation measures that would provide for the dedication of open space and management of these areas includes previously incorporated Mitigation Measures SP-4.6-21 through SP-4.6-26 (Open space dedication of the River Corridor SMA), SP-4.6-36 through SP-4.6-42 (Open space dedication of the River Corridor SMA and the High Country SMA). In addition, some of the new measures presented in this document include Mitigation Measures BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) and BIO-62 (dedication to the public of at least 1,900 acres of Open Area to an NLMO).

These areas support the same types of habitat that would be lost through construction and would be further enhanced through ongoing restoration and management activities. Some of these activities would include the establishment of native vegetation communities in currently disturbed habitat, a reduction in cattle grazing except where grazing may be used as a management tool to control exotics, the removal of agricultural practices, and the management of exotic species. These measures provide additional mechanisms to ensure the dedication and management of natural lands and open space to mitigate the effects of the proposed project to coastal scrub communities in the project area.

The restoration of temporarily disturbed coastal scrub communities has a suite of challenges, not least of which is depleted or nonexistent native seed banks (Cione *et al.* 2002). Semi-arid shrub ecosystems are often colonized by exotics such as brome grasses, due in part to high levels of nitrogen deposition associated with automobile emissions (Allen 2004; Cox and Allen 2008) and type conversion following more frequent fires (Allen 1998). As many areas of the RMDP are already colonized by weedy annuals, restoration efforts will require diligence to ensure the effective replacement of lost functional services/values. Restoration of shrublands or disturbed areas consisting of primarily exotic seed banks is also problematic in that there is little to no natural recruitment of native species, and the establishment of native species is reliant on seeding and planting (Cione *et al.* 2002). However, the applicant would implement measures to ensure the establishment of native riparian and upland vegetation communities in temporarily disturbed areas. Temporary impacts to vegetation communities would be mitigated through restoration and revegetation, with the intent of restoring the functional services/values of the habitat prior to disturbance. These temporary disturbance areas would not all be restored to the same coastal scrub associations and alliances as currently present, but would be restored as part of channel reconstruction and would be converted to native riparian and upland vegetation communities, which may include coastal scrub at higher elevations along the channel banks.

Further protection of this vegetation type would be achieved though the use of buffers and monitored perimeters as described for riparian vegetation communities; and California annual grassland, agriculture, and disturbed land. To further reduce the impacts of the proposed RMDP from accidental clearing or trampling of vegetation the applicant would implement previously incorporated Mitigation Measures SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA); SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the River Corridor SMA and the High Country SMA); and BIO-52 (pre-construction educational

meetings, construction limit staking, and biological monitoring during vegetation clearing and grading activities). Implementation of these measures would reduce these effects to less-than-significant levels.

Following development, the continued preservation of this vegetation community would be accomplished through restricted access, long-term management, and dedication of the River Corridor SMA, High Country SMA, and Salt Creek area. To further reduce the impacts of the proposed Project, the applicant would implement previously incorporated Mitigation Measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA); and BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas) and BIO-73 (permanent fencing along trails in the River Corridor SMA). Implementation of these measures would reduce these effects to less-than-significant levels.

Long-term management activities would include a reduction in cattle grazing except where grazing may be used as a management tool to control exotics, and the management of exotic species within restoration areas associated with the RMDP. The specific mitigation measures that would provide for the dedication of open space and management of these areas includes previously incorporated Mitigation Measures SP-4.6-21 through SP-4.6-26 (Open space dedication of the River Corridor SMA), SP-4.6-36 through SP-4.6-42 (Open space dedication of the River Corridor SMA and the High Country SMA), and SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA). In addition, some of the new measures presented in this document include Mitigation Measures BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126), BIO-20 (preservation of approximately 1,900 acres of coastal scrub on site), BIO-21 (restoration/enhancement of coastal scrub in High Country SMA, Salt Creek area, and River Corridor SMA), and BIO-62 (dedication to the public of at least 1,900 acres of Open Area to an NLMO). These measures provide additional mechanisms to ensure the dedication and management of natural lands and open space to mitigate the effects of the proposed project to coastal scrub vegetation communities. These areas support the same types of habitat that would be lost through construction and would be further enhanced through management activities.

Implementation of these mitigation measures would reduce this impact to a level that would be adverse but not significant for Alternative 2. The specific mitigation measures that would be utilized to reduce the direct impacts of the

proposed RMDP to a level that is adverse but not significant (with the exception of BIO-20 and BIO-21, noted above), are identified above in **Table 4.5-30**, Applicable Mitigation Measures for Direct Impacts to California Annual Grassland, Agriculture, and Disturbed Land.

Indirect Permanent Impacts

The majority of the impacts to scrub communities would occur from build-out of the Specific Plan development, specifically through construction related activities and the development of residential housing, commercial properties, and infrastructure.

Construction activities associated with the build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent removal of approximately 1,493 acres of scrub communities, or 34.4% of the total acreage of scrub communities present on site. In relation to each planning area, approximately 1,327 acres of scrub communities would be removed from the Specific Plan planning area, 38 acres would be removed from the VCC development, and 129 acres from the Entrada site (**Table 4.5-27**).

Some scrub communities would be impacted to a greater degree than others. No impacts would occur to burned California sagebrush/undifferentiated chaparral or disturbed California sagebrush – purple sage. However, a total of 768 acres (47.3%) of California sagebrush scrub, 251 acres (60.7%) of California sagebrush – California buckwheat scrub, and 194 acres (49.2%) of California sagebrush – purple sage would be permanently impacted through the indirect effects of the build-out of the Specific Plan, VCC, and Entrada developments. See **Table 4.5-27** for a complete analysis of the vegetation acreages affected by the proposed Project.

Significance Finding: Significant absent mitigation for Alternative 2. While many scrub communities are considered common and are not typically protected by state or federal law the vegetation present in the project area is known to support a variety of sensitive plant and wildlife species. As such the permanent impacts associated with the build-out of the Specific Plan, VCC, and Entrada planning areas would constitute a substantial adverse effect on the vegetation community and would threaten to eliminate the land cover type in the planning area. Construction activities would also have the potential to substantially reduce the number or restrict the range of special-status species known to occur in the planning area (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2.

The removal of these vegetation communities from the build-out of the Specific Plan, VCC, and Entrada planning areas and the applicable mitigation measures would be the same as described for direct impacts associated with implementation of the RMDP (see Significance Finding for Direct Permanent and Temporary Impacts, above).

The implementation of these mitigation measures would reduce this impact to a level that is adverse but not significant for Alternative 2.

Mitigation Strategy for Indirect Permanent Impacts

The removal of coastal scrub vegetation communities from the build-out of the Specific Plan, VCC, and Entrada planning areas and the applicable mitigation measures would be the same as described for direct impacts associated with implementation of the RMDP (see Significance Finding, Mitigation Strategy for Direct Permanent and Temporary Impacts, and **Table 4.5-30**, Applicable Mitigation Measures for Direct Impacts to California Annual Grassland, Agriculture, and Disturbed Land, above). To reduce or minimize the large scale removal of vegetation the applicant has proposed the dedication of lands in the High Country SMA, River Corridor SMA, and Salt Creeks area, and in the Open Area. These areas would mitigate the lost vegetation community/land covers by preserving at a 1.5:1 ratio lands supporting the same types of plants and wildlife lost through the implementation of the proposed Project. The implementation of these mitigation measures would reduce this impact to a level that is adverse but not significant for Alternative 2.

Secondary Impacts

Secondary impacts to scrub communities are expected to occur both from the implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas. Secondary impacts to scrub communities located adjacent to the proposed development areas would be subject to the same types of secondary effects as California annual grassland, agriculture, and disturbed land. This can include impacts due to fugitive dust; runoff, sedimentation, chemical pollution, and erosion; hydrological alterations; litter; and accidental clearing, grading, and trampling. Long-term development-related effects including landscape-level impacts and "edge" effects include the increased risk of non-native, invasive plant and animal species, litter, hydrological alterations, human disturbance, and modified fire frequency.

The secondary effects of the proposed Project would be the same as described for California annual grassland, agriculture, and disturbed land. The only difference is the magnitude of the effect. The quality of the scrub communities in the project area varies

depending on its location and historic disturbance regime. In some areas the habitat has been severely degraded by cattle grazing while other areas support near pristine scrub communities. Other areas have been subject to recent wildfires and show strong evidence of native recruitment. In addition, many scrub species are crown sprouting which suggests that native plant communities will recover in these areas. Heavily disturbed scrub communities in adjacent areas are less likely to recover if subject to repeated disturbance or other anthropogenic activities.

Secondary effects such as excessive dust from short-term construction-related secondary impacts or altered hydrology can adversely affect these communities and inhibit the recruitment of native plant communities. Similar to California annual grassland, agriculture, and disturbed land this can also lead to the establishment of more disturbed or exotic plant communities. Vegetation can also be crushed through the inadvertent clearing of vegetation located outside the designated project footprint and human activity along the open space-urban interface may also result in the trampling of vegetation and compaction of soils.

Fertilizer and herbicide use could lead to the degradation of adjacent habitats or the spread of exotic plants. Invasive plant species that thrive in edge habitats are a well documented problem along the open space-urban interface in Southern California and semi-arid shrub ecosystems are often colonized by exotics such as brome grasses. The spread of exotic species and increased human presence can lead to altered fire regimes in the project area. As described for California annual grassland, agriculture, and disturbed land altered wildfire regimes and particularly increased incidence of fires may occur in urbanized areas.

Wildfire in Mediterranean type ecosystems such as scrub and chaparral communities affects the structure and function of vegetation communities. In most cases, fires are quickly suppressed for public safety and to protect property, but in some cases fires become uncontrollable and catastrophic, in part because past fire suppression has resulted in much greater fuel loads in urbanized environments than would occur under natural regimes. These types of fire regime alteration (suppression and catastrophic and/or frequent fires) can drastically affect plant and animal communities such as California sagebrush scrub through increases or decreases in the natural fire interval to which the plant and animal communities have adapted. Longer than natural fire intervals can result in excessive buildup of fuel loads, so that when fires do occur, they are catastrophic. Unnaturally long fire intervals can also result in senescence of plant communities such as chaparral that rely on shorter intervals for rejuvenation. Shorter than natural fire return intervals can preclude recovery of the native vegetation between fires, weaken the ecological system, allow for invasion of exotic species, and, in some cases, result in permanent transitions of the vegetation to nonnative communities such as annual

grassland and weedy communities (*e.g.*, Malanson and O'Leary 1982; Keeley 1987; O'Leary *et al.* 1992). The alteration of vegetation communities consequently has profound effects on the wildlife species communities.

Significance Finding: Significant absent mitigation for Alternative 2. Potential short-term construction-related secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include dust; runoff, sedimentation, erosion, and chemical pollutants; hydrological alterations; litter; and accidental clearing, grading, and trampling. Potential long-term development-related secondary impacts include non-native, invasive plant and animal species; litter; hydrological alterations; increased risk of human disturbance; and increased risk of fire frequency. These short-term and long-term secondary impacts would constitute a substantial adverse effect on the vegetation community, threaten to eliminate this vegetation community on site, and substantially reduce the number or restrict the range of special-status species (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact is significant, absent mitigation, for Alternative 2.

Mitigation Strategy for Secondary Impacts

In order to reduce short-term and long-term secondary impacts to coastal scrub communities resulting from implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas, the Project applicant would implement the same general mitigation measures as described for California annual grassland, agriculture, and disturbed land. This would include the existing mitigation measures approved for the Specific Plan EIR and additional measures that are designed to reduce or minimize the effects of the Project on these resources.

Secondary effects associated with dust, runoff, erosion, sedimentation, and chemical pollutants would be the same as those described for California annual grassland, agriculture, and disturbed land. Mitigation measures have been designed to limit the amount of particulate matter (dust) that leaves the construction area control dust and include actions such as daily watering of disturbed areas and the use of chemical tackifiers. BMPs would also be employed to reduce secondary impacts associated with runoff, erosion, sedimentation, and chemical pollutants. The applicable mitigation measures to reduce impacts from fugitive dust, runoff, erosion, sedimentation, and chemical pollutants include the previously incorporated measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA), SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA), SP-4.6-32 (trail design and construction

to minimize impacts to native habitats within the High Country SMA), and SP-4.6-44 and SP-4.6-45 (drainage guidelines); as well as Mitigation Measures BIO-45 (pre-construction diversion of all stream flows within a work zone), BIO-46 (requiring the presence of a qualified biologist during stream diversion), BIO-47 (slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area), BIO-49 (prevention of mud and pollutants from entering streams and storm flows), BIO-52 (pre-construction educational meetings, construction limit staking, and biological monitoring during vegetation clearing and grading activities), BIO-70 (project design features, construction notes, erosion and dust control, and SWPPP BMPs (erosion and dust control, staging/storage area restrictions, equipment maintenance restrictions, trash restrictions) to ensure protection of vegetation communities and special status species), and BIO-71 (dust control measures to protect vegetation communities and special status aquatic wildlife species).

To reduce the effects of invasive and noxious plants or altered fire ecology the applicant would implementation Mitigation Measures SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) and SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs) as well as Mitigation Measures BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation). These measures include the education of homeowners regarding the sensitivity of natural lands, the use of landscape species that have a limited potential to spread or are considered non-invasive, routine weeding of restored habitat, and the use of buffer areas that physically separate residential landscaping from natural areas. In addition, FMZs would be located adjacent to structures such as residential and commercial properties to reduce the potential for the spread of wildfires form urban to vegetated areas. Applicable mitigation measures to reduce the potential for increased fire frequency include the previously incorporated Mitigation Measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-31 (prohibition of hunting, fishing, or motor or trail bikes within the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs), and SP-4.6-49 through SP-4.6-52 (wildfire fuel modification plan and standards for FMZs).

Short-term impacts resulting from accidental clearing, and grading, and long-term effects of trampling would be the same measures as those described for California annual grassland, agriculture, and disturbed land. The applicable mitigation measures to reduce impacts from trampling and clearing of vegetation outside of the construction zone include the previously incorporated measures SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River

Corridor SMA), SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA), as well as Mitigation Measure BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities). These measures include guidance regarding the use of clearly identified construction areas, full-time biological monitoring, the preservation of mitigation lands, and the education of homeowners regarding the sensitivity of natural lands.

Long-term effects of trampling and littering would be reduced through the preservation of mitigation lands, the education of homeowners regarding the sensitivity of natural lands, signage, and fencing. These include Mitigation Measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-29 through SP-4.6-32 (recreational usage and access restrictions within the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), and SP-4.6-39 (High Country SMA grazing and recreational use restrictions); as well as Mitigation Measures BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas) and BIO-73 (permanent fencing along trails in the River Corridor SMA). While it is inevitable that some human disturbance will occur in natural lands; the applicant will provide designated trails within open areas and natural lands that are intended to provide recreational opportunities in a manner consistent with resource protection and recreational usage.

The implementation of these mitigation measures would reduce this impact to a level that is adverse but not significant for Alternative 2. A summary description of the specific mitigation measures that reduce the secondary impacts of the proposed Project are described in **Table 4.5-31**, Applicable Mitigation Measures for Secondary Impacts to California Annual Grassland, Agriculture, and Disturbed Land.

Summary of Impacts and Mitigation Strategy for Coastal Scrub Vegetation Communities. Construction of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent removal of coastal scrub vegetation communities. Implementation of the RMDP facilities would also result in the temporary loss of these vegetation communities/land covers. In total, implementation of the proposed RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent loss of 1,524 acres and the temporary removal of 2.3 acres of the total 4,336 acres of these vegetation communities that occur on site.

Typically, the loss of non-sensitive plant communities including coastal scrub vegetation communities would not be considered a significant impact. These communities are not sensitive, and are locally and regionally abundant. Generally additional mitigation would

not be required unless these communities occur within designated critical habitat for a federally listed species or are known to support special-status plant species or wildlife that utilize these areas for foraging or nesting. Because coastal scrub vegetation communities on site are known to provide important foraging, nesting, and movement areas for special-status plants and wildlife, the permanent land conversion of these vegetation communities would be considered significant.

Implementation of the mitigation measures described for Direct, Indirect, and Secondary Impacts above would reduce the effects of the proposed Project on coastal scrub vegetation communities to less-than-significant levels. These measures include restoration of temporary impact areas, as well as the dedication and preservation of large areas of natural lands intended to off-set the permanent removal of these vegetation communities/land covers. The dedicated areas described in Direct and Indirect Impacts would also be managed for the preservation and enhancement of natural communities.

Secondary impacts from short-term construction include fugitive dust, runoff, accidental clearing, grading, and trampling; or long-term development-related impacts from urbanization or "edge" effects that generally occur along the open space urban interface would also be reduced or mitigated through the implementation of the previously adopted measures from the Specific Plan EIR and the comprehensive mitigation measures described above.

Both the previously adopted measures from the Specific Plan EIR and the mitigation measures described for this project would be implemented to reduce the effects of the proposed Project on coastal scrub vegetation communities. Implementation of these measures would reduce direct, indirect, and secondary impacts to coastal scrub vegetation communities to a level that is adverse but not significant.

Impacts to Chaparral Communities

Existing Conditions. Undifferentiated chaparral scrub is a drought- and fire-adapted community of broad-leafed shrubs, 1.5 to 3.0 meters tall, typically forming dense, impenetrable stands. It develops primarily on mesic north-facing slopes and in canyons. This association is typically a mixture of chamise, hoaryleaf ceanothus (*Ceanothus crassifolius*), scrub oak (*Quercus berberidifolia*), laurel sumac (*Malosma laurina*), and black sage. Dominant chaparral species on site include a mixture of chamise, hoaryleaf ceanothus, spiny redberry (*Rhamnus crocea*), sugar bush, and toyon. Other species that occur in this community on site include chaparral bushmallow, hollyleaf redberry (*Rhamnus ilicifolia*), mainland (hollyleaf) cherry (*Prunus ilicifolia* ssp. *ilicifolia*), and coastal scrub species as described above. Chamise chaparral (at least 60% cover chamise) is a variation of chaparral scrub, with a sparse distribution of other chaparral species. On site, scrub oak chaparral is dominated by scrub oak, and also supports other

chaparral and coastal scrub species. On site, eriodictyon scrub is dominated by an almost monotypic stand of yerba santa, with a sparse distribution of other chaparral and coastal scrub species.

The distribution of this plant community is limited to relatively small areas within the southern portion of the Entrada planning area. Undifferentiated chaparral scrub in the Entrada planning area is relatively intact and undisturbed, and contains typical dominant plant species for this community. This plant community occurs in the higher elevations of the Specific Plan area, primarily in the eastern and southern portions. Undifferentiated chaparral scrub in the Specific Plan area is relatively intact and undisturbed, likely because of its distribution in the higher and steeper elevations, except for burned portions through the center of the Specific Plan along Salt Creek and eastward to Pico Canyon. Chamise chaparral on site is limited to a few locations, including upper Chiquito Canyon, west of lower Long Canyon, along the Specific Plan/Legacy Village boundary in upper Long Canyon, and east of Lion Canyon. Scrub oak chaparral occurs in only one location, in the upper portion of the East Fork of Salt Creek. Eriodictyon scrub occurs in the Specific Plan area along the southern end of Magic Mountain Canyon and is contiguous with an off-site patch on Legacy Village. Chaparral communities provide potential habitat for several special-status plants (Peirson's morning glory, southern California black walnut, and island mountain-mahogany) and special-status wildlife species, including coast horned lizard, silvery legless lizard, coastal western whiptail, rosy boa, San Bernardino ringneck snake, loggerhead shrike, Bell's sage sparrow, black-chinned sparrow, sharp-shinned hawk, and mountain lion.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

Implementation of the proposed RMDP and the SCP would result in both permanent and temporary impacts to chaparral vegetation communities. **Table 4.5-27**, Impacts of the Proposed Project to Vegetation Communities and Land Covers, provides a detailed analysis of the vegetation acreage affected by each project component.

The sources of direct impacts (*i.e.*, clearing and grading) to chaparral vegetation communities would be the same as for riparian vegetation communities.

Construction activities associated with the development of RMDP facilities (*e.g.*, buried bank protection, levees, bridges, and ancillary structures) would result in the permanent removal of approximately 26 acres and the temporary removal of

1.5 acre of chaparral communities on site. These impacts would occur to burned undifferentiated, undifferentiated, and chamise chaparral communities. Direct impacts to these communities would include the permanent loss of 21 acres of undifferentiated chaparral, 4.1 acres of burned undifferentiated chaparral, and 1.6 acres of chamise chaparral; and the temporary loss of 0.7 acre of burned undifferentiated chaparral and 0.9 acre of undifferentiated chaparral. Permanent and temporary impacts would not occur to eriodictyon scrub or scrub oak chaparral from implementation of the proposed RMDP. These temporary disturbance areas would not all be restored to the same chaparral associations and alliances as currently present, but would be restored as part of channel reconstruction and would be converted to native riparian and upland vegetation communities, which may include chaparral at higher elevations along the channel banks.

As a relative index of the habitat availability on site, approximately 2,146 acres of chaparral communities occur in the proposed RMDP project area. Thus, the approximate loss of these habitats relative to their availability from direct impacts is less than 1.0% of the existing chaparral communities present in the Project area. However, the total percentage of loss of any given community may range from a low of 0% for scrub oak chaparral to approximately 3.0% for chamise chaparral. What is important to recognize is the total percentage of a vegetation community lost only reflects the percent of the habitat that occurs in the project area. That is, while the total percentage of chamise chaparral affected by the proposed project is highest among chaparral communities, the total acreage lost is 1.6 acres out of approximately 56 acres that occur on site. Conversely, undifferentiated chaparral would only be subject to a loss of approximately 2.0% (a total of 21 acres) of the 1,131 acres of this community present in the project area.

Significance Finding: Significant absent mitigation for Alternative 2. In Southern California chaparral communities are locally and regionally abundant. Data compiled from CNDDB lists 1,329,674 acres of chamise chaparral; 54,116 acres of mixed chaparral; and 36,385 acres of scrub oak chaparral occurring within the State of California (CDFG 1995; BLM 2005). Furthermore, much of this habitat in the region is not likely to be developed as it is under state or federal ownership such as the BLM or the USDA Forest Service. In the project area large stands of this community type occur in the Los Padres National Forest and the Angeles National Forest.

Chaparral communities are not considered sensitive by federal, state, or local regulatory agencies. However while relatively common, these communities provide nesting and foraging habitat for numerous special-status wildlife species

within the Project area and the loss of these habitats can result in the spread of noxious or invasive weeds and alter the fire regime of a given area Therefore the loss of these communities associated with the RMDP and SCP study area would constitute a substantial adverse effect on the vegetation community and would threaten to eliminate the land cover type in the Project area. The Project would also have the potential to substantially reduce the number or restrict the range of special-status species listed above (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2.

Chaparral communities would be subject to the same type of construction related impacts as described for Coastal Scrub Vegetation Communities (described above). These effects result from the permanent removal of these vegetation communities from the RMDP planning area. Temporary disturbance to these vegetation communities would also occur from clearing and grading associated with the construction of access roads, grade control structures, buried bank protection, installation of culverts and other improvements. These temporary disturbance areas would not all be restored to the same chaparral associations and alliances as currently present, but would be restored as part of channel reconstruction and would be converted to native riparian and upland vegetation communities, which may include chaparral at higher elevations along the channel banks. **Section 4.5.5.1**, Impact Analysis Approach and Methods of this EIS/EIR contains a detailed description of the different direct, indirect, and secondary effects that could occur from the implementation of the proposed RMDP.

The primary difference regarding this vegetation community type is it occurs on steep hillsides and in areas where construction related to the RMDP would be less likely to directly affect large blocks of contiguous habitat. The majority of the impacts to chaparral communities would occur from build-out of the Specific Plan development, specifically through construction related activities and the development of residential housing, commercial properties, and infrastructure.

Another important difference is how temporary project effects would be mitigated through restoration. One goal of restoration is to establish a native community largely free of exotic species (Allen 1998). This requires establishing a stable community resistant to invasion. As previously described for riparian and scrub communities each habitat type have different natural abilities to resist invasion from exotic species. For example, chaparral appears to naturally resist colonization by exotic species more readily than coastal sage scrub, oak woodlands, or native California grasslands (Allen 1998). The ability of chaparral to resist colonization is apparently due to the closed canopy maintained

throughout the dry season, and where openings occur, colonization by exotics can also occur (Allen 1998). Therefore restoration efforts in this community type are likely to fairly successful if adequately managed.

Mitigation Strategy for Direct Permanent and Temporary Impacts

The primary mechanism for mitigating the permanent loss of chaparral communities in the RMDP and Specific Plan area is the implementation of measures designed to mitigate vegetation communities that were lost through construction by the dedication of existing natural lands in the River Corridor SMA, High Country SMA, and Salt Creek area. The specific mitigation measures that would provide for the dedication of open space and management of these areas includes previously incorporated Mitigation Measures SP-4.6-21 through SP-4.6-26 (Open space dedication of the River Corridor SMA), SP-4.6-36 through SP-4.6-42 (Open space dedication of the River Corridor SMA and the High Country SMA). In addition, some of the new measures presented in this document include Mitigation Measures BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) and BIO-62 (dedication to the public of at least 1,900 acres of Open Area to an NLMO).

These areas support the same types of habitat that would be lost through construction and would be further enhanced through ongoing restoration and management activities. Some of these activities would include the establishment of native vegetation communities in currently disturbed habitat, a reduction in cattle grazing except where grazing may be used as a management tool to control exotics, the removal of agricultural practices, and the management of exotic species within restoration areas associated with the RMDP. These measures provide additional mechanisms to ensure the dedication and management of natural lands and open space to mitigate the effects of the proposed project to chaparral communities in the project area.

Further protection of this vegetation type would be achieved though the use of buffers and monitored perimeters as described for scrub communities. To further reduce the impacts of the proposed RMDP from accidental clearing or trampling of vegetation the applicant would implement previously incorporated Mitigation Measures SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA); SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the River Corridor SMA and the High Country SMA); and BIO-52 (pre-construction educational meetings, construction limit staking, and biological monitoring during vegetation clearing

and grading activities). Implementation of these measures would reduce these effects to less-than-significant levels.

Following development, the continued preservation of this vegetation community would be accomplished through restricted access, long-term management, and dedication of natural areas. Applicable mitigation measures for the long-term maintenance of the River Corridor SMA, the High Country SMA, Salt Creek area, and Open Area include SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA); and BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas), and BIO-73 (permanent fencing along trails in the River Corridor SMA).

Long-term management activities would include a reduction in cattle grazing except where grazing may be used as a management tool to control exotics, and the management of exotic species within restoration areas associated with the RMDP. The specific mitigation measures that would provide for the dedication of open space and management of these areas includes previously incorporated Mitigation Measures SP-4.6-21 through SP-4.6-26 (Open space dedication of the River Corridor SMA), SP-4.6-36 through SP-4.6-42 (Open space dedication of the River Corridor SMA and the High Country SMA), and SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA). In addition, some of the new measures presented in this document include Mitigation Measures BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) and BIO-62 (dedication to the public of at least 1,900 acres of Open Area to an NLMO). These measures provide additional mechanisms to ensure the dedication and management of natural lands and open space to mitigate the effects of the proposed project to chaparral vegetation communities. These areas support the same types of habitat that would be lost through construction and would be further enhanced through ongoing restoration and management activities.

The applicant would implement measures to ensure the establishment of chaparral vegetation in temporarily disturbed areas. Temporary disturbance to vegetation communities would be mitigated through restoration and revegetation, with the intent of restoring the functional services/values of the habitat prior to disturbance. These temporary disturbance areas would not all be restored to the same chaparral associations and alliances as currently present, but would be restored as part of channel reconstruction and would be converted to native riparian and upland vegetation communities, which may include chaparral at higher elevations along the channel banks.

Implementation of these mitigation measures will reduce this impact to a level that is adverse but not significant for Alternative 2. The specific mitigation measures that would be utilized to reduce the direct impacts of the proposed RMDP to a level that is adverse but not significant are identified above in **Table 4.5-30**, Applicable Mitigation Measures for Direct Impacts to California Annual Grassland, Agriculture, and Disturbed Land.

Indirect Permanent Impacts

The majority of the impacts to chaparral communities would occur from build-out of the Specific Plan development, specifically through construction related activities and the development of residential housing, commercial properties, and infrastructure.

Construction activities associated with the build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent removal of approximately 431 acres of chaparral communities, or 20.1% of the total acreage of chaparral communities present on site. In relation to each planning area, approximately 406 acres of chaparral communities would be removed from the Specific Plan planning area and 25 acres would be removed from the Entrada development. No chaparral communities would be removed at the VCC site (**Table 4.5-27**).

Significance Finding: Significant absent mitigation for Alternative 2. While chaparral communities are considered common and are not protected by state or federal law the vegetation present in the project area is known to support a variety of sensitive plant and wildlife species. As such the permanent impacts associated with build-out of the Specific Plan, VCC, and Entrada planning areas would constitute a substantial adverse effect on the vegetation community. Construction activities would also have the potential to substantially reduce the number or restrict the range of special status species known to occur in chaparral in the planning area (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2.

The removal of these vegetation communities from the build-out of the Specific Plan, VCC, and Entrada planning areas and the applicable mitigation measures would be the same as described for direct impacts associated with implementation of the RMDP (see Significance Finding for Direct Permanent and Temporary Impacts, above).

Implementation of these mitigation measures would reduce this impact to a level that is adverse but not significant for Alternative 2.

Mitigation Strategy for Indirect Permanent Impacts

The removal of chaparral vegetation communities from the build-out of the Specific Plan, VCC, and Entrada planning areas and the applicable mitigation measures would be the same as described for direct impacts associated with implementation of the RMDP (see Significance Finding, Mitigation Strategy for Direct Permanent and Temporary Impacts, and **Table 4.5-30**, Applicable Mitigation Measures for Direct Impacts to California Annual Grassland, Agriculture, and Disturbed Land, above). To reduce or minimize the large scale removal of vegetation the applicant has proposed the dedication and enhancement of lands in the High Country SMA, River Corridor SMA, Salt Creek area, and in the Open Area. These areas would mitigate the lost vegetation community/land covers by preserving at a 1:1 ratio lands supporting the same types of plants and wildlife lost through the implementation of the proposed Project. The implementation of these mitigation measures would reduce this impact to a level that is adverse but not significant for Alternative 2.

Secondary Impacts

Secondary impacts to chaparral communities are expected to occur both from the implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas. Secondary impacts to chaparral communities located adjacent to the proposed development areas would be subject to the same types of secondary effects as coastal scrub vegetation communities. This can include impacts due to fugitive dust; runoff, sedimentation, chemical pollution, and erosion; hydrological alterations; litter; and accidental clearing, grading, and trampling. Long-term development-related effects including landscape-level impacts and "edge" effects include the increased risk of non-native, invasive plant and animal species, litter, hydrological alterations, human disturbance, and modified fire frequency.

The secondary effects of the proposed Project would be the same as described for coastal scrub communities. Secondary effects such as excessive dust from short-term construction-related secondary impacts or altered hydrology can adversely affect these communities and inhibit the recruitment of native plant communities. Similar to coastal scrub communities this can also lead to the establishment of more disturbed or exotic plant communities. However, this community type is more resistant to colonization by exotic species that scrub or riparian communities. Vegetation can also be crushed through the inadvertent clearing of vegetation located outside the designated project

footprint and human activity along the open space-urban interface may also result in the trampling of vegetation and compaction of soils.

Fertilizer and herbicide use would have the same effects as described above for coastal scrub communities and could lead to the degradation of adjacent habitats or the spread of exotic plants. The spread of exotic species and increased human presence can lead to altered fire regimes in the project area. As described for coastal scrub communities altered wildfire regimes and particularly increased incidence of fires may occur in urbanized areas. For chaparral communities wildfires may be a significant concern due to the extremely high fuel loads that can develop after decades of altered fire regimes. As described above, in California most fires are quickly suppressed for public safety and to protect property. These types of fire regime alteration can drastically affect plant and animal communities. Longer than natural fire intervals can result in excessive buildup of fuel loads, so that when fires do occur, they are catastrophic. Unnaturally long fire intervals can also result in senescence of plant communities such as chaparral that rely on shorter intervals for rejuvenation.

Significance Finding: Significant absent mitigation for Alternative 2. Potential short-term construction-related secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include dust; runoff, sedimentation, erosion, and chemical pollutants; hydrological alterations; litter; and accidental clearing, grading, and trampling. Potential long-term development-related secondary impacts include non-native, invasive plant and animal species; litter; hydrological alterations; increased risk of human disturbance; and increased risk of fire frequency. These short-term and long-term secondary impacts would constitute a substantial adverse effect on the vegetation community, threaten to eliminate this vegetation community on site, and substantially reduce the number or restrict the range of special-status species (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2.

Mitigation Strategy for Secondary Impacts

In order to reduce short-term and long-term secondary impacts to chaparral communities resulting from implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas, the Project applicant will implement the same general mitigation measures as described for California Annual Grassland, Agriculture, and Disturbed Land and Scrub Communities. This would include the existing mitigation measures approved for the Specific Plan EIR and additional measures that are designed to reduce or minimize the effects of the Project on these resources.

Secondary effects associated with dust, runoff, erosion, sedimentation, and chemical pollutants would be the same as those described for scrub vegetation communities. Mitigation measures have been designed to limit the amount of particulate matter (dust) that leaves the construction area and include actions such as daily watering of disturbed areas and the use of chemical tackifiers. BMPs would also be employed to reduce secondary impacts associated with runoff, erosion, sedimentation, and chemical pollutants. The applicable mitigation measures to reduce impacts from fugitive dust, runoff, erosion, sedimentation, and chemical pollutants include the previously incorporated measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA), SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), and SP-4.6-44 and SP-4.6-45 (drainage guidelines); as well as Mitigation Measures BIO-45 (pre-construction diversion of all stream flows within a work zone), BIO-46 (requiring the presence of a qualified biologist during stream diversion), BIO-47 (slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area), BIO-49 (prevention of mud and pollutants from entering streams and storm flows), BIO-52 (pre-construction educational meetings, construction limit staking, and biological monitoring during vegetation clearing and grading activities), BIO-70 (project design features, construction notes, erosion and dust control, and SWPPP BMPs (erosion and dust control, staging/storage area restrictions, equipment maintenance restrictions, trash restrictions) to ensure protection of vegetation communities and special status species), and BIO-71 (dust control measures to protect vegetation communities and special status aquatic wildlife species).

To reduce the effects of invasive and noxious plants or altered fire ecology the applicant would implementation Mitigation Measures SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) and SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs) as well as Mitigation Measures BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation). These measures include the education of homeowners regarding the sensitivity of natural lands, the use of landscape species that have a limited potential to spread or are considered non-invasive, routine weeding of restored habitat, and the use of buffer areas that physically separate residential landscaping from natural areas. In addition, Fuel Management Zones (FMZ) would be located adjacent to structures such as residential and commercial properties to reduce the potential for the spread of wildfires form urban to vegetated areas. Applicable mitigation measures to reduce the potential for increased fire frequency include the previously incorporated measures SP-4.6-17

(standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-31 (prohibition of hunting, fishing, or motor or trail bikes within the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs), and SP-4.6-49 through SP-4.6-52 (wildfire fuel modification plan and standards for FMZs).

Short-term impacts resulting from accidental clearing, and grading, and long-term effects of trampling would be the same measures as those described for scrub communities. The applicable mitigation measures to reduce impacts from trampling and clearing of vegetation outside of the construction zone include the previously incorporated measures SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA), SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA), as well as Mitigation Measure BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities). These measures include guidance regarding the use of clearly identified construction areas, full-time biological monitoring, the preservation of mitigation lands, and the education of homeowners regarding the sensitivity of natural lands.

Long-term effects of trampling and littering would be reduced through the preservation of mitigation lands, the education of homeowners regarding the sensitivity of natural lands, signage, and fencing. These include Mitigation Measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-29 through SP-4.6-32 (recreational usage and access restrictions within the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), and SP-4.6-39 (High Country SMA grazing and recreational use restrictions); as well as Mitigation Measures BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas) and BIO-73 (permanent fencing along trails in the River Corridor SMA). While it is inevitable that some human disturbance will occur in natural lands; the applicant will provide designated trails within open areas and natural lands that are intended to provide recreational opportunities in a manner consistent with resource protection and recreational usage.

The implementation of these mitigation measures would reduce this impact to a level that is adverse but not significant for Alternative 2. A summary description of the specific mitigation measures that reduce the secondary impacts of the proposed Project are described in **Table 4.5-31**, Applicable Mitigation Measures for Secondary Impacts to California Annual Grassland, Agriculture, and Disturbed Land.

Summary of Impacts and Mitigation Strategy for Chaparral Communities. Construction of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent removal of chaparral vegetation communities. Implementation of the RMDP facilities would also result in the temporary loss of these vegetation communities/land covers. In total, implementation of the proposed RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent loss of 457 acres and the temporary disturbance of 1.5 acres of the total 2,146 acres of the chaparral vegetation communities that occur on site. These temporary disturbance areas would not all be restored to the same chaparral associations and alliances as currently present, but would be restored as part of channel reconstruction and would be converted to native riparian and upland vegetation communities, which may include chaparral at higher elevations along the channel banks.

Typically, the loss of non-sensitive plant communities including chaparral vegetation communities would not be considered a significant impact. These communities are not sensitive, and are locally and regionally abundant. Generally additional mitigation would not be required unless these communities occur within designated critical habitat for a federally listed species or are known to support special-status plant species or wildlife that utilize these areas for foraging or nesting. Because chaparral vegetation communities on site are known to provide important foraging, nesting, and movement areas for special-status plants and wildlife, the permanent land conversion of these vegetation communities would be considered significant.

Implementation of the mitigation measures described for Direct, Indirect, and Secondary Impacts above would reduce the effects of the proposed Project on chaparral vegetation communities to less-than-significant levels. These measures include restoration of temporary impact areas, as well as the dedication and preservation of large areas of natural lands intended to off-set the permanent removal of these vegetation communities/land covers. The dedicated areas described in Direct and Indirect Impacts would also be managed for the preservation and enhancement of natural communities. The temporary disturbance areas would be converted to native riparian and upland vegetation communities, which may include chaparral at higher elevations along the channel banks.

Secondary impacts from short-term construction include fugitive dust, runoff, accidental clearing, grading, and trampling; or long-term development-related impacts from urbanization or "edge" effects that generally occur along the open space urban interface would also be reduced or mitigated through the implementation of the previously adopted measures from the Specific Plan EIR and the comprehensive mitigation measures described above.

Both the previously adopted measures from the Specific Plan EIR and the mitigation measures described for this project would be implemented to reduce the effects of the proposed Project on chaparral vegetation communities. Implementation of these measures would reduce direct, indirect, and secondary impacts to chaparral vegetation communities to a level that is adverse but not significant.

Impacts to Oak Woodland Communities (Coast Live Oak Woodland, Mixed Oak Woodland, Valley Oak/Grass, Valley Oak Woodland)

Existing Conditions. The oak woodland vegetation communities present in the project area include, coast live oak woodland, mixed oak woodland, valley oak/grass, and valley oak woodland. Coast live oak woodland in the Specific Plan area occurs mostly in the southern half of the area, generally in south-facing canyons and along the Santa Clara River tributaries. In accessible areas along Salt Creek, the understory of this woodland community has been impacted by past and ongoing grazing practices and is dominated by non-native grasses.

Coast live oak woodland provides potential habitat for Cooper's hawk, long-eared owl, and loggerhead shrike and provides nesting habitat and/or acorns that are a food source for a number of wildlife species, including oak titmouse, Lawrence's goldfinch, merlin, sharp-shinned hawk, white-tailed kite, San Bernardino ringneck snake, silvery legless lizard, coast horned lizard, and coastal western whiptail, and provides general cover for larger mammal species such as mountain lion.

Mixed oak woodland occurs in the Specific Plan area within the High Country SMA and Salt Creek area. Mixed oak woodland occurs in patches, typically where other oak woodland associations such as coast live oak woodland and valley oak/grass intergrade, and is typically dominated by aggressive non-native grasses such as bromes. This community provides potential habitat for Cooper's hawk, long-eared owl, and mountain lion, as well as potential nesting habitat for white-tailed kite.

Valley oak/grass appears to coincide with grazing pressure, primarily in the southern portion of the Specific Plan area, where open woodland provides cattle with ideal forage and shade. Valley oak/grass provides potential habitat for Cooper's hawk, golden eagle, turkey vulture, northern harrier, loggerhead shrike, merlin, sharp-shinned hawk, coastal western whiptail, San Bernardino ringneck snake, silvery legless lizard, coast horned lizard, and mountain lion, as well as potential nesting habitat for white-tailed kite.

Valley oak woodland includes a predominance of valley oaks in sufficient numbers to constitute between 20% to 50% cover. Valley oak woodland occurs within the Specific Plan area along Salt Creek and within the southern portion of the High Country SMA and Salt Creek area. This association appears to coincide with grazing pressure, primarily in

the southern portion of the Specific Plan area, where open woodland provides cattle with ideal foraging and shade. Valley oak woodland is found within the High Country SMA and is relatively intact. This community provides potential habitat for long eared owl, Lawrence's goldfinch, Cooper's hawk, loggerhead shrike, sharp shinned hawk, merlin, San Bernardino ringneck snake, coastal western whiptail, coast horned lizard, silvery legless lizard, and mountain lion, as well as potential nesting habitat for white tailed kite.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

Construction activities associated with the development of RMDP facilities (*e.g.*, buried bank protection, levees, bridges, and ancillary structures) would result in the permanent removal of 9.3 acres and temporary removal of 1.4 acre of oak woodland communities (including coast live oak woodland, valley oak woodland and valley oak/grass) on site. Direct impacts to coast live oak woodland would include the permanent/temporary loss of 8.3/1.2 acres. Direct impacts to valley oak woodland would be limited to temporary impacts to 0.8/0.1 acre. Direct impacts to valley oak/grass would include the permanent/temporary loss of 0.2/0.0 acre. Permanent and temporary impacts from implementation of the proposed RMDP would not occur to mixed oak woodland. **Table 4.5-27**, Impacts of the Proposed Project to Vegetation Communities and Land Covers, provides a detailed analysis of the vegetation acreage affected by each project component.

As a relative index of the habitat availability on site, approximately 1,468 acres of oak woodland communities occur in the proposed RMDP project area. Thus, the approximate loss of these habitats relative to their availability from direct impacts is less than 1.0% of the existing oak woodland communities present in the Project area. The greatest impacts would occur to coast live oak woodland, of which 8.3 acres (1.1%) would be directly impacted by development of the RMDP.

Significance Finding: Significant absent mitigation for Alternative 2. Statewide, the overall trend for oak woodlands is a decrease in acreage and density, and one important contributing factor is a low rate of regeneration. However, residential development, woodcutting, agriculture, fire, rangeland development, and sudden oak death are all contributing to the decline of oak woodlands throughout the state (Light and Pedroni 2002).

Oak woodlands are a significant biological resource in the project area because they provide nesting and roosting habitat for a number of special-status avian and

bat species. In addition, oak tree communities are protected by various local ordinances that require mitigation for their removal. Valley oak/grass is also considered a special status community by CDFG (2003). Oak communities provide valuable mast (acorn) crops which are important to foraging wildlife, and oak trees are very slow growing. Even modest impacts may take years to replace lost functional values. The permanent and temporary impacts associated with the RMDP would constitute a substantial adverse effect on the vegetation community; may threaten to eliminate this plant community; may substantially reduce the number or restrict the range of an endangered, rare, or threatened species (oak trees are considered special status per the CLAOTO); and may conflict with local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance (significance criteria 1, 2, 5, and 7). This impact would be significant, absent mitigation, for Alternative 2.

Oak woodland communities would be subject to the same types of construction-related impacts (*i.e.*, clearing and grading) as described for Riparian Vegetation Communities, Coastal Scrub Communities, and Chaparral Communities. These effects result from the permanent removal of these vegetation communities from the RMDP planning area. Temporary disturbance to these vegetation communities would also occur from clearing and grading associated with the construction of access roads, grade control structures, buried bank protection, installation of culverts and other improvements. **Subsection 4.5.5.1**, Impact Analysis Approach and Methods, of this EIS/EIR contains a detailed description of the different direct, indirect, and secondary effects that could occur from the implementation of the proposed RMDP.

For the RMDP only small sections of oak woodlands would be subject to project disturbance. Similar to riparian communities, oak woodlands can be highly susceptible to damage from clearing and grading activities even in areas adjacent to existing oak trees. Repair or widening of existing roads to support construction equipment that occurs under the canopy of oak trees may result in damage to individual trees, limbs, and/or their root systems potentially causing mortality.

These types of disturbances can kill trees and facilitate the expansion or colonization of exotic weeds. Aggressive weeds can inhibit the germination of oak seedling by reducing access to water or light. Increased predation from rodents that occur in weedy areas can also increase the mortality of oak seedlings.

Mitigation Strategy for Direct Permanent and Temporary Impacts

For oak woodlands the primary mitigation strategy is to mitigate lost habitat through the dedication of mitigation lands in the High Country SMA, Salt Creek

SMA, and River Corridor SMA. Open space located with the Project area would also support and protect existing oak trees. These measures include Mitigation Measures SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA), SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA), and SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA). In addition, some of the new measures presented in this document include Mitigation Measures BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) and BIO-62 (dedication to the public of at least 1,900 acres of Open Area to an NLMO).

Construction within the driplines of oak trees, and incidental trimming or damage to trees in the project area would also be reduced through the implementation of Mitigation Measure BIO-42 (protective fencing around oaks during clearing and grading activities). This measure would ensure that clearing (including brush clearing) or areas to be graded shall be enclosed in a temporary fenced zone for the duration of the clearing or grading activities. Fencing shall extend to the root protection zone (*i.e.*, the area at least 15 feet from the trunk or five feet beyond the drip line, whichever distance is greater). No parking or storage of equipment, solvents, or chemicals that could adversely affect the trees shall be allowed within 25 feet of the trunk at any time. Removal of the fence shall occur only after the Project arborist or qualified biologist confirms the health of preserved trees. Use of this measure would reduce the effects of construction to less-than-significant levels.

To further reduce the effects of the RMDP on oak woodlands, oak tree replacement in, or adjacent to, existing oak woodlands and savannahs would also occur. While many county and city oak tree protection ordinances focus on individual trees, the functional unit that should be considered for restoration is the oak woodland. Mitigation such as restoration and compensation should focus on oak woodlands rather than a certain number or size of individual trees (Light and Pedroni 2002). Protecting trees only over a certain size results in loss of woodlands as the younger components of the woodland are removed, and structural complexity is lost. The mitigation measures proposed to replace impacted oak tree habitat; restore, enhance, and maintain the communities on site; and create new or expand existing oak woodland communities do consider the community as a whole. These measures would replace the lost habitat and provide for the long-term perseveration of oak communities in the project area. The three-part strategy incorporates (1) planting replacement trees, per the requirements of CLAOTO and previously incorporated Mitigation Measure SP-4.6-48; (2) additional replacement ratios recommended in this EIS/EIR for

impacts to oak trees and oak woodlands where they occur within stream channels falling under CDFG and Corps jurisdiction, per 1600 and 404 (BIO-2); and (3) additional measures recommended in this EIS/EIR for tree replacement or woodland restoration/enhancement to mitigate for oak trees and woodland occurring in uplands, outside CDFG and Corps jurisdiction (BIO-22).

The project's impacts to oak trees and oak woodlands are related but are not identical. Losses of oak trees are to be mitigated by planting replacement trees (per the requirements of CLAOTO, BIO-22b, and previously incorporated Mitigation Measure SP-4.6-48), supplementing those numbers with additional replacement trees as described in BIO-22c (for upland oak trees) and BIO-2.

This EIS/EIR requires additional oak woodland replacement at a range of 2:1 to 3:1 for any oak woodland lost within jurisdictional streambeds (BIO-2) and at a ratio of 1:1 for woodland acreages lost outside of jurisdictional areas (BIO-22d). For impacts to upland oak woodlands, Newhall Land may enhance existing degraded woodland areas, at the increased ratio of 2:1.

All oak trees to be planted for CLAOTO compliance will be subject to species and performance criteria as specified in CLAOTO (see BIO-22b). Where CLAOTO replacement trees are planted in natural open areas such as the High Country and Salt Creek areas, the planting areas will be planted and managed as natural woodlands, to include other characteristic woodland species and to provide habitat for a broader variety of wildlife than is possible in close proximity to development.

As described in the Draft Newhall Ranch Mitigation Feasibility Study (Dudek 2007A), potential mitigation sites for three oak vegetation communities—valley oak/grass, coast live oak woodland, and valley oak woodland—were identified in the High Country SMA and Salt Creek area (**Figure 4.5-158**, Newhall Land – Potential Oak Mitigation Sites). A comprehensive evaluation identified approximately 111 acres considered suitable for creating specific oak vegetation communities, including 87 acres of valley oak/grass, 10 acres of coast live oak woodland, and 0.4 acre of valley oak woodland.

In addition, this EIS/EIR requires replacement of oak trees at a ratio of 0.5:1 for oak trees with dbh of 8 to 35 inches, and at a ratio of 2.5:1 for oak trees with dbh of 36 or more inches lost or impacted in uplands (BIO-22c). These trees are in addition to the CLAOTO requirement described above. These additional trees may also be incorporated into woodland habitat enhancement or creation.

This oak mitigation strategy will be outlined in an Oak Resource Management Plan, to be prepared by the applicant and submitted for approval to CDFG and County of Los Angeles, and implemented upon approval. The Plan shall identify areas suitable for oak woodland enhancement and creation. The Plan shall distinguish between oaks to be planted in compliance with CLAOTO (BIO-22b) and the additional measures required by this EIS/EIR (BIO-2 for woodlands in jurisdictional streambeds; and BIO-22c and 22d for upland areas).

The Oak Resource Management Plan shall include measures to create or enhance woodlands as follows: (1) locations and acreages of mitigation sites where woodland creation or enhancement will; (2) a description of proposed cover and number of native trees, shrubs and grasses per acre to be established. This description shall be based on comparable intact woodlands in the area of impact or elsewhere within the RMDP planning area, consistent with conditions of the proposed mitigation site; (3) site preparation measures to include (as appropriate) topsoil treatment, soil decompaction, erosion control, weed grow/kill cycle, or as otherwise approved by the agencies; (4) methods for the removal of non-native plants (e.g., mowing, weeding, raking, herbicide application, or burning); (5) a plant palette listing all species, including sizes, planting densities, or seeding rates, to be based on target vegetation; (6) the source of all plant propagules (seed, potted nursery stock, etc) and the quantity and species of seed or potted stock of all plants to be introduced or planted into the mitigation areas; (7) temporary irrigation, protection from herbivores, fertilizer, weeding, etc; (8) a schedule and action plan to maintain and monitor the enhancement/restoration areas, to include at minimum, qualitative annual monitoring for revegetation success and site degradation due to erosion, trespass, or animal damage for a period no less than 5 years total and no less than 2 years after removal of irrigation (if any); (9) where sites are near trails or other access points, measures such as fencing, signage, or security patrols to exclude unauthorized entry into the mitigation areas shall be implemented as needed; (10) tree protection standards to be implemented for individual trees or woodlands adjacent to development activity; (11) success criteria as stated in BIO-22b and BIO-22d; and (12) contingency measures, such as replanting, erosion control, irrigation system repair, or understory re-seeding, to be implemented if habitat improvement / restoration efforts do not meet the success criteria stated in the plan. The Oak Resource Management Plan would reduce impacts to oak woodland communities by replacing and enhancing habitat in the project area.

The primary measures that would be implemented to restore or enhance habitat within riparian the River Corridor and the High Country SMA include the previously incorporated measures SP-4.6-1 through SP-4.6-16 and SP-4.6-63

(habitat restoration/enhancement in the River Corridor SMA; 1:1 riparian resource replacement), SP-4.6-26a (riparian revegetation and oak tree replacement opportunities in the High Country SMA), SP-4.6-28 (mitigation banking for various habitat types in the High Country SMA), SP-4.6-43 (Open Area use for mitigation of riparian or oak resources or elderberry scrub), SP-4.6-47a (allowing mitigation banking for riparian habitats, oak resources, and Mexican elderberry within the River Corridor SMA, High Country SMA, and Open Area), as well as new Mitigation Measures BIO-1 through BIO-16 (wetlands mitigation plan and riparian restoration activities on the Project site). CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

The applicant would implement measures to ensure the establishment of oak woodland vegetation in temporarily disturbed areas. Temporary impacts to vegetation communities would be mitigated through restoration and revegetation, with the intent of restoring the functional services/values of the habitat prior to disturbance

Further protection of vegetation communities would be achieved through the creation of buffers and biologically monitored perimeters during construction periods. Biologically monitored perimeters would limit the potential for the contractor to disturb vegetation outside the proposed construction footprint. The use of these measures would identify the limits of construction and provide a biological monitor to review the construction area in the field with the contractor and be present during initial vegetation clearing and grading. To further reduce the impacts of the proposed RMDP from accidental clearing or trampling of vegetation the applicant would implement previously incorporated Mitigation Measures SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA); SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA); and BIO-52 (pre-construction educational meetings, construction limit staking, and biological monitoring during vegetation clearing and grading activities). Implementation of these measures would reduce these effects to less-than-significant levels.

Following development, continued preservation of the dedicated areas would be accomplished through restricted access and long-term management of the River Corridor SMA, High Country SMA, and Salt Creek area. The use of buffers

would limit the potential for the spread of exotic weeds and limit the potential for the spread of wildfires (buffers are described in detail under Secondary Impacts of the Proposed Project). To further reduce the impacts of the proposed Project, the applicant would implement previously incorporated Mitigation Measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA); and BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas) and BIO-73 (permanent fencing along trails in the River Corridor SMA). Implementation of these measures would reduce these effects to less-than-significant levels.

The implementation of these mitigation measures will reduce this impact to a level that is adverse but not significant for Alternative 2. The specific mitigation measures that reduce the direct permanent and temporary impacts of the proposed RMDP to a level that is adverse but not significant are identified below in **Table 4.5-32**.

Table 4.5-32
Applicable Mitigation Measures for Direct Impacts to Oak Woodland Vegetation Communities

Mitigation Measure(s)	Issue Mitigating
SP-4.6-1 through SP-4.6-16 (habitat restoration/enhancement in the River Corridor SMA)	Vegetation Removal
SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA)	Vegetation Removal
SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA)	Vegetation Removal
SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA)	Vegetation Removal
SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA)	Vegetation Removal
SP-4.6-26a (riparian revegetation and oak tree replacement opportunities in the High Country SMA)	Vegetation Removal
SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA)	Vegetation Removal
SP-4.6-28 (mitigation banking for various habitat types in the High Country SMA)	Vegetation Removal
SP-4.6-34 (marking and inspection of grading perimeters prior to impacts within or adjacent to the High Country SMA)	Vegetation Removal
SP-4.6-35 (avoidance of inadvertent impacts to biological resources within or adjacent to the High Country SMA)	Vegetation Removal
SP-4.6-36 through SP-4.6-42 (open space dedication of the High Country SMA)	Vegetation Removal
SP-4.6-43 (Open Area use for mitigation of riparian or oak resources or elderberry scrub)	Vegetation Removal
SP-4.6-47a (allowing mitigation banking for riparian habitats, oak resources, and Mexican elderberry within the River Corridor SMA, High Country SMA, and Open Area)	Vegetation Removal
SP-4.6-48 (restoration and enhancement of oak resources in the High Country SMA and Open Area)	Vegetation Removal

Table 4.5-32
Applicable Mitigation Measures for Direct Impacts to Oak Woodland Vegetation Communities

Mitigation Measure(s)	Issue Mitigating
SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA; 1:1 riparian resource replacement)	Vegetation Removal
BIO-1 through BIO-16 (wetlands mitigation plan and riparian restoration activities on the Project site)	Vegetation Removal
BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126)	Vegetation Removal
BIO-22 (preparation and implementation of an Oak Resource Management Plan identifying areas suitable for oak woodland enhancement and creation)	Vegetation Removal
BIO-42 (protective fencing around oaks during clearing and grading activities)	Vegetation Removal
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Vegetation Removal
BIO-62 (dedication to the public of at least 1,900 acres of Open Area to an NLMO)	Vegetation Removal
BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas)	Vegetation Removal
BIO-73 (permanent fencing along trails in the River Corridor SMA)	Vegetation Removal

Indirect Permanent Impacts

The indirect impacts to oak woodland communities would occur from build-out of the Specific Plan development, specifically through construction related activities and the development of residential housing, commercial properties, and infrastructure.

Construction activities associated with the build-out of the Specific Plan area would result in the permanent removal of approximately 85 acres of oak woodland communities (primarily in canyons south of the Santa Clara River and ridges south of Potrero Canyon), or 5.8% of the total acreage of oak woodland communities present on site. In relation to each oak woodland type, approximately 60 acres of coast live oak woodland, 21 acres of valley oak/grass, 4.7 acres of valley oak woodland, and no acreage from mixed oak woodland would be removed from the Specific Plan planning area. Impacts to oak woodlands would not occur from the build-out of the VCC and Entrada planning areas (**Table 4.5-27**).

As described in **Subsection 4.5.5.1**, Impact Analysis Approach and Methods, there are no temporary impacts associated with the build-out of the Specific Plan, VCC, and Entrada planning areas as all construction-related activities would occur within the proposed development footprint.

Significance Finding: Significant absent mitigation for Alternative 2. These permanent impacts have the potential to have a substantial adverse effect on the vegetation community; may threaten to eliminate this plant community; may substantially reduce the number or restrict the range of an endangered, rare, or threatened species; and may conflict with local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance (significance criteria 1, 2, 5, and 7). This impact would be significant for Alternative 2.

The removal of these vegetation communities from the build-out of the Specific Plan, VCC, and Entrada planning areas and the applicable mitigation measures would be the same as described for direct impacts associated with implementation of the RMDP (see Significance Finding for Direct Permanent and Temporary Impacts, above).

The implementation of these mitigation measures would reduce this impact to a level that would be adverse but not significant for Alternative 2.

Mitigation Strategy for Indirect Permanent Impacts

The removal of oak woodland vegetation communities from the build-out of the Specific Plan, VCC, and Entrada planning areas and the applicable mitigation measures would be the same as described for direct impacts associated with implementation of the RMDP (see Significance Finding, Mitigation Strategy for Direct Permanent and Temporary Impacts, and **Table 4.5-32**, Applicable Mitigation Measures for Direct Impacts to Oak Woodland Vegetation Communities, above). To reduce or minimize the large-scale removal of vegetation the applicant has proposed the dedication and enhancement of lands in the High Country SMA, River Corridor SMA, Salt Creek area, and in the Open Area. These areas would mitigate the lost vegetation community/land covers and consist of lands supporting the same types of plants and wildlife lost through the implementation of the proposed Project. In addition, oak tree buffers adjacent to development and oak tree replacement in High Country SMA, River Corridor SMA, Salt Creek area, and in open space would further minimize impacts to oak woodlands vegetation communities. The implementation of these mitigation measures would reduce this impact to a level that is adverse but not significant for Alternative 2.

Secondary Impacts

Secondary impacts to oak woodland communities are expected to occur both from the implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas. Secondary impacts to oak woodland communities located

adjacent to the proposed development areas would be subject to the same types of secondary effects as scrub vegetation communities. This can include impacts due to fugitive dust; runoff, sedimentation, chemical pollution, and erosion; hydrological alterations (causing water stress to the root systems even though no visible damage to the tree occurs); litter; and accidental clearing, grading, and trampling. Long-term development-related effects including landscape-level impacts and "edge" effects include the increased risk of non-native, invasive plant and animal species, litter, hydrological alterations, human disturbance, and modified fire frequency.

The primary concern to oak woodland communities from secondary effects of the proposed Project would be altered hydrology, soil compaction, exotic weeds, and altered fire regimes. Altered hydrology that results in increase soil moisture beyond what the specific tree has acclimated to may lead to mortality over time. With large oaks, the concern is that increases in moisture and other deleterious effects may take years to be recognized. Fertilizer and herbicide can also have slow but permanent effects to established oak trees. The spread of exotic species and increased human presence can further lead to soil compaction, low seedling establishment, and lead to altered fire regimes in the project area.

As described for riparian and scrub communities altered wildfire regimes and particularly increased incidence of fires may occur in urbanized areas. Frequent wildfires in oak woodland communities may remove small trees from the planning area and ultimately lead to senescence of oak tree populations. Where extremely high fuel loads have developed after decades of altered fire regimes, high intensity fires can kill or substantially affect existing oak populations.

Significance Finding: Significant absent mitigation for Alternative 2. Potential short-term construction-related secondary impacts associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas include dust; runoff, sedimentation, erosion, and chemical pollutants; hydrological alterations; litter; and accidental clearing, grading, and trampling. Potential long-term development-related secondary impacts include non-native, invasive plant and animal species; litter; hydrological alterations; increased risk of human disturbance; and increased risk of fire frequency. These short-term and long-term secondary impacts would constitute a substantial adverse effect on the vegetation community; threaten to eliminate this vegetation community on site; may conflict with local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance; and substantially reduce the number or restrict the range of special-status species (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact is significant, absent mitigation, for Alternative 2.

Mitigation Strategy for Secondary Impacts

In order to reduce short-term and long-term secondary impacts to oak woodland communities resulting from implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas, the Project applicant will implement the same general mitigation measures as described for Riparian Communities and Scrub Communities.

Secondary effects associated with dust, runoff, erosion, sedimentation, and chemical pollutants would be the same as those described for riparian vegetation communities. Mitigation measures have been designed to limit the amount of particulate matter (dust) that leaves the construction area and include actions such as daily watering of disturbed areas and the use of chemical tackifiers. BMPs would also be employed to reduce secondary impacts associated with runoff, erosion, sedimentation, and chemical pollutants. The applicable mitigation measures to reduce impacts from fugitive dust, runoff, erosion, sedimentation, and chemical pollutants include the previously incorporated measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA), SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), and SP-4.6-44 and SP-4.6-45 (drainage guidelines); as well as Mitigation Measures BIO-45 (pre-construction diversion of all stream flows within a work zone), BIO-46 (requiring the presence of a qualified biologist during stream diversion), BIO-47 (slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area), BIO-49 (prevention of mud and pollutants from entering streams and storm flows), BIO-52 (pre-construction educational meetings, construction limit staking, and biological monitoring during vegetation clearing and grading activities), BIO-70 (project design features, construction notes, erosion and dust control, and SWPPP BMPs (erosion and dust control, staging/storage area restrictions, equipment maintenance restrictions, trash restrictions) to ensure protection of vegetation communities and special status species), and BIO-71 (dust control measures to protect vegetation communities and special status aquatic wildlife species).

The effects of invasive and noxious plants or altered fire ecology on oak vegetation communities would occur. To offset this impact, the applicant would require the implementation of mitigation measures that include the education of homeowners regarding the sensitivity of natural lands, the use of landscape species that have a limited potential to spread or are considered non-invasive, routine weeding of restored habitat, and the use of buffer areas that physically separate residential landscaping from natural

areas. Some of the specific measures include previously incorporated Mitigation Measures SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) and SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs; as well as Mitigation Measure BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation).

In addition, FMZs would be located adjacent to structures such as residential and commercial properties. Measures to control the use of motorized vehicles in the High Country and River Corridor SMA, authorize the use of designated trails only, and restrict smoking in natural areas would also be the same as for riparian communities. During construction, the applicant would develop and implement a fuel modification plan that specifically addresses the use of welding equipment and designated fire watches in vegetated areas, ensures vehicles are equipped with spark arrestors, and identifies approved smoking areas. Applicable mitigation measures to reduce the potential for increased fire frequency include the previously incorporated measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-31 (prohibition of hunting, fishing, or motor or trail bikes within the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs), and SP-4.6-49 through SP-4.6-52 (wildfire fuel modification plan and standards for FMZs).

Short-term impacts resulting from accidental clearing, and grading, and long-term effects of trampling and litter would be the same as those described for riparian communities. These impacts would be minimized through the use of clearly identified construction areas, full-time biological monitoring, the preservation of mitigation lands, and the education of homeowners regarding the sensitivity of natural lands. These include Mitigation Measures SP-4.6-20 (marking and inspection of grading perimeters; avoiding inadvertent impacts to riparian resources in the River Corridor SMA), SP-4.6-34 and SP-4.6-35 (guidelines for grading activities in the High Country SMA); as well as BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities).

Long-term effects of trampling and littering would be reduced through the preservation of mitigation lands, the education of homeowners regarding the sensitivity of natural lands, signage, and fencing. These include Mitigation Measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-29 through SP-4.6-32 (recreational usage and access restrictions within the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), and SP-4.6-39 (High Country SMA grazing and

recreational use restrictions); as well as Mitigation Measures BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas) and BIO-73 (permanent fencing along trails in the River Corridor SMA). While it is inevitable that some human disturbance will occur in natural lands; the applicant will provide designated trails within open areas and natural lands that are intended to provide recreational opportunities in a manner consistent with resource protection and recreational usage.

The implementation of these mitigation measures will reduce this impact to a level that is adverse but not significant for Alternative 2. A concise summary of the specific mitigation measures that reduce the secondary impacts of the proposed Project are described above in **Table 4.5-29**, Applicable Mitigation Measures for Secondary Impacts to Riparian Vegetation Communities.

Summary of Impacts and Mitigation Strategy for Oak Woodland Communities (Coast Live Oak Woodland, Mixed Oak Woodland, Valley Oak/Grass, Valley Oak Woodland). Construction of RMDP facilities and build-out of the proposed development would both result in the permanent removal of oak woodland vegetation communities from the planning area. Implementation of the RMDP facilities would also result in the temporary loss of riparian vegetation communities. In total, implementation of the proposed RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent loss of 95 acres and the temporary removal of 1.4 acres of the total 1,468 acres of oak woodland communities that occur on site. Implementation of the SCP would not directly impact any oak woodland vegetation community. The direct and indirect impacts associated with the proposed project would result in significant impacts absent mitigation.

Implementation of the mitigation measures described for Direct, Indirect, and Secondary Impacts above would reduce the effects of the proposed Project on oak woodland vegetation communities to less-than-significant levels. These measures include creation, enhancement, and/or restoration of oak woodland vegetation communities, as well as the dedication and preservation of large areas of natural lands intended to off-set the permanent removal of riparian vegetation. The dedicated areas described in Direct and Indirect Impacts would also be managed for the preservation and enhancement of natural communities. These measures would ultimately be designed to mitigate impacted oak woodland communities by restoring, enhancing, and maintaining natural oak woodland vegetation communities; and creating new oak woodland vegetation communities after development.

Secondary impacts from short term construction include fugitive dust, runoff, accidental clearing, grading, and trampling; or long-term development-related impacts from

urbanization or "edge" effects that generally occur along the open space urban interface would also be reduced or mitigated through the implementation of the previously adopted measures from the Specific Plan EIR and the comprehensive mitigation measures described above.

Both the previously adopted measures from the Specific Plan EIR and the mitigation measures described for this project would be implemented to reduce the effects of the proposed Project on riparian vegetation communities. Implementation of these measures would reduce direct, indirect, and secondary impacts to this vegetation class to a level that is adverse but not significant.

Impacts to Purple Needlegrass Grasslands

Existing Conditions. Purple needlegrass grasslands in the project area provide nesting and foraging habitat for species such as Swainson's hawk, golden eagle, turkey vulture, merlin, loggerhead shrike, California horned lark, prairie falcon, grasshopper sparrow, tricolored blackbird, sharp-shinned hawk, and northern harrier. Other wildlife, such as coastal western whiptail, San Bernardino ringneck snake, coast horned lizard, and silvery legless lizard also utilize purple needlegrass.

Although purple needlegrass grassland is not considered a special-status community by CDFG (2007d), for purposes of this document, this vegetation community is considered to be special-status. This needlegrass grassland is defined as containing at least 10.0% of vegetative cover composed of perennial, native grasses. Purple needlegrass grassland is rare in southern California even though it typically includes non-native annual species intermixed with native perennial grasses and forbs. There is less than 1.0 acre of purple needlegrass grassland in the Project area, located in the Salt Creek area in the south-central portion of the Specific Plan area.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

The purple needlegrass grassland occurs within the High Country SMA and implementation of the proposed RMDP and the SCP would not result in permanent or temporary impacts to this community.

Significance Finding: No impact for Alternative 2. Development of the proposed RMDP and the SCP would not directly impact purple needlegrass grassland. Construction activities would avoid this vegetation community.

Therefore, there would be no impact to purple needlegrass grassland from the development of the RMDP and the SCP and no mitigation would be required.

Mitigation Strategy

None required.

Indirect Permanent Impacts

Purple needlegrass grasslands are not known to occur in the VCC or Entrada sites and would not be impacted by build-out of these areas. This vegetation community does occur in a limited area within the Salt Creek area in the south-central portion of the Specific Plan area; however, development of the Specific Plan area would not occur in areas supporting purple needlegrass grassland. Therefore impacts to purple needlegrass grassland would not occur.

Significance Finding: No impact for Alternative 2. The build-out of the Specific Plan, VCC, and Entrada planning areas would not result in the permanent land conversion of any purple needlegrass grassland. Therefore, there would be no impact to this community and no mitigation would be required.

Mitigation Strategy

None required.

Secondary Impacts

Secondary impacts are expected to occur both from the implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas. Secondary impacts to purple needlegrass grassland would consist of the same types of secondary impacts discussed above under effects to riparian communities and upland scrub and chaparral communities. These impacts include effects from fugitive dust, runoff, sedimentation, chemical pollution, erosion, litter, and accidental clearing. A proposed trail would be located within several hundred feet of the purple needlegrass, and trampling by pedestrians leaving the trail could also occur. Long-term development-related effects including landscape-level impacts and "edge" effects including the increased risk of non-native, invasive plant and animal species, litter, hydrological alterations, human disturbance, and modified fire frequency.

Significance Finding: Significant absent mitigation for Alternative 2. The secondary effects to purple needlegrass grassland would be the same as those described for Riparian Vegetation Communities and California Annual Grassland, Agriculture, and Disturbed Land. Purple needlegrass can be composed of up to 90.0% exotic species, but this

community is still considered rare and worthy of consideration by CDFG (2003) and provides habitat for several special-status species as described above. Therefore, any loss or damage to this vegetation community is considered significant absent mitigation.

Increases in human activity along the open space-urban interface would also be the same as described above for riparian communities. The proposed trail, located several hundred feet away from the purple needlegrass grassland, would increase the risk of trampling, which could also lead to soil compaction and changes in hydrology. This can affect the long-term viability of plant communities and degrade wildlife habitat quality. Trampling of vegetation and compaction of soils also interacts with the soil chemistry and can affect soil moisture, water penetration, surface flows, and erosion.

As described above, urbanization can affect the natural fire regime and lead to increased and higher-intensity wildfires. Although California native grasslands are adapted to fire, the increased frequency and intensity of altered fire regimes can lead to type conversion to a more exotic or disturbed vegetation community.

These short-term and long-term secondary impacts would constitute a substantial adverse effect on purple needlegrass grassland and would threaten to eliminate this land cover type in the planning area. Construction activities would also have the potential to substantially reduce the number or restrict the range of special-status species known to occur in the planning area (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2.

Mitigation Strategy for Secondary Impacts

The purple needlegrass grassland occurs in the High Country SMA, well away from the proposed residential and commercial development. This vegetation community occurs several hundred feet away from a proposed trail and the secondary impacts are primarily related to increased fire frequency and the risk of trampling.

In order to reduce short-term and long-term secondary impacts to purple needlegrass grassland resulting from implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas, the Project applicant would implement the same general mitigation measures as described for California Annual Grassland, Agriculture, and Disturbed Land (**Mitigation Strategy for Secondary Impacts**). This would include the existing mitigation measures approved for the Specific Plan EIR and additional measures that are designed to reduce or minimize the effects of the Project on these resources.

This vegetation community would be subject to the effects of invasive and noxious plants or altered fire ecology. The applicant would require the implementation of mitigation measures that include the education of homeowners regarding the sensitivity of natural lands, the use of landscape species that have a limited potential to spread or are considered non-invasive, routine weeding of restored habitat, and the use of buffer areas that physically separate residential landscaping from natural areas. Some of the specific measures include previously incorporated Mitigation Measures SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs); as well as Mitigation Measure BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation).

In addition, FMZs would be located adjacent to structures such as residential and commercial properties. Measures to control the use of motorized vehicles in the High Country and River Corridor SMA, authorize the use of designated trails only, and restrict smoking in natural areas would also be the same as for riparian communities. During construction, the applicant would develop and implement a fuel modification plan that specifically addresses the use of welding equipment and designated fire watches in vegetated areas, ensures vehicles are equipped with spark arrestors, and identifies approved smoking areas. Applicable mitigation measures to reduce the potential for increased fire frequency include the previously incorporated measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-31 (prohibition of hunting, fishing, or motor or trail bikes within the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs), and SP-4.6-49 through SP-4.6-52 (wildfire fuel modification plan and standards for FMZs).

Long-term effects of trampling and littering would be reduced through the preservation of mitigation lands, the education of homeowners regarding the sensitivity of natural lands, signage, and fencing. This includes Mitigation Measure BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas). While it is inevitable that some human disturbance will occur in natural lands; the applicant will provide designated trails within open areas and natural lands that are intended to provide recreational opportunities in a manner consistent with resource protection and recreational usage.

The implementation of these mitigation measures will reduce this impact to a level that is adverse but not significant for Alternative 2. A concise summary of the specific mitigation measures that reduce the secondary impacts of the proposed Project are

described below in **Table 4.5-33**, Applicable Mitigation Measures for Secondary Impacts to Purple Needlegrass.

Table 4.5-33
Applicable Mitigation Measures for Secondary Impacts to Purple Needlegrass

Mitigation Measure(s)	Issue Mitigating
SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA)	Fire frequency
SP-4.6-31 (prohibition of hunting, fishing, motor or trail bikes within the High Country SMA)	Fire frequency
SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA)	Fire frequency
SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs)	Invasive plants; fire frequency
SP-4.6-49 through SP-4.6-52 (wildfire fuel modification plan and standards for FMZs)	Fire frequency
BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas)	Trampling and littering
BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation)	Invasive plants

Summary of Impacts and Mitigation Strategy for Purple Needlegrass. Construction of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would not result in the permanent or temporary loss of purple needlegrass grassland.

Implementation of the mitigation measures described for secondary impacts above would reduce the effects of the proposed Project on purple needlegrass grassland. Secondary impacts from short-term construction include trampling; or long-term development-related impacts from urbanization or "edge" effects that generally occur along the open space urban interface would be reduced or mitigated through the implementation of the previously adopted measures from the Specific Plan EIR and the comprehensive mitigation measures described above.

Both the previously adopted measures from the Specific Plan EIR and the mitigation measures described for this project would be implemented to reduce the effects of the proposed Project on purple needlegrass grassland. Implementation of these measures would reduce secondary impacts to purple needlegrass grassland to a level that is adverse but not significant.

Impacts to California Walnut Woodland

Existing Conditions. California walnut woodland is found very locally in the southwestern corner of the Specific Plan, mostly within the Salt Creek area on south-facing slopes. California walnut woodland provides potential habitat for loggerhead shrike, sharp-shinned hawk, merlin, San Bernardino ringneck snake, coastal western whiptail, silvery legless lizard, and coast horned lizard.

California walnut woodland is considered a special-status community by CDFG (2007d). There are 27.2 acres of California walnut woodland in the Project area, located in the Salt Creek area in the south-central portion of the Specific Plan area. Individual southern California walnut trees are found throughout the RMDP and SCP area and have been observed in a variety of vegetation communities, sometimes as the dominant species of California walnut woodland, and sometimes as an occasional component of undifferentiated chaparral, coastal scrub alliances and associations, and alluvial scrub, oak woodland (coast live oak woodland, mixed oak woodland and forest, valley oak woodland), and southern cottonwood–willow riparian.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

A total of 27 acres of California walnut woodland occur on site and would not be impacted by development of RMDP facilities.

Significance Finding: No impact for Alternative 2. Development of the proposed RMDP and the SCP would not directly impact populations of California walnut woodland. Construction activities would avoid this vegetation community. Therefore, there would be no impact to California walnut woodland from the development of the RMDP and the SCP and no mitigation would be required.

Mitigation Strategy

None required.

Indirect Permanent Impacts

Indirect impacts to California walnut woodland on site would not occur from build-out of the Specific Plan, VCC, or Entrada planning areas.

Significance Finding: No impact for Alternative 2. The build-out of the Specific Plan, VCC, and Entrada planning areas would not result in the permanent land conversion of California walnut woodland. Therefore, there would be no impact to this community and no mitigation would be required.

Mitigation Strategy

None required.

Secondary Impacts

Secondary impacts are expected to occur both from the implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas. Secondary impacts to California walnut woodland would consist of the same types of secondary impacts discussed above under effects to riparian communities and upland scrub and chaparral communities. These impacts include effects from fugitive dust, runoff, sedimentation, chemical pollution, erosion, litter, and accidental clearing. A proposed trail would be located adjacent to the California walnut woodland, and trampling by pedestrians leaving the trail could also occur. Long-term development-related effects including landscape-level impacts and "edge" effects including the increased risk of non-native, invasive plant and animal species, litter, hydrological alterations, human disturbance, and modified fire frequency.

Significance Finding: Significant absent mitigation for Alternative 2. The secondary effects to California walnut woodland would be the same as those described for Riparian Vegetation Communities and California Annual Grassland, Agriculture, and Disturbed Land. This vegetation community is considered special-status by CDFG (2007d) and provides habitat for several special-status species as described above. Therefore, any loss or damage to this vegetation community is considered significant absent mitigation.

Increases in human activity along the open space-urban interface would also be the same as described above for riparian communities. The proposed trail near the occurrence of California walnut woodland would increase the risk of trampling, which could also lead to soil compaction and changes in hydrology. This can affect the long-term viability of plant communities and degrade wildlife habitat quality. Trampling of vegetation and compaction of soils also interacts with the soil chemistry and can affect soil moisture, water penetration, surface flows, and erosion.

As described above, urbanization can affect the natural fire regime and lead to increased and higher-intensity wildfires. Although California native woodlands are adapted to fire, the increased frequency and intensity of altered fire regimes can lead to type conversion to a more exotic or disturbed vegetation community.

These short-term and long-term secondary impacts would constitute a substantial adverse effect on California walnut woodland and would threaten to eliminate this land cover type in the planning area. Construction activities would also have the potential to substantially reduce the number or restrict the range of special-status species known to occur in the planning area (see **Subsection 4.5.5.3**, Impacts to Special-Status Species) (significance criteria 1, 2, and 7). This impact would be significant, absent mitigation, for Alternative 2.

Mitigation Strategy for Secondary Impacts

California walnut woodland occurs in the High Country SMA, well away from the proposed residential and commercial development. This vegetation community occurs adjacent to a proposed trail and the secondary impacts are primarily related to increased fire frequency and the risk of trampling.

In order to reduce short-term and long-term secondary impacts to California walnut woodland resulting from implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas, the Project applicant will implement the same general mitigation measures as described for Riparian Plant Communities and California Annual Grassland, Agriculture, and Disturbed Land. This would include the existing mitigation measures approved for the Specific Plan EIR and additional measures that are designed to reduce or minimize the effects of the Project on these resources. The primary difference in the application of mitigation measures is that specific measures related only to riparian plant communities would not apply in upland areas. Otherwise all other measures would be utilized.

In order to reduce short-term and long-term secondary impacts to California walnut woodland resulting from implementation of the RMDP and as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas, the Project applicant would implement the same general mitigation measures as described for California Annual Grassland, Agriculture, and Disturbed Land (**Mitigation Strategy for Secondary Impacts**). This would include the existing mitigation measures approved for the Specific Plan EIR and additional measures that are designed to reduce or minimize the effects of the Project on these resources.

This vegetation community would be subject to the effects of invasive and noxious plants or altered fire ecology. The applicant would require the implementation of mitigation measures that include the education of homeowners regarding the sensitivity of natural lands, the use of landscape species that have a limited potential to spread or are considered non-invasive, routine weeding of restored habitat, and the use of buffer areas that physically separate residential landscaping from natural areas. Some of the specific measures include previously incorporated Mitigation Measures SP-4.6-33 (protection of

transition areas along the High Country SMA, including planting palettes and FMZs); as well as Mitigation Measure BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation).

In addition, FMZs would be located adjacent to structures such as residential and commercial properties. Measures to control the use of motorized vehicles in the High Country and River Corridor SMA, authorize the use of designated trails only, and restrict smoking in natural areas would also be the same as for riparian communities. During construction, the applicant would develop and implement a fuel modification plan that specifically addresses the use of welding equipment and designated fire watches in vegetated areas, ensures vehicles are equipped with spark arrestors, and identifies approved smoking areas. Applicable mitigation measures to reduce the potential for increased fire frequency include the previously incorporated Mitigation Measures SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA), SP-4.6-31 (prohibition of hunting, fishing, or motor or trail bikes within the High Country SMA), SP-4.6-32 (trail design and construction to minimize impacts to native habitats within the High Country SMA), SP-4.6-33 (protection of transition areas along the High Country SMA, including planting palettes and FMZs), and SP-4.6-49 through SP-4.6-52 (wildfire fuel modification plan and standards for FMZs).

Short-term impacts resulting from accidental clearing, and grading, and long-term effects of trampling and litter would be the same as those described for riparian communities. These impacts would be minimized through the use of clearly identified construction areas, full-time biological monitoring, the preservation of mitigation lands, and the education of homeowners regarding the sensitivity of natural lands. This includes Mitigation Measure BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities).

Long-term effects of trampling and littering would be reduced through the preservation of mitigation lands, the education of homeowners regarding the sensitivity of natural lands, signage, and fencing. This includes Mitigation Measure BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural habitat areas). While it is inevitable that some human disturbance will occur in natural lands; the applicant will provide designated trails within open areas and natural lands that are intended to provide recreational opportunities in a manner consistent with resource protection and recreational usage.

The implementation of these mitigation measures will reduce this impact to a level that is adverse but not significant for Alternative 2. A concise summary of the specific mitigation measures that reduce the secondary impacts of the proposed Project are

described above in **Table 4.5-33**, Applicable Mitigation Measures for Secondary Impacts to Purple Needlegrass.

Summary of Impacts and Mitigation Strategy for California Walnut Woodland. Construction of RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas would not result in the permanent or temporary loss of California walnut woodland.

Implementation of the mitigation measures described for secondary impacts above would reduce the effects of the proposed Project on California walnut woodland. Secondary impacts from short-term construction include trampling; or long-term development-related impacts from urbanization or "edge" effects that generally occur along the open space urban interface would be reduced or mitigated through the implementation of the previously adopted measures from the Specific Plan EIR and the comprehensive mitigation measures described above.

Both the previously adopted measures from the Specific Plan EIR and the Mitigation Measures described for this project would be implemented to reduce the effects of the proposed Project on California walnut woodland. Implementation of these measures would reduce secondary impacts to California walnut woodland to a level that is adverse but not significant.

4.5.5.2.3.2.2 Impacts to Vegetation Communities and Land Covers—Alternatives 3 through 7

Alternative 3 consists of a larger Entrada Preserve Area than that included in the Proposed Project. This alternative would provide a total of 222 acres of spineflower preserves and would protect 77.2% of the cumulative habitat occupied by spineflower on site. The Potrero Canyon Road Bridge would not be constructed under this alternative. Although major tributaries would be re-graded and realigned under this alternative, the channels would be wider than those of the proposed Project, and the cismontane alkali marsh in lower Potrero Canyon would be avoided.

Alternative 4 consists of larger spineflower preserves and the inclusion of a preserve within the VCC planning area. This alternative would provide a total of 260 acres of spineflower preserves and would protect 82.2% of the cumulative habitat occupied by spineflower on site. The Potrero Canyon Road Bridge would not be constructed under this alternative. Although major tributaries would be re-graded and realigned under this alternative, the cismontane alkali marsh in lower Potrero Canyon would be avoided.

Alternative 5 consists of larger spineflower preserves and the inclusion of a preserve within the VCC planning area. This alternative would provide a total of 339 acres of

spineflower preserves and would protect 84.0% of the cumulative habitat occupied by spineflower on site. Major tributaries would be re-graded and realigned under this alternative, and three bridges would be constructed. No development would be facilitated within the VCC planning area.

Alternative 6 consists of one large spineflower preserve that encompasses all six populations. This alternative would provide a total of 891 acres of spineflower preserves and would protect 88.3% of the cumulative habitat occupied by spineflower on site. Two major roadway bridges would be constructed under this alternative. Major tributaries would be re-graded and realigned under this alternative, and all realigned channels would be many times wider than the proposed Project. The majority of road crossings along the channels would be bridges as opposed to culverts. No development would be facilitated within the VCC planning area.

Alternative 7 was designed to achieve maximal avoidance of cumulative habitat occupied by spineflower. This alternative would provide a total of 661 acres of spineflower preserves and would protect 98.2% of the cumulative habitat occupied by spineflower on site. One roadway bridge would be constructed under this alternative. Major tributaries would not be re-graded or realigned under this alternative. Bank stabilization would be constructed to protect development but would be located outside of the 100-year floodplains of these drainages. In addition, the Middle Canyon and Magic Mountain Canyon drainages would be preserved and would not be converted to buried storm drains as under the proposed Project. No development would be facilitated within the VCC planning area.

Impacts to Riparian Vegetation Communities. The source of impacts (*i.e.*, clearing and grading) to riparian communities under Alternatives 3 through 7 would be the same as the proposed Project, but would vary in magnitude based on the acreages affected. Impacts would primarily result from permanent land use conversion from current uses to urban development.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to riparian vegetation communities (**Table 4.5-27** and **Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 90 acres (7.7%) of permanent loss and 110 acres of temporary loss;
- Alternative 4 – 91 acres (7.7%) of permanent loss and 100 acres of temporary loss;
- Alternative 5 – 97 acres (8.1%) of permanent loss and 117 acres of temporary loss;
- Alternative 6 – 74 acres (6.2%) of permanent loss and 107 acres of temporary loss; and
- Alternative 7 – 18 acres (1.5%) of permanent loss and 100 acres of temporary loss.

Compared to Alternative 2, which would result in 116 acres (9.8%) of permanent loss and 103 acres of temporary loss, Alternatives 3 through 7 would have reduced impacts. The difference between the impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under the successive alternatives, which would result in fewer permanent impacts. The temporary loss of riparian vegetation communities would not be substantially different for Alternatives 3 through 7 compared to Alternative 2.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is not substantially different than overall habitat loss under Alternative 2, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for direct permanent and temporary impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only) and Entrada planning areas would result in the following indirect impacts to riparian vegetation communities (**Table 4.5-27** and **Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 85 acres (7.2%) of permanent loss;
- Alternative 4 – 67 acres (5.7%) of permanent loss;
- Alternative 5 – 64 acres (5.4%) of permanent loss;

- Alternative 6 – 36 acres (3.0%) of permanent loss; and
- Alternative 7 – 22 acres (1.8%) of permanent loss.

Compared to Alternative 2, which would result in 109 acres (9.2%) of permanent loss of riparian vegetation communities, Alternatives 3 through 7 would have reduced impacts. Each successive alternative would have fewer impacts because there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that reduce impacts to riparian vegetation communities.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the loss of riparian vegetation communities. The indirect permanent loss of riparian vegetation communities as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for indirect permanent impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to riparian vegetation communities (**Table 4.5-27**):

- Alternative 3 – 175 acres (14.7%) of permanent loss;
- Alternative 4 – 159 acres (13.3%) of permanent loss;
- Alternative 5 – 161 acres (13.5%) of permanent loss;
- Alternative 6 – 110 acres (9.2%) of permanent loss; and
- Alternative 7 – 39 acres (3.3%) of permanent loss.

Compared to Alternative 2, which would result in 225 acres (18.9%) of combined direct and indirect permanent loss of riparian vegetation communities, Alternatives 3 through 7 would have reduced impacts, as described above for the discussions of direct and indirect impacts. Reduced impacts would occur because of additional pullbacks from the Santa Clara River (and its tributaries), and other

Project footprint reductions would occur under the successive alternatives compared to Alternative 2. The combined direct and indirect permanent loss of suitable habitat for riparian vegetation communities occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for direct and indirect permanent impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be the same as those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The loss of or degradation of riparian vegetation communities due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for secondary impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Impacts to California Annual Grassland, Agriculture, Disturbed Land, and Developed Land. Impacts to California annual grassland, agriculture, disturbed land, and developed land, would consist of the same types of impacts as the proposed Project, and the magnitude of those impacts are largely similar to those of the proposed Project. Impacts to developed land were not significant for the proposed Project and so are not carried forward in the analysis of Alternatives 3 through 7 below.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to California annual grassland, agriculture, and disturbed land (**Table 4.5-27** and **Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 197 acres (3.8%) of permanent loss and 132 acres of temporary loss;
- Alternative 4 – 179 acres (3.5%) of permanent loss and 142 acres of temporary loss;
- Alternative 5 – 234 acres (4.6%) of permanent loss and 118 acres of temporary loss;
- Alternative 6 – 238 acres (4.6%) of permanent loss and 132 acres of temporary loss; and
- Alternative 7 – 112 acres (2.2%) of permanent loss and 438 acres of temporary loss.

Compared to Alternative 2, which would result in 212 acres (4.1%) of permanent loss and 94 acres of temporary disturbance, Alternatives 3 through 6 would not have substantially different impacts. The difference between the impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under the successive alternatives. The difference between Alternative 7 and Alternative 2 impacts is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts under that alternative.

Implementation of the proposed SCP would result in native vegetation restoration of California annual grassland, agriculture, and disturbed land within the proposed spineflower preserves.

- Alternative 3 – 105 acres of native vegetation restoration;
- Alternative 4 – 120 acres of native vegetation restoration;
- Alternative 5 – 140 acres of native vegetation restoration;

- Alternative 6 – 302 acres of native vegetation restoration; and
- Alternative 7 – 271 acres of native vegetation restoration.

Compared to Alternative 2, which would result in the restoration of 81 acres of California annual grassland, agriculture, and disturbed land, Alternatives 3 through 6 would result in greater acres of restoration. The difference among the alternatives is that each successive alternative includes successively larger spineflower preserves.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is not substantially different than overall habitat loss under Alternative 2, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for direct permanent and temporary impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect impacts to California annual grassland, agriculture, and disturbed land (**Table 4.5-27** and **Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 2,955 acres (57.8%) of permanent loss;
- Alternative 4 – 2,821 acres (55.1%) of permanent loss;
- Alternative 5 – 2,767 acres (54.1%) of permanent loss;
- Alternative 6 – 2,548 acres (49.8%) of permanent loss; and
- Alternative 7 – 2,087 acres (40.8%) of permanent loss.

Compared to Alternative 2, which would result in 3,079 acres (60.2%) of permanent loss of California annual grassland, agriculture, and disturbed land, Alternatives 3 through 7 would have reduced impacts. Each successive alternative would have fewer impacts because there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that reduce impacts to California annual grassland, agriculture, disturbed land and developed land.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the loss of California annual grassland, agriculture, and disturbed land. The indirect permanent loss of California annual grassland, agriculture, and disturbed land as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for indirect permanent impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to California annual grassland, agriculture, and disturbed land (**Table 4.5-27**):

- Alternative 3 – 3,152 acres (61.6%) of permanent loss;
- Alternative 4 – 3,000 acres (58.6%) of permanent loss;
- Alternative 5 – 3,001 acres (58.6%) of permanent loss;
- Alternative 6 – 2,785 acres (54.4%) of permanent loss; and
- Alternative 7 – 2,200 acres (43.0%) of permanent loss.

Compared to Alternative 2, which would result in 3,291 acres (64.3%) of combined direct and indirect permanent loss of California annual grassland, agriculture, and disturbed land, Alternatives 3 through 7 would have reduced impacts, as described above for the discussions of direct and indirect impacts. Reduced impacts would occur because of additional pullbacks from the Santa Clara River (and its tributaries), and other Project footprint reductions would occur under the successive alternatives compared to Alternative 2. The combined direct and indirect permanent loss of suitable habitat for California annual grassland, agriculture, and disturbed land occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for direct and indirect permanent impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 and would be the same as those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The loss of or degradation of California annual grassland, agriculture, and disturbed land due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for secondary impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Impacts to Scrub Communities. The source of impacts (*i.e.*, clearing and grading) to scrub communities under Alternatives 3 through 7 would be the same as the proposed Project, but would vary in magnitude based on the acreages affected. Impacts would primarily result from permanent land use conversion from current uses to urban development.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to coastal scrub vegetation communities (**Table 4.5-27** and **Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 29 acres (0.6%) of permanent loss and 4.5 acres of temporary loss;

- Alternative 4 – 29 acres (0.6%) of permanent loss and 2.0 acres of temporary loss;
- Alternative 5 – 33 acres (0.7%) of permanent loss and 6.0 acres of temporary loss;
- Alternative 6 – 29 acres (0.7%) of permanent loss and 7.6 acres of temporary loss; and
- Alternative 7 – 19 acres (0.4%) of permanent loss and 13 acres of temporary loss.

Compared to Alternative 2, which would result in 31 acres (0.7%) of permanent loss and 2.3 acres of temporary disturbance, permanent and temporary impacts associated with Alternatives 3 through 6 would be substantially the same. The difference between Alternatives 2 and 7 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries under the Alternative 7, which would result in fewer permanent impacts and greater temporary impacts to coastal scrub vegetation communities.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is not substantially different than overall loss of coastal scrub vegetation communities under Alternative 2, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for direct permanent and temporary impacts to coastal scrub vegetation communities would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only) and Entrada planning areas would result in the following indirect impacts to coastal scrub vegetation communities (**Table 4.5-27** and **Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 1,415 acres (32.6%) of permanent loss;
- Alternative 4 – 1,374 acres (31.7%) of permanent loss;
- Alternative 5 – 1,322 acres (30.3%) of permanent loss;
- Alternative 6 – 1,094 acres (25.2%) of permanent loss; and
- Alternative 7 – 1,013 acres (23.4%) of permanent loss.

Compared to Alternative 2, which would result in 1,493 acres (34.4%) of permanent loss of coastal scrub vegetation communities, Alternatives 3 through 7 would have reduced impacts. Each successive alternative would have fewer impacts because there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that reduce impacts to coastal scrub vegetation communities.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the loss of coastal scrub vegetation communities. The indirect permanent loss of coastal scrub vegetation communities as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for indirect permanent impacts to coastal scrub vegetation communities would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to coastal scrub vegetation communities (**Table 4.5-27**):

- Alternative 3 – 1,443 acres (33.3%) of permanent loss;
- Alternative 4 – 1,403 acres (32.4%) of permanent loss;
- Alternative 5 – 1,355 acres (31.3%) of permanent loss;
- Alternative 6 – 1,123 acres (25.9%) of permanent loss; and
- Alternative 7 – 1,032 acres (23.8%) of permanent loss.

Compared to Alternative 2, which would result in 1,524 acres (35.1%) of combined direct and indirect permanent loss of coastal scrub vegetation communities, Alternatives 3 through 7 would have reduced impacts, as described above for the discussions of direct and indirect impacts. Reduced impacts would occur because of additional pullbacks from the Santa Clara River (and its tributaries), and other Project footprint reductions would occur under the successive alternatives compared to Alternative 2. The combined direct and indirect permanent loss of suitable habitat for coastal scrub vegetation communities occurring as a result of

implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for direct and indirect permanent impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be the same as those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The loss of or degradation of coastal scrub vegetation communities due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for secondary impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Impacts to Chaparral Communities. The source of impacts (*i.e.*, clearing and grading) to chaparral communities under Alternatives 3 through 7 would be the same as the proposed Project, but would vary in magnitude based on the acreages affected. Impacts would primarily result from permanent land use conversion from current uses to urban development.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to chaparral vegetation communities (**Table 4.5-27** and **Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 25 acres (1.2%) of permanent loss and 1.8 acres of temporary loss;
- Alternative 4 – 27 acres (1.3%) of permanent loss and 1.5 acres of temporary loss;
- Alternative 5 – 27 acres (1.3%) of permanent loss and 1.8 acres of temporary loss;
- Alternative 6 – 24 acres (1.1%) of permanent loss and 1.8 acres of temporary loss; and
- Alternative 7 – 21 acres (1.0%) of permanent loss and 9.1 acres of temporary loss.

Compared to Alternative 2, which would result in 26 acres (1.2%) of permanent loss and 1.5 acres of temporary disturbance, permanent and temporary impacts associated with Alternatives 3 through 7 would be substantially the same, with minor differences associated with variations on the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternatives 3 through 7; the exception being temporary impacts under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts to chaparral vegetation communities.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is not substantially different than overall loss of chaparral vegetation communities under Alternative 2, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for direct permanent and temporary impacts to chaparral vegetation communities would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Indirect Permanent Impacts

Build-out of the Specific Plan and Entrada planning areas would result in the following indirect impacts to chaparral vegetation communities (**Table 4.5-27** and **Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 417 acres (19.4%) of permanent loss;
- Alternative 4 – 408 acres (19.0%) of permanent loss;
- Alternative 5 – 409 acres (19.1%) of permanent loss;

- Alternative 6 – 407 acres (18.9%) of permanent loss; and
- Alternative 7 – 327 acres (15.2%) of permanent loss.

Compared to Alternative 2, which would result in 431 acres (20.1%) of permanent loss of chaparral vegetation communities, Alternatives 3 through 7 would have reduced impacts. Each successive alternative would have fewer impacts because there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that reduce impacts to chaparral vegetation communities.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the loss of chaparral vegetation communities. The indirect permanent loss of chaparral vegetation communities as a result of build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for indirect permanent impacts to chaparral vegetation communities would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas would result in the following impacts to chaparral vegetation communities (**Table 4.5-27**):

- Alternative 3 – 443 acres (20.6%) of permanent loss;
- Alternative 4 – 435 acres (20.3%) of permanent loss;
- Alternative 5 – 436 acres (20.3%) of permanent loss;
- Alternative 6 – 431 acres (20.1%) of permanent loss; and
- Alternative 7 – 348 acres (16.2%) of permanent loss.

Compared to Alternative 2, which would result in 457 acres (21.3%) of combined direct and indirect permanent loss of chaparral vegetation communities, Alternatives 3 through 7 would have reduced impacts, as described above for the discussions of direct and indirect impacts. Reduced impacts would occur because of additional pullbacks from the Santa Clara River (and its tributaries), and other

Project footprint reductions would occur under the successive alternatives compared to Alternative 2. The combined direct and indirect permanent loss of suitable habitat for chaparral vegetation communities occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for direct and indirect permanent impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 and would be the same as those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The loss of or degradation of chaparral vegetation communities due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for secondary impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Impacts to Oak Woodland Communities (Coast Live Oak Woodland, Mixed Oak Woodland, Valley Oak/Grass, Valley Oak Woodland). The source of impacts (*i.e.*, clearing and grading) to oak woodland communities under Alternatives 3 through 7 would be the same as the proposed Project, but would vary in magnitude based on the acreages affected. Impacts would primarily result from permanent land use conversion from current uses to urban development.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct impacts to oak woodland vegetation communities (**Table 4.5-27** and **Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 9.5 acres (0.6%) of permanent loss and 1.4 acres of temporary loss;
- Alternative 4 – 8.9 acres (0.6%) of permanent loss and 1.4 acres of temporary loss;
- Alternative 5 – 13 acres (0.9%) of permanent loss and 1.4 acres of temporary loss;
- Alternative 6 – 18 acres (1.2%) of permanent loss and 1.4 acres of temporary loss; and
- Alternative 7 – 5.6 acres (0.4%) of permanent loss and 13 acres of temporary loss.

Compared to Alternative 2, which would result in 9.3 acres (0.6%) of permanent loss and 1.4 acres of temporary disturbance, permanent and temporary impacts associated with Alternatives 3 through 7 would be substantially the same, with minor differences associated with variations on the pullback of RMDP facilities from the Santa Clara River and its tributaries under Alternatives 3 through 7; the exception being temporary impacts under Alternative 7, which would result in fewer permanent impacts and greater temporary impacts to oak woodland vegetation communities.

Because the overall loss of habitat from implementation of the RMDP and the SCP under Alternatives 3 through 7 is not substantially different than overall loss of oak woodland vegetation communities under Alternative 2, impacts for Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for direct permanent and temporary impacts to oak woodland vegetation communities would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Indirect Permanent Impacts

Build-out of the Specific Plan and Entrada planning areas would result in the following indirect impacts to oak woodland vegetation communities (**Table 4.5-27** and **Figures 4.5-34-A1** through **4.5-38-D2**):

- Alternative 3 – 66 acres (4.5%) of permanent loss;
- Alternative 4 – 65 acres (4.4%) of permanent loss;
- Alternative 5 – 66 acres (4.5%) of permanent loss;
- Alternative 6 – 41 acres (2.8%) of permanent loss; and
- Alternative 7 – 44 acres (3.0%) of permanent loss.

Compared to Alternative 2, which would result in 85 acres (5.8%) of permanent loss of oak woodland vegetation communities, Alternatives 3 through 7 would have reduced impacts. Each successive alternative would have fewer impacts because there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint that reduce impacts to oak woodland vegetation communities.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, these impacts would still be substantially adverse because of the loss of oak woodland vegetation communities. The indirect permanent loss of oak woodland vegetation communities as a result of build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for indirect permanent impacts to oak woodland vegetation communities would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas would result in the following impacts to oak woodland vegetation communities (**Table 4.5-27**):

- Alternative 3 – 76 acres (5.2%) of permanent loss;
- Alternative 4 – 74 acres (5.0%) of permanent loss;

- Alternative 5 – 79 acres (5.4%) of permanent loss;
- Alternative 6 – 59 acres (4.0%) of permanent loss; and
- Alternative 7 – 50 acres (3.4%) of permanent loss.

Compared to Alternative 2, which would result in 95 acres (6.5%) of combined direct and indirect permanent loss of oak woodland vegetation communities, Alternatives 3 through 7 would have reduced impacts, as described above for the discussions of direct and indirect impacts. Reduced impacts would occur because of additional pullbacks from the Santa Clara River (and its tributaries), and other Project footprint reductions would occur under the successive alternatives compared to Alternative 2. The combined direct and indirect permanent loss of suitable habitat for oak woodland vegetation communities occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for direct and indirect permanent impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 and would be the same as those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The loss of or degradation of oak woodland vegetation communities due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for secondary impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Impacts to Purple Needlegrass. Impacts to purple needlegrass grasslands would be the same for Alternatives 3 through 7 compared to the proposed Project.

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

Purple needlegrass grasslands would not be impacted by implementation of Alternatives 3 through 7 nor the proposed Project.

Indirect Permanent Impacts

Purple needlegrass grasslands would not be impacted by implementation of Alternatives 3 through 7 nor the proposed Project.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 and would be the same as those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The loss of or degradation of purple needlegrass grassland due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for secondary impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

Impacts to California Walnut Woodland. Impacts to California walnut woodland would be the same for Alternatives 3 through 7 compared to the proposed Project

Impacts

Removal of Vegetation

Direct Permanent and Temporary Impacts

California walnut woodland would not be impacted by Alternatives 3 through 7 nor the proposed Project.

Indirect Permanent Impacts

California walnut woodland would not be impacted by Alternatives 3 through 7 nor the proposed Project.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 and would be the same as those presented above for Alternative 2 because each alternative has essentially the same short-term construction activities and long-term effects due to factors such as runoff, sedimentation, erosion, and chemical and toxic compound pollution; exposure to fugitive dust; the introduction of non-native, invasive plant species; hydrologic alterations and water quality impacts; and increased human activity, trampling, and soil compaction. The loss of or degradation of California walnut woodland due to secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

The same mitigation measures required for the proposed Project for secondary impacts would be required under Alternatives 3 through 7. These measures are listed above under the proposed Project (Alternative 2) impact analysis.

INTENTIONALLY LEFT BLANK

4.5.5.2.3.3 *RMDP and SCP Components within Unique Landscape Features*

The RMDP and SCP study areas include three unique landscape features: River Corridor SMA (SEA 23), High Country SMA (SEA 20) and Salt Creek area, and Middle Canyon Spring (**Figure 4.5-39**). These unique landscape features were identified during the development of the Specific Plan as preserve areas and are elements of the larger proposed Project preserve system. Implementation of the RMDP and the SCP would result in the installation of RMDP facilities (and related facilities) and management and monitoring of spineflower preserves. Vegetation community–specific impacts and mitigation are discussed above in **Subsection 4.5.5.2.3.2**. Species-specific impacts and mitigation are discussed below in **Subsection 4.5.5.2.3.4** and **Subsection 4.5.5.3**.

RMDP components and related facilities within the River Corridor SMA would occupy between 31 acres and 86 acres, depending on the alternative (see **Table 4.5-34**). The remainder of the River Corridor SMA would be offered for dedication to the public and managed by an NLMO.

Table 4.5-34
RMDP Components and Related Facilities within the River Corridor SMA by Alternative

	Alternative 2	Alternative 3	Alternative 4	Alternative 5	Alternative 6	Alternative 7
Direct Permanent	62 acres	44 acres	44 acres	48 acres	39 acres	17 acres
Indirect Permanent	24 acres	23 acres	23 acres	24 acres	16 acres	14 acres
Total	**86 acres**	**67 acres**	**67 acres**	**72 acres**	**55 acres**	**31 acres**

The Middle Canyon Spring occurs within the River Corridor SMA and supports the undescribed snail and undescribed sunflower species. RMDP components and related facilities would not occur within the Middle Canyon Spring for Alternatives 2 through 7. The Middle Canyon Spring Survey and Status Report (Dudek 2007C) will be implemented to monitor and manage biological resources within and adjacent to the Middle Canyon Spring complex.

RMDP components and related facilities within the High Country SMA and Salt Creek area would occupy 27 acres for Alternatives 2 through 7. The remainder of the High Country SMA and Salt Creek area would be offered for dedication to the public and managed by an NLMO.

INTENTIONALLY LEFT BLANK

4.5.5.2.3.4 *Impacts to Common Wildlife*

This subsection provides an analysis of direct, indirect, and secondary impacts only to common wildlife species that would occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7. The effects to special-status wildlife are addressed in **Subsection 4.5.5.3**. The species addressed in this subsection are not federally or state-listed as threatened or endangered, or otherwise designated sensitive, special-status, or rare species by federal, state, or local agencies, or environmental organizations. The only regulatory protection provided to these common wildlife species is for native birds under the Migratory Bird Treaty Act (MBTA) and Fish and Game Code sections 3503 and 3503.4 (birds of prey), which provides protection for nests, eggs, and nestlings during the breeding season, for species for which hunting or depredation permits are required.

The impacts discussion is organized by wildlife guilds that group common wildlife species on the basis of similar ecological resource requirements and similar roles in the ecological community. As described in **Subsection 4.5.5.1**, Project impacts generally will be similar for species within the same guild. Fourteen wildlife guilds were identified in the Project area:

- Insect
- Mollusk
- Reptile – Low Mobility
- Reptile and Amphibian – Semi-Aquatic
- Fish
- Bird – Raptor
- Bird – Riparian
- Bird – Upland Grassland
- Bird – Upland Scrub and Chaparral
- Bird – Upland Woodland
- Bat
- Mammal – Low Mobility
- Mammal – Moderate Mobility
- Mammal – High Mobility.

Although this subsection focuses on common wildlife in the Project area, there are many special-status wildlife species that are members of these guilds, as listed in **Table 4.5-35**.

The direct, indirect, and secondary impacts for these species are analyzed in species-specific detail in **Subsection 4.5.5.3**.

Table 4.5-35
Special-Status Species Occurring or with Potential to Occur on the Project Site, Organized by Guild

Species Guild	Common Name
Insect (Butterflies)	monarch butterfly (wintering sites)
	San Emigdio blue butterfly
Mollusk	undescribed species of snail
Reptile – Low Mobility	coast horned lizard
	coast patch-nosed snake
	coastal western whiptail
	rosy boa
	San Bernardino ringneck snake
	silvery legless lizard
Reptile and Amphibian – Semi-Aquatic	arroyo toad
	California red-legged frog
	south Coast garter snake
	southwestern pond turtle
	two-striped garter snake
	western spadefoot toad
Fish	arroyo chub
	Santa Ana sucker
	southern steelhead
	unarmored threespine stickleback
Bird – Raptor	American peregrine falcon
	California condor
	Cooper's hawk (nesting)
	ferruginous hawk
	golden eagle (nesting and wintering)
	loggerhead shrike
	long-eared owl (nesting)
	merlin (wintering)
	northern harrier (nesting)
	prairie falcon (nesting)
	sharp-shinned hawk (nesting)
	short-eared owl (nesting)
	turkey vulture
	western burrowing owl (burrow sites)
	white-tailed kite (nesting)
Bird – Riparian	black-crowned night-heron (rookery)
	least Bell's vireo (nesting)
	Nuttall's woodpecker (nesting)

Table 4.5-35
Special-Status Species Occurring or with Potential to Occur on the Project Site, Organized by Guild

Species Guild	Common Name
	willow flycatcher/southwestern willow flycatcher (nesting)
	summer tanager (nesting)
	tricolored blackbird (nesting colony)
	vermilion flycatcher (nesting)
	western yellow-billed cuckoo (nesting)
	yellow-breasted chat (nesting)
	yellow-headed blackbird
	yellow warbler (nesting)
Bird – Upland Grassland	California horned lark
	grasshopper sparrow
Bird – Upland Scrub and Chaparral	Allen's hummingbird (nesting)
	Bell's sage sparrow (nesting)
	black-chinned sparrow (nesting)
	coastal California gnatcatcher
	Costa's hummingbird (nesting)
	rufous hummingbird (nesting)
	southern California rufous-crowned sparrow
Bird – Upland Woodland	chipping sparrow (nesting)
	hermit warbler (nesting)
	Lawrence's goldfinch
	oak titmouse (nesting)
Bat	fringed myotis
	long-legged myotis
	pallid bat
	pocketed free-tailed bat
	Townsend's big-eared bat
	western mastiff bat
	western red bat
	western small-footed myotis
	Yuma myotis
Mammal – Low Mobility	San Diego desert woodrat
	southern grasshopper mouse
Mammal – Moderate Mobility	American badger
	ringtail
	San Diego black-tailed jackrabbit
Mammal – High Mobility	black bear
	mountain lion
	mule deer

The focus of the impact analysis is for common, non-special-status species in each guild. The guild-based impact analyses and significance findings for the guilds and wildlife overall are necessarily generalized and are not intended to address specific or unique impacts to a particular species. This analysis also does not consider the community-wide or community relationship effects of these impacts, such as the effect of the loss of common rodents as prey for special-status species. These types of effects are, however, analyzed in **Subsection 4.5.5.3** in the context of impacts to special-status species. For example, the loss of common rodents due to the effects of rodenticides is considered in the analysis of the Project's effects on special-status raptors or snakes that rely on rodents as prey. Each of the special-status wildlife species is analyzed separately and in much greater detail than provided here for common species at the guild level, including impact significance findings and mitigation for each species on an individual basis.

Significance findings are made for direct, indirect, and secondary (short-term construction-related and long-term development-related) impacts to the common species in each wildlife guild. Where applicable, mitigation measures that would reduce significant impacts to a level less than significant are identified. In addition, although not required by CEQA, where impacts are considered to be adverse but not significant, mitigation measures for other impacts to biological resources that would further reduce these less-than-significant impacts are identified.

It is important to note that the impact acreages reported in this subsection may be different from those reported in **Subsection 4.5.5.3** because habitat types are generalized to be broadly applicable to the guild, while habitat associations are tailored to the individual species in the detailed analyses in **Subsection 4.5.5.3**. Because the habitat types for the guild are more inclusive than in the detailed species analyses, the impacts reported here in many cases overestimate the impact to a particular special-status species in a guild. For example, the southern California rufous-crowned sparrow is part of the Bird – Upland Scrub and Chaparral guild, but at the species-specific level it is considered to only use California sagebrush scrub habitats. Further, the significance findings for impacts to common wildlife may be different from the significance finding for a particular special-status species.

The impact significance criteria described in **Subsection 4.5.4** are applied to the different wildlife guilds discussed below. The three key significance criteria for common wildlife impacts are:

(1) Have a substantial adverse effect, either directly or *via* habitat modifications, on any "special-status species" as such species are defined in **Subsection 4.5.3.1** of this EIS/EIR; or violate any federal, state, or local law which protects biological resources;

(4) Interfere substantially with the movement of any native resident or migratory fish or wildlife species, or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites; and

(7) Have the potential to substantially reduce the habitat of a fish or wildlife species; cause a fish or wildlife population to drop below self-sustaining levels; threaten to eliminate a plant or animal community; or substantially reduce the number or restrict the range of an endangered, rare, or threatened species**.**

Insect Guild. Common insects observed on site include more than 35 species of butterflies (Lepidoptera) representing six families: Papilionidae (swallowtails), Nymphalidae (brush footed butterflies), Riodinidae (metalmarks), Lycaenidae (blue, hairstreaks, coppers), Pieridae (white and sulfurs), and Hesperiidae (skippers). Common butterflies species observed on site included checkered white, buckeye, west coast lady, western tiger swallowtail, chalcedon checkerspot, western checkered skipper, common hairstreak, pigmy blue, among others (also see **Subsection 4.5.3.4.3**, General Wildlife, and Compliance Biology, Inc. 2004A, 2004B, 2004C, 2005). These species occur in suitable habitat throughout the site, although many are associated with specific vegetation communities, while others are habitat generalists that may occur in virtually all natural habitats. For example, pigmy blue and acmon blue are abundant throughout Project area in all habitats, including disturbed areas, while Behr's metalmark is abundant, but closely associated with California buckwheat (Compliance Biology 2004C). Only two special-status species are included in the Insect guild: the San Emigdio blue butterfly and the monarch butterfly. These two special-status species are addressed in **Subsection 4.5.5.3**. A variety of other insect taxa also occur on site, including Archeognatha (bristletails), Coleoptera (beetles and weevils), Dermaptera (earwigs), Diptera (true flies, gnats, midges, and mosquitoes), Ephemeroptera (mayflies), Hemiptera (true bugs), Homoptera (cicadas, leafhoppers, aphids, and scale insects), Hymenoptera (ants, bees, and wasps), Mantodea (mantises), Odonata (dragonflies and damselflies), Orthoptera (grasshoppers, locusts, katydids, and crickets), Phasmatodea (stick insects), Psocoptera (lice), Tricoptera (caddisflies) (Jones *et al.* 2004; ABCL 2008).

All vegetation communities and land covers (except developed land) in the Project area are considered suitable habitat for the Insect guild in general because of the broad diversity of habitat relationships in this guild. A total of 14,288 acres of suitable habitat for common species in the Insect guild is present in the Project area.

Direct Impacts

Implementation of the RMDP and the SCP would result in both impacts to insect individuals and permanent and temporary loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 394 acres (2.8%) of permanent loss and 201 acres of temporary impact;
- Alternative 3 – 351 acres (2.5%) of permanent loss and 250 acres of temporary impact;
- Alternative 4 – 335 acres (2.3%) of permanent loss and 247 acres of temporary impact;
- Alternative 5 – 404 acres (2.8%) of permanent loss and 244 acres of temporary impact;
- Alternative 6 – 383 acres (2.7%) of permanent loss and 249 acres of temporary impact; and
- Alternative 7 – 172 acres (1.2%) of permanent loss and 572 acres of temporary impact.

The overall loss of potential habitat for common insects in the Project area in general would be relatively small under Alternatives 2 through 7 in relation to the total acreage of vegetation communities and land covers on site. Due to wider channel construction (see **Subsection 4.5.5.2**), Alternative 5 would have the greatest direct permanent impacts to vegetation communities and land covers and Alternative 7 would have the smallest permanent direct impact.

Because of the relatively small amount of habitat loss for the Insect guild species, direct impacts resulting from implementation of the RMDP and the SCP would be adverse but not significant under Alternatives 2 through 7.

Indirect Impacts

The build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would result in both impacts to common insect individuals and loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 5,200 acres (36.4%) of permanent loss;
- Alternative 3 – 4,941 acres (34.6%) of permanent loss;
- Alternative 4 – 4,736 acres (33.1%) of permanent loss;
- Alternative 5 – 4,629 acres (32.4%) of permanent loss;
- Alternative 6 – 4,311 acres (30.2%) of permanent loss; and
- Alternative 7 – 3,728 acres (26.1%) of permanent loss.

There would be progressively smaller impacts with each successive alternative, but there would be substantial impacts to individual insects and loss of their habitat in large portions of the Project area under each alternative. However, the insects observed in the Project area are very common and widespread and therefore will persist in the undeveloped portions of the Project area, such as the River Corridor SMA, High Country SMA, Salt Creek area, and Open Area.

Indirect impacts to Insect guild species from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Secondary Impacts

Potential short-term construction-related secondary impacts to the Insect guild resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas include inadvertent clearing or trampling of vegetation, including potential host plants, fugitive dust, contact with polluted runoff, and changes in hydrology. The level of these impacts would be similar for Alternatives 2 through 7. Because these impacts would be limited to the period of construction, short-term construction-related impacts would be adverse but not significant under Alternatives 2 through 7.

Potential long-term development-related secondary impacts to the Insect guild include habitat fragmentation and isolation that would occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7. Regional landscape connectivity will be maintained through preservation of the High Country SMA, Salt Creek area, and River Corridor SMA under Alternatives 2 through 7. However, internal habitat connectivity allowing for insect movement and dispersal among open space patches within the developed portions of the Project area will be constrained, although it would differ among the alternatives. As described above for vegetation communities, the potential for insect movement and dispersal along natural drainages will vary depending on whether drainage crossings are bridges or culverts, with bridges providing better conduits for movement beneath them because they are more open and provide a more natural environment. Alternative 2 has relatively more culverts than bridges in the tributary drainages, with progressively fewer culverts and more bridges in successive alternatives.

Members of the Insect guild are also vulnerable to a variety of secondary impacts, such as invasive animal species (*e.g.*, Argentine ant), pesticides and other chemical pollutants, and several types of impacts that can degrade habitat over the long term, including fuel modification practices, invasive plants, soil erosion or compaction, and increased fire

frequency. These potential secondary impacts would be similar for Alternatives 2 through 7.

Although short-term construction-related and long-term development-related secondary impacts to Insect guild species are expected to occur, these species are common and widespread and are expected to persist in the undeveloped portions of the Project area such as the River Corridor SMA, High Country SMA, Salt Creek area, and Open Area.

Secondary impacts to Insect guild species from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Mitigation Strategy and Summary

All direct, indirect, and secondary impacts to Insect guild species were determined to be adverse but not significant and, therefore, no mitigation is required. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to Insect guild species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA, High Country SMA, and Salt Creek area—areas that will form a large, contiguous open space system composed of upland, riparian, and aquatic habitats that support a high diversity of common insect species. It is expected that common insect species will persist in these areas after build-out of the Project area. These mitigation measures also will reduce short-term secondary effects, such as dust during construction; and long-term effects, such as pesticides, pollutants, and non-native species, such as Argentine ant. The key mitigation measures that will reduce impacts to Insect guild species are listed in **Table 4.5-36.**

Table 4.5-36
Applicable Mitigation Measures for Impacts to the Insect Guild

Mitigation Measure(s)	Issue(s) Mitigating
SP-4.6-1 through SP-4.6-16, SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA) SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA) SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA) SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA) BIO-1 through BIO-16, BIO-22 (wetlands mitigation plan and riparian and oak restoration activities on the Project site) BIO-19 (dedication of the Salt Creek area to the public and	Loss and degradation of habitat. Long-term effects of hydrologic and geomorphic alterations, reduced water quality, non-native plant species.

Table 4.5-36
Applicable Mitigation Measures for Impacts to the Insect Guild

Mitigation Measure(s)	Issue(s) Mitigating
enhancement of existing agricultural undercrossing at SR-126)	
SP-4.6-58 (conformance with NPDES and RWQCB permit provisions) BIO-49 (prevention of mud and pollutants from entering streams and storm flows)	Short-term and long-term effects on water quality.
BIO-64 (develop an integrated pest management (IPM) plan that addresses pesticide use)	Long-term effect of pesticides that may result in poisoning.
BIO-70 (project design features, construction notes, erosion and dust control, and Stormwater Pollution Prevention Plan (SWPPP) Best Management Practices (BMPs) to ensure protection of vegetation communities and special-status species) BIO-71 (dust control measures to protect vegetation communities and special-status aquatic wildlife species)	Short-term effects of construction on water quality and the effects of excessive dust on habitat quality and prey.
BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation)	Long-term effects of invasive species.

Mollusk Guild. With the exception of the undescribed snail discovered in Middle Canyon Spring and discussed in detail in **Subsection 4.5.5.3**, the only other documented freshwater snail in the Project area is *Physa* sp., which is generally common in the Santa Clara River and lower Potrero Canyon Creek (Swift 2009). However, the Project area is highly likely to support introduced snails and slugs that are considered to be pest species. The brown garden snail (*Helix aspersa*), which was introduced from France during the 1850s for use as food, and the gray garden slug (*Agriolimax reticulates*), also introduced in the 1800s from Europe, are the most common non-native mollusks and are severe garden and agricultural pests (Flint 2003). Because both the brown garden snail and the gray garden slug are non-native invasive species, there would be no adverse effects of the Project on this guild.

Reptile – Low Mobility Guild. This guild includes several relatively common and sedentary reptile species, including side-blotched lizard, western fence lizard, alligator lizard, gopher snake, common kingsnake, western blindsnake, red coachwhip, California whipsnake, and western rattlesnake (see **Subsection 4.5.3.4.3**, General Wildlife). Special-status species in this guild include coast horned lizard, coast patch-nosed snake, coastal western whiptail, rosy boa, San Bernardino ringneck snake, and silvery legless

lizard, which are analyzed in detail in **Subsection 4.5.5.3.** The common species listed above generally do not have the capacity to move large distances over unsuitable habitat in a short period of time and most of the species probably inhabit the same general area for their entire lifetime. Although there are some differences among these species in their habitat associations, they generally use scrub, chaparral, and grassland habitats, although most also will use river wash and dry riparian areas, such as terrace habitats in the Santa Clara River. The California Natural Diversity Database (CNDDB) (CDFG 2003) general physiognomic and location classification for these habitats is scrub and chaparral, with the addition of California annual grassland (classified as a grass and herb dominated community). A total of 8,782 acres of suitable habitat for common species in the Reptile – Low Mobility guild is present in the Project area.

Direct Impacts

Implementation of the RMDP and the SCP would result in injury or mortality of common reptile individuals in this guild and the permanent and temporary loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 81 acres (0.9%) of permanent loss and 14 acres of temporary impact;
- Alternative 3 – 86 acres (1.0%) of permanent loss and 20 acres of temporary impact;
- Alternative 4 – 80 acres (0.9%) of permanent loss and 14 acres of temporary impact;
- Alternative 5 – 102 acres (1.2%) of permanent loss and 24 acres of temporary impact;
- Alternative 6 – 118 acres (1.3%) of permanent loss and 27 acres of temporary impact; and
- Alternative 7 – 61 acres (0.7%) of permanent loss and 76 acres of temporary impact.

The overall loss of potential habitat for common species in the Reptile – Low Mobility guild in the Project area in general would be relatively small under Alternatives 2 through 7 in relation to the total acreage of vegetation communities and land covers on site. Alternative 6 would have the greatest direct permanent impacts to vegetation communities and land covers and Alternative 7 would have the smallest permanent direct impact.

Because of the relatively small amount of habitat loss for the Reptile – Low Mobility guild species, direct impacts resulting from implementation of the RMDP and the SCP would be adverse but not significant under Alternatives 2 through 7.

Some individuals of these species could be harmed or lost during construction activities such as vegetation clearing and/or grading activities under Alternatives 2 through 7. Many of these species use rodent burrows that could be destroyed or crushed, directly killing or entombing individuals. Most species in this guild have weak, if any, burrowing abilities, and likely could not dig their way out of crushed burrows. Individuals that are flushed from vegetation or burrows during construction are also at a much greater risk of vehicle collisions, exposure, and predation if forced to the surface during the day. Generally, however, relatively few individuals are anticipated to be lost or harmed during construction activities during implementation of the RMDP and the SCP because of the limited amount of suitable habitat that would be affected.

Because of the small amount of habitat loss and the fact that these species utilize a variety of habitats and generally have widespread distributions, direct impacts resulting from implementation of the RMDP and the SCP would be adverse but not significant under Alternatives 2 through 7.

Indirect Impacts

The build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would result in injury or mortality to individuals of common species in the Reptile – Low Mobility guild and the loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 2,967 acres (33.8%) of permanent loss;
- Alternative 3 – 2,799 acres (31.9%) of permanent loss;
- Alternative 4 – 2,693 acres (30.7%) of permanent loss;
- Alternative 5 – 2,611 acres (29.7%) of permanent loss;
- Alternative 6 – 2,438 acres (27.8%) of permanent loss; and
- Alternative 7 – 2,201 acres (25.1%) of permanent loss.

There would be progressively smaller impacts with each successive alternative, but there would be substantial impacts to individuals and loss of their habitat in large portions of the Project area under each alternative. However, the snakes in this guild observed in the Project area are still commonly observed and widespread, and the lizards are very common and widespread. Species in this guild therefore will persist in the large,

undeveloped portions of the Project area, such as the River Corridor SMA, High Country SMA, Salt Creek area, and Open Area.

Indirect impacts to Reptile – Low Mobility guild species from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Similar to direct impacts, individuals of these species could be directly killed or harmed during construction activities such as vegetation clearing and/or grading activities under Alternatives 2 through 7. The potential for injury or mortality to individuals due to build-out of the Specific Plan, VCC, and Entrada planning areas is much greater compared to implementation of the RMDP because much more suitable habitat for these species would be affected. However, because these species utilize a variety of habitats and are widespread throughout their ranges, the indirect impacts from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would have the potential to affect Reptile – Low Mobility guild species in areas adjacent to construction zones. These impacts include disruptions associated with increased human activity, noise, and nighttime illumination, the latter of which may disrupt the natural activity cycle of both diurnal and nocturnal species, making them more vulnerable to predation by nocturnal predators such as owls and coyotes.

Habitat fragmentation and isolation is a long-term secondary impact that may especially affect Reptile – Low Mobility guild species due to their relative lack of mobility and high risk of vehicle collisions. However, large intact areas of suitable habitat for this guild will be preserved in the High Country SMA, Salt Creek area, and River Corridor SMA and several existing culverts under SR-126 allow north–south movement between large habitat areas. Landscape-level habitat connectivity will be maintained under Alternatives 2 through 7 for species in this guild. Build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7, however, would result in internal habitat fragmentation and potential isolation of some local populations of Reptile – Low Mobility guild species, making them more vulnerable to extirpation from small habitat patches. At a local level within the developed Project area, species in this guild are expected to occur in the constrained but intact natural drainages on site, such as Potrero Canyon, Long Canyon, San Martinez Grande Canyon, Chiquito Canyon, Lion Canyon, and Castaic Creek, and to use these drainages for both resident and movement habitat. Species in this guild are unlikely to be significantly constrained in

their movement through these drainages where crossings are culverted (*e.g.*, under Alternative 2) rather than bridged (*e.g.*, under Alternative 7). Small reptiles readily move through small culverts (Ruediger and DiGiorgio 2007), especially those with natural, soft-bottom substrates. Therefore, the potential for movement of these species through the Project area is similar for Alternatives 2 through 7.

In addition, over the long term, the close proximity of urban development to suitable habitat for Reptile – Low Mobility guild species under Alternatives 2 through 7 could result in disruption of essential behavioral activities (*e.g.*, foraging and reproduction) and greater vulnerability to several potential secondary impacts, including human-caused habitat degradation (*e.g.*, trampling of vegetation and introduction of invasive species) and harassment and collection; predation by pet, stray, and feral cats and dogs as well as other mesopredators; increased predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; increased non-native species, such as Argentine ant; increased roadkill; and increased use of rodenticides that may be used to control prey species (*e.g.*, small rodents), resulting in both the loss of burrows used for refuge and a reduction in the prey base for the larger snake species. These potential impacts are expected to be similar for Alternatives 2 through 7.

Although both short-term construction-related and long-term secondary impacts from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas are expected to occur, because the species in the Reptile – Low Mobility guild are still common and widespread, and will persist in the large open space area comprising the River Corridor SMA, High Country SMA, and Salt Creek area, these secondary impacts would be adverse but not significant Alternatives 2 through 7.

Mitigation Strategy and Summary

These species are commonly observed utilizing a variety of habitats and have widespread geographic distributions. All direct, indirect, and secondary impacts to the Reptile – Low Mobility guild species were determined to be adverse but not significant and, therefore, no mitigation is required. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to these species. These mitigation measures include habitat preservation, restoration, enhancement, and management of approximately 3,430 acres of the River Corridor SMA, High Country SMA, and Salt Creek area—areas that will form a large, contiguous open space system comprising upland habitats that support the common reptile species. It is expected that common reptile species in this guild will persist in these areas after build-out of the Project area. These mitigation measures also will reduce short-term secondary effects, such as increased noise, lighting, and increased human activity during construction, through biological monitoring and controls on lighting; and long-term effects, such as

habitat degradation; increased human activity; pet, stray and feral cats and dogs; lighting; pesticides and pollutants; and non-native species, such as Argentine ant. The key mitigation measures that will reduce impacts to Reptile – Low Mobility guild species are listed in **Table 4.5-37.**

Table 4.5-37
Applicable Mitigation Measures for Impacts to the Reptile – Low Mobility Guild

Mitigation Measure(s)	Issue(s) Mitigating
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Short-term construction-related impacts from increased human activity and inadvertent injury or mortality to individuals and impacts to their habitat.
SP-4.6-1 through SP-4.6-16, SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA, which includes terrestrial habitats) SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA) SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA) SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA) SP-4.6-30 through SP-4.6-32 (pet, public access, and recreational use restrictions in High Country SMA) SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA) BIO-1 through BIO-16, BIO-22 (wetlands mitigation plan and riparian and oak restoration activities on the Project site) BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural areas)	Loss, fragmentation, and degradation of habitat. Long-term secondary effects of non-native plant species, and increased human and pet activity.
SP-4.6-56 (downcast lighting design along boundaries of natural areas)	Control of lighting impacts to nocturnal reptiles during construction and over the long term due to development.
BIO-63 (control of pet, stray, and feral cats and dogs in or near open space areas)	Harassment and predation of slow-moving reptiles.
BIO-64 (develop an IPM plan that addresses pesticide use)	Long-term effect of pesticides that may result in poisoning.
BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation) BIO-85 (prevention of Argentine ant invasion) BIO-87 (quarterly monitoring and control measures for Argentine ants for up to 50 years)	Long-term effects of invasive plant and wildlife species.

Reptile and Amphibian – Semi-Aquatic Guild. This guild includes reptiles and amphibians that rely on both aquatic and terrestrial habitat for critical parts of their life cycles, Common Reptile and Amphibian – Semi-Aquatic guild species in the Project area include western toad, California treefrog, and Pacific treefrog, which is very common in the Santa Clara River and probably occurs throughout drainages in the Project area where there is adequate hydrology to support breeding. This guild also includes several special-status species, including arroyo toad, western spadefoot toad, California red-legged frog, two-striped garter snake, south coast garter snake, and southwestern pond turtle. These species are analyzed in detail in **Subsection 4.5.5.3**. The River corridor and tributaries that have intermittent flows provide the most suitable habitat for the species in this guild, including aquatic sites, such as ponds and potential breeding pools, depending on local site and general environmental conditions (*e.g.*, precipitation levels, river flow dynamics) as well as adjacent terrestrial habitats in the River floodplain that provide suitable foraging, nesting, and aestivation sites in close proximity to the aquatic sites. For the quantitative analysis of habitat impacts, the focus was on wetland and riparian habitats because these habitats are the main limiting factor for the distribution of the species in this guild on site. It was assumed that the large majority of habitat use by these species is confined to the River corridor floodplain and mesic and hydric tributaries, including terrestrial habitats within the floodplain, although most of these species are capable of making relatively far movements into adjacent upland habitats, including agricultural areas.

The general physiognomic and location classifications (CDFG 2003) that include wetland and riparian habitats are bog and marsh and riparian and bottomland habitat. There is a total of 1,189 acres of these habitats in the Project area. Impacts to potential upland terrestrial habitats, such as scrubs and grasslands, were not quantified because use of these areas is probably only sporadic.

Direct Impacts

Implementation of the RMDP and the SCP would result in injury and mortality of common semi-aquatic amphibian and reptile individuals and the permanent and temporary loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 116 acres (9.8%) of permanent loss and 103 acres of temporary impact;
- Alternative 3 – 90 acres (7.6%) of permanent loss and 110 acres of temporary impact;
- Alternative 4 – 91 acres (7.6%) of permanent loss and 100 acres of temporary impact;

- Alternative 5 – 97 acres (8.2%) of permanent loss and 117 acres of temporary impact;
- Alternative 6 – 78 acres (6.6%) of permanent loss and 107 acres of temporary impact; and
- Alternative 7 – 16 acres (1.3%) of permanent loss and 100 acres of temporary impact.

Permanent and temporary impacts to bog and marsh and riparian and bottomland habitat for Reptile and Amphibian – Semi-Aquatic guild species are small under Alternatives 2 through 7. However, these impacts occur within the tributary drainages and along the banks of the Santa Clara River corridor. Although some of these impacts would occur in the tributary drainages, the Flood Technical Report (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions within the River corridor downstream of the Project area as a result of the proposed Project improvements under any of the alternatives. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County over the long term. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue. As a result, the mosaic of habitats in the River that support the Reptile and Amphibian – Semi-Aquatic guild species would be maintained, and the populations of the species within and immediately adjacent to the River corridor would not be substantially affected.

Because of the relatively small amount of habitat loss for the Reptile and Amphibian – Semi-Aquatic guild species, and because the species in this guild are still common and widespread, direct impacts resulting from implementation of the RMDP and the SCP would be adverse but not significant under Alternatives 2 through 7.

Injury or mortality to individuals in the Reptile and Amphibian – Semi-Aquatic guild could occur under Alternatives 2 through 7; in particular, from bank stabilization and bridge construction in the Santa Clara River corridor. All alternatives would have similar bank stabilization impacts, ranging from 25,561 linear feet under Alternative 7 to 29,844 linear feet under Alternative 2. Three bridges would be constructed across the Santa Clara River under Alternatives 2 and 5; two bridges would be constructed under Alternatives 3, 4, and 6; and one bridge would be constructed under Alternative 7.

Construction activities could result in impact to individuals in the Reptile and Amphibian – Semi-Aquatic guild in the disturbance zone as a result of direct contact of adults, subadults, juveniles, hatchlings, and eggs with construction equipment. Grading in upland habitat areas could directly kill or entomb aestivating or hibernating individuals.

In addition, construction and/or grading activities that result in degradation of aquatic habitats, such as that caused by introduction of mud, silt, or chemical pollutants, may cause species in this guild to abandon the site and make them more vulnerable to impacts such as vehicle collisions, exposure, and predation.

Although there is a high potential for injury or mortality to individuals, these species are abundant and have widespread distributions. Impacts would not substantially reduce populations of species in this guild on site or rangewide. Therefore direct impacts to individuals would be adverse but not significant.

Indirect Impacts

The build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would result in injury or mortality to common semi-aquatic amphibian and reptile individuals and the loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 109 acres (9.2%) of permanent loss;
- Alternative 3 – 85 acres (7.1%) of permanent loss;
- Alternative 4 – 67 acres (5.6%) of permanent loss;
- Alternative 5 – 64 acres (5.4%) of permanent loss;
- Alternative 6 – 42 acres (3.5%) of permanent loss; and
- Alternative 7 – 23 acres (1.9%) of permanent loss.

Similar to direct impacts, indirect impacts to habitat for the semi-aquatic reptiles and amphibians would be small, and they would be progressively smaller with each successive alternative. In addition, the species in this guild are still relatively common and widespread; species such as the Pacific treefrog and western toad occur wherever suitable habitat is present, even in urbanized settings. Species in this guild therefore will persist in the large, undeveloped portions of the Project area, such as the River Corridor SMA, High Country SMA, and Salt Creek area. The more urban-adapted species, such as Pacific treefrog and western toad, will also persist in Open Area and within the reconstructed stream channels where there is adequate hydrology to support breeding.

Indirect impacts to Reptile and Amphibian – Semi-Aquatic guild species from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Similar to direct impacts, individuals of these species could be directly killed or harmed during construction activities such as vegetation clearing and/or grading activities under

Alternatives 2 through 7. The potential for injury or mortality to individuals due to build-out of the Specific Plan, VCC, and Entrada planning areas would be similar to implementation of the RMDP because similar amounts of suitable habitat for these species would be affected. However, because these species are still common and widespread throughout their ranges and will persist on site after build-out, the indirect impacts from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would have the potential to affect Reptile and Amphibian – Semi-Aquatic guild species in areas adjacent to construction zones. These impacts include disruptions associated with increased human activity, noise, and nighttime illumination, the latter of which may disrupt the natural activity cycle of both diurnal and nocturnal species, making them more vulnerable to predation by nocturnal predators such as owls and coyotes. These potential impacts would be common to Alternatives 2 through 7.

The RMDP includes the construction of bridges and bank stabilization within the Santa Clara River corridor that could have long-term effects on hydrology and geomorphology in the Santa Clara River corridor. As noted above, however, there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area as a result of the proposed Project improvements under any of the alternatives (PACE 2009). In addition, habitat within the reconstructed stream channels would provide suitable breeding habitat where there is adequate hydrology.

Although long-term secondary impacts of the RMDP on hydrology and geomorphology would not be substantial, the proposed Project could affect Reptile and Amphibian – Semi-Aquatic guild species downstream of work areas through short-term hydrologic or water quality alterations of the River during construction. In addition, RMDP-related work could disperse sediments and pollutants from construction on upland portions of the site into the Santa Clara River. Hydrologic and water-quality-related impacts could include chemical pollution, increased turbidity, excessive sedimentation, flow interruptions, and changes in water temperature due to short-term changes to the active channel morphology. These factors could result in harm to or mortality of Reptile and Amphibian – Semi-Aquatic guild species and/or the degradation of habitat quality. These impacts could occur under Alternatives 2 through 7, but generally would be relatively less for each alternative with reductions in the amount of improvements successively from Alternative 2 to Alternative 7. The construction of large-span bridges over the

Santa Clara River and associated piers and abutments will occur under Alternatives 2 through 7. Three bridges would be constructed under Alternatives 2 and 5; two bridges under Alternatives 3, 4, and 6; and one bridge under Alternative 7.

Potential long-term secondary impacts to Reptile and Amphibian – Semi-Aquatic guild species related to build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be greatest for Alternatives 2 and 3, due to construction of the VCC development; intermediate for Alternatives 4 through 6; and somewhat less for Alternative 7, because of the pullback from the edge of the Santa Clara River in Landmark Village and Homestead Village East compared to the other alternatives. Under Alternatives 2 through 7, the proximity of urban development to habitat for Reptile and Amphibian – Semi-Aquatic guild species could result in disruption of both diurnal and nocturnal activities; greater vulnerability to predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; greater vulnerability to predation by pet, stray, and feral cats and dogs as well as other mesopredators (Crooks and Soulé 1999); collecting by children; degradation of habitat from increased human use (*e.g.*, trampling, trash, and off-road vehicles); altered fire regimes (probably too frequent fire); invasion by non-native plant (*e.g.*, giant reed, tamarisk, and pampas grass) and wildlife species (*e.g.*, bullfrogs, African clawed frogs, non-native fish, and crayfish); pesticides, and increased risk of vehicle collisions on roads adjacent to occupied areas.

Both short-term and long-term secondary impacts from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas are expected to occur. However, because the species in the Reptile and Amphibian – Semi-Aquatic guild are common and widespread and these species will persist in the undeveloped portions of the Project area, such as the River Corridor SMA, High Country SMA, Salt Creek area, and Open Area, these secondary impacts would be adverse but not significant under Alternatives 2 through 7.

Mitigation Strategy and Summary

Species in this guild are common and have widespread distributions. All direct, indirect, and secondary impacts to the Reptile and Amphibian – Semi-Aquatic guild species were determined to be adverse but not significant and, therefore, no mitigation is required. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to these species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA, High Country SMA, and Salt Creek area—areas that will form a large, contiguous open space system comprising riparian and aquatic habitats as well as adjacent upland habitats, which support a high diversity of common species in this guild. It is expected that these species will persist in these areas after build-out of the Project

area. These mitigation measures also will reduce short-term secondary effects, such as increased noise, lighting, increased human activity, and impaired water quality and altered hydrology during construction, through biological monitoring and controls on lighting; and long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; pesticides and pollutants; and non-native species, such as African clawed frogs, bullfrogs, and crayfish. The key mitigation measures that will reduce impacts to Reptile and Amphibian – Semi-Aquatic guild species are listed in **Table 4.5-38.**

Table 4.5-38
Applicable Mitigation Measures for Impacts to the Reptile and Amphibian – Semi-Aquatic Guild

Mitigation Measure(s)	Issue(s) Mitigating
SP-4.6-55 (obtaining agency permits prior to development or disturbance within wetlands) SP-4.6-58 (conformance with NPDES and RWQCB permit provisions) BIO-44 (temporary crossing of Santa Clara River by bridges, culverts, or other feasible method and preparation of a Stream Crossing and Diversion Plan) BIO-45 (stream diversion bypass channels constructed in active wetted channel within the work zone) BIO-49 (prevention of mud and pollutants from entering streams and storm flows)	Short-term and long-term effects on habitat quality, including vegetation, water quality, and hydrology.
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Short-term construction-related impacts from increased human activity and inadvertent injury or mortality to individuals and impacts to their habitat.
SP-4.6-1 through SP-4.6-16, SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA) SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA) SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA) SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA) SP-4.6-30 through SP-4.6-32 (pet, public access, and recreational use restrictions in High Country SMA) SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA) BIO-1 through BIO-16, BIO-22 (wetlands mitigation plan and riparian and oak restoration activities on the Project site) BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural areas)	Loss, fragmentation, and degradation of habitat. Long-term secondary effects of non-native plant species, and increased human and pet activity.

Table 4.5-38
Applicable Mitigation Measures for Impacts to the Reptile and Amphibian – Semi-Aquatic Guild

Mitigation Measure(s)	Issue(s) Mitigating
SP-4.6-56 (downcast lighting design along boundaries of natural areas)	Control of lighting impacts to the nocturnal reptiles and amphibians during construction and over the long term due to development.
BIO-63 (control of pet, stray, and feral cats and dogs in or near open space areas)	Harassment and predation of slow-moving reptiles.
BIO-64 (develop an IPM plan that addresses pesticide use)	Long-term effect of pesticides that may result in poisoning and other toxic effects.
BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation) BIO-80 (monitoring and control of invasive, non-native aquatic species for up to 50 years) BIO-85 (prevention of Argentine ant invasion) BIO-87 (quarterly monitoring and control measures for Argentine ants for up to 50 years)	Long-term effects of invasive plant and wildlife species.

Fish Guild. The Fish guild includes three non-special-status species: the California native prickly sculpin (likely introduced in the watershed); and largemouth bass, and western mosquitofish, which are non-native to California and introduced. Ventura County is the approximate southern extent of the prickly sculpin's range (which extends north to the Kenai Peninsula, Alaska); this species is adapted to a wide range of environments, including urbanized settings, although it may be absent in polluted aquatic environments (Moyle 2002). It may be abundant were it occurs and appears to co-exist well with non-native species such as largemouth bass (Moyle 2002). Four special-status fish species that have been documented in the Santa Clara River: unarmored threespine stickleback, arroyo chub, Santa Ana sucker, and southern steelhead (ENTRIX 2009; Stoeker and Kelly 2005). The special-status fish are analyzed in detail in **Subsection 4.5.5.3**.

Direct Impacts

Implementation of the RMDP, including construction of buried bank structures and bridges, could cause impacts to fish individuals during construction work within the River. The potential for impacts from installation of these structures is increased as the construction is planned for marginal areas of the riparian zone where fish may inhabit backwater areas.

Implementation of the proposed RMDP, specifically bank stabilization and construction of bridges, including placement of piers, across the River, under Alternatives 2 through 7 would result in physical changes to the Santa Clara River corridor that could affect suitable habitat for Fish guild species. Implementation of the RMDP would result in physical impacts that would affect fish species. There are no expected impacts to the Santa Clara River tributaries. No fish species have been found in the tributaries. In addition, only a few tributaries support perennial flow and none have surface water connectivity with the Santa Clara River, except in Middle and Potrero canyons, which have substantial blockages (bedrock headcuts or cascades) impassable to fish (ENTRIX 2009).

The only common native fish expected to be affected by the implementation of the RMDP is the prickly sculpin. Because this fish is very widespread (Ventura County to Alaska), is often abundant where it occurs (including in inland reservoirs), and appears to be very adaptive to different aquatic environments, including disturbed settings (Moyle 2002), no long-term adverse direct impacts to habitat from implementation of the RMDP are expected. Construction-related impacts to individuals, including injury or mortality, could occur as a result of stream diversions and any construction activities occurring in flowing water. However, because these impacts would be temporary and because this species is common and has a wide geographic range along the western coast of North America, these impacts would be adverse but not significant.

Impacts to non-native, introduced largemouth bass and mosquitofish during construction activities are not considered adverse effects, because removal of these fish from the Santa Clara River would benefit the aquatic system.

Indirect Impacts

Build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be limited to upland areas. Therefore, impacts to fish habitat would not occur.

Secondary Impacts

The RMDP has the potential to affect fish species downstream of work areas through short-term hydrologic or water quality alterations of the River under Alternatives 2 through 7. In addition, although the tributary drainages within the RMDP site do not contain suitable fish habitat due to lack of perennial flows, these drainages could disperse pollutants into the Santa Clara River. Hydrologic and water-quality-related impacts could include chemical pollution, increased turbidity, excessive sedimentation, flow interruptions, and changes in water temperature due to short-term changes to the active channel morphology. These impacts could occur under Alternatives 2 through 7, but

generally would be relatively less for each alternative, with reductions in the amount of improvements successively from Alternative 2 to Alternative 7. The construction of large-span bridges over the Santa Clara River and associated piers and abutments will occur under Alternatives 2 through 7. Three bridges would be constructed under Alternatives 2 and 5; two bridges under Alternatives 3, 4, and 6; and one bridge under Alternative 7.

Potential long-term secondary impacts to fish species associated with build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas include increased urban runoff (including from roadways due to increased vehicle traffic); incidental litter; domestic pet impacts from recreational activities; and increased risk of erosion and sedimentation resulting from increased wildfires. These potential long-term secondary impacts would be similar for Alternatives 2 through 7. It should be noted that invasive species that may be predators of or competitors with many native fish, such as bullfrog, African clawed frog, crayfish, mosquitofish, green sunfish, and largemouth bass, do not appear to be a threat to the prickly sculpin. These threats to special-status fish, however, are discussed in detail in **Subsection 4.5.5.3**.

Because the prickly sculpin is common and widespread and adaptable to a variety of aquatic environments, short-term construction-related and long-term secondary impacts from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Mitigation Strategy and Summary

The only common California native fish is the prickly sculpin, which is widespread and common. All direct, indirect, and secondary impacts to the Fish guild (*i.e.*, prickly sculpin) were determined to be adverse but not significant and, therefore, no mitigation is required. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA which provides aquatic habitat for the Fish guild. It is expected that Fish guild species will persist in the River Corridor SMA after build-out of the Project area. These mitigation measures also will reduce impacts to individuals during construction and short-term secondary effects, such as impaired water quality and altered hydrology during biological monitoring, compliance with wetland permits and authorizations, Best Management Practices (BMPs); and long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; and pesticides and pollutants. The key mitigation measures that will reduce impacts to the Fish guild are listed in **Table 4.5-39.**

Table 4.5-39
Applicable Mitigation Measures for Impacts to the Fish Guild

Mitigation Measure(s)	Issue(s) Mitigating
SP-4.6-55 (obtaining agency permits prior to development or disturbance within wetlands) SP-4.6-58 (conformance with NPDES and RWQCB permit provisions) BIO-44 (temporary crossing of Santa Clara River by bridges, culverts, or other feasible method and preparation of a Stream Crossing and Diversion Plan) BIO-45 (stream diversion bypass channels constructed in active wetted channel within the work zone) BIO-46 (biological monitoring during any stream diversion or culvert installation activity and inspection for stranded fish) BIO-47 **(**slow moving water habitats provided upstream and downstream of any river crossing or bridge construction area to provide refuge for fishes during construction) BIO-48 **(**bridges, culverts, or other structures will not impair the movement of fish and aquatic life) BIO-49 (prevention of mud and pollutants from entering streams and storm flows)	Short-term and long-term effects on individuals and habitat quality, including vegetation, water quality, and hydrology.
SP-4.6-1 through SP-4.6-16, SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA) SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA) SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA) SP-4.6-30 through SP-4.6-32 (pet, public access, and recreational use restrictions in High Country SMA) BIO-1 through BIO-16 (wetlands mitigation plan and riparian restoration activities on the Project site)	Long-term secondary effects of urban runoff and pollutants, non-native plant species, and increased human and pet activity.
BIO-63 (control of pet, stray, and feral cats and dogs in or near open space areas)	Harassment and predation of fish.
BIO-64 (develop an IPM plan that addresses pesticide use)	Long-term effect of pesticides that may result in poisoning and other toxic effects.

Bird – Raptor. This guild includes raptors known to occur on site or in the Project vicinity and nesting and/or foraging species. Common raptors that occur in the Project area include red-tailed hawk, red-shouldered hawk, American kestrel, barn owl, and great horned owl. Special-status species in this guild are American peregrine falcon, California condor, Cooper's hawk, ferruginous hawk, golden eagle, loggerhead shrike (the shrike is included in this guild because of its raptor-like foraging behavior and because it is

sensitive to several of the secondary effects on raptors discussed below), long-eared owl, merlin, northern harrier, prairie falcon, sharp-shinned hawk, short-eared owl, turkey vulture, western burrowing owl, and white-tailed kite. These special-status species are analyzed in detail in **Subsection 4.5.5.3**.

Most common raptors are breeding residents in the Project area and would therefore be affected by the loss of both nesting and foraging habitat. As a whole, Bird – Raptor guild species may use virtually all of the vegetation communities and land covers present in the Project area for breeding or foraging, or both. All vegetation communities and land covers in the Project area, therefore, are considered suitable habitat for the Bird – Raptor guild. A total of 14,288 acres of suitable habitat for species in this guild is present in the Project area.

Direct Impacts

Implementation of the RMDP and the SCP would result in both impacts to raptor individuals and permanent and temporary loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 394 acres (2.8%) of permanent loss and 201 acres of temporary impact;
- Alternative 3 – 197 acres (1.4%) of permanent loss and 250 acres of temporary impact;
- Alternative 4 – 335 acres (2.3%) of permanent loss and 247 acres of temporary impact;
- Alternative 5 – 404 acres (2.8%) of permanent loss and 244 acres of temporary impact;
- Alternative 6 – 383 acres (2.7%) of permanent loss and 249 acres of temporary impact; and
- Alternative 7 – 172 acres (1.2%) of permanent loss and 572 acres of temporary impact.

These raptors are common and have widespread distributions throughout California. The overall loss of potential habitat or these species in the Project area in general would be small under Alternatives 2 through 7 in relation to the total acreage of vegetation communities and land covers available on site and in the Project vicinity. Alternative 5 would have the greatest direct permanent impacts to vegetation communities and land covers, and Alternative 7 would have the smallest permanent direct impact. Direct impacts resulting from implementation of the RMDP and the SCP would be adverse but not significant under Alternatives 2 through 7.

Direct injury or mortality of adult birds is unlikely because they are highly mobile. However, construction activities could result in the loss of nests, eggs, nestlings, and fledglings from vegetation clearing and/or grading activities due to implementation of the RMDP under Alternatives 2 through 7 if such activities occurred during the nesting season. These impacts would violate the MBTA and Fish and Game Code sections 3503 and 3503.4 (birds of prey) (significance criterion 1) and thus would be significant, absent mitigation.

Implementation of the SCP would not directly impact these species.

Indirect Impacts

The build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would result in injury or mortality to common raptor individuals and the loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 5,200 acres (36.4%) of permanent loss;
- Alternative 3 – 4,941 acres (34.6%) of permanent loss;
- Alternative 4 – 4,736 acres (33.1%) of permanent loss;
- Alternative 5 – 4,629 acres (32.4%) of permanent loss;
- Alternative 6 – 4,311 acres (30.2%) of permanent loss; and
- Alternative 7 – 3,728 acres (26.1%) of permanent loss.

There would be progressively smaller impacts with each successive alternative, but there would be substantial impacts to raptor individuals and loss of their habitat in large portions of the Project area under each alternative. However, these raptors species are relatively common and widespread and therefore will persist in the undeveloped portions of the Project area, such as the River Corridor SMA, High Country SMA, Salt Creek area, and Open Area.

Indirect impacts to Bird – Raptor guild species from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Similar to direct impacts, nests, eggs, nestlings, and fledglings of species in this guild could be destroyed, damaged, killed, or injured by construction activities such as vegetation clearing and/or grading activities due to build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 2 through 7, if such activities occurred during the nesting season. These impacts would violate the MBTA and Fish and Game

Code sections 3503 and 3503.4 (birds of prey) (significance criterion 1), and thus would be significant, absent mitigation.

Secondary Impacts

Short-term construction-related impacts associated with implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would potentially affect raptors in areas adjacent to construction zones. These impacts include construction-related noise, ground vibration, and general human activity that could disrupt breeding behavior and reduce reproductive success.

With regard to potential long-term secondary impacts, as a group, raptors are vulnerable to a generally consistent set of secondary impacts: pesticides (including rodenticides, which reduce prey abundance or directly poison raptors through consumption of contaminated prey, and pesticides such as DDT that cause egg-shell thinning); other contaminants (*e.g.*, lead, microtrash); collisions with vehicles, aircraft, buildings, powerlines (entanglement and electrocution), and other structures, such as towers; human and pet disturbance of nest sites; noise; lighting; disease; mesopredators; and clean farming techniques that remove vegetation and prey. Although each of these potential impacts is likely to affect each of the raptor species somewhat differently, all have been implicated as contributors to the decline of this group of species. Because these impacts are generally associated with urban and agricultural development, including increased vehicle traffic and utility infrastructure (transmission and distribution lines, cell towers), they could occur under Alternatives 2 through 7 at similar levels.

Both short-term construction-related and long-term secondary impacts from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas are expected to occur. However, because Bird – Raptor species are common and widespread, and because they will persist in the large, undeveloped portion of the Project area, these secondary impacts would be adverse but not significant under Alternatives 2 through 7.

Mitigation Strategy and Summary

Impacts to individuals during the nesting season include damage, injury or mortality of nests, eggs, nestlings, and fledglings, would be significant, absent mitigation because such impacts would violate the MBTA and California Fish and Game codes (significance criterion 1). These impacts will be avoided through pre-construction surveys within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site. The survey shall be conducted to determine if active nests of native bird species are present in the disturbance zone or within 500 feet. The surveys shall continue on a

weekly basis. If active nests are found, clearing and construction in the vicinity shall be postponed within 500 feet of the nest, or until the nest is vacated or the young have fledged. The buffer may be modified in consultation with CDFG.

The raptors in this guild are common and have widespread geographic distributions. These species are routinely observed in the River Corridor SMA, High Country SMA, Salt Creek area, and adjacent undeveloped areas. The direct and indirect loss of habitat and direct and indirect secondary impacts to the Bird – Raptor guild species were determined to be adverse but not significant and, therefore, no mitigation is required for these impacts. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to these species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA, High Country SMA and Salt Creek area—areas that will form a large, contiguous open space system. It is expected that the common species in this guild will persist in these areas after build-out of the Project area. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction because individuals will have access to nesting and foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction, and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; and pesticides will also be mitigated through a variety of measures. Raptor-specific mitigation measures to reduce collisions and entanglements with and electrocutions from contact with utilities (*i.e.*, utility towers, poles, lines, etc.) will be implemented. The key mitigation measures that will reduce impacts to Bird – Raptor guild species are listed in **Table 4.5-40.**

Table 4.5-40
Applicable Mitigation Measures for Impacts to the Bird – Raptor Guild

Mitigation Measure(s)	Issue(s) Mitigating
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Short-term construction-related impacts from increased human activity and inadvertent injury or mortality to individuals and impacts to their habitat.
BIO-56 (pre-construction surveys for nesting raptors and 500-foot construction setbacks for active nests)	Construction-related impacts to nests, eggs, nestlings, and fledglings.
SP-4.6-1 through SP-4.6-16, SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA) SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA) SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) SP-4.6-21 through SP-4.6-26 (open space dedication of the	Loss, fragmentation, and degradation of habitat. Long-term secondary effects of non-native plant species, and increased human and pet activity.

Table 4.5-40
Applicable Mitigation Measures for Impacts to the Bird – Raptor Guild

Mitigation Measure(s)	Issue(s) Mitigating
River Corridor SMA) SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA) SP-4.6-30 through SP-4.6-32 (pet, public access, and recreational use restrictions in High Country SMA) SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA) BIO-1 through BIO-16, BIO-22 (wetlands mitigation plan and riparian and oak restoration activities on the Project site) BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural areas)	
SP-4.6-56 (downcast lighting design along boundaries of natural areas)	Control of lighting impacts to raptor behavior and roost/nest sites during construction and over the long term due to development.
BIO-63 (control of pet, stray, and feral cats and dogs in or near open space areas)	Harassment and predation.
BIO-64 (develop an IPM plan that addresses pesticide use)	Long-term effect of pesticides that may result in poisoning and other toxic effects.
BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation)	Long-term effects of invasive plant and wildlife species.
BIO-81 (restrictions on installation of towers/poles in the High Country SMA and Salt Creek area) BIO-82 (Anti-perching devices and debris control guidelines for towers/poles in the High Country SMA and Salt Creek area)	Impacts to raptors such as collisions, entanglement, and electrocution.

Bird – Riparian. This guild includes non-raptor birds whose habitat is primarily riparian and wetland habitats. Many common species are in the Bird – Riparian guild, including house wren, Swainson's thrush, common yellowthroat, and various herons and egrets, woodpeckers, flycatchers, and warblers. This guild includes are large number of special-status species, including Nuttall's woodpecker, summer tanager, yellow warbler, yellow-breasted chat, yellow-headed blackbird, black-crowned night heron, least Bell's vireo, willow flycatcher/southwestern willow flycatcher, tricolored blackbird, vermilion flycatcher, and western yellow-billed cuckoo. These special-status species are analyzed in detail in **Subsection 4.5.5.3**. The large number of species that occurs in riparian communities reflects the high wildlife diversity of riparian and wetland habitats (excluding open waters such as lakes, reservoirs, and ponds). The life histories of the Bird – Riparian guild species are diverse, most are highly mobile, and many of the

species are migratory summer residents that nest on site and winter elsewhere (*e.g.*, neo-tropical migrants). The general physiognomic and location classifications (CDFG 2003) that include wetland and riparian habitats are bog and marsh and riparian and bottomland habitat. There is a total of 1,189 acres of these habitats in the Project area.

Direct Impacts

Implementation of the RMDP and the SCP would result in injury and mortality to common Bird – Riparian guild individuals and the permanent and temporary loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 116 acres (9.8%) of permanent loss and 103 acres of temporary impact;
- Alternative 3 – 90 acres (7.6%) of permanent loss and 110 acres of temporary impact;
- Alternative 4 – 91 acres (7.6%) of permanent loss and 100 acres of temporary impact;
- Alternative 5 – 97 acres (8.2%) of permanent loss and 117 acres of temporary impact;
- Alternative 6 – 78 acres (6.6%) of permanent loss and 107 acres of temporary impact; and
- Alternative 7 – 16 acres (1.3%) of permanent loss and 100 acres of temporary impact.

Permanent and temporary impacts would occur in the Santa Clara River corridor and tributaries to the River. Alternative 2 would have the greatest amount of permanent impact, with 9.8% of the habitat impacted. Alternative 7 would have the smallest impact, at 1.3%. Alternatives 3 through 6 would have intermediate amounts of impacts.

Because species in the Bird – Riparian guild are common, have a widespread distribution, and large amounts of riparian habitat will remain undisturbed, these species will continue to use the Project area. In addition, there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions within and downstream of the Project area as a result of the proposed Project improvements under any of the alternatives (PACE 2009). Therefore, riparian communities used by species in this guild would not be substantially altered within the River corridor on site or downstream. Direct impacts resulting from implementation of the RMDP and the SCP therefore would be adverse but not significant under Alternatives 2 through 7.

Nests, eggs, nestlings, and fledglings of species in this guild could be damaged, injured, or killed by construction activities such as vegetation clearing and/or grading activities due to implementation of the RMDP under Alternatives 2 through 7, if such activities occurred during the nesting season. These impacts would violate the MBTA and Fish and Game Code section 3503 (significance criterion 1), and would be significant, absent mitigation.

Implementation of the SCP would not directly impact these species.

Indirect Impacts

The build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would result in injury or mortality to common Bird – Riparian guild individuals and the loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 109 acres (9.2%) of permanent loss;
- Alternative 3 – 85 acres (7.1%) of permanent loss;
- Alternative 4 – 67 acres (5.6%) of permanent loss;
- Alternative 5 – 64 acres (5.4%) of permanent loss;
- Alternative 6 – 42 acres (3.5%) of permanent loss; and
- Alternative 7 – 23 acres (1.9%) of permanent loss.

Similar to direct impacts, indirect impacts to habitat for Bird – Riparian guild species would be progressively smaller with each successive alternative. In addition, the species in this guild are still relatively common and widespread and there will be substantial undisturbed riparian habitat available. Species in this guild therefore will persist in the riparian communities preserved within the large, undeveloped portions of the Project area, such as the River Corridor SMA, High Country SMA, and Salt Creek area.

Indirect impacts to common Bird – Riparian guild species resulting from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Similar to direct impacts, nests, eggs, nestlings, and fledglings could be damaged, killed, or injured during construction activities such as vegetation clearing and/or grading activities under Alternatives 2 through 7. The potential for impacts to individuals due to build-out of the Specific Plan, VCC, and Entrada planning areas would be similar to implementation of the RMDP, because similar amounts of suitable habitat for these species would be affected. These impacts would violate the MBTA and Fish and Game

Code section 3503 (significance criterion 1), and thus would be significant, absent mitigation.

Secondary Impacts

Short-term, construction-related impacts associated with implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas could affect Bird – Riparian guild species in areas adjacent to construction zones under Alternatives 2 through 7. These impacts include construction-related noise and ground vibration, fugitive dust, nighttime illumination, and reduced water quality, resulting in potential harm to individual birds, young, and/or eggs. In particular, construction-related noise, vibration, and nighttime illumination could adversely affect nesting and breeding behavior as well as other activities, resulting in decreased nesting success. These impacts could occur under Alternatives 2 through 7, but generally would be relatively less for each alternative with reductions in the amount of improvements successively from Alternative 2 to Alternative 7. The construction of large-span bridges over the Santa Clara River and associated piers and abutments will occur under Alternatives 2 through 7. Three bridges would be constructed under Alternatives 2 and 5; two bridges under Alternatives 3, 4, and 6; and one bridge under Alternative 7.

Long-term secondary impacts to Bird – Riparian guild species associated with use of RMDP facilities also could occur. Chronic traffic noise and lighting associated with roads and bridges in close proximity to potential breeding habitat in the River corridor could have adverse effects on the establishment of breeding territories and reproductive success.

Potential long-term secondary impacts to Bird – Riparian guild species related to build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be greatest for Alternatives 2 and 3, due to construction of the VCC development (Alternatives 2 and 3 only); intermediate for Alternatives 4 through 6; and somewhat less for Alternative 7, because of the pullback from the edge of the Santa Clara River in Landmark Village and Homestead Village East compared to the other alternatives. Under Alternatives 2 through 7, the proximity of urban development to habitat for Bird – Riparian guild species would result in potential long-term secondary impacts, including noise, nighttime illumination, hydrologic and geomorphic alterations, reduced water quality, invasion by non-native plant species such as giant reed and tamarisk, increased trash, nest parasitism by brown-headed cowbirds, harassment by humans, harassment and predation by pet, stray, and feral cats and dogs, and increased mesopredators (*e.g.*, skunks, raccoons, and opossums).

Both short-term construction-related and long-term secondary impacts from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2

and 3 only), and Entrada planning areas are expected to occur. However, because Bird – Riparian species are common and widespread, and because they will persist in the large, undeveloped portion of the Project area, these secondary impacts would be adverse but not significant under Alternatives 2 through 7.

Mitigation Strategy and Summary

Impacts to individuals during the nesting season, including damage, injury or mortality of nests, eggs, nestlings, and fledglings would be significant, absent mitigation, because such impacts would violate the MBTA and Fish and Game Code section 3503 (significance criterion 1). These impacts will be avoided through pre-construction surveys within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site. The survey shall be conducted to determine if active nests of native bird species are present in the disturbance zone or within 300 feet. The surveys shall continue on a weekly basis. If active nests are found, clearing and construction in the vicinity shall be postponed at the discretion of the biologist, until the nest is vacated.

The direct and indirect loss of habitat and direct and indirect secondary impacts to the Bird – Riparian guild species were determined to be adverse but not significant and, therefore, no mitigation is required for these impacts. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to these species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA, High Country SMA, and Salt Creek area—areas that will form a large, contiguous open space system that includes about 820 acres of suitable riparian communities, of which about 733 are in the River Corridor SMA. In addition, habitat within the reconstructed stream channels would provide suitable nesting and breeding habitat where there is adequate hydrology to support riparian vegetation. It is expected that the common species in this guild will persist in these areas after build-out of the Project area. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction because individuals will have access to nesting and foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction, and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; cowbird parasitism; and pesticides will also be mitigated through a variety of measures. The key mitigation measures that will reduce impacts to Bird – Riparian guild species are listed in **Table 4.5-41.**

Table 4.5-41
Applicable Mitigation Measures for Impacts to the Bird – Riparian Guild

Mitigation Measure(s)	Issue(s) Mitigating
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Short-term construction-related impacts from increased human activity and inadvertent injury of mortality to individuals and impacts to their habitat.
BIO-56 (pre-construction surveys for nesting native birds and construction setbacks for active nests)	Construction-related impacts to nests, eggs, nestlings, and fledglings.
SP-4.6-1 through SP-4.6-16, SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA) SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA) SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA) SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA) SP-4.6-30 through SP-4.6-32 (pet, public access, and recreational use restrictions in High Country SMA) SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA) BIO-1 through BIO-16, BIO-22 (wetlands mitigation plan and riparian and oak restoration activities on the Project site) BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural areas)	Loss, fragmentation, and degradation of habitat. Long-term secondary effects of non-native plant species, and increased human and pet activity.
SP-4.6-56 (downcast lighting design along boundaries of natural areas)	Control of lighting impacts to the nocturnal reptiles and amphibians during construction and over the long term due to development.
BIO-63 (control of pet, stray, and feral cats and dogs in or near open space areas)	Harassment and predation of slow-moving reptiles.
BIO-64 (develop an IPM plan that addresses pesticide use)	Long-term effect of pesticides that may result in poisoning and other toxic effects.
BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation)	Long-term effects of invasive plant and wildlife species.
BIO-78 (cowbird monitoring and trapping program)	Control of cowbird nest parasitism of native species.

Bird – Upland Grassland. This guild includes non-raptor birds whose habitat use on site is primarily grassland. There are relatively few birds that are almost exclusively

grassland species, but two common birds in this guild occurring on site are western meadowlark and savannah sparrow. The guild also includes only two special-status species: California horned lark, which has been observed on site but is not documented as nesting, and grasshopper sparrow, which has not been observed on site but has moderate potential to occur. These special-status species are analyzed in detail in **Subsection 4.5.5.3**. California annual grassland is the grassland community used by this guild, and it totals 2,300 acres in the Project area.

Direct Impacts

Implementation of the RMDP would result in injury or mortality to individuals in this guild and permanent and the temporary loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 24 acres (1.0%) of permanent loss and 10 acres of temporary impact;
- Alternative 3 – 32 acres (1.4%) of permanent loss and 14 acres of temporary impact;
- Alternative 4 – 24 acres (1.0%) of permanent loss and 10 acres of temporary impact;
- Alternative 5 – 42 acres (1.8%) of permanent loss and 16 acres of temporary impact;
- Alternative 6 – 66 acres (2.9%) of permanent loss and 18 acres of temporary impact; and
- Alternative 7 – 19 acres (0.8%) of permanent loss and 55 acres of temporary impact.

The permanent loss of potential habitat for common species in the Bird – Upland Grassland guild in the Project area generally would be similar under Alternatives 2 through 7 in relation to the total acreage of California annual grassland on site, ranging from 0.8% impact under Alternative 7 to 2.9% impact under Alternative 6. Temporary impacts would be similar for Alternatives 2 through 6, and somewhat higher for Alternative 7.

The western meadowlark and savannah sparrow are commonly observed in grassland and have widespread geographic distributions. The loss of habitat for the Bird – Upland Grassland guild species resulting from implementation of the RMDP and the SCP would not substantially affect the abundance and distribution of these species on site and therefore would be adverse but not significant under Alternatives 2 through 7.

Nests, eggs, nestlings, and fledglings of species in this guild could be damaged, killed, or injured by construction activities, such as vegetation clearing and/or grading activities due to implementation of the RMDP under Alternatives 2 through 7, if such activities occurred during the nesting season. These impacts would violate the MBTA and Fish and Game Code section 3503 (significance criterion 1), and thus would be significant, absent mitigation.

Implementation of the SCP would not directly impact these species.

Indirect Impacts

The build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would result in both impacts to common species in the Bird – Upland Grassland guild and loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 1,043 acres (45.3%) of permanent loss;
- Alternative 3 – 966 acres (42.0%) of permanent loss;
- Alternative 4 – 911 acres (39.6%) of permanent loss;
- Alternative 5 – 880 acres (38.3%) of permanent loss;
- Alternative 6 – 846 acres (36.8%) of permanent loss; and
- Alternative 7 – 722 acres (31.4%) of permanent loss.

There would be progressively smaller impacts with each successive alternative, but there would be substantial loss of their habitat in large portions of the Project area under each alternative. However, western meadowlark and savannah sparrow are still commonly observed in grassland and have widespread geographic distributions and therefore would persist in the large, undeveloped portions of the Project area, such as the High Country SMA, Salt Creek area, and Open Area.

Indirect impacts to Bird – Upland Grassland guild species from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Similar to direct impacts, nests, eggs, nestlings, and fledglings could be damaged, killed, or injured during construction activities, such as vegetation clearing and/or grading activities under Alternatives 2 through 7. The potential for impacts to individuals due to build-out of the Specific Plan, VCC, and Entrada planning areas is greater compared to implementation of the RMDP because much more suitable habitat for these species

would be affected. These impacts would violate the MBTA and Fish and Game Code section 3503 (significance criterion 1), and thus would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would have the potential to affect Bird – Upland Grassland guild species in areas adjacent to construction zones. These impacts could include exposure to construction-related dust, noise, ground vibration, and nighttime illumination that could inhibit the species from using suitable habitat for foraging or nesting, and thus affect the reproductive success of species that nest on site. These potential impacts would be similar for Alternatives 2 through 7.

Build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7 would result in some level of habitat fragmentation, making Bird – Upland Grassland guild species more vulnerable to edge effects and local extirpation from smaller habitat patches. The savannah sparrow is a migrant, and thus is a highly mobile species that can move through modified landscapes, but small habitat patches would make the species more vulnerable to edge effects associated with build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7. Meadowlarks are not migratory, but may form large winter flocks and are highly mobile. Potential edge effects include disturbance associated with human activity that could result in a decrease in nesting and foraging success, including abandonment of nests and greater vulnerability to predation by pet, stray, and feral cats and dogs and other mesopredators; increased vulnerability to predation by nocturnal predators (such as owls and coyotes) due to nighttime illumination; pesticides; mowing; and noise.

Both short-term construction-related and long-term secondary impacts from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas are expected to occur. However, because Bird – Upland Grassland species are common and widespread, and because they will persist in the large, undeveloped portion of the Project area, these secondary impacts would be adverse but not significant under Alternatives 2 through 7.

Mitigation Strategy and Summary

Impacts to individuals during the nesting season, including damage, killing, and injury of nests, eggs, nestlings, and fledglings, would be significant, absent mitigation because such impacts would violate the MBTA and Fish and Game Code section 3503 (significance criterion 1). These impacts will be avoided through pre-construction surveys within 30 days of ground-disturbing activities associated with construction or

grading occurring during the nesting/breeding season of native bird species potentially nesting on the site. The survey shall be conducted to determine if active nests of native bird species are present in the disturbance zone or within 300 feet. The surveys shall continue on a weekly basis. If active nests are found, clearing and construction in the vicinity shall be postponed at the discretion of the biologist, until the nest is vacated.

The direct and indirect loss of habitat and direct and indirect secondary impacts to the Bird – Upland Grassland guild species were determined to be adverse but not significant and, therefore, no mitigation is required for these impacts. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to these species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the High Country SMA and Salt Creek area—areas that will form a large, contiguous open space system that includes 653 acres of California annual grassland. It is expected that the common species in this guild will persist in these areas after build-out of the Project area. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction because individuals will have access to nesting and foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction, and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; and pesticides will also be mitigated through a variety of measures. The key mitigation measures that will reduce impacts to Bird – Upland Grassland guild species are listed in **Table 4.5-42.**

Table 4.5-42
Applicable Mitigation Measures for Impacts to the Bird – Upland Grassland Guild

Mitigation Measure(s)	Issue(s) Mitigating
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Short-term construction-related impacts from increased human activity and inadvertent injury or mortality to individuals and impacts to their habitat.
BIO-56 (pre-construction surveys for nesting native birds and construction setbacks for active nests)	Construction-related impacts to nests, eggs, nestlings, and fledglings.
SP-4.6-27 (removal of grazing in the High Country SMA) SP-4.6-30 through SP-4.6-32 (pet, public access, and recreational use restrictions in High Country SMA) SP-4.6-36 through SP-4.6-42 (open space dedication of the High Country SMA) BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural areas)	Loss, fragmentation, and degradation of habitat. Long-term secondary effects of non-native and plant and wildlife species, and increased human and pet activity.

Table 4.5-42
Applicable Mitigation Measures for Impacts to the Bird – Upland Grassland Guild

Mitigation Measure(s)	Issue(s) Mitigating
SP-4.6-56 (downcast lighting design along boundaries of natural areas)	Control of lighting impacts during construction and over the long term due to development.
BIO-63 (control of pet, stray, and feral cats and dogs in or near open space areas)	Harassment and predation of slow-moving reptiles.
BIO-64 (develop an IPM plan that addresses pesticide use)	Long-term effect of pesticides that may result in secondary poisoning or loss or prey.

Bird – Upland Scrub and Chaparral. This guild includes birds whose occurrence on site is primarily in upland scrub and/or chaparral habitats. Common birds in this guild include western scrub-jay, bushtit, California quail, California thrasher, California towhee, spotted towhee, and wrentit. This guild also includes several special-status species that have been documented on site or that have potential to occur in the Project area, including Allen's hummingbird, Costa's hummingbird, rufous hummingbird, Bell's sage sparrow, black-chinned sparrow, southern California rufous-crowned sparrow, and California gnatcatcher. These special-status species are analyzed in detail in **Subsection 4.5.5.3**. Although this guild includes both migrants and permanent residents and some of the species may use non-scrub or chaparral habitat during dispersal or migration, or as "secondary" habitats (*e.g.*, habitats that may be used opportunistically, but are not essential to meet their life history needs), they all breed in scrub and/or chaparral and in most cases would not occur on site in the absence of these habitats. The general physiognomic and location classifications (CDFG 2003) for these habitats are scrub and chaparral. There is a total of 6,482 acres of suitable habitat in the Project area.

Direct Impacts

Implementation of the RMDP would result in injury or mortality to individuals in this guild and the permanent and temporary loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 57 acres (0.9%) of permanent loss and 3.8 acres of temporary impact;
- Alternative 3 – 54 acres (0.8%) of permanent loss and 6.3 acres of temporary impact;
- Alternative 4 – 56 acres (0.9%) of permanent loss and 3.5 acres of temporary impact;

- Alternative 5 – 60 acres (0.9%) of permanent loss and 7.8 acres of temporary impact;
- Alternative 6 – 52 acres (0.8%) of permanent loss and 9.4 acres of temporary impact; and
- Alternative 7 – 42 acres (0.6%) of permanent loss and 21 acres of temporary impact.

The permanent loss of potential habitat associated with RMDP facilities for common species in the Bird – Upland Scrub and Chaparral guild in the Project area would be similar under Alternatives 2 through 7 in relation to the total acreage of scrub and chaparral on site, ranging from 0.6% for Alternative 7 to 0.9% for Alternative 5, which is only marginally higher than Alternatives 2, 3, 4, and 6. Temporary impacts to habitat would be similar for Alternatives 2 through 6 and somewhat higher for Alternative 7.

Species in this guild are commonly observed in scrub and chaparral habitat and have widespread geographic distributions. The loss of habitat for the Bird – Upland Scrub and Chaparral guild species resulting from implementation of the RMDP and the SCP would not substantially affect the abundance and distribution of these species on site and therefore would be adverse but not significant under Alternatives 2 through 7.

Nests, eggs, nestlings, and fledglings of species in this guild could be damaged, killed, or injured by construction activities, such as vegetation clearing and/or grading activities due to implementation of the RMDP under Alternatives 2 through 7, if such activities occurred during the nesting season. These impacts would violate the MBTA and Fish and Game Code section 3503 (significance criterion 1), and thus would be significant, absent mitigation.

Implementation of the SCP would not directly impact these species.

Indirect Impacts

The build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would result in injury or mortality to individuals of common species in the Bird – Upland Scrub and Chaparral guild and the loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 1,924 acres (29.7%) of permanent loss;
- Alternative 3 – 1,833 acres (28.3%) of permanent loss;
- Alternative 4 – 1,782 acres (27.5%) of permanent loss;
- Alternative 5 – 1,731 acres (26.7%) of permanent loss;

- Alternative 6 – 1,592 acres (24.6%) of permanent loss; and
- Alternative 7 – 1,479 acres (22.8%) of permanent loss.

There would be progressively smaller impacts with each successive alternative, but there would be substantial loss of their habitat in large portions of the Project area under each alternative. However, the birds in this guild observed in the Project area are still common and have widespread geographic distributions and therefore would persist in the large, undeveloped portions of the Project area, such as the River Corridor SMA (which includes about 60 acres of scrub and chaparral), High Country SMA, Salt Creek area, and Open Area.

Indirect impacts to Bird – Upland Scrub and Chaparral guild species from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Similar to direct impacts, nests, eggs, nestlings, and fledglings could be damaged, killed, or injured during construction activities such as vegetation clearing and/or grading activities under Alternatives 2 through 7. The potential for impacts to individuals due to build-out of the Specific Plan, VCC, and Entrada planning areas is greater compared to implementation of the RMDP because much more suitable habitat for these species would be affected. These impacts would violate the MBTA and Fish and Game Code section 3503 (significance criterion 1), and thus would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP implementation and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would have the potential to affect Bird – Upland Scrub and Chaparral guild species in areas adjacent to construction zones. These impacts could include exposure to construction-related dust, noise, ground vibration, and nighttime illumination that could inhibit the species from using suitable habitat for foraging or nesting, and thus affect the reproductive success of species that nest on site. These potential impacts would be similar for Alternatives 2 through 7.

Build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7 would result in habitat fragmentation and potential isolation of some local populations of Bird – Upland Scrub and Chaparral guild species, making them more vulnerable to local extirpation. It is difficult to generalize habitat fragmentation and isolation effects to all the species in this guild because of their different life histories and movement capabilities (*e.g.*, migrant *vs.* resident species), but some species in the guild could be extirpated from small habitat patches (*e.g.*, Bolger, Scott *et al.* 1997). However, these common species are expected to be less affected by

habitat fragmentation than some special-status species such as Bell's sage sparrow (Bolger, Scott *et al.* 1997), because of their apparent persistence in already fragmented habitats in southern California.

Other long-term secondary impacts associated with build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7 include disturbance associated with human activity that could result in a decrease in nesting and foraging success, including abandonment of nests and greater vulnerability to predation by pet, stray and feral cats and dogs and other mesopredators; increased vulnerability to predation by other nocturnal predators (such as owls and coyotes) due to nighttime illumination; brood parasitism by cowbirds; noise; and frequent wildfires that may degrade scrub and chaparral habitat over the long term. These potential effects would be common to Alternatives 2 through 7.

Both short-term construction-related and long-term secondary impacts from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas are expected to occur. However, because these species are common and widespread, and because they will persist in the large, undeveloped portion of the Project area, these secondary impacts would be adverse but not significant under Alternatives 2 through 7.

Mitigation Strategy and Summary

Impacts to individuals during the nesting season, including damage, killing, and injuring of nests, eggs, nestlings, and fledglings would be significant, absent mitigation because such impacts would violate the MBTA and Fish and Game Code section 3503 (significance criterion 1). These impacts will be avoided through pre-construction surveys within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site. The survey shall be conducted to determine if active nests of native bird species are present in the disturbance zone or within 300 feet. The surveys shall continue on a weekly basis. If active nests are found, clearing and construction in the vicinity shall be postponed at the discretion of the biologist, until the nest is vacated.

The direct and indirect loss of habitat and direct and indirect secondary impacts to the Bird – Upland Scrub and Chaparral guild species were determined to be adverse but not significant and, therefore, no mitigation is required for these impacts. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to these species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA, High Country SMA, and Salt Creek area—areas that will form a large, contiguous open space system comprising upland habitats that support a high diversity of common scrub

and chaparral species. It is expected that common species in this guild will persist in these areas after build-out of the Project area. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction because individuals will have access to nesting and foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction, and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; cowbird parasitism; and pesticides will also be mitigated through a variety of measures. The key mitigation measures that will reduce impacts to Bird – Upland Scrub and Chaparral guild species are listed in **Table 4.5-43.**

Table 4.5-43
Applicable Mitigation Measures for Impacts to the Bird – Upland Scrub and Chaparral Guild

Mitigation Measure(s)	Issue(s) Mitigating
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Short-term construction-related impacts from increased human activity and inadvertent injury or mortality to individuals and impacts to their habitat.
BIO-56 (pre-construction surveys for nesting native birds and construction setbacks for active nests)	Construction-related impacts to nests, eggs, nestlings, and fledglings.
SP-4.6-27 (removal of grazing in the High Country SMA) SP-4.6-30 through SP-4.6-32 (pet, public access, and recreational use restrictions in High Country SMA) SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA) BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) BIO-20 (preservation of approximately 1,900 acres of coastal scrub on site) BIO-21 (restoration/enhancement of coastal scrub in High Country SMA, Salt Creek area, and River Corridor SMA) BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural areas)	Loss, fragmentation, and degradation of habitat. Long-term secondary effects of non-native and plant and wildlife species, and increased human and pet activity.
SP-4.6-56 (downcast lighting design along boundaries of natural areas)	Control of lighting impacts during construction and over the long term due to development.
BIO-63 (control of pet, stray, and feral cats and dogs in or near open space areas)	Harassment and predation of slow-moving reptiles.
BIO-64 (develop an IPM plan that addresses pesticide use)	Long-term effect of pesticides that may result in secondary poisoning or loss or prey.
BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation)	Long-term effects of invasive plant and wildlife species.

Table 4.5-43
Applicable Mitigation Measures for Impacts to the Bird – Upland Scrub and Chaparral Guild

Mitigation Measure(s)	Issue(s) Mitigating
BIO-78 (cowbird monitoring and trapping program)	Control of cowbird nest parasitism of native species.

Bird – Upland Woodland. This guild includes non-raptor birds whose habitat use on site is upland woodland, primarily oak woodlands. Common birds in this guild include acorn woodpecker, lark sparrow, ash-throated flycatcher, and western bluebird. This guild includes several special-status species: hermit warbler, chipping sparrow, Lawrence's goldfinch, and oak titmouse (**Table 4.5-35**). These special-status species are analyzed in detail in **Subsection 4.5.5.3**. The general physiognomic and location classification (CDFG 2003) for upland woodland habitats is broad leafed upland tree dominated. There is a total of 1,468 acres of upland woodland habitat in the Project area.

Direct Impacts

Implementation of the RMDP would result in injury or mortality to individuals in this guild and the permanent and temporary loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 9.3 acres (0.6%) of permanent loss and 1.4 acres of temporary impact;
- Alternative 3 – 9.5 acres (0.6%) of permanent loss and 1.4 acres of temporary impact;
- Alternative 4 – 8.9 acres (0.6%) of permanent loss and 1.4 acres of temporary impact;
- Alternative 5 – 13 acres (0.9%) of permanent loss and 1.4 acres of temporary impact;
- Alternative 6 – 17 acres (1.1%) of permanent loss and 1.4 acres of temporary impact; and
- Alternative 7 – 5.8 acres (0.4%) of permanent loss and 13.2 acres of temporary impact.

The permanent loss of potential habitat associated with RMDP facilities for common species in the Bird – Upland Woodland guild in the Project area in general would similar

under Alternatives 2 through 7 in relation to the total acreage of woodland communities on site, ranging from 0.4% for Alternative 7 to 1.1% for Alternative 6. Temporary impacts to habitat would be identical for Alternatives 2 through 6, and somewhat higher for Alternative 7.

Some of the species in this guild, such as the acorn woodpecker, are abundant and commonly observed in woodland habitat. Other species, such as western bluebird, lark sparrow and ash-throated flycatcher are not as abundant, but are still considered to be common or fairly common and have widespread geographic distributions. The small amount of habitat loss for the Bird – Upland Woodland guild species resulting from implementation of the RMDP and the SCP would not substantially affect the abundance and distribution of these species on site and therefore would be adverse but not significant under Alternatives 2 through 7.

Nests, eggs, nestlings, and fledglings of species in this guild could be damaged, killed, or injured by construction activities such as vegetation clearing and/or grading activities due to implementation of the RMDP under Alternatives 2 through 7 if such activities occurred during the nesting season. These impacts would violate the MBTA and Fish and Game Code section 3503 (significance criterion 1), and thus would be significant, absent mitigation.

Implementation of the SCP would not directly impact these species.

Indirect Impacts

The build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would result in injury or mortality to individuals in the Bird – Upland Woodland guild and the loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 85 acres (5.7%) of permanent loss;
- Alternative 3 – 66 acres (4.5%) of permanent loss;
- Alternative 4 – 65 acres (4.4%) of permanent loss;
- Alternative 5 – 66 acres (4.5%) of permanent loss;
- Alternative 6 – 45 acres (3.1%) of permanent loss; and
- Alternative 7 – 47 acres (3.2%) of permanent loss.

The permanent loss of habitat would generally be progressively smaller under successive alternatives (except for Alternative 5) and would range from 5.7% for Alternative 2 to 3.2% for Alternative 7.

The birds in this guild are still common or relatively common and have widespread geographic distributions. These species would persist in woodland habitat in the large, undeveloped portions of the Project area, such as the River Corridor SMA, High Country SMA, Salt Creek area, and Open Area. Indirect impacts to Bird – Upland Woodland guild species from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas therefore would be adverse but not significant under Alternatives 2 through 7.

Similar to direct impacts, nests, eggs, nestlings, and fledglings could be damaged, killed, or injured during construction activities, such as vegetation clearing and/or grading activities under Alternatives 2 through 7. The potential for impacts to individuals due to build-out of the Specific Plan, VCC, and Entrada planning areas is greater compared to implementation of the RMDP because much more suitable habitat for these species would be affected. These impacts would violate the MBTA and Fish and Game Code section 3503 (significance criterion 1), and thus would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would have the potential to affect Bird – Upland Woodland guild species in areas adjacent to construction zones. These impacts could include exposure to construction-related dust, noise, ground vibration, and nighttime illumination that could inhibit the species from using suitable habitat for foraging or nesting, and thus affect the reproductive success of species that nest on site. These potential impacts would be similar for Alternatives 2 through 7.

Build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7 would result in some level of habitat fragmentation, making Bird – Upland Woodland guild species more vulnerable to edge effects and local extirpation. Species in this guild are highly mobile and probably can move between relatively isolated woodland patches, but smaller patches in closer proximity to urban development would make them more vulnerable to edge effects associated with build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7. These potential edge effects include disturbance associated with human activity that could result in a decrease in nesting and foraging success, including abandonment of nests and greater vulnerability to predation by pet, stray, and feral cats (dogs are unlikely to prey on these species because their nests tend to be in trees and thickets out of reach of dogs) and other mesopredators; increased vulnerability to predation by nocturnal predators (such as owls) due to nighttime illumination; brood parasitism by cowbirds; noise; and competition for cavity nest sites (*e.g.*, acorn woodpecker) by European starlings.

Both short-term construction-related and long-term secondary impacts from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas are expected to occur. However, because Bird – Upland Woodland species are common and widespread, and because they will persist in the large, undeveloped portion of the Project area, these secondary impacts would be adverse but not significant under Alternatives 2 through 7.

Mitigation Strategy and Summary

Impacts to individuals during the nesting season, including damage, destruction, killing, and injuring of nests, eggs, nestlings, and fledglings, would be significant, absent mitigation because such impacts would violate the MBTA and Fish and Game Code section 3503 (significance criterion 1). These impacts will be avoided through pre-construction surveys within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site. The survey shall be conducted to determine if active nests of native bird species are present in the disturbance zone or within 300 feet. The surveys shall continue on a weekly basis. If active nests are found, clearing and construction in the vicinity shall be postponed at the discretion of the biologist, until the nest is vacated.

The direct and indirect loss of habitat and direct and indirect secondary impacts to the Bird – Upland Woodland guild species were determined to be adverse but not significant and, therefore, no mitigation is required for these impacts. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to these species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA, High Country SMA, and Salt Creek area—areas that will form a large, contiguous open space system that includes about 1,293 acres of suitable woodland habitats. It is expected that the common species in this guild will persist in these areas after build-out of the Project area. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction because individuals will have access to nesting and foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction, and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; cowbird parasitism; and pesticides will also be mitigated through a variety of measures.. The key mitigation measures that will reduce impacts to Bird – Upland Woodland guild species are listed in **Table 4.5-44.**

Table 4.5-44
Applicable Mitigation Measures for Impacts to the Bird – Upland Woodland Guild

Mitigation Measure(s)	Issue(s) Mitigating
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Short-term construction-related impacts from increased human activity and inadvertent injury or mortality to individuals and impacts to their habitat.
BIO-56 (pre-construction surveys for nesting native birds and construction setbacks for active nests)	Construction-related impacts to nests, eggs, nestlings, and fledglings.
SP-4.6-1 through SP-4.6-16, SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA) SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA) SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA) SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA) SP-4.6-30 through SP-4.6-32 (pet, public access, and recreational use restrictions in High Country SMA) SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA) BIO-1 through BIO-16, BIO-22 (wetlands mitigation plan and riparian and oak restoration activities on the Project site) BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural areas)	Loss, fragmentation, and degradation of habitat. Long-term secondary effects of non-native plant species, and increased human and pet activity.
SP-4.6-56 (downcast lighting design along boundaries of natural areas)	Control of lighting impacts to the nocturnal reptiles and amphibians during construction and over the long term due to development.
BIO-63 (control of pet, stray, and feral cats and dogs in or near open space areas)	Harassment and predation of slow-moving reptiles.
BIO-64 (develop an IPM plan that addresses pesticide use)	Long-term effect of pesticides that may result in poisoning and other toxic effects.
BIO-72 (review of plant palettes and inspection of container plants for use within 100 feet of native vegetation for pests and disease; restrictions on invasive plants and irrigation)	Long-term effects of invasive plant and wildlife species.
BIO-78 (cowbird monitoring and trapping program)	Control of cowbird nest parasitism of native species.

Bats. The Bat guild includes several common and special-status bat species that have been documented in the Project area through focused bat surveys (Impact Sciences 2005, Johnson 2006). The potential for other species that were not documented through focused

surveys was based on their rangewide distribution and the availability of habitat on site. Common bat species that were detected or have potential to occur in the Project area include Mexican free-tailed bat, western pipistrelle, big brown bat, California myotis, and little brown bat. The special-status species that were detected or have potential to occur in the Project area include fringed myotis, long-legged myotis, western small-footed myotis, Yuma myotis, pallid bat, pocketed free-tailed bat, Townsend's big-eared bat, western mastiff bat, and western red bat. These special-status species are analyzed in detail in **Subsection 4.5.5.3**.

Most of the common and special-status bat species detected or potentially occurring are foraging habitat generalists. They forage over almost any habitat where prey species (primarily moths and other flying insects) occur. However, many bats tend to concentrate foraging activities in riparian and wetland habitats where insect abundance is high. Most of the species also use a variety of natural features and manmade structures for day roosts (including colonial maternal sites) and night roosts, including natural caves and tunnels, crevices, rocky outcrops, cliff faces, mines, buildings, tree cavities, and bark crevices, to a limited extent. One pallid bat maternity nest site was located in a shed during the bat surveys conducted in middle Potrero Canyon (Johnson 2006) (see **Subsection 4.5.5.3**). Day roosts were also observed by Johnson (2006) at two bridges over the Santa Clara River during a daytime survey. At least three species were determined to be roosting underneath the I-5 Bridge in a crevice designed for bat habitat, based on the guano types present: Mexican free-tailed bats, big brown bats and/or pallid bats, and myotis bats (species unknown). Bats were also observed night roosting under the I-5 Bridge deck at both abutments.

Based on the bat surveys, the common bats are expected to forage throughout the Project area in suitable habitat. The Santa Clara River is probably the most important foraging area because many of the bat species in the Project area forage in riparian and wetland areas where there is high abundance and diversity of insect prey. Other tributaries to the River, such as Potrero Canyon, that support riparian and wetland habitat with adequate hydrology are also considered to be important foraging areas.

Because the common bats on site are mostly foraging habitat generalists, all natural habitats in the Project area are considered potential foraging habitat. The general physiognomic and location classifications (CDFG 2003) included in the impact analysis are scrub and chaparral, grass and herb dominated communities, bog and marsh, riparian and bottomland habitat, and broad leafed upland tree dominated. There is a total of 11,439 acres of suitable habitat in the Project area.

Direct Impacts

Implementation of the RMDP would result in permanent and temporary loss of habitat for the Bat guild species as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 206 acres (1.8%) of permanent loss and 118 acres of temporary impact;
- Alternative 3 – 185 acres (1.6%) of permanent loss and 132 acres of temporary impact;
- Alternative 4 – 180 acres (1.6%) of permanent loss and 115 acres of temporary impact;
- Alternative 5 – 212 acres (1.9%) of permanent loss and 142 acres of temporary impact;
- Alternative 6 – 213 acres (1.9%) of permanent loss and 135 acres of temporary impact; and
- Alternative 7 – 83 acres (0.7%) of permanent loss and 189 acres of temporary impact.

The permanent loss of potential habitat for common species in the Bat guild in the Project area in general would be similar under Alternatives 2 through 6, ranging from 1.6% for Alternatives 3 and 4 to 1.9% for Alternatives 5 and 6. Alternative 7 would have the smallest permanent direct impact, with 0.7% of the total impacted. Temporary impacts to habitat would also be similar, with the largest temporary impact occurring under Alternative 7.

The Santa Clara River corridor and adjacent upland habitat supports large numbers of common bats. Implementation of the RMDP will result in the temporary impacts to foraging habitat in the tributary drainages; however, construction of these facilities would be phased over many years and would not result in simultaneous construction and impacts to habitat. Because these bats are common and have widespread geographic distributions, and large areas of contiguous suitable habitat will remain, implementation of the RMDP and the SCP would not substantially affect the use of the Project area for foraging. Therefore impacts would be adverse but not significant under Alternatives 2 through 7.

Construction activities associated with implementation of the RMDP are not expected to result in mortality of adults foraging in this habitat. Adult bats are nocturnal and highly mobile and construction activities are not anticipated to occur during nighttime hours. However, if adults are flushed from a day roost site during construction activities, these

individuals could become disoriented and unable to safely relocate to another roost site, resulting in an increased risk of injury or mortality. If construction activities directly impacted an active day roost (solitary or colonial maternity site), individuals, including young, could be harassed, injured, or killed. Furthermore, even if young escaped direct harm, the loss of a maternity site resulting from implementation of the RMDP before young are independent of the mother likely would result in mortality of the young. No day roosts for common bat species have been documented on site; however, there are structures or habitat features (*e.g.*, trees) that potentially provide day roost sites.

Implementation of the Project is not expected to result in injury or mortality to common bat species. Nighttime construction activities, if they should occur in foraging areas or in proximity to roost sites, could result in adverse effects, including altered foraging behavior and increased predation risk. Because these bats are common and have widespread geographic distributions, and large areas of contiguous suitable habitat will remain, these impacts resulting from implementation of the RMDP would be adverse but not significant under Alternatives 2 through 7.

Implementation of the SCP would not directly impact these species.

Indirect Impacts

The build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would result in the permanent loss of habitat for species in the Bat guild as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 3,161 acres (27.6 %) of permanent loss;
- Alternative 3 – 2,950 acres (25.8%) of permanent loss;
- Alternative 4 – 2,825 acres (24.7%) of permanent loss;
- Alternative 5 – 2,741 acres (24.0%) of permanent loss;
- Alternative 6 – 2,524 acres (22.1%) of permanent loss; and
- Alternative 7 – 2,271 acres (19.8 %) of permanent loss.

There would be progressively smaller impacts with each successive alternative, but there would be substantial impacts to individuals and loss of their habitat in large portions of the Project area under each alternative, ranging from 19.8% for Alternative 7 to 27.6% for Alternative 2. However, the bats in this guild observed or potentially occurring in the Project area are still common and have widespread geographic distributions and therefore would continue to forage in the large, undeveloped portions of the Project area, such as the River Corridor SMA, High Country SMA, Salt Creek area, and Open Area.

Indirect impacts to Bat guild species from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Similar to direct impacts, if construction activities associated with build-out of the Specific Plan, VCC, and Entrada planning areas directly impacted an active day roost, then individuals, including young, could be harassed, injured, or killed.

Secondary Impacts

Construction activities associated with RMDP facilities and the build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas have the potential to affect bats in areas adjacent to construction zones, because they generally are very sensitive to human disturbance (Zeiner *et al.* 1990B). Any day roosts in proximity to construction zones may be affected by short-term construction activities, including noise and increased human activity. Use of RMDP facilities (*e.g.*, roads, bridges, and lighting) could impact both day and night roost sites, as well as alter foraging behavior. In addition, because bats are highly sensitive to human disturbance, any day roosts in close proximity to urban development probably would be abandoned and thus permanently impacted in the long term. These impacts would be similar for Alternatives 2 through 7.

With regard to foraging activities, because bats are relatively mobile and are active at night, no substantial secondary direct impacts to foraging behavior due to construction activities are anticipated. Bats may change their foraging behavior somewhat to avoid construction zones and developed areas, but adequate remaining foraging habitat would be available in the Project area.

Both short-term construction-related and long-term secondary impacts to roost sites from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas could occur. However, because Bat guild species are common and widespread, and because they will continue to forage in the large, undeveloped portion of the Project area, these secondary impacts would be adverse but not significant under Alternatives 2 through 7.

Mitigation Strategy and Summary

The direct and indirect loss of habitat, including any roost sites, and direct and indirect secondary impacts to the Bat guild species were determined to be adverse but not significant and, therefore, no mitigation is required for these impacts. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to these species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA,

High Country SMA, and Salt Creek area—areas that will form a large, contiguous open space system providing foraging and potential roosting habitat for bats. It is expected that the common species in this guild will continue to forage in these areas after build-out of the Project area. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction because individuals will have access to nesting and foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction, and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; and pesticides will also be mitigated through a variety of measures. The key mitigation measures that will reduce impacts to Bat guild species are listed in **Table 4.5-45.**

Table 4.5-45
Applicable Mitigation Measures for Impacts to the Bat Guild

Mitigation Measure(s)	Issue(s) Mitigating
SP-4.6-1 through SP-4.6-16, SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA) SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA) SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA) SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA) SP-4.6-30 through SP-4.6-32 (pet, public access, and recreational use restrictions in High Country SMA) SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and High Country SMA) SP-4.6-48 (standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area) BIO-1 through BIO-16, BIO-22 (wetlands mitigation plan and riparian and oak restoration activities on the Project site) BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural areas)	Loss and degradation of foraging habitat. Long-term secondary effects of increased human and pet activity.
SP-4.6-56 (downcast lighting design along boundaries of natural areas)	Control of lighting impacts to bat foraging behavior during construction and over the long term due to development.
BIO-63 (control of pet, stray, and feral cats and dogs in or near open space areas)	Harassment and predation.

Mammal – Low Mobility. Several common small mammals in this guild have been documented on site during mammal studies using live-trapping and track/scent station methods, including California ground squirrel, Botta's pocket gopher, desert cottontail,

brush rabbit, deer mouse, brush mouse, cactus mouse, California mouse, western harvest mouse, dusky-footed woodrat, California vole, California pocket mouse, and kangaroo rat[1] (Impact Sciences 2005). Several of these common rodents and the desert shrew were also captured during pitfall trapping for reptiles and amphibians (Impact Sciences 2006A). This guild also includes two special-status species: the San Diego desert woodrat, which is relatively common in suitable habitat on site, and the southern grasshopper mouse, which has not been documented in the Project area but has potential to occur on site. These special-status species are analyzed in detail in **Subsection 4.5.5.3**.

With the exception of the kangaroo rat, these species generally do not have the capacity to move large distances over unsuitable habitat in a short period of time, and even most dispersal movements by the kangaroo rat are relatively short distance. Most of these species probably inhabit the same general area for their entire lifetime. Although there are some differences among these species in their habitat associations, they generally use scrub, chaparral, and grassland habitats, although most will also use river wash and dry riparian areas, such as terrace and riparian ecotone habitats in the Santa Clara River. The general physiognomic and location classifications (CDFG 2003) for these habitats are scrub and chaparral and grass and herb dominated communities. A total of 8,782 acres of suitable habitat for common species in the Mammal – Low Mobility guild is present in the Project area.

Direct Impacts

Implementation of the RMDP and the SCP would result in injury or mortality of individuals of common species in the Mammal – Low Mobility guild and the permanent and temporary loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 81 acres (0.9%) of permanent loss and 14 acres of temporary impact;
- Alternative 3 – 86 acres (1.0%) of permanent loss and 20 acres of temporary impact;
- Alternative 4 – 80 acres (0.9%) of permanent loss and 14 acres of temporary impact;
- Alternative 5 – 102 acres (1.2%) of permanent loss and 24 acres of temporary impact;

[1] Impact Sciences identified the resident kangaroo rat on site as the Pacific kangaroo rat (*Dipodomys agilis*), but based on the relatively low elevation on site, the species may have been the Dulzura kangaroo rat (*D. simulans*) according to a study by Sullivan and Best (1997) that separates the two species.

- Alternative 6 – 118 acres (1.3%) of permanent loss and 27 acres of temporary impact; and
- Alternative 7 – 61 acres (0.7%) of permanent loss and 76 acres of temporary impact.

The permanent loss of potential habitat with implementation of the RMDP for common species in the Mammal – Low Mobility guild in the Project area in general would be similar in relation to the total acreage of vegetation communities and land covers on site, ranging from 0.7% for Alternative 7 to 1.3% for Alternative 6. Temporary impacts would be similar for Alternatives 2 through 6, and somewhat greater for Alternative 7.

The species in this guild range from being abundant in a diversity of habitats (*e.g.*, deer mouse) to common in suitable habitat (*e.g.*, pocket gopher, pocket mouse, kangaroo rat) and all have widespread geographic ranges. Therefore, habitat loss for the Mammal – Low Mobility guild species resulting from implementation of the RMDP and the SCP would be adverse but not significant under Alternatives 2 through 7.

Because species in this guild are fossorial (burrowing or digging) and are not highly mobile, implementation of the RMDP would result in injury or mortality of individuals occupying this habitat during construction and/or grading activities. Individuals may be directly killed or injured by construction equipment or entombed in burrows. Individuals that escape from burrows may be killed by construction equipment or vehicles, suffer from predation, or be unable to find refuge in the construction zone.

Although some individuals may be harmed or lost during construction associated with the RMDP, because the species in this guild are common to abundant and have widespread geographic distributions, direct impacts resulting from implementation of the RMDP would be adverse but not significant under Alternatives 2 through 7.

Implementation of the SCP would not directly impact these species.

Indirect Impacts

The build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would result in injury or mortality to individuals of common species in the Mammal – Low Mobility guild and the permanent loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 2,967 acres (33.8%) of permanent loss;
- Alternative 3 – 2,799 acres (31.9%) of permanent loss;
- Alternative 4 – 2,693 acres (30.7%) of permanent loss;

- Alternative 5 – 2,611 acres (29.7%) of permanent loss;
- Alternative 6 – 2,438 acres (27.8%) of permanent loss; and
- Alternative 7 – 2,201 acres (25.1%) of permanent loss.

There would be progressively smaller impacts with each successive alternative, but there would be substantial loss of their habitat in large portions of the Project area under each alternative. However, these species are common to abundant in suitable habitat and have wide geographic ranges. They will persist in the large, undeveloped portions of the Project area, such as the River Corridor SMA, High Country SMA, Salt Creek area, and Open Area, as well as adjacent undeveloped habitat.

Indirect impacts to Mammal – Low Mobility guild species from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Similar to direct impacts, individuals of these species could be directly killed or harmed during construction activities, such as vegetation clearing and/or grading activities under Alternatives 2 through 7. The potential for impacts to individuals due to build-out of the Specific Plan, VCC, and Entrada planning areas is much greater compared to implementation of the RMDP because much more suitable habitat for these species would be affected. However, because these species are still common to abundant on site and have wide geographic ranges. Therefore, the indirect impacts to individuals from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Secondary Impacts

Short-term construction activities associated with implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas could cause collapsed burrows due to ground vibration; abandonment of burrows; and disruptions associated with increased human activity, noise, and nighttime illumination.

Habitat fragmentation and isolation is a secondary impact that may especially affect Mammal – Low Mobility guild species due to their relative lack of mobility and high risk of vehicle collisions. Exceptions are two urban-adapted species: California ground squirrel and Botta's pocket gopher. However, large intact areas of suitable habitat for this guild will be preserved in the High Country SMA, Salt Creek area, and River Corridor SMA and several existing culverts under SR-126 allow north–south movement. Landscape-level habitat connectivity will be maintained under Alternatives 2 through 7 for species in this guild. Build-out of the Specific Plan, VCC (Alternatives 2 and 3 only),

and Entrada planning areas under Alternatives 2 through 7 would result in internal habitat fragmentation and potential isolation of some local populations of the Mammal – Low Mobility guild species, making them more vulnerable to extirpation in smaller habitat patches. At a local level within the developed Project area, species in this guild are expected to occur in the constrained but intact natural drainages and adjacent uplands in open space on site, such as Potrero Canyon, Long Canyon, San Martinez Grande Canyon, Chiquito Canyon, Lion Canyon, and Castaic Creek, and use these drainages for both resident and movement habitat. Species in this guild are unlikely to be significantly constrained in their movement through these drainages where crossings are culverted (*e.g.*, under Alternative 2) rather than bridged (*e.g.*, under Alternative 7). Small mammals readily move through small culverts, especially those with natural, soft-bottom substrates (Ruediger and DiGiorgio 2007). Therefore, the potential for movement of these species through the Project area is similar for Alternatives 2 through 7.

In addition, over the long term, the close proximity of urban development to suitable habitat for species in this guild could result in abandonment of burrows; disruption of nocturnal activities; greater vulnerability to predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; greater vulnerability to predation by pet, stray, and feral cats and dogs as well as other mesopredators (Crooks and Soulé 1999); and vulnerability to rodenticides that may be used to control pest rodents (*e.g.*, ground squirrels in landscaped areas or golf courses). These potential impacts are expected to be similar for Alternatives 2 through 7.

Although both short-term construction-related and long-term secondary impacts from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas are expected to occur, because the species in the Mammal – Low Mobility guild are still common and widespread, and will persist in the large open space area comprising the River Corridor SMA, High Country SMA, and Salt Creek area, these secondary impacts would be adverse but not significant under Alternatives 2 through 7.

Mitigation Strategy and Summary

All direct, indirect, and secondary impacts to the Mammal – Low Mobility guild species were determined to be adverse but not significant and, therefore, no mitigation is required. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to these species. These mitigation measures include habitat preservation, restoration, enhancement, and management of the River Corridor SMA, High Country SMA, and Salt Creek area—areas that will form a large, contiguous open space system that supports the common mammal species in this guild. It is expected that these species will persist in these areas after build-out of the Project area. The set-aside of lands also will reduce short-term secondary effects, such as

increased noise, vibration, lighting, and increased human activity during construction because individuals will have access to nesting and foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction, and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; and pesticides will also be mitigated through a variety of measures. The key mitigation measures that will reduce impacts to Mammal – Low Mobility guild species are listed in **Table 4.5-46.**

Table 4.5-46
Applicable Mitigation Measures for Impacts to the Mammal – Low Mobility Guild

Mitigation Measure(s)	Issue(s) Mitigating
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Short-term construction-related impacts from increased human activity and inadvertent injury or mortality to individuals and impacts to their habitat.
SP-4.6-1 through SP-4.6-16, SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA, which includes terrestrial habitats) SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA) SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA) SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA) SP-4.6-30 through SP-4.6-32 (pet, public access, and recreational use restrictions in High Country SMA) SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA) BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) BIO-20 (preservation of approximately 1,900 acres of coastal scrub on site) BIO-21 (restoration/enhancement of coastal scrub in the High Country SMA, Salt Creek area, and River Corridor SMA) BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural areas)	Loss, fragmentation, and degradation of habitat. Long-term secondary effects of non-native plant species, and increased human and pet activity.
SP-4.6-56 (downcast lighting design along boundaries of natural areas)	Control of lighting impacts to nocturnal reptiles during construction and over the long term due to development.
BIO-63 (control of pet, stray, and feral cats and dogs in or near open space areas)	Harassment and predation of slow-moving reptiles.
BIO-64 (develop an IPM plan that addresses pesticide use)	Long-term effect of rodenticides.

Mammal – Moderate Mobility. Common species in this guild known in the Project area include gray fox, long-tailed weasel, and raccoon. Special-status species in this guild include the American badger, ringtail cat, and San Diego black-tailed jackrabbit. These special-status species are analyzed in detail in **Subsection 4.5.5.3**. The raccoon and gray fox primarily use riparian and upland woodlands and forest or shrublands associated with water. The long-tailed weasel is a habitat generalist that occurs in most habitats that support prey except desert scrubs. Because these species use different habitats, a generalized analysis of direct habitat loss from implementation of the RMDP and indirect habitat loss from build-out of the Specific Plan, VCC, and Entrada planning areas is not applicable to this guild as a whole. Therefore, the raccoon and gray fox are analyzed separately from the long-tailed weasel. The habitat used for the raccoon and gray fox analysis is riparian and bottomland habitat and broad leafed upland tree dominated, which totals 2,450 acres in the Project area. Because the long-tailed weasel uses virtually all habitats on site, all vegetation communities and land covers (except developed) are used for this species, which total 14,288 acres in the Project area (the same acreage used above for the Insect guild).

Direct Impacts

Implementation of the RMDP and the SCP would result in injury or mortality to the raccoon and gray fox and the permanent and temporary loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 113 acres (4.6%) of permanent loss and 100 acres of temporary impact;
- Alternative 3 – 91 acres (3.7%) of permanent loss and 107 acres of temporary impact;
- Alternative 4 – 92 acres (3.8%) of permanent loss and 97 acres of temporary impact;
- Alternative 5 – 101 acres (4.1%) of permanent loss and 112 acres of temporary impact;
- Alternative 6 – 86 acres (3.5%) of permanent loss and 103 acres of temporary impact; and
- Alternative 7 – 21 acres (0.9%) of permanent loss and 108 acres of temporary impact.

The permanent loss of habitat due to implementation of the RMDP would be similar for Alternatives 2 through 6 in relation to the total amount of habitat in the Project area, ranging from 3.5% for Alternative 6 to 4.6% for Alternative 2. Permanent loss of habitat

under Alternative 7 would be reduced, at 0.9%. Temporary impacts to habitat would be similar under all of the alternatives.

As shown in detail above for the Insect guild, permanent loss of habitat for the long-tailed weasel would generally be similar under Alternatives 2 through 6, with a range of 335 acres (2.3%) under Alternative 4 to 404 acres (2.8%) under Alternative 5. Permanent impacts under Alternative 7 would be substantially less at 172 acres. Temporary impacts would range from 201 acres under Alternative 2 to 572 acres under Alternative 7.

The species in the Mammal – Moderate Mobility guild, although not occurring in high densities, are commonly observed or detected by sign *(e.g.*, tracks, scat) in suitable habitat and they have widespread geographic distributions. There would be substantial remaining suitable habitat in the Project area and adjacent undeveloped lands to support these species. Therefore direct loss of habitat resulting from implementation of the RMDP would be adverse but not significant under Alternatives 2 through 7.

Although in most cases, adults in the Mammal – Moderate Mobility guild are mobile enough to escape from the direct effects of construction and/or grading activities, implementation of the RMDP could result in mortality of young in a natal den (raccoon and fox) or burrow (weasel). In addition, adults that are flushed from dens or burrows or that try to escape from construction areas are at much higher risk of a vehicle collision. Individuals that cannot find suitable habitat for refuge or are disoriented from being displaced would also be at greater risk of mortality. However, because species in the Mammal – Moderate Mobility guild would persist on site in the large open space system and because they are common and have broad geographic ranges, direct impacts to individuals resulting from implementation of the RMDP would be adverse but not significant under Alternatives 2 through 7.

Implementation of the SCP would not directly impact these species.

Indirect Impacts

The build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would result in injury or mortality to the raccoon and gray fox and the permanent loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 192 acres (7.8%) of permanent loss;
- Alternative 3 – 151 acres (6.2%) of permanent loss;
- Alternative 4 – 131 acres (5.3%) of permanent loss;
- Alternative 5 – 130 acres (5.3%) of permanent loss;

- Alternative 6 – 86 acres (3.5%) of permanent loss; and
- Alternative 7 – 70 acres (2.9%) of permanent loss.

There would be progressively smaller permanent impacts to habitat for gray fox and raccoon with each successive alternative, with a range of 7.8% for Alternative 2 to 2.9% for Alternative 7. As shown in detail above for the Insect guild, permanent loss of habitat for the long-tailed weasel as a result of build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would also be progressively smaller with each successive alternative, ranging from 4,491 acres (34.6%) under Alternative 2 to 3,728 acres (26.1%) under Alternative 7.

These species will persist in the large, undeveloped portions of the Project area, such as the River Corridor SMA, High Country SMA, Salt Creek area, and Open Area. Indirect impacts for the long-tailed weasel would be substantially greater, but this species also will persist in the undeveloped portions of the Project area. In addition, the species in this guild have widespread distributions and are relatively common throughout their geographic ranges. Therefore, indirect impacts to Mammal – Moderate Mobility guild species from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

As noted above, adults in this guild are mobile enough to escape from the direct effects of construction and/or grading activities, but young in dens or burrows could be affected, flushed adults would be vulnerable to vehicle collision, and individuals that cannot find suitable habitat for refuge would also be at greater risk of mortality. However, because species in the Mammal – Moderate Mobility guild would persist on site in the large open space system and because they are common and have broad geographic ranges, indirect impacts to individuals resulting from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would have the potential to affect species in this guild in areas adjacent to construction zones. These impacts, such as vibration, noise, lighting, and increased human activity, could result in disruptions of essential behavioral activities (*e.g.*, foraging, breeding, and rearing of young).

Habitat fragmentation and isolation and associated roads adjacent to suitable habitat for Mammal – Moderate Mobility guild species will result in an increased risk of vehicle collisions for species in this guild. Raccoons in particular suffer a particularly high level

of vehicle collisions in urban and agricultural areas. However, large intact areas of suitable habitat for this guild will be preserved in the High Country SMA, Salt Creek area, and River Corridor SMA and several existing culverts under SR-126 allow north–south movement. Landscape-level habitat connectivity will be maintained under Alternatives 2 through 7 for species in this guild. Build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7 would result in internal habitat fragmentation and potential isolation of some local populations of the Mammal – Moderate Mobility guild species, making them more vulnerable to extirpation. Species in this guild will probably continue to use constrained drainages, such as Potrero Canyon, Long Canyon, San Martinez Grande Canyon, Chiquito Canyon, Lion Canyon, and Castaic Creek as resident habitat after build-out of the Project area where adequate vegetative cover is present, and as movement habitat where there is a lack of cover. None of the species in this guild are likely to be significantly constrained in their movement through these drainages where crossings are culverted (*e.g.*, under Alternative 2) rather than bridged (*e.g.*, under Alternative 7). These species readily move through small culverts, especially those with natural, soft-bottom substrates (Ruediger and DiGiorgio 2007). Therefore, the potential for movement of these species through the Project area is similar for Alternatives 2 through 7.

Other long-term secondary impacts include nighttime illumination, which could affect essential behavioral activities; increased human activity; potential harassment by humans and pet, stray, and feral cats and dogs; and use of rodenticides.

Although both short-term construction-related and long-term secondary impacts from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas are expected to occur, because the species in the Mammal – Moderate Mobility guild are still common and widespread, and will persist in the large open space area comprising the River Corridor SMA, High Country SMA, and Salt Creek area, these secondary impacts would be adverse but not significant under Alternatives 2 through 7.

Mitigation Strategy and Summary

All direct, indirect, and secondary impacts to the Mammal – Moderate Mobility guild species were determined to be adverse but not significant and, therefore, no mitigation is required. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to these species. These mitigation measures include habitat preservation, restoration, enhancement, and management of upland and riparian habitat areas in the River Corridor SMA, High Country SMA, and Salt Creek area that will form a large, contiguous open space system that supports the common mammal species in this guild. It is expected that these species will persist in these areas after build-out of the Project area. The set-aside of lands also will reduce

short-term secondary effects, such as increased noise, vibration, lighting, and increased human activity during construction because individuals will have access to nesting and foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction, and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral cats and dogs; lighting; and rodenticides will also be mitigated through a variety of measures. The key mitigation measures that will reduce impacts to Mammal – Moderate Mobility guild species are listed in **Table 4.5-47.**

Table 4.5-47
Applicable Mitigation Measures for Impacts to the Mammal – Moderate Mobility Guild

Mitigation Measure(s)	Issue(s) Mitigating
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Short-term construction-related impacts from increased human activity and inadvertent injury or mortality to individuals and impacts to their habitat.
SP-4.6-1 through SP-4.6-16, SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA, which includes terrestrial habitats) SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA) SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA) SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA) SP-4.6-30 through SP-4.6-32 (pet, public access, and recreational use restrictions in High Country SMA) SP-4.6-36 through SP-4.6-42 (open space dedication of the River Corridor SMA and the High Country SMA) BIO-1 through BIO-16, BIO-22 (wetlands mitigation plan and riparian and oak restoration activities on the Project site) BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) BIO-20 (preservation of approximately 1,900 acres of coastal scrub on site) BIO-21 (restoration/enhancement of coastal scrub in the High Country SMA, Salt Creek area, and River Corridor SMA) BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural areas)	Loss, fragmentation, and degradation of habitat. Long-term secondary effects of non-native plant species, and increased human and pet activity.
SP-4.6-56 (downcast lighting design along boundaries of natural areas)	Control of lighting impacts to nocturnal reptiles during construction and over the long term due to development.
BIO-63 (control of pet, stray, and feral cats and dogs in or near open space areas)	Harassment and predation of slow-moving reptiles.
BIO-64 (develop an IPM plan that addresses pesticide use)	Long-term effect of rodenticides.

Mammal – High Mobility. The common species in this guild known on site are the bobcat and coyote. Special-status species occurring within the Project area are the American black bear, mule deer, and mountain lion. All of these species, except the black bear, are resident on site. The black bear may use the Project area for dispersal between mountainous regions to the north and south of the site. The special-status species are analyzed in detail in **Subsection 4.5.5.3**.

The coyote and bobcat use a similar mix of riparian and upland habitats in the Project area, although coyotes will also forage in grassland areas that are less likely to be used by bobcats. For the purpose of this analysis, the general physiognomic and location classifications (CDFG 2003) for habitat typically used by both species are scrub and chaparral, riparian and bottomland habitat, and broad leafed upland tree dominated. A total of 8,932 acres of suitable habitat for the Mammal – High Mobility guild is present in the Project area.

Direct Impacts

Implementation of the RMDP and the SCP would result in injury or mortality of coyote and bobcat individuals and the permanent and temporary loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 170 acres (1.9%) of permanent loss and 104 acres of temporary impact;
- Alternative 3 – 145 acres (1.6%) of permanent loss and 113 acres of temporary impact;
- Alternative 4 – 148 acres (1.7%) of permanent loss and 100 acres of temporary impact;
- Alternative 5 – 161 acres (1.8%) of permanent loss and 120 acres of temporary impact;
- Alternative 6 – 139 acres (1.6%) of permanent loss and 113 acres of temporary impact; and
- Alternative 7 – 63 acres (0.7%) of permanent loss and 130 acres of temporary impact.

The permanent loss of suitable habitat for coyote and bobcat n the Project area would be similar for Alternatives 2 through 6 in relation to the total available habitat, ranging from 1.6% for Alternative 6 to 1.9% for Alternative 2. Alternative 7 would have the smallest permanent direct impact at 0.7%. Temporary impacts would be similar under all of alternatives.

Both the coyote and bobcat have wide geographic distributions. The coyote is common and adaptable to urban settings. The bobcat is less common than the coyote, but is still relatively common where there is suitable habitat. Because both species would persist on site in the large open space system and because they are common and have broad geographic ranges, direct loss of habitat resulting from implementation of the RMDP and indirect impacts would be adverse but not significant under Alternatives 2 through 7.

Because these species are highly mobile, they would be expected to leave and/or avoid construction zones. It is unlikely that RMDP construction activities would result in direct harm to or mortality of adults, although flushed individuals would be at higher risk of injury or mortality from vehicle collisions. In addition, both the bobcat and coyote may den in the RMDP project area and, therefore, construction activities may cause them to abandon dens and expose young to injury or mortality. Both the bobcat and coyote are still common and have wide geographic ranges and will persist on site and adjacent undeveloped habitat. Therefore impacts to individuals, including disturbance of a natal den, would be adverse but not significant under Alternatives 2 through 7.

Implementation of the SCP would not directly impact these species.

Indirect Impacts

The build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would result in injury and mortality to coyotes and bobcats and the permanent loss of their habitat as a result of vegetation clearing and grading under Alternatives 2 through 7, as follows:

- Alternative 2 – 2,116 acres (23.7%) of permanent loss;
- Alternative 3 – 1,984 acres (22.2%) of permanent loss;
- Alternative 4 – 1,913 acres (21.4%) of permanent loss;
- Alternative 5 – 1,861acres (20.8%) of permanent loss;
- Alternative 6 – 1,678 acres (18.8%) of permanent loss; and
- Alternative 7 – 1,549 acres (17.3%) of permanent loss.

Indirect impacts to habitat for the coyote and bobcat would be progressively smaller for each successive alternative, but would still be substantial under each alternative. However, both species are still common and have wide geographic ranges. Further, there would still be substantial habitat remaining for these species in the Project area in the High Country SMA, Salt Creek area, and River Corridor SMA, as well as undeveloped adjacent habitat. These species would persist in the Project vicinity. Therefore, indirect impacts to individuals and habitat resulting from build-out of the Specific Plan, VCC

(Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

As noted above, adults of these species are mobile enough to escape from the direct effects of construction and/or grading activities, but young in dens could be affected and flushed adults would be more vulnerable to vehicle collisions. However, because both the coyote and bobcat would persist on site in the large open space system and because they are common and have widespread geographic ranges, indirect impacts to individuals resulting from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would be adverse but not significant under Alternatives 2 through 7.

Secondary Impacts

Short-term secondary impacts associated implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas include nighttime illumination, noise, and human presence during construction activities. However, bobcats and coyotes typically forage and move at night, and alterations of foraging or movement behaviors outside the construction zones are expected to be minimal, except where lighting may spill into habitat.

Long-term secondary impacts associated with urban development would be variable. Both the bobcat and coyote would be expected to use the three large preserved open space areas—the High Country SMA, Salt Creek area, and River Corridor SMA—for movement through the Project vicinity after build-out. Because coyotes are urban-adapted, they would continue using the constrained linkages, including Potrero Canyon, San Martinez Grande Canyon, Chiquito Canyon, Long Canyon, and Castaic Creek. Bobcats also would use these linkages as long as adequate vegetative cover is provided, and both species would use both culverts and bridge openings along the drainages.

Other long-term secondary impacts that could affect coyotes and bobcats include nighttime illumination of areas adjacent to open space, which could disrupt foraging and movement behavior; increased vehicle collisions at new and expanded roadways; increased encounters with humans and pet, stray, and feral dogs (cats are not capable of preying on these animals or their young, due to their relative size and/or ferocity); and the use of rodenticides to control small mammals (*e.g.*, ground squirrels and rabbits, which are prey for bobcats and coyotes), which may reduce the prey populations and possibly cause secondary poisoning of predators.

Although both short-term construction-related and long-term secondary impacts from build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas are expected to occur, because the coyote and bobcat are still common and have widespread distributions, and will persist in the large open space area comprising the

River Corridor SMA, High Country SMA, and Salt Creek area, these secondary impacts would be adverse but not significant under Alternatives 2 through 7.

Mitigation Strategy and Summary

All direct, indirect, and secondary impacts to the common Mammal – High Mobility guild species (coyote and bobcat) were determined to be adverse but not significant and, therefore, no mitigation is required. However, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to these species. These mitigation measures include habitat preservation, restoration, enhancement, and management of upland and riparian habitat areas in the River Corridor SMA, High Country SMA, and Salt Creek area that will form a large, contiguous open space system that supports the common species in this guild. Riparian and coastal scrub restoration and enhancement, for example, will provide additional cover for bobcats and coyotes. It is expected that these species will persist in these areas after build-out of the Project area. The set-aside of lands also will reduce short-term secondary effects, such as increased noise, lighting, and increased human activity during construction because individuals will have access to denning and foraging habitat in undisturbed open space. Mitigation measures also include biological monitoring during construction, and controls on lighting. Long-term effects, such as habitat degradation; increased human activity; pet, stray, and feral dogs; lighting; and rodenticides will also be mitigated through a variety of measures. The key mitigation measures that will reduce impacts to Mammal – High Mobility guild species are listed in **Table 4.5-48.**

Table 4.5-48
Applicable Mitigation Measures for Impacts to the Mammal – High Mobility Guild

Mitigation Measure(s)	Issue(s) Mitigating
BIO-52 (pre-construction educational meetings, construction-limit staking, and biological monitoring during vegetation clearing and grading activities)	Short-term construction-related impacts from increased human activity and inadvertent injury or mortality to individuals and impacts their habitat.
SP-4.6-1 through SP-4.6-16, SP-4.6-63 (habitat restoration/enhancement in the River Corridor SMA, which includes terrestrial habitats) SP-4.6-17 (standards for trail design and limitations on human and pet access to the River Corridor SMA) SP-4.6-18 and SP-4.6-19 (transition areas along the River Corridor SMA) SP-4.6-21 through SP-4.6-26 (open space dedication of the River Corridor SMA) SP-4.6-27 (removal of grazing and enhancement of riparian habitat in the High Country SMA) SP-4.6-30 through SP-4.6-32 (pet, public access, and recreational use restrictions in High Country SMA) SP-4.6-36 through SP-4.6-42 (open space dedication of the	Loss, fragmentation, and degradation of habitat. Long-term secondary effects of non-native plant species, and increased human and pet activity.

Table 4.5-48
Applicable Mitigation Measures for Impacts to the Mammal – High Mobility Guild

Mitigation Measure(s)	Issue(s) Mitigating
River Corridor SMA and the High Country SMA) BIO-1 through BIO-16, BIO-22 (wetlands mitigation plan and riparian and oak restoration activities on the Project site) BIO-19 (dedication of the Salt Creek area to the public and enhancement of existing agricultural undercrossing at SR-126) BIO-20 (preservation of approximately 1,900 acres of coastal scrub on site) BIO-21 (restoration/enhancement of coastal scrub in the High Country SMA, Salt Creek area, and River Corridor SMA) BIO-69 (trail signage and homeowner education regarding sensitive resources in preserved natural areas)	
SP-4.6-56 (downcast lighting design along boundaries of natural areas)	Control of lighting impacts to nocturnal reptiles during construction and over the long term due to development.
BIO-59 (signage indicating road crossings for mule deer and mountain lion)	Reduce vehicle collisions at high-frequency crossings.
BIO-63 (control of pet, stray, and feral cats and dogs in or near open space areas)	Harassment and predation of slow-moving reptiles.
BIO-64 (develop an IPM plan that addresses pesticide use)	Long-term effect of rodenticides.

4.5.5.2.3.5 *Impacts to Special-Status Plant Species*

This subsection provides a general overview of impacts to special-status plant species that would occur as a result of implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 2 through 7. This general overview of impacts includes direct and indirect permanent loss, direct temporary loss, and secondary impacts. **Subsection 4.5.5.3**, Impacts to Special-Status Species, provides a more detailed species-by-species analysis, makes impact significance determinations, and identifies mitigation measures that would reduce significant impacts to a level less than significant.

As described in **Subsection 4.5.5.1**, Impact Analysis Approach, direct impacts would occur as a result of implementation of the RMDP and SCP and include the temporary disturbance and/or permanent loss of special-status plant species. Indirect impacts would occur as a result of build-out of the Specific Plan, VCC, and Entrada planning areas and would be permanent. The temporary disturbance and/or permanent impacts discussed here represent the absolute physical loss of individuals of a special-status plant species. As also described in **Subsection 4.5.5.1**, Impact Analysis Approach, for special-status plant species, loss of individuals is reported as the loss of individuals, loss of acreage of mapped plant population polygons, or acreage of habitat in which the species occurs, as applicable. As described in **Subsection 4.5.5.1**, Impact Analysis Approach, secondary impacts are those reasonably foreseeable effects caused by Project implementation, including implementation of the RMDP and SCP (direct) and build-out of the Specific Plan, VCC, and Entrada planning areas (indirect) on remaining or adjacent biological resources outside the construction disturbance zone. Secondary impacts include short-term effects immediately related to construction activities and long-term or chronic effects related to the human occupation of developed areas.

As described in **Subsection 4.5.3.2.2**, Botanical Surveys, polygons for SFVS were mapped with a GPS unit. Oak trees within the portions of the study area (including a 200-foot buffer) where development would occur were mapped with a GPS unit. The number of oak trees to be preserved within protected areas (*e.g.*, High Country and River Corridor SMAs, and the Salt Creek area) was estimated based on aerial photo interpretation and evaluated in the field *via* a sampling protocol and later statistically analyzed for population estimates. Other special-status species were mapped utilizing aerial photography and topographic maps, with the exception of CNPS List 4 species, which were considered to have a relatively low sensitivity level and were not mapped. These data were imported into a GIS database for analysis and the development of maps and graphics. The locations of the following special-status plant species were mapped: SFVS, slender mariposa lily, Plummer's mariposa lily, late-flowered mariposa lily, undescribed everlasting, undescribed sunflower, Ojai navarretia, and oak species. The locations of the following lower-sensitivity species were not mapped: southern California black walnut, southwestern spiny rush, oak-leaved nemophila, mainland cherry, island mountain mahogany, Parish's sagebrush, and Peirson's morning-glory.

The number of individual SFVS plants on site varies considerably from year to year. Potential impacts to this species are therefore primarily evaluated in terms of the loss of cumulative area occupied by SFVS mapped between 2002 and 2007, rather than by the number of individuals (**Table 4.5-49**).

Table 4.5-49
Permanent Direct Loss of Cumulative Area for SFVS Due to Implementation of the SCP for Alternatives 2 through 7 (Acres)

Alternative	2	3	4	5	6	7
Total cumulative occupied acres lost	6.36	4.54	3.53	3.18	2.32	0.36

Table 4.5-50 provides a summary of the remaining special-status plant species whose locations were mapped that would be lost as a result of the implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas for Alternatives 2 through 7.

Table 4.5-51 provides a summary of those special-status plant species whose locations were not mapped and whose suitable habitat would be lost as a result of the implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas for Alternatives 2 through 7. **Table 4.5-51** also includes the cumulative occupied area for slender mariposa lily.

[1] Permanent loss of suitable habitat for island mountain-mahogany, Peirson's morning-glory, slender mariposa lily, oak-leaved nemophila, and mainland cherry includes suitable habitat within both the permanent and temporary footprints, as these species occur primarily in non-jurisdictional (CDFG/Corps) upland vegetation communities.

[2] Permanent and temporary loss of suitable habitat are described for Parish's sagebrush and southwestern spiny rush, as these species occur primarily in jurisdictional (CDFG/Corps) riparian vegetation communities.

Direct Impacts

For special-status plant species for which number of individuals and/or occupied polygons and locations were mapped, impacts are assessed by loss of individuals. Implementation of the RMDP and SCP under Alternatives 2 through 7 would result in the direct permanent loss of documented SFVS, slender mariposa lilies, undescribed everlasting, and oak trees, including heritage oaks as defined by CLAOTO (County of Los Angeles 1988); and no direct temporary loss of any of the four (**Table 4.5-50**, Direct Loss (within Both the Permanent and Temporary Footprints) of Special-Status Plant Species for Alternatives 2 through 7). Impacts to slender mariposa lily were also calculated by cumulative occupied area, in addition to number of individuals (**Table 4.5-51,** Permanent and Temporary Loss of Suitable Habitat (or Cumulative Occupied Area where Noted) for Special-Status Plant Species). Implementation of Alternatives 2 through 7 would result in successively fewer direct impacts to SFVS as with each successive alternative, additional spineflower preserve acreage would be dedicated at the spineflower populations compared to Alternative 2, and a spineflower preserve would be established within the VCC planning area.

For slender mariposa lily, direct impacts under Alternatives 2 through 5 are similar in terms of number of individuals and cumulative occupied area lost as this species is associated with uplands vegetation communities and the differences among the alternatives focuses on varying degrees of avoidance of riparian areas and SFVS occurrence areas. Under Alternative 7, implementation of the RMDP and SCP would result in a decrease in permanent direct impacts to slender mariposa lily due to reduced grading within Lion Canyon.

For oak trees, direct permanent impacts under Alternatives 2 through 7 would not be substantially different in terms of number of individuals lost as this species is associated with uplands vegetation communities and upper terraces along the Santa Clara River, and the differences among the alternatives focus on varying degrees of avoidance of riparian areas and SFVS occurrence areas.

For special-status plant species whose locations were not mapped as individuals or occupied polygons, impacts are assessed in terms of acreage of suitable habitat impacted (**Table 4.5-51**, Permanent and Temporary Loss of Suitable Habitat (or Cumulative Occupied Area where Noted) for Special-Status Plant Species). Implementation of the RMDP and SCP under Alternatives 2 through 7 would result in the direct permanent loss of suitable habitat for the following special-status plant species: island mountain-mahogany, Peirson's morning-glory, southwestern spiny rush, Parish's sagebrush, oak-leaved nemophila, and mainland cherry. Permanent loss of suitable habitat for island mountain-mahogany, Peirson's morning-glory, oak-leaved nemophila,

and mainland cherry includes suitable habitat within both the permanent and temporary footprints, as these species occur primarily in non-jurisdictional (CDFG/Corps) upland vegetation communities. The non-jurisdictional (CDFG/Corps) temporary disturbance areas would not all be restored to the same vegetation community associations and alliances as currently present, but they would be restored as part of channel reconstruction and would be converted to native riparian and upland vegetation communities, which may include non-jurisdictional (CDFG/Corps) upland vegetation communities at higher elevations along the channel banks. Implementation of the RMDP would result in the temporary loss of suitable habitat for the following special-status plant species: southwestern spiny rush and Parish's sagebrush. Permanent and temporary loss of suitable habitat are described for Parish's sagebrush and southwestern spiny rush, as these species occur primarily in jurisdictional (CDFG/Corps) riparian vegetation communities. Temporary disturbance areas in jurisdictional (CDFG/Corps) riparian vegetation communities would be restored to the same vegetation community associations and alliances as currently present, including the native species components (such as Parish's sagebrush and southwestern spiny rush) of the existing communities.

In general, the direct permanent and temporary loss of suitable habitat for these species under Alternatives 2 through 6 is substantially the same. Under Alternative 7, the direct permanent loss of potential habitat is generally reduced, compared to Alternatives 2 through 6. Under Alternative 7, the direct temporary loss of suitable habitat is generally less, compared to Alternatives 2 through 6 for southwestern spiny rush. Both these increases in direct temporary impacts and decreases in direct permanent impacts can be attributed to pulling back the RMDP development footprint from the Santa Clara River and associated tributaries under Alternative 7. Under Alternative 7, the direct temporary loss of suitable habitat is generally greater, compared to Alternatives 2 through 6 for Parish's sagebrush. This is also due to pulling back the RMDP development footprint from the Santa Clara River and associated tributaries under Alternative 7, resulting in increased temporary disturbance to big sagebrush scrub located adjacent to the Santa Clara River and its tributaries.

Implementation of the proposed RMDP and SCP would not result in the direct permanent or temporary direct loss of the 27 acres of mapped California walnut woodland on site. Individual southern California black walnut trees are uncommon in other vegetation communities, but implementation of the RMDP is expected to result in the removal of occasional individual southern California black walnut trees that exist in vegetation communities other than California walnut woodland.

Individuals of these species would be directly harmed during construction activities such as vegetation clearing and/or grading activities. These impacts to special-status species and applicable mitigation measures are discussed fully in **Subsection 4.5.5.3**.

Indirect Impacts

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in the indirect permanent loss of documented slender mariposa lilies and oaks, including heritage oaks as defined by CLAOTO (County of Los Angeles 1988). Build-out of the Specific Plan, VCC, and Entrada planning areas would not result in any additional indirect impacts to SFVS compared to the direct impacts described above.

For slender mariposa lily, indirect impacts under Alternatives 2, 3, 4, and 6 are similar in terms of number of individuals lost, as this species is associated with uplands vegetation communities and the differences among the alternatives focuses on varying degrees of avoidance of riparian areas and SFVS occurrence areas. Under Alternatives 5 and 7, permanent indirect impacts to slender mariposa lily individuals would be substantially less because of an increase in size of the spineflower preserve areas. Additionally, no development would occur within the VCC planning area under Alternatives 4 through 7. Permanent indirect impacts to slender mariposa lily cumulative occupied area generally decrease from Alternative 2 through Alternative 7, due to successively reduced project footprints and an increase in size of the spineflower preserve areas (Alternative 6 provides the greatest area of spineflower preserves, which also benefits the slender mariposa lily).

For oak trees, indirect permanent impacts under Alternatives 3 through 7 would be reduced compared to Alternative 2. The reduced impacts would be due to successively greater pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions that would reduce impacts to oak trees, which are primarily associated with uplands vegetation communities and upper terraces along the Santa Clara River. Additionally, no development would occur within the VCC planning area under Alternatives 4 through 7.

Under Alternatives 2 and 3, indirect permanent impacts would result in the loss of 350 undescribed everlasting individuals within the VCC planning area. Because no development would occur at the VCC planning area under Alternatives 4 through 7, there would be no permanent indirect impacts to undescribed everlasting plants under these alternatives. It should be noted, however, that because the undescribed everlasting is a floodplain species, the location of individuals may change prior to construction commencement.

For special-status plant species whose locations were not mapped by individuals or occupied polygons, impacts are assessed in terms of acreage of suitable habitat impacted. Indirect impacts would result in the loss of suitable habitat for the following special-status plant species: island mountain-mahogany, Peirson's morning-glory, southwestern spiny rush, Parish's sagebrush, oak-leaved nemophila, and mainland cherry.

In general, indirect permanent loss of suitable habitat for these species due to build-out of the Specific Plan, VCC, and Entrada planning areas manifests a general trend of reduction in loss, successively from Alternative 2 to Alternative 7. This is primarily due to an increase in the size of the spineflower preserve areas. Additionally, no development would occur within the VCC planning area under Alternatives 4 through 7.

Build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 2 through 7 would not result in the indirect permanent loss of the 27 acres of mapped California walnut woodlands on site. However, Project implementation is expected to result in the loss of individual southern California black walnut trees that exist in vegetation communities other than California walnut woodlands.

As described above for direct impacts, individuals of these species would be directly harmed during construction activities such as vegetation clearing and/or grading activities. These impacts to special-status species and applicable mitigation measures are discussed fully in **Subsection 4.5.5.3.3**.

Secondary Impacts

Secondary impacts are those reasonably foreseeable effects to biological resources located outside the construction disturbance zone and caused by Project implementation on remaining or adjacent biological resources. Secondary impacts include short-term effects immediately related to construction activities and long-term or chronic effects related to the human occupation of developed areas. Both implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would result in short-term construction-related secondary impacts and long-term secondary impacts under Alternatives 2 through 7.

Short-Term Secondary Impacts (RMDP/SCP and Specific Plan/VCC/Entrada). Short-term secondary impacts that could occur to special-status plants species as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternatives 2 through 7 include the following:

Hydrologic Alterations and Water Quality Impacts. Construction of RMDP facilities, including bank stabilization, construction of bridges and associated piers and abutments, and construction of drainage culverts could result in hydrologic and water-quality-related impacts adjacent to and downstream of the impact area. Hydrologic alterations include changes in flow rates and patterns in streams and rivers, and dewatering that may affect adjacent and downstream aquatic, wetland, and riparian vegetation communities and their associated plant species. Potential water quality impacts include exposure to chemical and toxic compound pollution (fuel, oil, lubricants, paints, release agents, and other construction materials), erosion, increased turbidity, and excessive sedimentation.

Proposed development can also remove native vegetation and increase runoff from roads and other paved surfaces, resulting in increased erosion and transport of surface matter into known special-status plant populations. Altered erosion, increased surface flows, and underground seepage may lead to the establishment of non-native plants. Changed hydrologic conditions can also alter seed bank characteristics and modify habitat for ground-dwelling fauna. Short-term hydrologic alterations and water quality impacts due to implementation of the RMDP and SCP under Alternatives 2 through 7 would potentially affect the undescribed everlasting, undescribed sunflower, Peirson's morning-glory, southwestern spiny rush, Parish's sagebrush, southern California black walnut, oak trees, and mainland cherry. Short-term hydrologic alterations and water quality impacts due to build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7 would potentially affect SFVS, slender mariposa lily, undescribed everlasting, undescribed sunflower, island mountain-mahogany, Peirson's morning-glory, southwestern spiny rush, Parish's sagebrush, oak-leaved nemophila, southern California black walnut, oak trees, and mainland cherry.

Erosion and Chemical and Toxic Compound Pollution. Erosion and chemical pollution (fuel, oil, lubricants, paints, release agents, and other construction materials) may affect riparian and upland special-status plant species. The use of chemical pollutants during the development stage can decrease the number of plant pollinators, increase the existence of non-native plants, and can cause damage and destruction of native plants. Erosion and chemical pollution due to implementation of the RMDP and SCP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7 would potentially affect SFVS, slender mariposa lily, undescribed everlasting, undescribed sunflower, island mountain-mahogany, Peirson's morning-glory, southwestern spiny rush, Parish's sagebrush, oak-leaved nemophila, southern California black walnut, oak trees, and mainland cherry.

Dust. Excessive dust can decrease the vigor and productivity of plant communities, through effects on light, penetration, photosynthesis, respiration, transpiration, increased penetration of phytotoxic gaseous pollutants, and increased incidence of pests and diseases. Impacts due to dust from implementation of the RMDP and SCP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7 would potentially affect SFVS, slender mariposa lily, undescribed everlasting, undescribed sunflower, island mountain-mahogany, Peirson's morning-glory, southwestern spiny rush, Parish's sagebrush, oak-leaved nemophila, southern California black walnut, oak trees, and mainland cherry.

Accidental Clearing, Trampling, or Grading. Accidental clearing, trampling, or grading of vegetation communities outside designated construction zones may occur during

construction. These effects can damage individual special-status plants and alter their ecosystem, creating gaps in vegetation that allow exotic, non-native plant species to become established, increasing soil compaction and leading to soil erosion. Accidental clearing, trampling, or grading due to implementation of the RMDP and SCP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7 would potentially affect SFVS, slender mariposa lily, late-flowered mariposa lily, undescribed everlasting, undescribed sunflower, island mountain-mahogany, Peirson's morning-glory, southwestern spiny rush, Parish's sagebrush, oak-leaved nemophila, southern California black walnut, oak trees, and mainland cherry.

***Oak Tree Root Impacts*.** Oak tree root systems may be affected during construction due to soil compaction, pollutants, or toxic compounds. Implementation of the RMDP and SCP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7 may result in root impacts to oak trees.

Long-Term Secondary Impacts (RMDP/SCP and **Specific Plan/VCC/Entrada).** The following long-term secondary impacts could occur to special-status plant species as a result of build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas under Alternatives 2 through 7, and would potentially affect SFVS, slender mariposa lily, undescribed everlasting, undescribed sunflower, island mountain-mahogany, Peirson's morning-glory, southwestern spiny rush, Parish's sagebrush, oak-leaved nemophila, southern California black walnut, oak trees, and mainland cherry.

***Invasive Plant Species*.** Invasive plant species that thrive in edge habitats are a well-documented problem along the open space–urban interface in southern California as well as throughout the United States. The California Invasive Plant Council (Cal-IPC 2008) lists several adverse effects of non-native species in natural open space areas, including: non-native plants degrade wildlife habitat value (*e.g.*, by forming monocultures that displace native communities that provide food and shelter for native wildlife) and are considered to be the greatest threat to threatened and endangered species after habitat destruction; certain invasive plants can increase fuel loads compared to native plants and facilitate more frequent and catastrophic fires; and some invasive plants (*e.g.*, giant reed and tamarisk) consume enormous amounts of water that is lost to native plants and wildlife.

The introduction of non-native plants poses a significant threat to special-status plant species. Exotic (non-native) plants compete for light, water, and nutrients and can create a thatch that blocks sunlight from reaching smaller native plants. The successful invasion

of exotic plant species may alter habitats and displace native species over time, leading to extirpation of native plant species.

Non-native species have been found to invade and become established after repeated burnings, clearing of vegetation for fire protection, or following periods of drought and overgrazing—possible side effects of nearby human habitation. Exotic plants can alter hydrologic and biochemical cycles, disrupt natural fire regimes, and alter soil fertility within and adjacent to urban development. Development would also potentially fragment native plant populations, which could increase the likelihood of invasion by exotic plants due to the increased "edge," or interface, between natural habitats and urban areas.

Invasive plant species, and especially upland species, are often treated as an edge effect because they generally colonize modified or otherwise disturbed zones between development and natural open space areas. However, invasive species can colonize virtually any upland natural area that is subject to some kind of disturbance, such as road shoulders, cleared zones along railroad lines, clearing along utility easements, excessive fire, fire breaks, and grazing. Many species, like black mustard (*Brassica nigra*) and non-native annual grasses of Mediterranean origin (*e.g.*, *Bromus* spp., *Hordeum* spp., and *Avena* spp.) have become naturalized to the point that they are beyond realistic control measures at a landscape level. Currently, the main risk to upland areas by these species is the high frequency of fires in the region that could result in permanent transitions of coastal scrub and chaparral to annual grassland.

Riparian and wetland systems are also extremely vulnerable to invasive plants, such as giant reed (*Arundo donax*), tamarisk (*Tamarix* spp.), and pampas grass (*Cortaderia* sp.) because of the highly effective transport of these along rivers and streams. These species can dominate the biomass of riparian and wetlands communities where they become established, virtually choking out the native vegetation.

An increase in invasive plant species due to implementation of the RMDP and SCP under Alternatives 2 through 7 would potentially affect SFVS, slender mariposa lily, late-flowered mariposa lily, undescribed everlasting, undescribed sunflower, island mountain-mahogany, Peirson's morning-glory, southwestern spiny rush, Parish's sagebrush, oak-leaved nemophila, southern California black walnut, oak trees, and mainland cherry.

Increased Human Activity. Implementation of the RMDP would result in the permitted recreational use of trails in the High Country SMA by humans and their pets. This would result in the potential for unauthorized impacts, including trespassing, vandalism, motorized and non-motorized off-road vehicles, trampling of vegetation, and soil compaction. These impacts under Alternatives 2 through 7 would potentially affect slender mariposa lily and late-flowered mariposa lily.

Non-Native, Invasive Animal Species. The introduction of non-native, invasive animal species could negatively affect native species that may be pollinators of or seed dispersal agents for special-status plant species.

Vegetation Clearing. When native vegetation is cleared for fire protection or for the creation of roads or trails, non-native plant species may colonize gaps or bare areas. Clearing also causes local changes in wind, solar radiation and light exposure, and water that may have substantial effects on native vegetation (Saunders *et al.* 1991).

Trampling and Compaction of Soils. Increases in human activity along the open space–urban interface may result in trampling of vegetation and compaction of soils, affecting the viability of plant communities. Trampling can damage individual special-status plants and alter their ecosystem. Trampling can also create gaps in vegetation, allowing exotic, non-native plant species to become established. It can increase soil compaction and it can lead to soil erosion. Trampling of vegetation and compaction of soils probably also interacts with the microclimate/microhabitat alterations, discussed in Vegetation Clearing above, especially water alterations and related effects at habitat edges, such as changes in the rate of rainfall interception and evapotranspiration, soil moisture, water penetration pathways, surface flows, and erosion.

Altered Hydrology. Increased urban and stormwater runoff due to the increase in impervious surfaces from build-out of the Project area may result in long-term hydrologic alterations, including increased runoff volume, increased peak flow rates, increased duration of flows, and altered patterns in streams and rivers. Groundwater levels may be affected as a result of interference with groundwater recharge that could cause a deficit in aquifer volumes or lowering of the local groundwater table. These hydrologic alterations may affect adjacent and downstream riparian vegetation and associated special-status plant species.

Proposed development can also result in an increase in ornamental landscaping and lawns, which ultimately lead to increased irrigation and thus, increased erosion. Increased surface flows and underground seepage can allow for the establishment of non-native plants and invasion by Argentine ants.

Chemical Pollutants. The use of chemical pollutants by residents of new development may directly affect vegetation communities and habitat quality, may be directly toxic to species, may be indirectly toxic through prey vectors, can decrease the number of plant pollinators, and can increase the existence of non-native plants. These substances may penetrate the open space–urban interface through urban runoff from residential and commercial landscape areas and golf courses, overspray, wind, direct applications in interface areas, soil penetration, and wildlife vectors. Specifically, herbicide use can cause fragmentation of native plant populations, and insecticide use can result in

pollution drift. Fertilizers, especially nitrogen-rich fertilizers, can promote the growth of non-native species, to the detriment of native species not adapted to high nitrogen environments and/or that are unable to compete with non-native species.

Increased Fire Frequency/Extent/Intensity. Urbanization alters natural wildfire regimes in terms of frequency, extent, and intensity. These types of fire regime alteration can drastically affect plant communities. As stated in **Subsection 4.5.5.1**, longer-than-natural fire intervals can result in excessive buildup of fuel loads, so that when fires do occur, they are catastrophic. Unnaturally long fire intervals can also result in senescence of plant communities, such as chaparral, that rely on shorter intervals for rejuvenation. Shorter-than-natural fire return intervals can preclude recovery of the native vegetation between fires, weaken the ecological system, allow for invasion of exotic species, and in some cases, result in permanent transitions of the vegetation to non-native communities, such as annual grassland and weedy communities (*e.g.*, Malanson and O'Leary 1982; Keeley 1987; O'Leary *et al.* 1992).

Human Collection and Harassment of Native Species. An increased human population increases the risk for the collection of and damage to special-status plant species.

INTENTIONALLY LEFT BLANK

4.5.5.2.4 Impacts to Wildlife Movement and Habitat Connectivity

Subsection 4.5.5.2.3.4, Impacts to Common Wildlife, analyzed the direct, indirect, and secondary impacts of the proposed Project on general wildlife in the context of 14 wildlife guilds. The guild organization can also be used to discuss impacts to the relative abilities of the species in the different guilds to move through the landscape, and in particular through wildlife crossings, corridors, and linkages. Species in these guilds can then be discussed in the context Project impacts and of a post-development open space system. The guild organization used **Subsection 4.5.5.2.3.4** is slightly modified here to reflect issues related to wildlife movement through the landscape. For this reason, some of the guilds that were separated by habitat association or taxonomic group above are consolidated here because the habitat connectivity and movement considerations are similar. For the purpose of this analysis the wildlife guilds are consolidated as shown in **Table 4.5-52** with a cross-walk to the original 14 guilds. As noted in **Subsection 4.5.5.2.3.4**, assigning special-status species to guilds necessarily results in species generalizations in the context of the broader guild, and habitat requirements and potential impacts related to a particular species may not be applicable to the guild as a whole. **Subsection 4.5.3.3**, Impacts to Special Status Species provides more detailed species-specific analyses.

The impact analysis of wildlife movement and habitat connectivity provided in this subsection is divided into four elements:

1. Background information for each guild to provide the basis for the wildlife movement and habitat connectivity analysis (**Subsection 4.5.5.2.4.1**);
2. Impacts to landscape-scale habitat linkages resulting from Alternative 2 and a summary of the similarities and differences, if any, for Alternatives 3 through 7 (**Subsection 4.5.5.2.4.2**);
3. Impacts to wildlife corridors resulting from Alternative 2 and a summary of the similarities and differences, if any, for Alternatives 3 through 7 (**Subsection 4.5.5.2.4.3**); and
4. Impacts to wildlife crossings resulting from Alternative 2 and a summary of the similarities and differences, if any, for Alternatives 3 through 7 (**Subsection 4.5.5.2.4.4**).

The impact analysis of wildlife movement and habitat connectivity differs in format from the previous impact analyses where impacts were separately categorized as direct loss of habitat and direct impacts to individuals, indirect loss of habitat and indirect impacts to individuals, and secondary impacts. A more qualitative and holistic approach is applied to wildlife movement and habitat connectivity because impacts at the landscape scale, local corridor scale, and crossing scale area resulting from implementation of the RMDP and build-out of the Specific Plan, VCC,

and Entrada planning areas are interrelated and interactive. For example, the effectiveness of a culvert or bridge crossing for wildlife constructed as part of the RMDP will also depend on indirect effects of the build-out at that location. If Specific Plan build-out would constrain a particular wildlife corridor (*e.g.*, Exxon Canyon) and limit its use to coyotes, for example, analyzing a culvert in this constrained corridor in the context of mountain lion movement would irrelevant. For this reason, all impacts are discussed together in the context of the combined effects of the RMDP/SCP and build-out of the Specific Plan, VCC, and Entrada planning areas.

High Mobility Aerial	Bat Bird – Riparian Bird – Upland Woodland Bird – Upland Grassland Bird – Raptors Insect (Monarch Butterfly)[1]
Moderate Mobility Aerial	Bird – Upland Scrub and Chaparral Insect (San Emigdio Blue Butterfly)

[1] The Insect (Monarch Butterfly) was not part of the general wildlife guild analysis conducted in **Subsection 4.5.5.2.3.4**, but is included here because this special-status species has been observed on site.

4.5.5.2.4.1 *Habitat Connectivity and Wildlife Movement Background Information by Guild*

The background discussions for habitat connectivity and wildlife movement for each of the consolidated guilds are relatively brief and intended to provide the context for the impact analyses presented in the following subsections. A more complete discussion of these topics as applied to these guilds is provided in **Appendix 4.5** (*Newhall Ranch Resource Management and Development Plan: Wildlife Habitat Buffers and Connectivity White Paper* (Dudek 2008C))).

Aquatic Guild. The consolidated Aquatic guild includes the Mollusk (the undescribed snail in the Middle Canyon Spring) and Fish guilds described in **Subsection 4.5.5.2.3.4**. Species in the Aquatic guild are entirely dependent on aquatic environments for their life

histories and those present in the Santa Clara River system could travel throughout the River during periods of continuous flow or be transported during flood events to downstream areas. Native fish species such as Santa Ana sucker, unarmored threespine stickleback, and arroyo chub are adapted to surviving typical southern California stream cycles of winter storm floods and reduced summer flows. These native fish may persist in aquatic refugia of backwaters, ponds, and shallow streams during the summer dry months, and repopulate wider areas after winter floods. Additionally, artificially persistent flows such as from wastewater treatment plant or fish hatchery outflows may sustain populations of these native fish (Swift *et al.* 1993), although under artificial flow conditions they may be more susceptible to impacts by non-native fishes that are adapted to more consistent hydrological conditions. Flow conditions that emulate the natural cyclical conditions are probably most conducive to maintaining the native fish populations. Impacts that potentially disrupt natural flows may impede movement by these species in the Project area.

Semi-Aquatic Guild. The consolidated Semi-Aquatic guild is the same as the Reptile and Amphibian – Semi-Aquatic guild described in **Subsection 4.5.5.2.3.4**. The Semi-Aquatic guild species rely on aquatic environments for a portion of their life histories, and therefore their distributions are generally limited to areas in proximity to aquatic environment sources, including streams, rivers, ponds, reservoirs, and ephemeral wetlands (*e.g.*, vernal pools). While both the arroyo toad and southwestern pond turtle are capable of long dispersal movements through terrestrial habitat between suitable aquatic sites (66 FR 9413–9474; Holland 1994), within the Project area, instream movements along the Santa Clara River and its major tributaries are probably most important for these species. Any suitable aquatic habitats within the Project area and immediate region can be reached directly by moving along the River corridor. Furthermore, there are no suitable aquatic habitat areas (*i.e.*, major tributary drainages or streams) within their overland dispersal capabilities (at least up to 5.0 miles along streambeds for the arroyo toad (66 FR 9413–9474) and 3.0 miles overland for southwestern pond turtles (Holland 1994)) and that could not be reached by moving along the River corridor.

Mammal – High Mobility Guild. The consolidated Mammal – High Mobility guild is the same as the Mammal – High Mobility guild described in **Subsection 4.5.5.2.3.4**. These species have in common that their spatial activity (*i.e.*, home ranges, movements related to foraging, seeking mates, and dispersal) extends beyond the boundaries of the Project area and thus need to be addressed at a regional landscape level. Bobcat, coyote, mule deer, and likely mountain lion include all or portions of the undeveloped portions of the Project area as part of their home ranges. The black bear probably does not include the Project area within its normal home range in the region, but may pass through the

High Country SMA and Salt Creek area within the Project area during dispersal movements between higher elevation forested habitat north and south of the area. Habitat linkages and corridors that function for the mountain lion, mule deer, and black bear would also be adequate for the coyote and bobcat

The canyons and creeks within the High Country SMA and Salt Creek area provide natural conduits for movement between the Santa Susana Mountains and the Santa Clara River corridor after development, as illustrated by Salt Creek–High Country linkage No. 3, shown in **Figure 4.5-31**. Additionally, the South Coast Missing Linkages Project's linkage design shown in **Figure 4.5-22** overlaps with the Salt Creek–High Country linkage. Mountain lions in the Santa Ana Mountains of southern California, for example, preferentially move along canyon bottoms and gently sloping terrain rather than ridgelines and steep terrain and they prefer riparian vegetation for diurnal use and nocturnal travel (Dickson and Beier 2006; Dickson *et al.* 2005). The Salt Creek–High Country linkage is a natural feature expected to provide corridors of movement and dispersal along the natural northwest–southeast alignment of the canyons not only for mountain lion, but also the other Mammal – High Mobility guild species. The mule deer is expected to use the rugged terrain throughout the High Country SMA and Salt Creek area.

The Santa Clara River Corridor SMA serves as a major east–west linear linkage to canyons and hills along the length of the River and provides far-reaching linkages to larger open space area north and south of the River. This linkage provides a 1,000-foot-wide to 2,000-foot-wide swath of riverine habitat that probably can meet the life history needs of the bobcat, coyote, and mule deer, and many smaller and less mobile species, and function as dispersal habitat for the mountain lion and black bear

SR-126 is a significant existing barrier to north–south movement by Mammal – High Mobility species. Even for species that readily cross busy highways, such as coyotes, the high volume of existing and future traffic on SR-126 at all hours makes it a very dangerous at-grade crossing for wildlife. For the primary crossings of SR-126 in Ventura County, there are existing large arched culverts that serve ranch agricultural operations, as shown in **Figure 4.5-32**. These culverts measure about 4.4 meters (14 feet, 7 inches) in height, 7.5 meters (25 feet) in width, and 51.8 meters (170 feet) in length, resulting in an openness factor of 0.65, which well exceeds the openness factor of 0.25 found by Donaldson (2005) to be adequate for white-tailed deer, and are therefore large enough to accommodate black bear, mule deer, and mountain lion (see discussion of openness factor in **Subsection 4.5.3.4.7**). Also, in Banff National Park in Alberta, Canada, for example, black bears used underpasses that ranged in size from approximately 14 to 44 feet in width, eight to 13 feet in height, and 84 to 319 feet in length (Clevenger and

Waltho 2000). Beier (1995) observed mountain lions using box culverts less than 15 by 15 feet to cross under freeways. Ruediger and DiGiorgio (2007) recommend similar dimensions for black bear and mountain lion as well as mule deer (see **Table 4.5-22** in **Subsection 4.5.3.4.7**). The South Coast Missing Linkages Project acknowledged the value of the Ventura County crossings at Camulos Ranch and Tapo Canyon, as well as several smaller drainage culverts (where bobcat tracks were observed), and commented about the Tapo Canyon structures as follows (Penrod *et al.* 2006, p. 91):

> These structures should be maintained and enhanced during the next transportation improvement project. We strongly recommend maintaining the wild character of this branch of the linkage, one of the last remaining areas where natural habitats are still contiguous between the Santa Susana Mountains and the Sierra Madre Ranges.

Mammal – Moderate Mobility Guild. The consolidated Mammal – Moderate Mobility guild is the same as the Mammal – Moderate Mobility guild described in described in **Subsection 4.5.5.2.3.4**. These species are capable of dispersing wider than the Project area but typically have home ranges that could be wholly contained within the Project area. With the exception of the raccoon, which adapts well to urban settings, it is important to maintain sufficient habitat for these species that is buffered from urban-related impacts (see **Subsection 4.5.5.1** discussion of secondary impacts), as well as regional connectivity to larger conservation areas important for population dispersal.

Species in the Mammal – Moderate Mobility guild tend to require suitable habitat for movement and dispersal and are generally limited in their ability, and thus less apt, to traverse unsuitable habitat. However, raccoons are an exception, because, like coyotes, they can and often do use urban areas. For this reason, the discussion of connectivity is primarily focused on the badger, gray fox, black-tailed jackrabbit, and long-tailed weasel.

Badgers may be considered intermediate between highly mobile and moderately mobile species. While they are capable of long-distance dispersal (Messick and Hornocker (1981) documented a juvenile dispersal event of 68 miles), badgers may be relatively sedentary within home ranges where resources are plentiful. Various studies have documented badger home ranges varying from 400 to 600 acres (Messick and Hornocker 1981) and as high as 74,000 acres (RISC 2007). Their distribution in a landscape coincides with the availability of prey, burrowing sites, and mates, with males ranging wider than females during the breeding and summer months (Minta 1993). In general, badger activity within a home range tends to concentrate in areas with suitable soils for burrowing or colonies of ground squirrels.

Gray fox home ranges are also variable. In Wisconsin, home ranges varied from approximately 32 to 766 acres; in Florida, home ranges averaged 1,900 acres; in Utah, home ranges averaged 247 acres; and in Davis, California, the average home range for four females was 296 acres (Zeiner *et al.* 1990B).

Black-tailed jackrabbits are capable of dispersing long distances, but typical dispersal distances may be relatively short. French *et al.* (1965) recorded most dispersal distances at less than 0.25 mile, but 18% of juveniles dispersed greater distances and one individual dispersed 28 miles in 17 weeks. Most seasonal movements involve short distances and may be related to food availability (Bronson and Tiemeir 1959). Home ranges of the black-tailed jackrabbit are also variable, but typically range from 49 to 346 acres (Best 1996). French *et al.* (1965), however, recorded ranges of only 40 acres in southeastern Idaho, while Smith (1990), using radiotelemetry, estimated home ranges in northern Utah of 247 to 741 acres. Smith (1990) also found that jackrabbits tend to shift their home range over time, with the shifts occurring gradually.

Long-tailed weasels are known to occupy home ranges varying from approximately 25 to 640 acres, depending on the condition of habitat (Zeiner *et al.* 1990B). Gehring and Swihart (2004) monitored 11 long-tailed weasels in habitat fragmented by agriculture in Indiana and found that females occupied home ranges of 128 ± 20 acres and males occupied home ranges of 445.5 ± 149 acres. Male–male home ranges do not overlap. During the breeding season, male ranges increase in size to overlap those of more females. Increased road kill of males has been observed in western Washington during the breeding season, indicating higher levels of roaming in search of mates (Buchanan 1987).

Species in the Mammal – Moderate Mobility guild are expected to inhabit the River Corridor SMA, High Country SMA, and Salt Creek area, collectively totaling 6,700 acres. These areas combined are large enough to support from a few (*e.g.*, badgers and gray foxes) to many individuals (black-tailed jackrabbits and long-tailed weasels) in the moderate mobility guild. Animals in this guild will most likely disperse through the open space by diffusion of populations, but also occasionally through long-distance dispersal events (*e.g.*, badger and black-tailed jackrabbit), allowing gene flow between connected open space areas. The dispersal capabilities of the gray fox and long-tailed weasel are unknown, but it is expected that long-range dispersal events are possible, but would be relatively uncommon. Rare or occasional long distance dispersal events would be possible *via* the natural habitat linkages that these open space areas provide. Canyons and creeks within the High Country SMA and Salt Creek area provide natural conduits for movement, particularly because the species in this guild are associated with shrublands, riparian, and wash environments. The low biological energy cost of

movement provided for by the canyons (*i.e.,* gentle terrain, good cover) makes these primary pathways for movement and dispersal. The River Corridor SMA will serve as the major linkage to canyons and hills along the length of the River and will provide a regional linkage to larger open space areas for species in this guild. The direct connection of the High Country SMA and Salt Creek area with the River Corridor SMA provides an important cross-linkage for this guild for moving from the higher elevations to and through the River corridor.

The main constraint on north–south movement of species in the Mammal – Moderate Mobility guild in the Project area and to adjacent open space areas is SR-126. As described above for the Mammal – High Mobility guild species, however, there are existing arched culverts that serve ranch agricultural operations, as depicted in **Figure 4.5-32**. Because, as described above for Mammal – High Mobility guild species, these culverts are large enough to accommodate black bear, mule deer, and mountain lion, they will be more than adequate for the smaller, moderate mobility guild species. The South Coast Missing Linkages Project (Penrod *et al.* 2006) also noted several smaller drainage culverts (where bobcat tracks were observed) and indicated that these smaller culverts are the best connection for species such as the badger. Similarly, Ruediger and DiGiorgio (2007) indicated that round and box culverts with dimensions of 36 inches are suitable for badger and weasel (see **Table 4.5-22** in **Subsection 4.5.3.4.7**). With these existing culverts, along with new culverts and bridges associated with improvements and new roads, connectivity for Mammal – Moderate Mobility guild species will be maintained.

Low Mobility Guild. The consolidated Low Mobility guild includes the Mammal – Low Mobility and Reptile – Low Mobility guilds described in **Subsection 4.5.5.2.3.4**. Low Mobility guild species are relatively sedentary (*i.e.,* have relatively small home ranges and limited dispersal capabilities) throughout their life cycle and depend almost continuously on available suitable habitat that meets virtually all of their life history needs. For instance, Bleich and Schwartz (1975) estimated desert woodrat (*Neotoma lepida*) male and female home ranges in northern San Diego County at 0.09 acre and 0.11 acre, respectively. Frank and Heske (1992) used radiotelemetry to study spatial patterns of southern grasshopper mouse in the Chihuahuan Desert of southeastern Arizona and estimated average home ranges of breeding males at 9.1 acres versus 4.2 acres for females. No specific dispersal data are available for the grasshopper mouse, but Stapp (1997) reported that most juveniles had disappeared from their study site by autumn. Some spatial data are available for special-status reptiles that occur in the Project area. Radiotelemetry of several dozen coast horned lizards in southern California locations over a five-year period documented annual home range sizes of approximately 3.0 to 3.5 acres, with the likelihood that, across years, home range areas could be larger (Suarez,

pers. comm. 2005). Anderson (1993) reported coastal western whiptail home ranges in California of 2.5 acres for males and 0.8 acre for females. Diffendorfer *et al.* (2005) studied movements by the rosy boa at four sites in San Diego and Riverside counties for up to four years. Movement (measured as estimated distance moved per day) by the rosy boa was characterized by frequent short distant movements and rare long distance movement events that primarily occurred in the spring. Short-distance movements per day were predominantly less than 33 feet per day. Rosy boa home ranges were relatively small, with a largest recorded home range of 3.7 acres after four years of cumulative data. Fitch (1975) found that ringneck snakes could still be located after a number of years within 33 feet of their initial capture point, indicating strong site tenacity. Some ranges for ringneck snakes in Kansas tended to be elongated, with maximum axes of 460 feet (Fitch 1975). In areas with large seasonal temperature fluctuations, there appears to be some seasonal movement between habitats, with average movements between summer habitats and hibernacula of approximately 394 feet (Fitch 1975; Parker and Brown 1974).

Species in the Low Mobility guild may be capable of inhabiting confined open areas such as drainages, narrow canyons, and even edge environments that would otherwise restrict larger wildlife as long as suitable habitat is available. Additionally, species in this guild are usually incapable of traversing unsuitable habitat or have difficulty doing so because certain elements of the landscape mosaic pose physical or behavioral barriers to their movement (*e.g.*, roads, vertical barriers such as fences, walls, curbs, large open spaces) and these species are not agile enough to overcome these barriers.

Because species in the Low Mobility guild generally have small home ranges and limited dispersal capabilities, they typically do not cross large open spaces or unsuitable habitat. Furthermore, movement across a large landscape containing suitable habitat is more likely to occur by diffusion over generations rather than by discrete, long distance movements between disjunct habitat patches by an individual (*i.e.*, jump dispersal). For this reason, suitable continuous habitat is considered necessary to maintain connections between local populations and provide for dispersal and genetic exchange. This guild is less likely to exhibit metapopulation dynamics characterized by local extirpation and colonization by relatively mobile species; if an isolated habitat patch loses a species in this guild, it is unlikely to be recolonized. Because these species have low mobility and require continuous suitable habitat, they are also susceptible to edge effects at the open space–urban interface along habitat connections and corridors, as described in **Subsection 4.5.5.1**. As a result, narrow, long wildlife corridors that may adequately function for quickly moving Mammal – High Mobility, and even Mammal – Moderate Mobility guild species, are likely to be less effective for Low Mobility guild species. Ideally, the "interior habitat" (*i.e.*, habitat relatively unaffected by edge effects) in the linkage should be large enough to contain a typical home range of the species. For a

hypothetical species with a circular home range of two acres, the interior habitat would have to be approximately 330 feet wide (*i.e.*, the diameter of the circle). Assuming that edge effects penetrate 200 feet into open space from the open space–urban edge, for the interior habitat to be relatively free of edge effects, the total width of a habitat linkage bound on both sides by development would have to be 730 feet.[1] For a desert woodrat with a typical home range of 0.11 acre (assuming a circular range), the interior habitat would have to be approximately 78 feet wide and habitat linkage would have to be 478 feet wide to avoid edge effects.

As with the Mammal – High Mobility and Mammal – Moderate Mobility guild species, SR-126 is probably the main existing constraint for north–south population diffusion of species in the Low Mobility guild. Movement mostly will be limited to areas with existing and future culverts under the highway. For most of the species, the culverts themselves probably would not be suitable habitat, and thus individuals would have to quickly move through them to gain access to suitable habitat north and south of the highway. Use of these culverts, however, will be species-specific, with some species likely using the culverts at a relatively high frequency and others at a low frequency or not at all. However, the habitat areas that will be preserved in open space, particularly south of the SR-126, will be large enough to support viable populations of the Low Mobility guild species even without exchange of individuals and genetic material across SR-126.

High Mobility Aerial Guild. The consolidated High Mobility Aerial guild includes the Bat guild and all the bird guilds except Bird – Upland Scrub and Chaparral, as described in **Subsection 4.5.5.2.3.4**. For the purpose of this discussion, it also includes one insect: the migratory monarch butterfly. The High Mobility Aerial guild is comprised of species capable of long-distance flight. These species may utilize one or more habitats within the Project area for certain life history requirement such as nesting, roosting, foraging, or overwintering. The key assumption for the High Mobility Aerial guild species is that their movement in the Project area would not be highly constrained by local landscape conditions such as unsuitable habitat, urban development, or roads as long as there are suitable habitat patches that meet their life history requirements.

Moderate Mobility Aerial Guild. The consolidated Moderate Mobility Aerial guild is the same as the Bird – Upland Scrub and Chaparral guild, as described in **Subsection 4.5.5.2.3.4**. Although some of the bird species in this guild are migrants and

[1] In reality, most species have irregularly shaped home ranges related to a number of factors, such as microhabitats and the distribution of resources within the home range and the location of other individuals.

may be highly mobile, most of the resident species are relatively sedentary and typically do not disperse long distances. For the purpose of this discussion, this guild also includes butterflies with moderate mobility such as the San Emigdio blue butterfly. Moderate Mobility Aerial guild species are typically year-round residents, and a relatively small geographic area may meet all their life history needs. Dispersal by Moderate Mobility Aerial guild species usually occurs through diffusion across the landscape over generations (*e.g.*, moving to available territories adjacent or in close proximity to their natal territory), where flight allows saltatorial or jump-dispersal movements between disjunct habitat patches. Dispersal events, however, may occasionally occur across relatively long distances and unsuitable habitat. The California gnatcatcher, for example, had mean dispersal distances of 0.65 mile in Orange County (Galvin 1998) and 1.7 to 2.0 miles for males and females, respectively, on the Palos Verdes Peninsula in Los Angeles County (Atwood *et al.* 1996). However, Galvin (1998) recorded one dispersal event of 4.7 miles and Bailey and Mock (1998) suggest that gnatcatcher dispersal capability is underestimated based on the ability of the species to traverse highly modified landscapes at least for short distances. Bailey and Mock (1998) observed juvenile dispersal distances averaging less than 1.9 miles from the nest territory; however, the longest recorded juvenile dispersal averaged 9.9 miles (Mock 2004). Post-breeding season observations of the California gnatcatcher occurred in the Project area in October 2007 (Priest 2007A) and August 2008 (Ortega 2008), indicating that the site is used during dispersal even though there is no evidence of a breeding population on site (see California gnatcatcher account in **Subsection 4.5.5.3**), and the nearest other documented California gnatcatcher location is Chivas Canyon location, 3.6 miles southwest of the Project area.

Species in the Moderate Mobility Aerial guild can meet their entire life history needs within habitat wholly contained within the Project area and constitute subpopulations or portions of larger populations. However, the habitat requirements of the species in this guild are variable and species-specific. For example, four-wing saltbush (*Atriplex canescens*) is the primary host plant for the San Emigdio blue butterfly, and although this saltbush is widespread throughout the western United States, the distribution of the San Emigdio blue butterfly is much more localized, suggesting that other factors may determine habitat suitability (Murphy 1990), and thus restrict it to certain locations. On site, the San Emigdio blue butterfly is associated with quail brush (*A. lentiformis*). Rufous-crowned sparrow occupies moderate to steep hillsides that are rocky, grassy, or covered by coastal scrub or chaparral. This species appears to be relatively sedentary and has home ranges averaging approximately 3.7 acres, with average territories (*i.e.*, defended area) of approximately 2.0 acres (Zeiner *et al.* 1990A). The California gnatcatcher's territory size varies and is influenced by season and locale (Preston *et al.* 1998), but may be unrelated to vegetation structure (Braden *et al.* 1997). During the breeding season, territories in coastal areas are often smaller, averaging 5.7 acres

(Atwood, Tsai *et al.* 1998), than those in more inland regions, which average 8.4 acres (Braden *et al.* 1997). Territories for Bell's sage sparrow that use coastal scrub and chaparral communities in San Diego and Riverside counties varied from 1.9 to 14.1 acres (County of Riverside 2008). Territories for the black-chinned sparrow, which primarily occurs in chaparral, have been documented at 3.9 to 9.9 acres per pair (Tenney 1997).

Because species in this guild have moderate mobility, as long as there is adequate habitat connectivity (*i.e.*, suitable habitat patches that are within the flight capabilities of individuals) they may exhibit metapopulation dynamics characterized by local extirpation and recolonization. Habitat patches that are too isolated for recolonization (*i.e.*, beyond the flight capability of the species) may permanently lose species in this guild.

INTENTIONALLY LEFT BLANK

4.5.5.2.4.2 *Impacts to Wildlife Landscape Habitat Linkages*

To provide the context for the potential Project impacts to wildlife landscape habitat linkages, **Figure 4.5-22** shows the conceptual regional open space connectivity identified by Penrod *et al.* (2006) that would provide for landscape-scale habitat connectivity between the Santa Susana Mountains to the south and the Los Padres National Forest to the north. These conceptual linkages encompass the High Country SMA, Salt Creek area within the Project area, and the Santa Clara River west of the Project area. Penrod *et al.* (2006) considered the High Country SMA and Salt Creek area, along with regional open space conservation areas and initiatives such as "SOAR,"[1] in recommending a linkage design that would connect the Santa Monica Mountains, San Gabriel Mountains, and the Sierra Madre Mountains. This linkage design was also based on a "least cost analysis" that quantitatively models the most efficient routes target animals could take to travel between these open space areas. The least cost analysis incorporates available information for movement-limiting variables such as elevation, vegetation, topography, and road density. The "least cost path" is the most direct or optimum route utilizing suitable habitat and minimizing costs (*e.g.*, energy costs, risk of mortality), but does not represent all potential routes available to a species that may be more costly, but feasible, alternatives. Dispersing animals are often young adults, and behaviorally these animals may take routes that do not ensure the least cost or the highest rate of survivability or they may be inhibited from using such routes by adults. However, these least cost analyses quantitatively identify idealized linkages and corridors that would allow for the most efficient long-range dispersal and migration movement for wildlife between larger conservation areas.

The High Country SMA and Salt Creek area within the Project area comprise an important part of the least cost path linkage design identified by Penrod *et al.* (2006) (**Figure 4.5-22**). They provide a key part of the east–west linkage that crosses I-5 and connects to the Angeles National Forest in the San Gabriel Mountains to the east and Ventura County SOAR open space to the southwest. They also provide a significant part of the north–south linkage between the Santa Susana Mountains and the "Fillmore Greenbelt" to the northwest that further links to the Los Padres National Forest and the Angeles National Forest to the north.

As described in **Subsection 4.5.5.2.4.1**, most of the species in the upland habitat guilds, including Mammal – High Mobility, Mammal – Moderate Mobility, Low Mobility, and Moderate Mobility Aerial, are probably using all or much of the undeveloped upland portions of the Project area, although some species, such as mountain lion, mule deer, bobcat, coyote, and badger, may favor certain features, such as canyons, washes, ridgelines, dirt roads, and established game trails for movement. Other more sedentary species in the Low Mobility guild are more likely to be distributed throughout the Project area in suitable habitat.

[1] Save Open-Space and Agricultural Resources (SOAR) is a non-profit organization which seeks to maintain agricultural, open space, and rural lands within Ventura County and surrounding regions. Development activities within the SOAR boundaries are limited by County Ordinance.

Alternative 2

Implementation of the proposed Project will constrain the movement of wildlife in the Project area. However, as shown in **Figure 4.5-40**, the landscape habitat linkages that will remain functional after implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternative 2 are the High Country SMA, Salt Creek area, and River Corridor SMA. These contiguous areas are required open space elements of the proposed Project and combined total approximately 6,700 acres and provide both internal connectivity and connections to habitat areas beyond the Project area, as discussed above.

The Santa Clara River is a critical habitat linkage in the Project area because it provides significant north–south and east–west habitat connectivity as well as resident habitat for many wildlife species. The River corridor connects downstream and upstream areas, including tributary drainages, such as Salt Creek and Castaic Creek, that allow wildlife access to uplands from the River. Although the RMDP includes the construction of bridges and bank stabilization within the Santa Clara River corridor, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts in water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County over the long term. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue; post-development widths of the River floodplain would range from about 1,000 feet wide to 2,000 feet wide. As a result, the mosaic of habitats in the River that support various special-status species would be maintained, and the populations of the species within and immediately adjacent to the River corridor would not be substantially affected. Therefore, habitat connectivity in the River corridor for the Aquatic and Semi-Aquatic guild species would not be substantially affected. Likewise, any other species using the River corridor for movement or habitat connectivity would not be substantially affected, including the Mammal – High Mobility, Mammal – Moderate Mobility, Low Mobility, and Moderate Mobility Aerial guild species. Habitat connectivity along the River corridor for movement by the High Mobility Aerial guild is not an issue because of the ability of species in this guild to fly between disjunct habitat patches.

The combined High Country SMA and Salt Creek area provide a direct connection between the River corridor and large upland habitat areas south of the River (**Figure 4.5-22**). As noted above, the least cost analyses conducted by Penrod *et al.* (2006) identified these areas as important components of regional habitat connectivity.

As shown in **Figure 4.5-22**, the High Country SMA and Salt Creek area are part of the eastern arm of the conceptual linkage design identified by Penrod *et al.* (2006). Based on the Impact Sciences, Inc. (2005) mammal study and incidental observations by Dudek (2006B) in the High Country SMA and Salt Creek area, wildlife have been observed utilizing these areas despite ongoing agricultural and grazing activities. The most direct route for wildlife to move from the River corridor to upland areas south of the River is through the Salt Creek Confluence corridor.

Development of Potrero Village will impact the eastern edge of the conceptual linkage identified by Penrod *et al.* (2006) (**Figure 4.5-22**) and will limit the future use of this area by wildlife. However, the combined 5,220-acre High Country SMA and Salt Creek area is large enough to provide both buffer and core habitat to allow wildlife to use this landscape linkage without necessarily having to come into close contact with urban development, except at highway crossings discussed below in **Subsection 4.5.5.2.4.4**. The conceptual linkage identified by Penrod *et al.* (2006) in this area is about 4.5 miles (23,760 feet) wide, with the narrowest portion of the High Country SMA and Salt Creek area approximately 4,000 feet wide (**Figure 4.5-22**). This minimum 4,000-foot-wide zone will provide adequate buffer and core habitat for the Mammal – High Mobility guild species. This habitat linkage will remain fully intact after implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas, and is expected to function as it has in the past. Wildlife guilds expected to use the High Country SMA and Salt Creek area, in addition to the Mammal – High Mobility guild, include some of the Semi-Aquatic guild species (*e.g.*, southwestern pond turtle and two-striped garter snake), and the Mammal – Moderate Mobility, Low Mobility, and Moderate Mobility Aerial guilds. Many species in the High Mobility Aerial guild are also expected to use the High Country SMA and Salt Creek area, but habitat contiguity to support their movement is not an issue because of their ability to fly between suitable habitat patches. The High Country SMA and Salt Creek area generally do not support aquatic habitat suitable for the Aquatic guild species.

The Castaic/Hasley corridor will also remain intact as an Open Space/Open Area following implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas, but with a narrowing of the corridor that passes between the VCC and Entrada project areas (**Figure 4.5-40**). This corridor was not included by Penrod *et al.* (2006) as a regional linkage, but with its direct connection to the Santa Clara River corridor, it will still allow for movement of many species, including Mammal – High Mobility species such as coyote, mule deer, and possibly mountain lion and bobcat, and could function as live-in and movement habitat for species in the other guilds, although aquatic habitat for fish is limited to periods when Castaic Creek is flowing (ENTRIX 2006B). Although the vicinity of Castaic Creek north of the Project area is becoming increasingly developed, it will continue to have connectivity value

between the Santa Clara River and upland habitats to the northeast of the Project area extending to Castaic Lake and the Angeles National Forest, as illustrated in **Figure 4.5-22**.

Other existing habitat linkages on site, such as Potrero Canyon and Long Canyon south of the River corridor, and San Martinez Grande Canyon and Chiquito Canyon north of the River, will be constrained by build-out of the Specific Plan area and will lose some of their habitat function, although they will have some value as wildlife corridors in the Project area, as discussed below in **Subsection 4.5.5.2.4.3**.

Significance Finding for Impacts to Wildlife Landscape Habitat Linkages: Adverse but not significant for Alternative 2. The consideration of impacts to wildlife landscape habitat linkages falls under the following significance criteria as previously identified in **Subsection 4.5.4**: (4) Interfere substantially with the movement of any native resident or migratory fish or wildlife species, or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites; and (7) Have the potential to substantially reduce the habitat of a fish or wildlife species; cause a fish or wildlife population to drop below self-sustaining levels; threaten to eliminate a plant or animal community; or substantially reduce the number or restrict the range of an endangered, rare, or threatened species.

As discussed above, the River Corridor SMA is a critical habitat linkage in the Project area. The combined High Country SMA and Salt Creek area provide the most direct connections between the River corridor habitat and large upland habitat areas south of the River, and are those identified by Penrod *et al.* (2006) as important components of regional habitat connectivity. These habitat linkages will remain intact and functional after implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternative 2

The Castaic/Hasley corridor will also remain intact as Open Space/Open Area following implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas, allowing for movement of many Mammal – High Mobility species such as coyote, mule deer, and possibly mountain lion and bobcat, and will function as live-in habitat and movement habitat for the other species guilds. The Castaic/Hasley corridor will continue to have connectivity value between the Santa Clara River and upland habitats to the northeast of the Project area extending to Castaic Lake and the Angeles National Forest.

Other existing habitat areas that currently function as linkage habitat in the undeveloped landscape and that may currently be used by wildlife for north–south movement between the Santa Susana Mountains to the south and the Los Padres National Forest to the north will be constrained by build-out of the Specific Plan area. Prominent canyons that

probably currently provide this function include Potrero Canyon and Long Canyon south of the River corridor and Chiquito Canyon and San Martinez Grande Canyon north of the River (**Figure 4.5-40**). The loss of wildlife landscape habitat linkage function within these canyons on site due to build-out, however, would not meet the significance criteria listed above because of the alternative regional landscape habitat linkages that will remain intact and fully functional. Species currently using these other areas may be displaced as a result of Specific Plan build-out, but the landscape-scale habitat connections for regional wildlife movement would not be substantially affected.

Implementation of Alternative 2 would result in adverse, but not significant impacts to wildlife landscape habitat linkages.

Alternative 3

As depicted in **Figure 4.5-41**, implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternative 3 would result in similar impacts to wildlife landscape habitat linkages compared to Alternative 2.

Implementation of Alternative 3 would result in adverse but not significant impacts to wildlife landscape habitat linkages.

Alternative 4

As depicted in **Figure 4.5-42**, implementation of the RMDP and SCP and build-out of the Specific Plan and Entrada planning areas under Alternative 4 would result in similar impacts to wildlife landscape habitat linkages compared to Alternative 2, with the exception of the Castaic/Hasley Corridor, which will not be impacted under Alternative 4 because VCC would not be constructed.

Implementation of Alternative 4 would result in adverse but not significant impacts to wildlife landscape habitat linkages.

Alternative 5

As depicted in **Figure 4.5-43**, implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternative 5 would result in similar impacts to wildlife landscape habitat linkages compared to Alternative 2, with the exception of the Castaic/Hasley Corridor, which will not be impacted under Alternative 5 because VCC would not be constructed.

Implementation of Alternative 5 would result in adverse but not significant impacts to wildlife landscape habitat linkages.

Alternative 6

As depicted in **Figure 4.5-44**, implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternative 6 would result in similar impacts to wildlife landscape habitat linkages compared to Alternative 2, with the exception of the Castaic/Hasley Corridor, which will not be impacted under Alternative 6 because VCC would not be constructed

Implementation of Alternative 6 would result in adverse but not significant impacts to wildlife landscape habitat linkages.

Alternative 7

As depicted in **Figure 4.5-45**, implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternative 7 would result in similar impacts to wildlife landscape habitat linkages compared to Alternative 2, with the exception of the Castaic/Hasley Corridor, which will not be impacted under Alternative 7 because VCC would not be constructed.

Implementation of Alternative 7 would result in adverse but not significant impacts to wildlife landscape habitat linkages.

4.5.5.2.4.3 *Impacts to Wildlife Corridors*

The High Country SMA, Salt Creek area, and River Corridor SMA are the foundation for post-development dispersal and movement across the regional landscape by the different species guilds, as discussed above in **Subsection 4.5.5.2.4.2**. This subsection addresses local habitat connectivity and wildlife movement within the immediate Project area after implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas.

As described above in **Subsection 4.5.3.4.7**, wildlife corridors within the Project area were identified primarily by using existing scent station/track station data (Impact Sciences 2005), topographic analysis, incidental field observations (Dudek 2006B), and professional judgments based on known habitat associations of wildlife species in the Project area. The Impact Sciences (2005) scent/track stations were located throughout the Specific Plan area, including along Salt Creek Canyon from the eastern portion toward the Ventura County line, north above Potrero Mesa, throughout Long Canyon and around the agriculture field north of Long Canyon, south of Lion Canyon and Grapevine Mesa, dispersed throughout Exxon Canyon and Middle Canyon, and in a few portions of Chiquito Canyon, San Martinez Grande Canyon, and Entrada. Impact Sciences, Inc. (2005) also conducted nighttime spotlight surveys along roadways throughout the Project area five nights a week between July 28 and September 30, 2004. The Dudek (2006B) general wildlife study focused on the Salt Creek area and High Country SMA and included meandering transects throughout the canyons and ridgelines in these areas and identification of wildlife by direct observation, calls, and other signs, such as tracks and scat.

In an undeveloped landscape, high and moderate mobility wildlife (including birds and mammals) can be expected to travel relatively freely throughout an area because there are no significant obstacles to movement. However, some species prefer certain habitat types related to vegetation cover and topography, such as mule deer preferring rugged terrain and slopes that allow them to escape from predators (Lingle 2002; Pierce *et al.* 2004) and mountain lions preferring canyon bottoms and gently sloping terrain (Dickson and Beier 2006; Dickson *et al.* 2005). Therefore, with the understanding that an open landscape allows wildlife to range freely, areas that exhibit the characteristics of wildlife corridors with the RMDP Alternative 2 build-out scenario (*i.e.*, linear landscape elements that connect larger habitat patches) were included in this corridor analysis. Corridors were identified that would allow Mammal – High Mobility guild species to move through areas in a single generation and would contain sufficient habitat components for permanent occupation by Mammal – Moderate Mobility, Low Mobility, and Moderate Mobility Aerial guild species. These less mobile guild species that are unlikely or unable to move through a corridor in a lifetime require sufficient habitat to allow diffusion of the species over more than one generation (intergenerational) through the area. High Mobility Aerial species were not considered in this analysis because of their ability to fly between disjunct habitat patches and their relative independence of wildlife corridors.

Thirteen potential corridors within the Project area were identified in this analysis (**Figure 4.5-31**):

1. Santa Clara River Corridor
2. Salt Creek Confluence
3. Salt Creek–High Country
4. East Fork Salt Creek
5. Potrero Canyon–Salt Creek
6. Potrero Canyon
7. Long Canyon
8. Short Canyons–River Corridor
    a. Humble Canyon
    b. Lion Canyon
    c. Exxon Canyon
    d. Dead End Canyon
    e. Middle Canyon
    f. Magic Mountain Canyon
9. Chiquito Canyon
10. San Martinez Grande Canyon
11. Off-Haul Canyon
12. Homestead Canyon
13. Castaic/Hasley Corridor.

The Santa Clara River, Castaic/Hasley, Salt Creek Confluence, Salt Creek–High Country, and East Fork Salt Creek corridors were discussed above in **Subsection 4.5.5.2.4.2** in the context of their pre- and post-development function as landscape-level habitat linkages that provide both permanent resident and movement habitat for the various wildlife species guilds.

Alternative 2

As shown in **Figure 4.5-40**, a number of the potential wildlife corridors would be developed, would become dead-ends, or would be highly constrained for wildlife after implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternative 2. Corridors No. 8d: Dead End Canyon; No. 8e: Middle Canyon; No. 8f: Magic Mountain Canyon; and No. 11: Off-Haul Canyon would be developed and eliminated as wildlife corridors. Corridors No. 8a: Humble Canyon; No. 8b: Lion Canyon; and No. 8c: Exxon Canyon would become dead-ends. The canyons that would become dead-ends may still provide suitable habitat for some of the species in the Mammal – High Mobility, Mammal – Moderate Mobility, Low Mobility, Moderate Mobility Aerial, High Mobility Aerial, and Semi-Aquatic guilds (*e.g.*, terrestrial habitat for southwestern pond turtle), but these dead-ends would not

allow for movement or dispersal between large habitat areas. These dead-ends, which are tributaries to the Santa Clara River, do not support Aquatic guild species.

The potential wildlife corridors that would remain fully functional after implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternative 2 area are No. 1: Santa Clara River Corridor; No. 2: Salt Creek Confluence; No. 3: Salt Creek–High Country; and No. 4: East Fork Salt Creek. These corridors will provide habitat connections among the protected open space areas—High Country SMA, Salt Creek area, and River Corridor SMA—and will provide connections to habitat areas beyond the Project area, as discussed above in **Subsection 4.5.5.2.4.2**, in the context of the regional landscape-level habitat connections. Corridor No. 13: Castaic/Hasley would also remain functional, but would be somewhat constrained by VCC, as discussed above in **Subsection 4.5.5.2.4.2**.

Corridors No. 5: Potrero Canyon–Salt Creek; No. 6: Potrero Canyon; No. 7: Long Canyon; No. 9: Chiquito Canyon; No. 10: San Martinez Grande Canyon; and No. 12: Homestead Canyon would become constrained wildlife corridors due to surrounding development.

In addition to the proposed adjacent development, corridors No. 6: Potrero Canyon; No. 7: Long Canyon; No. 9: Chiquito Canyon; and No. 10: San Martinez Grande Canyon would be further constricted by the installation of culverts for proposed road crossings.

- Potrero Canyon would have five road crossing culverts;
- Long Canyon would have three road crossing culverts;
- Chiquito Canyon would have three road crossing culverts, and the existing triple box culvert under SR-126 would be replaced with a bridge crossing for the SR-126 and westbound and eastbound on-ramps. A trail bridge would be constructed over the creek about 50 feet south of SR-126.
- San Martinez Grande Canyon would have two road crossing culverts and a trail bridge constructed over the creek about 50 feet south of SR-126 (existing culvert under SR-126 would be remain at the existing 87 feet).

Table 4.5-53 describes the culvert/bridge type and size dimensions for the proposed road crossings, along with their openness factors (see discussion of openness factor in **Subsection 4.5.3.4.7**).

Table 4.5-53
Summary of Proposed Road Crossing Culverts/Bridges in Constrained Wildlife Corridors

Crossing	Crossing Type[1]	Height (ft)	Width (ft)	Length (ft)	Openness Factor[2]	Adequate for Mule Deer Passage[3]
Potrero 1	Triple Box Culvert	10	12	100	0.37	Yes
Potrero 2	Double Box Culvert	10	12	100	0.37	Yes
Potrero 3	Double Box Culvert	10	12	100	0.37	Yes
Potrero 4	Double Box Culvert	10	12	100	0.37	Yes
Potrero 5	Double Box Culvert	10	12	100	0.37	Yes
Long 1	Double Box Culvert	12	15	140	0.39	Yes
Long 2	Double Box Culvert	12	15	320	0.17	No
Long 3	Double Box Culvert	12	12	440	0.10	No
Chiquito 1	Double Box Culvert	10	12	120	0.30	Yes
Chiquito 2	Double Box Culvert	10	12	70	0.52	Yes
Chiquito 3	Double Box Culvert	10	12	60	0.61	Yes
Chiquito 4	Main Line Bridge over SR-126 (replaces existing triple box culvert)	10	100 (maximum)	180	1.69	Yes
	Westbound On-ramp	10	100 (maximum)	70	4.35	Yes
	Eastbound On-ramp	10	100 (maximum)	40	7.62	Yes
	Pedestrian Bridge	10 to 15	90	85	3.23 to 4.84	Yes
San Martinez 1	Double Box Culvert	10	12	150	0.24	Yes
San Martinez 2	Double Box Culvert	10	12	64	0.57	Yes
San Martinez 3	Trail Bridge	8	90	12	18.29	Yes
	Existing Bridge Over SR-126	10 to 15	90	85	3.23 to 4.84	Yes

[1] The dimensions for the box culverts are for each box separately; *i.e.*, for Potrero 1 each section of the triple box culvert would be 10 feet x 12 feet x 100 feet.

[2] Openness factor = (height (meters) x width (meters)) / length (meters)

[3] The standard for mule deer passage is an openness factor of 0.25 based on Donaldson (2005). Because the mule deer are considered to be the species in the Project area most sensitive to the size dimensions of culverts, this species serves as a surrogate for analyzing the effectiveness of a culvert for conveying wildlife movement.

[4] Because the openness factor is a relatively non-precise value and effectiveness of a crossing also depends on other factors such as vegetation cover, topography, *etc.*, the value of 0.24 for San Martinez 1 is close enough to the 0.25 standard to be considered a functional crossing for mule deer.

Table 4.5-53 shows, based on the openness factor calculations, that most of the proposed crossings would be adequate for mule deer, likely the species most sensitive to the size dimensions of the culverts. Only two culverts (Long Canyon 2 and 3) would clearly be too constrained for mule deer. San Martinez 1, with an openness factor of 0.24, is

considered to be adequate, but is slightly more constrained than the standard of 0.25 (Donaldson 2005).

Constraints on these potential corridors as a result of adjacent development and culverts in the drainages will have variable effects on wildlife in the different guilds. Mammal – High Mobility guild species, such as mountain lion and American black bear, are not expected to regularly use these constrained corridors after build-out of the Specific Plan because of the general effects of urban development, although an occasional individual may wander into these areas. Because of the adjacent development, any mountain lions or black bears that do wander into these areas would be at a high risk of negative interactions with humans or vehicle collisions. Other Mammal – High Mobility guild species, such as mule deer, coyote, and bobcat, would be more likely to use these constrained corridors for movement, especially in areas with some vegetative cover, because they are less sensitive to urban development. While most of the culverts in these corridors under Alternative 2 are expected to function for these species, the two culverts in Long Canyon may be a barrier to mule deer and may result in blockage of movement in these areas or increased risk of vehicle collisions. Mammal – Moderate Mobility guild species are also likely to use the constrained corridors and would not be constrained by culverts under Alternative 2. Risk of vehicle collisions for Mammal – Moderate Mobility guild species, such as badger, however, would increase because individuals may wander onto or try to cross roads. The ringtail is not expected to use these constrained linkages, due to a lack of habitat and proximity to urban development. Low Mobility, Moderate Mobility Aerial, and some Semi-Aquatic guild species would also be likely to use these corridors as resident habitat where there is sufficient habitat (such as San Diego desert woodrat or some resident passerines with small home ranges/territories, such as rufous-crowned sparrow). The Low Mobility and Semi-Aquatic guild species should be able to disperse along these corridors through culverts. The Moderate Mobility Aerial guild species may be inhibited from moving through these corridors where there are small culverts. The High Mobility Aerial guild species may use suitable habitat in these corridors, and their movement would not be constrained because of their ability to fly between disjunct habitat patches. These constrained corridors do not provide suitable habitat for Aquatic guild species.

In addition to physical constraints on movement, these constrained corridors will introduce secondary effects that make them less suitable for wildlife, including increased lighting; noise; increased human activity; pet, stray, and feral cats and dogs; other mesopredators; and invasive species. Lighting affects the behavior of many species. Species that are typically diurnal (*e.g.*, many birds) may be stressed by lighting and have their behavioral patterns and circadian cycles altered. Lighting may also increase predation due to making prey more detectable to nocturnal predators. Nocturnal species may avoid lighted areas, thus spatially and temporally altering their movement patterns.

Noise related to traffic and other activities (*e.g.*, active recreation) may also induce stress, alter behavior, and potentially mask the noise made by predators, thus increasing predation rates. Increased human activity may generally alter behavior patterns, induce stress, and increase the chance of negative encounters. Pet, stray, and feral cats and dogs, as well as mesopredators where coyotes become less common, would increase predation rates on native birds and rodents. Invasive plant species would degrade native habitat and cover for species moving through built-out areas of the Project. Argentine ants would be attracted to areas with increased moisture, disrupting predator–prey relationships due to displacement of native invertebrates, and potentially preying on nestlings.

Although some wildlife species will move through these constrained corridors and others may permanently occupy portions of these corridors where there is adequate habitat, in general, these constrained corridors are not considered to effectively contribute to long-term habitat connectivity function in the Project area.

Significance Finding for Impacts to Wildlife Corridors: Significant absent mitigation for Alternative 2. The consideration of impacts to wildlife corridors falls under the following significance criteria as previously identified in **Subsection 4.5.4**: (4) Interfere substantially with the movement of any native resident or migratory fish or wildlife species, or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites; and (7) Have the potential to substantially reduce the habitat of a fish or wildlife species; cause a fish or wildlife population to drop below self-sustaining levels; threaten to eliminate a plant or animal community; or substantially reduce the number or restrict the range of an endangered, rare, or threatened species.

As discussed above, the following wildlife corridors that would remain fully functional after implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas are: No. 1: Santa Clara River Corridor; No. 2: Salt Creek Confluence; No. 3: Salt Creek–High Country; No. 4: East Fork Salt Creek; and No. 13: Castaic/Hasley Corridor. These corridors will provide habitat connections among the protected open space areas—High Country SMA, Salt Creek area, and River Corridor SMA—and will provide connections to habitat areas beyond the Project area. As discussed above, these wildlife corridors are expected to provide resident and movement habitat for the all of the consolidated wildlife guilds listed in **Table 4.5-53**. The exception is the Aquatic Mollusk guild that includes the undescribed snail that is only known to occur in Middle Canyon Spring and is not expected to occur in these corridors.

Under Alternative 2, corridors No. 5: Potrero Canyon–Salt Creek; No. 6: Potrero Canyon; No. 7: Long Canyon; No. 9: Chiquito Canyon; No. 10: San Martinez Grande Canyon;

and No. 12: Homestead Canyon would become constrained wildlife corridors due to surrounding development. In addition to the proposed adjacent development, No. 6: Potrero Canyon; No. 7: Long Canyon; No. 9: Chiquito Canyon; and No. 10: San Martinez Grande Canyon would be further constricted by the installation of culverts for proposed road crossings. However, based on the openness factors presented in **Table 4.5-53**, all of the culverts will be adequate for mule deer use, except for the culverts at Long Canyon 2 and Long Canyon 3. Following implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas, the remaining wildlife corridors are expected to provide varying resident and movement habitat for the other wildlife guilds. The Semi-Aquatic and Low Mobility guild species are expected to use the constrained corridors where there is suitable habitat. The Mammal – Moderate Mobility guild species would also be likely to use the constrained corridors, although badgers moving through these corridors would be at a relatively high risk of vehicle collisions and ringtails are not expected to occur. The Moderate Mobility Aerial guild species may use portions of these corridors as resident habitat, but their movements may be constrained by culverts, forcing them to cross roadways during dispersal and, thus, either inhibiting dispersal or increasing their risk of vehicle collisions. The Mammal – High Mobility species would be variably affected. Mountain lions and black bears would be less likely to use these constrained corridors because of adjacent urban development and individuals that attempt to move through them would be at a high risk of negative interactions with humans and vehicle collisions. Coyotes and bobcats would be able to use these corridors without difficulty as long as adequate vegetative cover is available, although the risk to bobcats would be elevated due to negative interactions with humans and vehicle collisions. Mule deer would be likely to use most the corridors, but may be inhibited by smaller culverts in Long Canyon and forced to cross roads, thus increasing their risk of vehicle collisions. The High Mobility Aerial guild species would use portions of these corridors where there is suitable habitat and their movements would not be constrained. In addition, as described above, these constrained corridors will also introduce secondary effects that make them less suitable for wildlife, including lighting; noise; increased human activity; pet, stray, and feral cats and dogs; other mesopredators; and invasive species.

Because the movement of several of the wildlife guild species would be substantially affected under Alternative 2, these impacts to potential wildlife corridors would be significant, absent mitigation (significance criteria 4 and 7).

Alternative 3

Implementation of the RMDP and SCP and build-out of the Specific Plan, VCC, and Entrada planning areas under Alternative 3 (**Figure 4.5-41**) would result in similar impacts to wildlife corridors compared to Alternative 2. Alternative 3 differs from

Alternative 2 in that Potrero Canyon would have three road crossing culverts and two bridges (instead of five road crossing culverts as in Alternative 2); and San Martinez Grande Canyon would have one road crossing culvert and one bridge (instead of two road crossing culverts as in Alternative 2). All the bridge crossings would have openness factors of at least 3.23 and thus would be passable by all wildlife.

Although bridges have been substituted for road crossing culverts within Potrero Canyon and San Martinez Grande Canyon, the corridors would still be constrained by urban development and are not considered to effectively contribute to long-term habitat connectivity function in the Project area. As described for Alternative 2, these constrained corridors will also introduce secondary effects that make them less suitable for wildlife, including lighting; noise; increased human activity; pet, stray, and feral cats and dogs; other mesopredators; and invasive species. The impacts to wildlife guilds discussed above for Alternative 2 would be similar under Alternative 3. Therefore, Alternative 3 would result in impacts to wildlife corridors that would be significant, absent mitigation.

Alternative 4

Implementation of the RMDP and SCP and build-out of the Specific Plan and Entrada planning areas under Alternative 4 (**Figure 4.5-42**) would result in similar impacts to wildlife corridors compared to Alternative 2. Alternative 4 differs from Alternative 2 in that Potrero Canyon would have three road crossing culverts and two bridges (instead of five road crossing culverts as in Alternative 2). All the bridge crossings would have openness factors of at least 3.23 and thus would be passable by all wildlife. Alternative 4 also differs from Alternative 2 in that VCC would not be constructed and corridor No. 13: Castaic/Hasley would not be constrained.

Although bridges have been substituted for road crossing culverts within Potrero Canyon, and the Castaic/Hasley corridor would not be constrained, the other corridors would still be constrained by urban development and are not considered to effectively contribute to long-term habitat connectivity function in the Project area. The impacts to wildlife guilds discussed above for Alternative 2 would be similar under Alternative 4. In addition, as described for Alternative 2, these constrained corridors will introduce secondary effects that make them less suitable for wildlife, including lighting; noise; increased human activity; pet, stray, and feral cats and dogs; other mesopredators; and invasive species. Therefore, Alternative 4 would result in impacts to wildlife corridors that would be significant, absent mitigation.

Alternative 5

Implementation of the RMDP and SCP and build-out of the Specific Plan and Entrada planning areas under Alternative 5 (**Figure 4.5-43**) would result in similar impacts to wildlife corridors compared to Alternative 2. Alternative 5 differs from Alternative 2 in that Potrero Canyon would have one road crossing culvert and four bridges (instead of five road crossing culverts as in Alternative 2); Chiquito Canyon would have two road crossing culverts and one bridge (instead of three road crossing culverts as in Alternative 2). All the bridge crossings would have openness factors of at least 3.23 and thus would be passable by all wildlife. Alternative 5 also differs from Alternative 2 in that VCC would not be constructed and corridor No. 13: Castaic/Hasley would not be constrained.

Although bridges have been substituted for road crossing culverts within Potrero Canyon and Chiquito Canyon, and the Castaic/Hasley corridor would not be constrained, the other corridors would still be constrained by urban development and are not considered to effectively contribute to long-term habitat connectivity function in the Project area. The impacts to wildlife guilds discussed above for Alternative 2 would be similar under Alternative 5. In addition, as described for Alternative 2, these constrained corridors will introduce secondary effects that make them less suitable for wildlife, including lighting; noise; increased human activity; pet, stray, and feral cats and dogs; other mesopredators; and invasive species. Therefore, Alternative 5 would result in impacts to wildlife corridors that would be significant, absent mitigation.

Alternative 6

Implementation of the RMDP and SCP and build-out of the Specific Plan and Entrada planning areas under Alternative 6 (**Figure 4.5-44**) would result in similar impacts to wildlife corridors compared to Alternative 2. Alternative 6 differs from Alternative 2 in that Potrero Canyon would have five bridges (instead of five road crossing culverts as in Alternative 2); San Martinez Grande Canyon would have two bridges (instead of two road crossing culverts as in Alternative 2). All the bridge crossings would have openness factors of at least 3.23 and thus would be passable by all wildlife. Alternative 6 also differs from Alternative 2 in that VCC would not be constructed and corridor No. 13: Castaic/Hasley would not be constrained.

Although bridges have been substituted for road crossing culverts within Potrero Canyon and San Martinez Grande Canyon, and the Castaic/Hasley corridor would not be constrained, the corridors would still be constrained by urban development and are not considered to effectively contribute to long-term habitat connectivity function in the Project area. The impacts to wildlife guilds discussed above for Alternative 2 would be similar under Alternative 6. In addition, as described for Alternative 2, these constrained corridors will introduce secondary effects that make them less suitable for wildlife,

including lighting; noise; increased human activity; pet, stray, and feral cats and dogs; other mesopredators; and invasive species. Therefore, Alternative 6 would result in impacts to wildlife corridors that would be significant, absent mitigation.

Alternative 7

Implementation of the RMDP and SCP and build-out of the Specific Plan and Entrada planning areas under Alternative 7 (**Figure 4.5-45**) would result in similar impacts to wildlife corridors compared to Alternative 2. Alternative 7 differs from Alternative 2 in that Potrero Canyon would have six bridges (instead of five road crossing culverts as in Alternative 2); Long Canyon would have two bridges (instead of three road crossing culverts as in Alternative 2); Chiquito Canyon would have three bridges (instead of three road crossing culverts as in Alternative 2); and San Martinez Grande Canyon would have two bridges instead of two road crossing culverts as in Alternative 2). All the bridge crossings would have openness factors of at least 3.23 and thus would be passable by all wildlife. Development in Middle Canyon and Off-Haul Canyon is also minimized. Alternative 7 also differs from Alternative 2 in that VCC would not be constructed and corridor No. 13: Castaic/Hasley would not be constrained.

Although bridges have been substituted for road crossing culverts within Potrero Canyon, Long Canyon, Chiquito Canyon, and San Martinez Grande Canyon, and the Castaic/Hasley corridor would not be constrained, the corridors would still be constrained by urban development and are not considered to effectively contribute to long-term habitat connectivity function in the Project area. The impacts to wildlife guilds discussed above for Alternative 2 would be similar under Alternative 7. In addition, as described for Alternative 2, these constrained corridors will introduce secondary effects that make them less suitable for wildlife, including lighting; noise; increased human activity; pet, stray, and feral cats and dogs; other mesopredators; and invasive species. Therefore, Alternative 7 would result in impacts to wildlife corridors that would be significant, absent mitigation.

Mitigation Summary and Strategy

Implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would have a significant impact, absent mitigation, to existing wildlife corridors with the Project area under Alternatives 2 through 7. The primary impacts of the Project would occur as a result of the build-out because most of the tributaries would be bordered by development, resulting in wildlife corridors that are long and narrow. As noted above, species that can move rapidly and/or are relatively unaffected by urban development, such as coyotes, are expected to regularly use these constrained corridors. Other species that are somewhat tolerant of human presence, but generally require vegetative cover habitat, such as bobcat and mule deer, are also likely to use these constrained corridors. Mountain lion and

American black bear are expected to be generally excluded from these constrained corridors. As described above for Alternative 2, most of the culverts will be passable by wildlife, with the exception of two culverts in Long Canyon that may be a barrier to mule deer. In addition, as described in detail for Alternative 2, these constrained corridors will introduce secondary effects that make them less suitable for wildlife, including lighting; noise; increased human activity; pet, stray, or feral cats and dogs; other mesopredators; and invasive species.

Then primary mitigation strategy for offsetting impacts to local wildlife corridors is protection, enhancement, and management of the River Corridor SMA, High Country SMA, and Salt Creek area, together comprising approximately 6,300 acres of contiguous habitat. These areas were identified by Penrod *et al.* (2006) as important regional wildlife habitat linkages. Wildlife would be expected to use these areas to move across the landscape. In addition, because the Project would be phased over a period of up to 20 years, wildlife would be able to incrementally adjust their use of and movement in the Project vicinity over time. This large open space system will provide important resources to support wildlife, including perennial water sources, cover, refuge, foraging habitat, and resting areas.

The following sections identify the mitigation measures that would reduce general significant impacts to wildlife corridors to a level that would be adverse but not significant. Species-specific mitigation measures are discussed below in **Subsection 4.5.5.3**.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will help mitigate significant impacts to wildlife corridors in the Project area that would occur under all of the alternatives. These mitigation measures primarily involve protection, restoration/enhancement, and management of the River Corridor SMA and High Country SMA. These areas will provide wildlife within adequate movement and resident habitat to ensure the connectivity in the region is maintained. The lighting mitigation measure below will mitigate for secondary lighting effects, which could induce physiological stress, alter daily cycles and disrupt behavior patterns, and increase predation within the constrained corridors and along the open space–urban interface.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources. This mitigation will ensure that habitat conditions and values in the River Corridor SMA are maintained and provide cover and refuge for wildlife using and moving through this area.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects and provide wildlife with movement habitat (**Figures 4.5-3** and **4.5-22**).

Several mitigation measures will be implemented to control human activities in the River Corridor SMA and High Country SMA. These measures will help ensure that wildlife movement through and use of these areas will relatively undisturbed. SP-4.6-17 and SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the River Corridor SMA and High Country SMA.

SP-4.6-56 will be implemented to control nighttime illumination by requiring that all lighting along the perimeter of natural areas be downcast luminaries with light patterns directed away from natural areas. This measure will control some of the lighting edge effects that could occur along the constrained linkages and at the interface between the large open spaces areas (River Corridor SMA, High Country SMA, and Salt Creek area).

Measures Recommended by EIS/EIR

The EIS/EIR recommends the following mitigation measures that will reduce and mitigate significant impacts to wildlife corridors, including loss of movement habitat within the development areas, and as a result of secondary effects such as vehicle collisions; non-native species; increased human activity; pet, stray, and feral cats and dogs; and Argentine ants. These mitigation measures also involve restoration/enhancement, and management of the River Corridor SMA and High Country SMA, as well as protection, restoration/enhancement, and management of the Salt Creek area, which will provide wildlife within adequate movement and resident habitat in the region.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios. This

mitigation will ensure that habitat conditions and values in the River Corridor are maintained and provide cover and refuge for wildlife using and moving through this area.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The addition of the Salt Creek area to the open space system provides a large, contiguous habitat landscape that will allow wildlife movement through the region without the need for animals to travel through developed areas. BIO-19 includes a provision to enhance the existing agricultural undercrossing and agricultural land at the base of Salt Creek to facilitate wildlife movement between the north side of SR-126 and the Salt Creek area. This enhancement would include dedication of a portion of the agricultural field north of SR-126 and planting of trees and/or scrub habitat north and south of the existing undercrossing of the highway.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, fire ecology, erosion, drought, or unforeseen events.

BIO-59 specifies that a wildlife movement corridor plan shall be prepared and implemented to reduce vehicle collisions. The plan will include design criteria for road crossings and methods to encourage passage, such as lighting, bubblers, and vegetation planting. Signs shall be installed along roadways, indicating potential wildlife crossings where mountain lions and mule deer are likely to cross. Road under-crossings will be built in accordance with current wildlife corridors used by mountain lions and mule deer, and, as such, will accommodate a variety of wildlife.

BIO-63, BIO-69, and BIO-73 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs. These measures will collectively minimize human-related impacts to wildlife using and moving through open space areas.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all River Corridor SMA trails to prevent impacts to protected vegetation communities and special-status plant and wildlife species due to increased human and pet presence.

BIO-72, BIO-85, and BIO-87 address impacts from Argentine ants. Although Argentine ants generally will not affect highly mobile species moving through the Project area, they can affect small native species, and especially native reptiles and amphibians and small birds, through displacement of native invertebrate prey (*e.g.*, loss of native ants that are primary prey for coast horned lizard) and through predation of young. These impacts could reduce habitat quality within the constrained corridors for resident species and reduce the function of these constrained corridors as conduits for dispersal of these species.

BIO-72 will mitigate impacts from the introduction of non-native invasive plant species by specifying that plant palettes proposed for use within 100 feet of native vegetation communities be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible. This measure will also benefit yellow warbler by generally controlling the invasion of open space area by Argentine ants, although complete eradication of the ant from riparian areas is not feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Impacts to Wildlife Corridors After Mitigation

After mitigation, impacts to wildlife corridors would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

4.5.5.2.4.4 *Wildlife Crossings*

The discussion of wildlife crossings in this subsection focuses on the existing crossings that are primarily located under SR-126, linking the Santa Clara River corridor through drainages to areas north of the Project area and the variable number of large bridge crossings of the Santa Clara River under the different alternatives. **Subsection 4.5.5.2.4.3** addressed culvert and bridge crossings that would be constructed in the various tributary canyons within the Specific Plan area and their effects on movement by species in the different wildlife guilds.

Figure 4.5-32 shows the six main existing crossing locations, including three crossings in Ventura County west of the Project area that can be accessed by wildlife moving along the Santa Clara River. The three off-site crossings, which are associated with current agricultural operations, are arched culverts large enough for vehicles to pass through and are large enough to convey the Mammal – High Mobility guild species, as discussed above in **Subsection 4.5.3.4.7**. These crossings measure about 4.4 meters (14 feet, 7 inches) in height, 7.5 meters (25 feet) in width, and 51.8 meters (170 feet) in length, resulting in an openness factor of 0.65, which well exceeds the openness factor of 0.25 found by Donaldson (2005) to be adequate for white-tailed deer. The easternmost of these will serve wildlife movement within and through the Project area *via* the Salt Creek corridors discussed above in **Subsections 4.5.5.2.4.2** and **4.5.5.2.4.3**, as well as Tapo Canyon in Ventura County. These crossings were identified by Penrod *et al*. (2006) as serving regional habitat connectivity.

Within the Project area, there are existing crossings at San Martinez Grande and Chiquito canyons and at the Castaic Creek confluence north of SR-126 and the Santa Clara River. These crossings are short and include soft-bottom overpasses and box culverts, as shown in **Figure 4.5-32**. Currently all three crossings are large and open enough to accommodate most of the wildlife guild species, although the Chiquito Creek box culverts are becoming increasingly constricted by a build up of sediments. However, the Chiquito Creek box culverts will be replaced by a bridge structure, so this crossing will be adequate for the wildlife passage in the future. The bridge structure over San Martinez Grande will remain the same size and added on-ramps will also be bridge structures that will allow wildlife movement (see discussion in **Subsection 4.5.5.2.4.3**).

The alternatives analysis in the remainder of this subsection addresses potential impacts of the bridge crossings of the Santa Clara River. Potential impacts to Mammal – High Mobility guild species resulting from construction of these bridges are discussed. It is assumed, for the purpose of this analysis, that clearance under these bridges that would accommodate the Mammal – High Mobility guild species would also accommodate the other terrestrial wildlife guilds. The impact of the RMDP, including bridge construction, on the Aquatic (Fish) guild was discussed above in **Subsection 4.5.5.2.4.2**, with the conclusion that fish passage would not be significantly affected by the RMDP.

Alternative 2

Implementation of the RMDP and SCP under Alternative 2 would result in the construction of three large-span bridges across the Santa Clara River corridor (Commerce Center Drive Bridge, Long Canyon Road Bridge, and Potrero Canyon Road Bridge). These bridges would not inhibit wildlife movement along the River because the proposed structures would span long lengths and would allow sufficient daylight. Commerce Center Drive Bridge would be 1,260 feet long, 120 feet wide, and have a vertical clearance of 25 feet. The Long Canyon Road Bridge would be 980 feet long, 114 feet wide, and have a vertical clearance of 19 feet. The Potrero Canyon Road Bridge would be 1,350 feet long, 100 feet wide, and have a vertical clearance of 16 feet. All three bridge vertical clearances exceed the recommended minimum height of 10 feet for black bear, mountain lion, and deer by Ruediger and DiGiorgio (2007) (**Table 4.5-22** in **Subsection 4.5.3.4.7**). The minimum openness factor of the three bridges would be 49.78 for the Long Canyon Bridge, which far exceeds the 0.25 openness factor considered necessary for deer (Donaldson 2005).

These bridges would be adequate for passage of Mammal – High Mobility guild species and would accommodate species in the other guilds as well. Although these bridges dimensionally are adequate for passage, the behavioral patterns of some species may be altered by secondary effects of the bridges, including traffic noise and lighting. Species that would normally pass through the River at any time of day may restrict their movements near the bridges to the nighttime when noise levels and other human activity are reduced. Bridge lighting may alter the movement routes taken by some wildlife.

Build-out of the Specific Plan, VCC, and Entrada planning areas would not result in the construction of any bridges across the Santa Clara River corridor.

Significance Finding for Impacts to Wildlife Crossings: Adverse but not significant for Alternative 2. The consideration of impacts to wildlife crossings falls under the following significance criteria as previously identified in **Subsection 4.5.4**: (4) Interfere substantially with the movement of any native resident or migratory fish or wildlife species, or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites; and (7) Have the potential to substantially reduce the habitat of a fish or wildlife species; cause a fish or wildlife population to drop below self-sustaining levels; threaten to eliminate a plant or animal community; or substantially reduce the number or restrict the range of an endangered, rare, or threatened species.

As discussed above, the wildlife crossings associated with implementation of the RMDP would not physically inhibit wildlife movement along the Santa Clara River because the proposed structures would span long lengths and would allow sufficient daylight. However, there may be some alterations in behavior as wildlife move through the River

corridor as a result of secondary impacts such as traffic noise and lighting. These secondary impacts are not considered to be substantial enough to meet the significance criteria because the River corridor is wide enough and well-vegetated enough to provide adequate protection for wildlife as they move along the corridor.

Implementation of Alternative 2 would result in adverse but not significant impacts to wildlife crossings of the Santa Clara River corridor.

Alternative 3

Implementation of the RMDP and SCP under Alternative 3 would result in the construction of two large-span bridges across the Santa Clara River corridor (Commerce Center Drive Bridge and Long Canyon Road Bridge). Alternative 3 differs from Alternative 2 in that Potrero Canyon Road Bridge would not be constructed. The height, width, and vertical clearance of Commerce Center Drive Bridge and Long Canyon Road Bridge under Alternative 3 are the same as under Alternative 2. The potential secondary impacts to wildlife discussed above for Alternative 2 also apply to Alternative 3.

Implementation of Alternative 3 would result in adverse but not significant impacts to wildlife crossings.

Alternative 4

Implementation of the RMDP and SCP under Alternative 4 would result in the construction of two large-span bridges across the Santa Clara River corridor (Commerce Center Drive Bridge and Long Canyon Road Bridge). Alternative 4 differs from Alternative 2 in that Potrero Canyon Road Bridge would not be constructed. The height, width, and vertical clearance of Commerce Center Drive Bridge and Long Canyon Road Bridge under Alternative 4 are the same as under Alternative 2. The potential secondary impacts to wildlife discussed above for Alternative 2 also apply to Alternative 4.

Implementation of Alternative 4 would result in adverse but not significant impacts to wildlife crossings.

Alternative 5

Implementation of the RMDP and SCP under Alternative 5 would result in the construction of three large-span bridges across the Santa Clara River corridor (Commerce Center Drive Bridge, Long Canyon Road Bridge, and Potrero Canyon Road Bridge). Alternative 5 differs from Alternative 2 in that Potrero Canyon Road Bridge is 2,290 feet long compared to 1,305 feet for Alternative 2 (width and vertical clearance are the same as for Alternative 2). The height, width, and vertical clearance of Commerce Center Drive Bridge and Long Canyon Road Bridge under Alternative 5 are the same as under

Alternative 2. The potential secondary impacts to wildlife discussed above for Alternative 2 also apply to Alternative 5.

Implementation of Alternative 5 would result in adverse but not significant impacts to wildlife crossings.

Alternative 6

Implementation of the RMDP and SCP under Alternative 6 would result in the construction of two large-span bridges across the Santa Clara River corridor (Long Canyon Road Bridge and Potrero Canyon Road Bridge). Alternative 6 differs from Alternative 2 in that Commerce Center Road Bridge would not be constructed, and Potrero Canyon Road Bridge is 2,390 feet long instead of 1,350 feet long as in Alternative 2 (width and vertical clearance are the same as for Alternative 2). The height, width, and vertical clearance of Long Canyon Road Bridge under Alternative 6 are the same as under Alternative 2. The potential secondary impacts to wildlife discussed above for Alternative 2 also apply to Alternative 6.

Implementation of Alternative 6 would result in adverse but not significant impacts to wildlife crossings.

Alternative 7

Implementation of the RMDP and SCP under Alternative 6 would result in the construction of one large-span bridge across the Santa Clara River corridor (Long Canyon Road Bridge). Alternative 7 differs from Alternative 2 in that Commerce Center Road Bridge and Potrero Canyon Road Bridge would not be constructed, and Long Canyon Road Bridge is 2,620 feet long instead of 980 feet long as in Alternative 2 (width and vertical clearance are the same as for Alternative 2). The potential secondary impacts to wildlife discussed above for Alternative 2 also apply to Alternative 7.

Implementation of Alternative 7 would result in adverse but not significant impacts to wildlife crossings.

Mitigation Summary and Strategy

Although impacts to wildlife crossings would not be significant and mitigation is not required, the protection of the River Corridor SMA, High Country SMA, and Salt Creek area, as discussed above for wildlife corridors, would reduce the effects of constrained wildlife crossings in the Project area by providing alternative routes for movement. In addition, improvements and enhancement of the existing wildlife crossing under SR-126 west of the Project area at the base of Salt Creek (see BIO-19) will facilitate north–south movement. The requirement for downcast lighting adjacent to open space areas will reduce lighting impacts on wildlife using both unconstrained and constrained crossings.

4.5.5.3 Impacts to Special-Status Species

This subsection describes the impacts to special-status species. As fully described in **Subsection 4.5.5.1**, impacts are categorized as direct, indirect, and secondary for each alternative.

Direct impacts would occur as a result of implementation of the RMDP and the SCP and include temporary disturbance to and/or permanent loss of special-status plant and animal species and/or their habitat from grading, clearing, and other construction-related activities. Direct permanent loss would result from proposed RMDP improvements, including:

- Construction of bridges and associated piers and abutments;
- Road crossing culverts;
- Bank stabilization/protection that includes ungrouted rock riprap, turf reinforcement mats, and exposed gunite slope-lining protection under bridge crossings and their abutments;
- Drainage facilities that include partially lined open channels;
- Grade controls and other channel improvements, including grade control structures in tributaries; engineered natural channels in Potrero, Long, and Lion canyons; grouted sloping boulder drops; non-grouted boulder step-pools; soil-cement grade control structures; sculpted concrete drop structures; and check structures;
- Water reclamation plant outfall;
- Water quality control features, such as water quality basins, debris basins, detention basins, catch basin inserts, and biorention features;
- Various roadway improvements to SR-126; and
- Recreation facilities.

Permanent loss of habitat (California annual grassland, agriculture, disturbed land) for some special-status species will also occur as a result of habitat restoration and enhancement activities.

Temporary loss of habitat for special-status species includes vegetation and land cover clearing, grading, and other Project-related disturbances (*e.g.*, temporary haul routes) in the Project area that temporarily displace the habitat that was present prior to construction. Temporary impacts would occur where grading or soil disturbance would occur for a short period of time (*e.g.*, along the edges of proposed facilities), but where no permanent structures would be constructed and no disturbance would occur.

Implementation of the proposed Project would also result in impacts to wildlife movement corridors and unique landscape features, such as the River Corridor SMA, High Country SMA, and Middle Canyon Spring.

Indirect impacts would occur as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. Indirect impacts also include permanent loss of special-status plant and animal species as a result of grading, clearing, and other construction-related activities. For purposes of analyzing indirect impacts, any temporary disturbance areas are included in the permanent footprint. (There are no temporary impacts identified for build-out of the Specific Plan, VCC, and Entrada planning areas.)

Secondary impacts are those reasonably foreseeable effects caused by Project implementation on remaining or adjacent biological resources outside the construction disturbance zone (*i.e.*, off-site impacts). Secondary impacts may affect areas within the defined Project area but outside the construction disturbance zone, including open space, and areas outside the Project area, such as downstream effects. Secondary impacts include short-term effects immediately related to construction activities and long-term or chronic effects related to the human occupation of developed areas. Both implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would result in short-term construction-related secondary impacts and long-term secondary impacts. These impacts are listed here and fully described in **Subsection 4.5.5.1.3**. It should be noted that many of the secondary impacts listed below may only be relevant to particular species or guilds; for example, hydrology and water quality impacts primarily affect aquatic, semi-aquatic, and riparian species.

Potential short-term construction-related impacts include hydrologic and water quality alterations; erosion and chemical and toxic compound pollution in uplands; dust; construction noise; vibration; lighting; increased human activity; temporary fencing; accidental clearing, trampling, and grading; oak tree root impacts; and trash and other debris.

Potential long-term secondary impacts resulting from implementation of the RMDP and the build-out of the Specific Plan, VCC, and Entrada planning areas generally can be categorized as (1) landscape-level impacts or (2) "edge" effects that generally occur along the open space–urban interface.

Landscape-level secondary impacts include bridge/road crossings, traffic noise, and lighting; altered hydrology; watershed-level water quality impacts; downstream effects of drainage and control facilities and water reclamation plant outfall; downstream effects of water quality control facilities; monitoring and maintenance of RMDP facilities; utility transmission lines; maintenance of utility crossings; recreational facilities; improvements to SR-126; stream restoration and enhancement activities; habitat fragmentation and isolation; altered natural wildfire regimes; increased traffic and vehicle collisions; air pollution; increased human activity; increased mesopredators; increased invasive plants; increased invasive aquatic and semi-aquatic species; microtrash (pertinent to condors); and increased risk of disease.

Open space–urban interface secondary impacts include increased noise; lighting; pet, stray, and feral animals; microclimate changes; invasive plant species; wildlife community alterations; trampling of vegetation and compaction of soils; pesticides, fertilizers, fungicides, herbicides, and rodenticides; and human collection and harassment of native species.

Table 4.5-54 shows the status and guild for each of the special-status species discussed in this subsection, as well as the order in which species appear in the text.

ARROYO TOAD (FE, CSC)

Life History

The arroyo toad (*Bufo californicus*) is found along low-gradient streams in coastal and desert drainages as well as high-elevation valleys in southern California and northern Baja California, Mexico. It uses aquatic, riparian, and upland habitats to different degrees depending on an individual's stage of development, the time of year, and the weather. Breeding and larval development occur within aquatic habitats; foraging may occur within drying stream beds, terraces adjacent to breeding sites, and nearby uplands, where aestivation and overwintering also occur. Breeding habitat for the arroyo toad is created and maintained by the fluctuating hydrological, geological, and ecological processes operating in riparian ecosystems and the adjacent uplands. Periodic flooding that modifies stream channels, redistributes channel sediments, and alters pool location and form, coupled with upper terrace stabilization by vegetation, is required to keep a stream segment suitable for all life stages of the arroyo toad (66 FR 9413–9474). Periodic flooding helps maintain areas of open, sparsely vegetated, sandy stream channels and terraces (Sweet 1992; Griffin and Case 2001). During the day and other periods of inactivity, arroyo toads seek shelter by burrowing into sand (Sweet 1992). Thus, areas of sandy or friable (readily crumbled) soils are the most important habitat for the species, and these soils can be interspersed with gravel or cobble deposits (70 FR 19562–19633). Radio telemetry studies at near-coastal locations (Griffin 1999) and montane sites (Ramirez 2002) documented extensive along-stream movements of adult and juvenile toads during their extended activity season. Arroyo toads may also seek temporary shelter under rocks or debris and have occasionally been found in mammal burrows (Griffin 1999). However, the use of burrows is not well understood and is believed to be an uncommon event (Haas 2005a).

Breeding generally occurs from late March until mid-June (Sweet 1989); however, depending on climatological and hydrologic conditions, breeding may commence as early as mid-February (Haas 2004) and extend into July. Arroyo toads move within streams and rivers to find suitable breeding and foraging habitats, as well as potential mates. In years when breeding conditions are fleeting, male advertisement may persist for extremely short periods, and the species' presence may be difficult to detect in the absence of frequent, early season surveys (Haas 2005A). Females rarely choose breeding sites under closed canopies; heavily shaded pools are generally unsuitable for eggs and larval arroyo toads because of lower water and soil temperatures and poor algal mat development (66 FR 9413–9474). Eggs are deposited in shallow aquatic habitats characterized by sandy and/or gravelly substrates and where silt deposition is minimal. The filter-feeding arroyo toad tadpoles require algal mats for development. Breeding sites are typically located adjacent to sandy terraces (59 FR 64589–64866); at or near the edge of shallow pools, low-flow stream channels, and ox-bows; and along in-stream sand bars with minimal current (zero to two kilometers (1.24 miles) per hour), and little or no emergent vegetation. After metamorphosis, which typically occurs in the period from May to July, neonate toads remain

along or very near breeding sites, in order to take advantage of available forage and ambient moisture—especially the moist, sandy substrate of drying pools. Over a period of several weeks, the neonates mature in size and they leave wet or moist stream areas and river edges once they are physically capable of burying themselves in local substrates (Sweet 1992).

In many drainages, the arroyo toad does not breed annually, and metapopulations of the arroyo toad may persist for seven years or more between breeding events (Haas 2005B). Moreover, early season breeding attempts may be unsuccessful if surface flows do not persist for the requisite 60 to 75 days necessary to support larvae to metamorphosis. Thus, early season surveys are necessary to determine presence/absence status of the arroyo toad, especially in years of below-average rainfall (Haas 2004). In years when heavy rains (or planned water releases) affect breeding sites, arroyo toad larvae may swim or be flushed downstream due to heavy currents (Griffin 1999). Survivorship of these individuals has never been documented; thus, the effects of such events are unknown.

Outside of the breeding season, juvenile and adult arroyo toads are terrestrial and spend most of their lives on open terraces and in riparian habitats, typically adjacent to breeding locations, and, less commonly, moving into upland habitats. Riparian areas used by juveniles and adults for foraging and burrowing include sand bars, alluvial terraces, and streamside benches that lack vegetation or are sparsely to moderately vegetated (Sweet 1992; Holland and Sisk 2001). Upland habitats occupied by the arroyo toad include alluvial scrubs, sage scrubs, open chaparral, grassland, and oak woodland (Griffin and Case 2001). Friable sandy soils used for burrowing are the common factor in these occupied habitats. Arroyo toads also have been found in agricultural fields (Griffin 1999), but these lands may be habitat sinks (areas where mortality rates are higher than reproduction rates and thus lead to population declines over the long term) due to soil type, tilling, pesticide and fertilizer applications, and heavy equipment use (Griffin and Case 2001).

Subadults and adults may range widely into the surrounding uplands; however, most individuals remain on sandy terraces adjacent to breeding habitat. Smaller numbers of juveniles and adults range widely into surrounding upland habitats, and may move up to one kilometer (0.6 mile) or more from breeding sites (Holland and Sisk 2000; Bloom 2007). In some cases, adults have been found at distances greater than one kilometer from riparian areas, such as in upper Cristianitos Canyon in southern Orange County, where at least one individual was detected 3.4 kilometers (2.1 miles) from the nearest breeding population (Bloom Biological 2007B). The distance traveled from a breeding site depends on topography (*e.g.*, mild slopes are more easily traversed than steeper slopes) and presence of navigable pathways (*e.g.*, roads, game trails, open habitats). Movements into uplands may facilitate foraging and dispersal; however, areas with extremely compact soils may act as habitat sinks, the use of which may result in desiccation and increased predator pressure.

Critical Habitat

Reaches of the Santa Clara River and Castaic Creek in the Project area were within Unit 6: Upper Santa Clara River Basin, Los Angeles County of the final rule designating arroyo toad critical habitat published on February 7, 2001 (66 FR 9413–9474). As stated in 66 FR 9418 of the 2001 critical habitat designation, the USFWS is "required to base critical habitat determinations on the best scientific and commercial data available and to consider those physical and biological features (primary constituent elements) that are essential to the conservation of the species."

The 2001 critical habitat designation identified Subunit 6b, which included Castaic Creek to its confluence with the Santa Clara River, and the River upstream to its confluence with San Francisquito Creek. Although the arroyo toad had not been documented in Santa Clara River at the time of the final rule, the USFWS considered the River to be essential to the dispersal of toads between Castaic Creek and San Francisquito Creek (66 FR 9422).

On October 30, 2002, the federal court of the District of Columbia set aside the 2001 critical habitat designation on the basis of a lawsuit challenging the designation of arroyo toad critical habitat, citing errors by the USFWS in promulgating the rule (69 FR 23256). On April 28, 2004, the USFWS proposed a new rule designating critical habitat that differed from the previous designation in regard to mapping grid size and new survey information for the arroyo toad. Unit 6 was retained in the proposed designation, but Subunit 6b was revised based on new survey information, including expansion of critical habitat to uplands to support breeding populations of the arroyo toad.

On April 13, 2005, the USFWS issued the final critical habitat designation for the arroyo toad (70 FR 19562). As the basis for the 2005 critical habitat designation, the USFWS identified the "primary constituent elements" that the USFWS considers to be the "physical and biological attributes that are essential to the conservation of the species and that may require special management considerations or protections" (59 FR 64846). The 2005 critical habitat designation identified the arroyo toad's primary constituent elements as:

1. Rivers or streams with hydrologic regimes that supply water to provide space, food, and cover needed to sustain eggs, tadpoles, metamorphosing juveniles, and adult breeding toads.

2. Low-gradient streams (less than 6% slope) with sandy or fine gravel substrates that support the formation of shallow pools and sparsely vegetated sand and gravel bars for breeding and rearing of tadpoles and juveniles.

3. A natural flooding regime, or one sufficiently corresponding to a natural regime, that will periodically scour riparian vegetation, rework stream channels and terraces, and

redistribute sands and sediments, such that breeding pools and terrace habitats with scattered vegetation are maintained.

4. Riparian and adjacent upland habitats (*e.g.*, alluvial scrub, coastal sage scrub, chaparral, and oak woodlands, but particularly alluvial streamside terraces and adjacent valley bottomlands that include areas of loose soil where toads can burrow underground) to provide foraging, aestivation, and living areas for subadult and adult arroyo toads.

5. Stream channels and adjacent upland habitats that allow for migration to foraging areas, overwintering sites, dispersal between populations, and recolonization of areas that contain suitable habitat.

The USFWS reduced the critical habitat area from the 95,655 acres proposed in February 2004 to 11,695 acres in the 2005 final designation (70 FR 19562–19633). Based solely on economic considerations, the final critical habitat designation excluded 13 units in the proposed rule, totaling 67,584 acres (including Unit 6), which encompassed the Project area.[1] These excluded units are located in Santa Barbara, Ventura, Los Angeles, Orange, Riverside, San Bernardino, and San Diego counties. Portions of two other units in Orange and San Diego counties were excluded from critical habitat based on economic considerations and a combination of other factors. All proposed critical habitat in Monterey, Orange, and San Diego counties was excluded in the final rule. The final rule, however, is the subject of pending litigation.

Because there is no critical habitat designation for the Project area, critical habitat is not further addressed in the arroyo toad analysis in this EIS/EIR.

Recovery Plan

The Arroyo Southwestern Toad Recovery Plan was published by the USFWS on July 24, 1999 (USFWS 1999A). The recovery strategy for the arroyo toad consists of five parts: (1) stabilize and maintain populations through the range of the arroyo toad in California by protecting sufficient breeding and nonbreeding habitat; (2) monitor the status of existing populations to ensure recovery actions are successful; (3) identify and secure, by appropriate management and monitoring, additional suitable arroyo toad habitat and populations; (4) conduct research to determine the population dynamics and ecology of the species to guide management efforts and determine the best methods for reducing threats; and (5) develop and implement an outreach program.

[1] Essential lands in Unit 6 were excluded from the critical habitat designation under Endangered Species Act section 4(b)(2) for economic reasons. See Application of Endangered Species Act sections 3(5)(A) and 4(a)(3) and Exclusions Under Endangered Species Act section 4(b)(2) (70 FR 19585).

The Santa Clara River basin is included in Subregion 7 of the Northern Recovery Unit. More specifically, waterways included in this Recovery Unit Subregion include Sespe Creek, Piru Creek, Agua Blanca Creek, Castaic Creek, San Francisquito Creek, and Bouquet Creek (USFWS 1999A). The inclusion of these waterways is based on current or historic occurrences of arroyo toad in portions of the drainages. The Santa Clara River is not directly identified in the Recovery Plan as having a conservation role in the recovery strategy for the species. Therefore, the Recovery Plan is not further addressed in the analysis for the arroyo toad in this EIS/EIR.

Threats

In addition to the direct loss of aquatic, riparian, and upland habitat, other factors associated with urban development that contribute to declining arroyo toad populations were identified in the 2001 final designation of critical habitat (66 FR 9413–9474). The natural flow of streams can be altered by surface runoff from urban development and agricultural uses. Water pollution, in the form of fertilizers, biocides, chlorine, and other pollutants, adversely affects amphibian development, survival, and habitat. Further, the introduction of exotic predators (*e.g.*, bullfrog, African clawed frog, and green sunfish) and increases in mesopredators (*e.g.*, raccoons and skunks) often associated with urban development can threaten or eliminate toad populations (69 FR 23254–23328). Exotic plant species (*e.g.*, tamarisk, giant reed, iceplant, and pampas grass) may also degrade arroyo toad habitat by contributing to altered hydrology, eliminating sandbars and breeding pools, and restricting access to and quality of upland habitats (69 FR 23254–23328). Other factors that may adversely affect the species include livestock grazing and recreational activities in riparian areas and human-related increases in fire frequency and light and noise levels that may affect the species' nocturnal foraging and breeding behavior (Barrass and Cohn 1984).

Survey Results

Protocol surveys and habitat evaluations for arroyo toad have been conducted throughout the portions of the Santa Clara River and Castaic Creek in the Project area (RECON 1999A; Aquatic Consulting Services, Inc., 2002A, 2002B, 2002C, 2002D; Sandburg 2001; Impact Sciences 2001, 2002; Ecological Sciences 2003A, 2003B, 2003C, 2003D, 2003E, 2003F, 2004A, 2004B, 2004C, 2004D; Compliance Biology 2004D; Bloom 2007). During these surveys, no adult or subadult arroyo toads were observed in the Project area. However, arroyo toad tadpoles were observed in the Specific Plan area during surveys conducted in 2000 (Aquatic Consulting Services, Inc., 2002A, 2002B, 2002C, 2002D). During these surveys Aquatic Consulting Services found arroyo toad tadpoles in the Santa Clara River upstream and downstream of the proposed Commerce Center Drive Bridge site and near the Valencia Water Treatment Plant (**Figure 4.5-46**, RMDP/SCP Arroyo Toad Species Occurrences).

Other documented occurrences of arroyo toad in the upper Santa Clara River watershed (but outside the Project area boundaries) include:

- Santa Clara River just east of I-5: one individual captured and released on July 20, 1994 (CDFG 2007A);
- Castaic Creek: occurrences have been documented on Department of Water Resources land and the Angeles National Forest, both above and below Castaic Lake Reservoir (70 FR 19562–19633);
- Upper San Francisquito Creek: calling male arroyo toads observed in 1997 near the old Saint Francis Dam (70 FR 19562–19633);
- Upper San Francisquito Creek: recent surveys (presumably on U.S. Forest Service land) "found evidence of the species" in the drainage (70 FR 19562–19633);
- Santa Clara River: report of six arroyo toad tadpoles adjacent to Castaic Junction in 2000 (CDFG 2007A);
- Santa Clara River: four adult arroyo toads reported by Sandburg near the confluence of San Francisquito Creek in April 2001 (unpublished notes sent to USFWS);
- Santa Clara River: a single adult was observed near the confluence of San Francisquito Creek (Impact Sciences 2002);
- Soledad Canyon area: 75 tadpoles reported from three sites located approximately 11 miles east of the I-5 crossing (Sandburg 2001); and
- Santa Clara River: in 2003, Ramirez reported "recent observations of arroyo toads and eggs" in the vicinity of the San Francisquito Creek confluence (70 FR 19562–19633).

As noted above, a small number of tadpoles and no adult or subadult arroyo toads have been detected in the Project area during multiple survey efforts conducted over more than a decade. Based on these survey results, a breeding population of arroyo toad has not been detected in the Project area. However, given the presence of upstream populations of arroyo toad, the fact that tadpoles have been observed in the eastern portion of the Project area (within the Santa Clara River), and the presence of high-quality habitat throughout the reaches of the Santa Clara River and Castaic Creek on the Project site, there is potential for a small breeding population of arroyo toad to occur in the portions of the Santa Clara River and Castaic Creek in the Project area as well as in adjacent riparian and upland habitats.

Suitable arroyo toad habitat mapped by Impact Sciences (2002) will be used for the purpose of this impact analysis. Impact Sciences conducted a habitat quality assessment for the arroyo toad along and adjacent to the Santa Clara River floodplain and adjacent uplands within the Project area. Upland areas within 500 meters (1,640 feet) on either side of arroyo toad protocol survey zones were included in the habitat evaluation, but with SR-126 set as the northern boundary where less than 500 meters of upland habitat was present between the riparian zone and the roadway (*i.e.*, suitable habitat did not extend north of SR-126). Within each reach, the total area was divided into "within riverbanks" and "outside riverbanks" zones. The two zones were

evaluated for their support of primary constituent elements identified in the critical habitat designation for the arroyo toad (70 FR 19562).

1. Rivers or streams with hydrologic regimes that supply water to provide space, food, and cover needed to sustain eggs, tadpoles, metamorphosing juveniles, and adult breeding toads;

2. Low-gradient streams (less than 6% slope) with sandy or fine gravel substrates that support the formation of shallow pools and sparsely vegetated sand and gravel bars for breeding and rearing of tadpoles and juveniles;

3. A natural flooding regime, or one sufficiently corresponding to a natural regime, that will periodically scour riparian vegetation, rework stream channels and terraces, and redistribute sands and sediments, such that breeding pools and terrace habitats with scattered vegetation are maintained;

4. Riparian and adjacent upland habitats (*e.g.*, alluvial scrub, coastal scrub, chaparral, and oak woodlands, but particularly alluvial streamside terraces and adjacent valley bottomlands that include areas of loose soil where toads can burrow underground) to provide foraging, aestivation, and living areas for subadult and adult arroyo toads; and

5. Stream channels and adjacent upland habitats that allow for migration to foraging areas, overwintering sites, dispersal between populations, and recolonization of areas that contain suitable habitat.

For the purpose of this analysis, "Category 1" habitats are defined as habitats that are capable of supporting all life history phases. In the Project area, Category 1 habitat falls primarily within the 100-year floodplain. "Category 2" habitats may support some phases of the arroyo toad's life history, such as foraging and aestivation/hibernation, but do not generally support adequate hydrology for breeding. Habitats missing two or more elements, especially where the hydrologic regime is absent, are defined as "Category 3" habitat. Category 3 habitat would be limited to supporting aestivation/hibernation, dispersal, and foraging. Category 3 habitat primarily includes upland areas, including agriculture, outside the Santa Clara River floodplain.

The habitat quality assessment identified 1,931 acres of suitable habitat for the arroyo toad within the Project area, including 797 acres of Category 1 habitat, 76 acres of Category 2 habitat, and 1,058 acres of Category 3 habitat (**Figure 4.5-47**, Arroyo Toad Habitat).

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the permanent loss of 159 acres (8.2%) of "suitable" habitat (including Category 1, Category 2, and Category 3 habitat) and temporary impacts to 118 acres (**Figure 4.5-48**, Alternative 2 Impacts to Arroyo Toad). The loss of these habitats would be as follows:

- Category 1 habitat – 52 acres (6.5%) of permanent loss and 65 acres of temporary loss;
- Category 2 habitat – 14 acres (18.7%) of permanent loss and 9.7 acres of temporary loss; and
- Category 3 habitat – 93 acres (8.8%) of permanent loss and 43 acres of temporary loss.

Arroyo toad tadpoles have been documented on the Project area, although no adults or subadult arroyo toads have been observed in the Project area. However, for the purposes of this analysis it is assumed that the Project area supports a small population of arroyo toads. Given the endangered status of the species and sporadic occurrence within the Santa Clara River and its tributaries, if adults or subadults were present at the time of impacts, the permanent and temporary loss of suitable habitat through implementation of the RMDP SCP would have a substantial direct adverse effect on this species; could interfere substantially with the movement of the species or impede the use of nursery sites; would have the potential to substantially reduce the habitat of the species on site or rangewide; could cause the species to drop below self-sustaining levels on site or rangewide; could threaten to eliminate the species on site or rangewide; or could substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent loss of 629 acres (32.6%) of suitable habitat (**Figure 4.5-48**, Alternative 2 Impacts to Arroyo Toad). The loss of Category 1, Category 2, and Category 3 habitat would be as follows:

- Category 1 habitat – 7.0 acres (0.9%) of permanent loss;
- Category 2 habitat – 11 acres (13.9%) of permanent loss; and
- Category 3 habitat – 612 acres (57.8%) of permanent loss.

A high amount and percentage of suitable habitat for the arroyo toad, albeit mostly Category 3 habitat (*i.e.*, upland aestivation/hibernation, dispersal, and foraging), would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. Category 3 habitat provides refugia from severe flooding, and would reduce the potential for animals using this area to be washed downstream. This loss of habitat could have a substantial adverse effect on the species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable arroyo toad habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 788 acres (40.8%). The loss of Category 1, Category 2, and Category 3 habitat would be as follows:

- Category 1 habitat – 59 acres (7.4%) of permanent loss;
- Category 2 habitat – 25 acres (32.6%) of permanent loss; and
- Category 3 habitat – 705 acres (66.6%) of permanent loss.

Because of the large amount and percentage of suitable habitat loss, including substantial acreage of Category 3 habitat that could provide dry refuge during severe flood events, the combined direct and indirect permanent impacts to suitable arroyo toad habitat could have a substantial adverse effect on the species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below

self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Although the Project area supports suitable habitat for arroyo toad, only a few tadpoles and no adult or subadult arroyo toads have been observed during multiple survey efforts conducted over more than a decade. Based on these survey results, a breeding population of arroyo toad was not detected in the Project area. However, given the presence of upstream populations of arroyo toad, the fact that tadpoles have been observed in the eastern portion of the Project area, and the presence of suitable habitat, a breeding population of the arroyo toad could be present in the Santa Clara River and Castaic Creek within the Project area as well as in surrounding riparian and upland habitats. The implementation of the RMDP would include the construction of bridges and bank stabilization within areas containing Category 1 arroyo toad habitat. Other construction activities would occur in areas containing Category 2 and Category 3 habitat. Should arroyo toad adults, subadults, tadpoles, or egg masses be present within the disturbance footprint, these activities could result in injury or mortality of arroyo toad individuals due to direct contact with construction equipment, entombment in burrows, and disturbances to aquatic breeding sites that could disturb egg masses and tadpoles. Implementation of the SCP would not directly impact this species.

Given its rarity in the Project region and its status as a federally listed endangered species, the loss of any arroyo toad adults, subadults, tadpoles, or egg masses could have a substantial direct adverse effect on this species; interfere substantially with the movement of the species or impede the use of nursery sites; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

The types of potential indirect permanent impacts to individuals would be the same as described above for direct impacts to individuals. However, because the build-out of the Specific Plan, VCC, and Entrada planning areas would result in substantially greater permanent impacts to upland habitats potentially occupied by arroyo toad adults and subadults, the risk of impacts to toads using these habitats for foraging and aestivation is

higher than for implementation of the RMDP. Should arroyo toad adults, subadults, tadpoles, or egg masses be present within the disturbance footprint, these activities could result in injury or mortality of arroyo toads.

Given its rarity in the Project region and its status as a federally listed endangered species, the loss of arroyo toad adults, juveniles, tadpoles, or egg masses could have a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of nursery sites; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect arroyo toads in the short term in areas adjacent to or downstream of construction zones. Construction activities could cause ground vibration that may disturb burrows or alter the arroyo toad's behavior, possibly causing them to emerge from burrows and increasing their risk of exposure, predation, and vehicle collisions. Grading activities could result in the dispersion of sediments and pollutants from upland portions of the site into downstream areas of the Santa Clara River. Hydrologic and water quality impacts could include chemical pollution, increased turbidity, excessive sedimentation, flow interruptions, and changes in water temperature due to short-term changes to the active channel morphology. Construction-related dust could also adversely affect water quality and prey species. These impacts could disturb on-site and downstream habitat quality and disrupt breeding activities. Trash may attract predators of arroyo toads, such as crows and ravens.

In the long term, use of RMDP facilities, such as bridges over the Santa Clara River, and the proximity of urban development to potential arroyo toad habitat could result in disruption of nocturnal activities and greater vulnerability to predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; greater vulnerability to predation by pet, stray, and feral cats and dogs as well as other mesopredators (see Crooks and Soulé 1999); collecting by children; degradation of habitat from increased human use (*e.g.*, trampling, trash, and off-road vehicles) and altered fire regimes (likely too frequent fire); invasion by exotic plant (*e.g.*, giant reed, tamarisk, and pampas grass) and wildlife species (*e.g.*, Argentine ants, bullfrogs, African clawed frogs, exotic fish, and crayfish); use of pesticides; and increased risk of roadkill on roads adjacent to occupied areas. In addition, grazing in or adjacent to tributaries or surrounding uplands could result in crushing or entombment in burrows.

Both the short-term and long-term secondary impacts could have a substantial adverse effect on this species; interfere substantially with the movement of the species or impede the use of

nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct and indirect secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP under Alternatives 3 through 7 would result in the following direct permanent and temporary impacts to suitable habitat for the arroyo toad (**Figures 4.5-49** through **4.5-53**, Alternatives 3 through 7 Impacts to Arroyo Toad):

- Alternative 3 – 112 acres (5.8%) of permanent loss and 140 acres of temporary loss;
  - Category 1 habitat – 30 acres (3.8%) of permanent loss and 65 acres of temporary loss;
  - Category 2 habitat – 11 acres (14.0%) of permanent loss and 13 acres of temporary loss;
  - Category 3 habitat – 71 acres (6.7%) of permanent loss and 62 acres of temporary loss;
- Alternative 4 – 112 acres (5.8%) of permanent loss and 140 acres of temporary loss;
  - Category 1habitat – 30 acres (3.8%) of permanent loss and 65 acres of temporary loss;
  - Category 2 habitat – 11 acres (14.0%) of permanent loss and 13 acres of temporary loss;
  - Category 3 habitat – 71 acres (6.7%) of permanent loss and 62 acres of temporary loss;
- Alternative 5 – 147 acres (7.6%) of permanent loss and 127 acres of temporary loss;
  - Category 1 habitat – 38 acres (4.8%) of permanent loss and 69 acres of temporary loss;
  - Category 2 habitat – 14 acres (18.0%) of permanent loss and 9.5 acres of temporary loss;

  - Category 3 habitat – 95 acres (9.0%) of permanent loss and 49 acres of temporary loss;
- Alternative 6 – 83 acres (4.3%) of permanent loss and 139 acres of temporary loss;
  - Category 1 habitat – 30 acres (3.7%) of permanent loss and 64 acres of temporary loss;
  - Category 2 habitat – 6.4 acres (8.5%) of permanent loss and 13 acres of temporary loss;
  - Category 3 habitat – 47 acres (4.4%) of permanent loss and 62 acres of temporary loss;
- Alternative 7 – 49 acres (2.6%) of permanent loss and 299 acres of temporary loss;
  - Category 1 habitat – 9.0 acres (1.1%) of permanent loss and 56 acres of temporary loss;
  - Category 2 habitat – 4.0 acres (5.3%) of permanent loss and 12 acres of temporary loss; and
  - Category 3 habitat – 36 acres (3.4%) of permanent loss and 232 acres of temporary loss.

Compared to Alternative 2, which would result in an overall total of 159 acres (8.2%) of permanent loss and 118 acres of temporary impacts to suitable habitat, the overall direct permanent impacts to suitable arroyo toad habitat under Alternatives 3 through 6 would range from marginally reduced (Alternative 5), to somewhat reduced (Alternatives 3 and 4), to substantially reduced (Alternatives 6 and 7). The large reduction in permanent loss of habitat under Alternative 7 compared to the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River. Temporary impacts under Alternatives 3 through 6 would be somewhat increased compared to Alternative 2 and substantially increased under Alternative 7 compared to the other alternatives.

With regard to Category 1, Category 2, and Category 3 habitat, Alternative 2 would have a relatively greater impact on Category 1 habitat, with a 6.5% permanent loss compared to a range of 1.1% (Alternative 7) to 4.8% (Alternative 5) for the other alternatives. For Category 2 and Category 3 habitat, permanent loss under Alternatives 3, 4, and 5 would be similar to Alternative 2, which would have 93 acres (8.8%) of permanent loss of Category 3 habitat and 14 acres (18.7%) of permanent loss of Category 2 habitat. Alternatives 6 and 7 would have substantially reduced permanent loss of Category 2 and Category 3 habitat compared to the other alternatives. Because of the pullback of RMDP

facilities from the Santa Clara River, Alternative 7 would have the least amount of impacts to Category 1, Category 2, and Category 3 habitat.

Temporary impacts to suitable habitat for the arroyo toad have similar levels of both overall impact and breakdowns for the different quality ratings for Alternatives 3 through 6 compared to Alternative 2. Alternative 7 would have somewhat reduced temporary impacts to Category 1 habitat, similar impacts to Category 2 habitat, and substantially greater impacts to Category 3 habitat compared to Alternatives 2 through 6.

The overall permanent loss of habitat and temporary impacts from implementation of the RMDP and the SCP under Alternatives 3 through 6 are reduced or similar in magnitude compared to Alternative 2, and permanent impacts are substantially reduced under Alternative 7 (albeit substantially increased for Category 3 habitat). However, because the arroyo toad is a listed endangered species and occurs sporadically in the Santa Clara River and its tributaries, any loss of occupied habitat would have a substantial adverse effect on this species. If adults or subadults were present when construction was initiated, the loss of permanent and temporary loss of habitat would be significant, absent mitigation, for Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the arroyo toad (**Figures 4.5-49** through **4.5-53**, Alternatives 3 through 7 Impacts to Arroyo Toad):

- Alternative 3 – 625 acres (32.4%) of permanent loss;
  - Category 1 habitat – 6.9 acres (0.9%) of permanent loss;
  - Category 2 habitat – 10 acres (13.8%) of permanent loss;
  - Category 3 habitat – 607 acres (57.4%) of permanent loss;
- Alternative 4 – 624 acres (32.3%) of permanent loss;
  - Category 1 habitat – 6.9 acres (0.9%) of permanent loss;
  - Category 2 habitat – 10 acres (13.8%) of permanent loss;
  - Category 3 – 607 acres (57.4%) of permanent loss;
- Alternative 5 – 613 acres (31.8%) of permanent loss;
  - Category 1 habitat – 7.3 acres (0.9%) of permanent loss;
  - Category 2 habitat – 11 acres (14.3%) of permanent loss;
  - Category 3 –595 acres (56.2%) of permanent loss;

- Alternative 6 – 502 acres (26.0%) of permanent loss;
  - Category 1 habitat – 6.7 acres (0.8%) of permanent loss;
  - Category 2 habitat – 4.2 acres (5.6%) of permanent loss;
  - Category 3 habitat – 492 acres (46.5%) of permanent loss;
- Alternative 7 – 311 acres (16.1%) of permanent loss;
  - Category 1 habitat – 0.2 acre (0.03%) of permanent loss;
  - Category 2 habitat – 4.7 acres (6.2%) of permanent loss; and
  - Category 3 habitat – 306 acres (28.9%) of permanent loss.

For overall indirect permanent loss of potential arroyo toad habitat, Alternatives 3 through 5 would not be substantially different compared to Alternative 2, which would result in a total of 629 acres (32.6%) of permanent loss. Both Alternatives 6 and Alternative 7 would have substantially reduced impacts. Alternative 7 would have the least impact by far because of the pullback from the Santa Clara River and avoidance of some agricultural areas adjacent to the River that would be impacted under the other alternatives.

With regard to indirect permanent loss of Category 1 and Category 2 habitat, impacts under Alternatives 3 through 6 would be similar to Alternative 2, which would have a permanent loss of 11 acres (13.9%) of Category 2 habitat and 7.0 acres (0.9%) of Category 1 habitat. Alternative 7 would have substantially reduced impacts to Category 3 and Category 2 habitat compared to the other alternatives. For Category 3 habitat, compared to Alternative 2 which would have 612 acres (57.8%) of permanent loss, Alternatives 3, 4, and 5 would have marginally reduced impacts, Alternative 6 would have somewhat reduced impacts, and Alternative 7 would have substantially reduced impacts.

Although indirect permanent impacts to suitable habitat would be reduced under Alternatives 3 through 7, they would still be substantially adverse because of the relatively large amount and percentage of suitable habitat lost on site (16.1% under Alternative 7 to 32.4% under Alternative 3). Although the large majority of the habitat permanently lost is Category 3 habitat, this habitat may be important as dry refugia during severe flood events. Therefore, the indirect permanent impacts to suitable habitat for the arroyo toad occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the arroyo toad:

- Alternative 3 – 736 acres (38.2%) of permanent loss;
  - Category 1 habitat – 37 acres (4.6%) of permanent loss;
  - Category 2 habitat – 21 acres (27.8%) of permanent loss;
  - Category 3 habitat – 678 acres (64.1%) of permanent loss;
- Alternative 4 – 736 acres (38.2%) of permanent loss;
  - Category 1 habitat – 37 acres (4.6%) of permanent loss;
  - Category 2 habitat – 21 acres (27.8%) of permanent loss;
  - Category 3 habitat – 678 acres (64.1%) of permanent loss;
- Alternative 5 – 760 acres (39.4%) of permanent loss;
  - Category 1 habitat – 45 acres (5.7%) of permanent loss;
  - Category 2 habitat – 24 acres (32.3%) of permanent loss;
  - Category 3 habitat – 690 acres (65.2%) of permanent loss;
- Alternative 6 – 585 acres (30.3%) of permanent loss;
  - Category 1 habitat – 37 acres (4.6%) of permanent loss;
  - Category 2 habitat – 11 acres (14.0%) of permanent loss;
  - Category 3 habitat – 538 acres (50.9%) of permanent loss;
- Alternative 7 – 360 acres (18.7%) of permanent loss;
  - Category 1 habitat – 9.2 acres (1.2%) of permanent loss;
  - Category 2 habitat – 8.7 acres (11.5%) of permanent loss; and
  - Category 3 habitat – 342 acres (32.3%) of permanent loss.

For overall combined direct and indirect permanent loss of suitable arroyo toad habitat, Alternatives 3 through 5 would be somewhat reduced compared to Alternative 2, which would result in a total of 788 acres (40.8%) of permanent loss. Alternatives 6 and 7 would have substantially reduced impacts and Alternative 7 would have the least impact by far because of the pullback of RMDP facilities from the Santa Clara River and avoidance of some agricultural areas adjacent to the River that would be impacted under the other alternatives.

For Category 1 habitat, compared to Alternative 2, which would have 59 acres (7.4%) of permanent loss, Alternatives 3 through 7 would have somewhat reduced impacts and Alternative 7 would have substantially reduced impacts. For Category 2 habitat, compared to Alternative 2 which would have 25 acres (32.6%) of permanent loss, Alternatives 3, 4, and 5 would have marginally reduced impacts, Alternative 6 would have somewhat reduced impacts, and Alternative 7 would have substantially reduced impacts. For Category 3 habitat, compared to Alternative 2 which would have 705 acres (66.6%) of permanent loss, Alternatives 3, 4, and 5 would have marginally reduced impacts, Alternative 6 would have somewhat reduced impacts, and Alternative 7 would have substantially reduced impacts.

Although Alternatives 3 through 7 would have reduced permanent loss of suitable habitat compared to Alternative 2, the combined direct and indirect impacts would still be substantially adverse under Alternatives 3 through 7 because of the relatively large percentage of potential habitat lost on site (including Category 3 habitat that may be used as dry refugia during severe flood events) ranging from 18.7% under Alternative 7 to 39.4% under Alternative 5. Therefore, the combined direct and indirect permanent loss of suitable habitat for the arroyo toad occurring as a result of implementation of the RMDP and SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual arroyo toads as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Because of the pullback from the Santa Clara River and avoidance of large areas of agriculture under Alternative 7, the potential for impacts to individuals would be substantially reduced under Alternative 7 compared to the other alternatives. However, given its rarity in the Project region and its status as a federally listed endangered species, the loss of arroyo toad adults, juveniles, tadpoles, or egg masses could have a substantial adverse effect on this species. Therefore, impacts to individual arroyo toads occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada

planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar short-term impacts from construction activities and long-term effects. Construction impacts could include dust, ground vibration, lighting, trash, and hydrologic and water quality impacts that could disturb on-site and downstream habitat quality and disrupt breeding activities. Potential long-term impacts include disruption of nocturnal activities and increased predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; increased predation by pet, stray, and feral cats and dogs as well as other mesopredators; collecting; habitat degradation by trampling, trash, off-road vehicles, and altered fire regimes; invasion by exotic plant and wildlife species; use of pesticides; and increased risk of roadkill on roads adjacent to occupied areas. In addition, grazing within or adjacent to tributaries could cause crushing or entombment in burrows.

Therefore, the loss or degradation of suitable habitat and impacts to individual arroyo toads due to short-term and long-term secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to arroyo toad: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

Impacts to individuals, including adults, juveniles, metamorphs, egg masses, and tadpoles, could occur during construction as a result of vegetation clearing and grading and construction activities in breeding pools, including injury and mortality due to direct contact with construction equipment, entombment of hibernating and aestivating individuals, and increased exposure of individuals flushed from burrows or left without protective cover. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys within the proposed disturbance area and within 1,000 feet of the construction zone and access road will be conducted by a qualified biologist in possession of a federal permit to capture and relocate arroyo toads. If detected, no work will be conducted within 500 feet of occupied habitat without concurrence of USFWS. A monitoring plan will prepared and implemented to protect the arroyo toad, if present, during construction in consultation with and approved by USFWS and CDFG. General procedures to avoid and minimize impacts to arroyo toad during construction will be implemented and a qualified biologist will be present during construction in order to relocate any identified remaining individuals, further reducing impacts to the species. In addition, several general measures will be implemented to protect wetland habitats that would reduce effects on the arroyo toad. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities; biological monitoring during any stream diversions; restrictions on construction equipment

operating in ponds or flowing water; design of bridges, culverts, and other structures so as not to impair the movement of aquatic species; and protection of water quality from mud, silt, and other pollutants.

The combined permanent loss of suitable habitat for the arroyo toad resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 360 acres (18.7%) under Alternative 7 to 788 acres (40.8%) under Alternative 2. For Category 1 arroyo toad habitat, impacts would range from 9.2 acres (1.2%) under Alternative 7 to 59 acres (7.4%) under Alternative 2. This would be a substantial loss of suitable habitat and would reduce the potential size and distribution of the arroyo toad population in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in large areas of suitable habitat for this species being protected in the River Corridor SMA (**Figure 4.5-9**). The majority of Category 1 suitable habitat for the arroyo toad would ultimately be preserved under all the alternatives (preserved habitat includes Category 1 habitat that would not impacted or temporarily impacted and restored): 734 acres (92.1%) under Alternative 2, 760 acres (95.4%) under Alternatives 3 and 4, 751 acres (94.2%) under Alternative 5, 760 acres (95.4%) under Alternative 6, and 787 acres (98.8%) under Alternative 7. In addition, the Flood Hydraulics Impacts Assessment(PACE 2009) found that there would be no significant impacts in water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area over the long term as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County. The technical analysis further determined that the River would still retain sufficient width to allow natural fluvial processes to continue. Following build-out, the River Corridor floodplain would remain 1,000 to 2,000 feet wide and retain the mosaic of habitats, including the relatively narrow wetted channel, benches, and dry terraces that would support the life history of the arroyo toad, including breeding, foraging, aestivation, hibernation, and dispersal.

Substantial dry refuge habitat would also be undeveloped under Alternatives 2 through 7, including adjacent uplands and agricultural areas. These areas include Category 3 habitat outside of the 100-year floodplain (**Figures 4.5-48** through **4.5-53**, Alternatives 2 through 7 Impacts to Arroyo Toad). These areas would be available as aestivation/hibernation, dispersal, and foraging area and would reduce the potential for adults and subadults using these areas to wash downstream during severe flood events. Under Alternative 2, 353 acres (33%) of a total of 1,058 existing acres, would be available, 379 acres (36%) would be available under Alternative 3, 380 acres (35.9%) would be available under Alternative 4, 368 acres (34.8%) would be available under Alternative 5, 519 acres (49%) would be available under Alternative 6, and 715 acres (67.6%) would be available under Alternative 7. Alternatives 6 and 7 would have substantially more Category 3 upland habitat available because of reduced impacts for Mission

Village under both alternatives and additional reduced permanent impacts for Landmark Village under Alternative 7 (**Figures 4.5-52** and **4.5-53**, Alternatives 6 and 7 Impacts to Arroyo Toad).

With respect to secondary effects, any arroyo toads occupying habitat in close proximity to construction zones may be disturbed by construction activities, including ground vibration, dust, and nighttime lighting. Ground vibration could cause toads to emerge from burrows and expose them to predators, adverse environmental conditions, and increase their chance of injury or mortality from construction equipment and vehicles. Lighting may increase their risk of predation from nocturnal predators and dust may adversely affect water quality and their insect prey. Potential breeding pools, including downstream pools, could be disturbed during construction by hydrological alterations and pollutants that impair water quality, thus adversely affecting egg masses and tadpoles. Unsecured trash could attract predators such as crows and ravens. Construction activities within 500 feet of occupied habitat will not be allowed without concurrence of USFWS and thus will help reduce the potential effects of noise, ground vibration, lighting, and dust. Specific dust suppression measures and the requirement that all lighting will be downcast away from habitat areas will also reduce dust and lighting impacts. Any arroyo toads detected emerging due to ground vibration will be relocated by a qualified biologist per the monitoring plan. Trash will be secured during construction activities to reduce the attraction of predators. Several general mitigation measures, as described above, will be implemented to protect on-site and downstream wetland and aquatic habitat quality, and in particular, to protect downstream water quality from mud, silt, and other pollutants. Potential long-term effects of development include increased human activity, including habitat degradation and collection; lighting; invasive species, including Argentine ant and invasive plants such as giant reed; pet, stray, and feral cats and dogs; vehicle collisions; and use of pesticides. The River Corridor SMA will provide adequate protected open space that will in large part offset these long-term impacts. Several specific mitigation measures will also be implemented to control human activities in the River Corridor SMA, including homeowner education and restrictions on recreational activities. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting along the open space–urban interface will be downcast. Pesticides will be controlled through an integrated pest management (IPM) plan. Argentine ant invasions of upland habitats in the open space system will be monitored and controlled to extent feasible. Implementation of these measures would allow this species to persist on site after development in the River Corridor SMA.

All mitigation measures for the arroyo toad are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-1 IMPACTS TO INDIVIDUALS – ARROYO TOAD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified four mitigation measures that will avoid, minimize, or mitigate the loss of arroyo toad individuals.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. These mitigation measures will ensure that up-to-date information about the status of the arroyo toad in the Project area is available prior to commencement of construction activities because USFWS protocol surveys will be required in potential habitat areas. These mitigation measures also require the specification of project-specific mitigation measures to avoid and minimize or reduce impacts during construction through habitat restoration, replacement, or enhancement, or some alternative compensation. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB. These mitigation measures will address avoidance and minimization of downstream hydrology and water quality effects that could adversely affect arroyo toad habitat and/or breeding populations.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that will reduce impacts to arroyo toad individuals during construction either through protecting individual toads or their habitat.

BIO-17 states that a qualified biologist shall conduct focused surveys for the arroyo toad prior to construction, within all construction sites and access roads with the riverbed and all riverbed areas within 1,000 feet of construction sites and access roads. If the arroyo toad is present, the applicant shall implement measures required by the USFWS Biological Opinion for arroyo toad that either supplement or supersede these measures.

The following three mitigation measures, BIO-46, BIO-48, and BIO-49, focus primarily on special-status fish, but they generally will also reduce impacts to the arroyo toad and other semi-aquatic species.

BIO-46 states that, during any stream diversion or culvert installation activity, a qualified biologist(s) shall be present and shall patrol the areas within, upstream, and downstream of the work area. The biologists shall inspect the diversion and inspect for stranded arroyo toads.

BIO-48 states that bridges, culverts, and other structures may not impair movement of fish and aquatic life and specifies relative depth requirements for temporary and permanent culverts.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-52 states that, prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-70 is a more generally applicable mitigation measure that specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts associated with the potential impacts to arroyo toad individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-2 LOSS OF HABITAT – ARROYO TOAD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures to mitigate for the loss of suitable habitat for the arroyo toad. The mitigation measures primarily relate to the establishment and management of a large open space system, with a focus on the River Corridor SMA, which will provide adequate suitable aquatic and terrestrial habitat for the arroyo toad such that any future breeding population will persist in the Project area.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 relate to habitat restoration and management of the River Corridor SMA, which has the highest potential in the Project area to support breeding populations of the arroyo toad in the future. These measures provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to provide potential terrestrial habitat adjacent to the River floodplain and to lessen the impact of the development on the conserved area within the River Corridor SMA. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. Although the High Country SMA has relatively low potential to support breeding habitat for the toad because of a lack of adequate hydrology, drainages within this area could be used for overwintering. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional measures to mitigate for the loss of suitable habitat for the arroyo toad. These measures also address habitat restoration in the River Corridor SMA that will reduce impacts to any future arroyo toad breeding populations in the River Corridor.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of

success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the arroyo toad would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-3 SECONDARY IMPACTS – ARROYO TOAD

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will mitigate for both short-term and long-term secondary impacts to the arroyo toad resulting from implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas. These mitigation measures address potential impacts to arroyo toads and their habitat related to hydrology and water quality, ground vibration, nighttime lighting, inadvertent impacts outside designated construction zones, increased human activity, and cattle grazing.

In order to mitigate impacts from chemical pollutants, increased sedimentation, increased turbidity, changes in flow, and changes in water temperature, SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

To help mitigate inadvertent habitat impacts and ground vibration, SP-4.6-20 requires that all grading perimeters within the River Corridor SMA shall be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor. While this mitigation measure does not address the off-site effects of ground vibration resulting from construction in the designated construction zone, it does minimize inadvertent effects by limiting the work to the designated area.

In order to mitigate impacts from nighttime lighting, SP-4.6-56 requires that all lighting along perimeter areas be downcast luminaries with light patterns directed away from natural areas.

In order to mitigate impacts from increased short-term human activity, SP-4.6-53 and SP-4.6-59, described above, will be implemented.

Mitigation measures for impacts resulting from increased human activity and related use of RMDP facilities such as trails and long-term occupation of the Specific Plan, VCC, and Entrada planning areas include measures related to preservation and habitat management of the River Corridor SMA, including SP-4.6-1 through SP-4.6-16, SP-4.6-18, SP-4.6-19, and SP-4.6-63. These mitigation measures are summarized above.

In addition, impacts resulting from public use of the River Corridor SMA, including trampling and litter, will be controlled by SP-4.6-17, which states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-24 also restricts recreational use to the established trail system.

To control cattle grazing, SP-4.6-12 states that grazing shall be removed from the River Corridor SMA except as permitted as a long-term resource management activity, SP-4.6-24 states that the River Corridor SMA conservation and public access easement shall prohibit grazing and agriculture, and SP-4.6-27 requires removal of grazing from the High Country SMA except for long-term resource management.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures that address potential short-term and long-term secondary effects to the arroyo toad, including construction-related impacts such as noise and ground vibration; lighting; inadvertent loss of habitat; introduction of disease; attraction of predators (*e.g.,* crows and ravens); hydrology and water quality; fugitive dust; increased human activity; pet, stray, and feral cats and dogs; invasive plant and animal species; and use of pesticides.

BIO-17, as described in detail above, will reduce construction-related secondary impacts such as noise, ground vibration, lighting, and inadvertent impacts to habitat by not allowing work within 500 feet of occupied habitat until the applicant provides concurrence from the USFWS to CDFG and Corps. Occupied habitat will be fenced to prevent equipment and vehicles from straying outside the designated construction zone. All trash will be secured so as not to attract predators to the construction area. The monitoring biologist(s) will follow the fieldwork code of practices developed by the Declining Amphibian Populations Task Force to ensure that diseases are not introduced to the construction area and surrounding habitat. The applicant shall implement measures required by the USFWS Biological Opinion for arroyo toad that either supplement or supersede these measures.

In order to mitigate impacts from chemical pollution, increased sedimentation, increased turbidity, changes in flow, and changes in water temperature, BIO-46, BIO-48, BIO-49, and

BIO-70, as summarized above, will be implemented. In addition, BIO-44, BIO-45, BIO-47, BIO-74, and BIO-77 will be implemented.

BIO-44 requires temporary bridges, culverts, or other feasible methods of providing access across the Santa Clara River. A Stream Crossing and Diversion Plan will be prepared that includes a description of diversion measures, such as berms, inflatable dams, sand bags, or other approved materials.

BIO-45 requires construction of bypass channels when the active wetted channel is within the work zone, in accordance with BIO-44. Equipment shall not be operated in areas of ponded or flowing water unless authorized by CDFG/USFWS.

BIO-47 requires that slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area that will provide refuge for arroyo toad during construction.

BIO-74 requires installation of temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to construction within 200 feet of the spring and, if applicable, within 100 feet of flowing water in the Middle Canyon drainage. Permanent fencing and signage shall be erected along the bordering subdivision tract following construction. A qualified biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. Any upslope runoff from construction areas will be directed away from the Middle Canyon Spring. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

BIO-77 describes preparation of a plan and mitigation measures to be implemented by the applicant specifically to maintain the populations of the undescribed snail and sunflower species, but these measures are also applicable to the arroyo toad. The plan will provide guidelines for collecting data on existing site conditions; developing a construction monitoring program and a post-development monitoring program; developing threshold parameters that activate adaptive management measures for water quality and water quantity issues; excluding unauthorized entry into the spring; and contingency measures. The plan shall be subject to the approval of CDFG prior to disturbance within 100 feet of flowing water in the Middle Canyon drainage and/or 200 feet of Middle Canyon Spring.

In order to mitigate impacts from human activity (short term and long term), collection, and pet, stray, and feral cats and dogs and other mesopredators, BIO-1 through BIO-16, as summarized above, will be implemented. In addition, BIO-19 through BIO-21, BIO-63, BIO-64, BIO-69, and BIO-73 will be implemented.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural

undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated. BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, fire ecology, erosion, drought, or unforeseen events. These three mitigation measure provide additional potential upland habitat for the arroyo toad that will be protected from adverse effects associated with an increased human population in the region.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent the pollution of suitable breeding habitat by pesticides and requires preparation of an IPM plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all River Corridor SMA trails to minimize impacts to protect vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-72, BIO-80, BIO-85, and BIO-87 will mitigate impacts from non-native invasive plant and animal species that could degrade arroyo toad habitat and directly affect individuals, including adults, juveniles, tadpoles, and egg masses.

BIO-72 specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

BIO-80 states that the Project applicant shall retain a qualified biologist to develop and implement an Eradication Plan for bullfrog, African clawed frog, and crayfish. Following construction, monitoring shall be conducted at sentinel locations along the River Corridor SMA (and other potential habitat areas) annually for five years. After five years, monitoring shall be conducted bi-annually for 50 years.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to arroyo toad and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

CALIFORNIA RED-LEGGED FROG (FT, CSC)

Life History

The California red-legged frog (*Rana draytonii*)[1] formerly occurred from Shasta County to Baja California, west of the mountains. It also occurred historically on a few desert slopes in the western Mojave and Colorado deserts. According to the USFWS (61 FR 25813–25833), the species has been extirpated from 70% of its former range and is now found primarily in wetlands and streams in coastal drainages of central California from Marin County to Ventura County. It has been all but eradicated from California's inland regions, including the foothills of the Sierra Nevada and coastal areas south of Ventura County (Jennings and Hayes 1994). The species occurs, or once occurred, at elevations ranging from sea level to 4,900 feet (1,500 meters) AMSL.

Breeding occurs in streams, deep pools, backwaters within streams and creeks, ponds, marshes, sag ponds, dune ponds, lagoons, and stock ponds. Red-legged frogs can occur in ephemeral ponds or permanent streams and ponds; however, populations probably cannot persist in ephemeral streams (Jennings and Hayes 1985). The species generally avoids large river channels with widely fluctuating flows because such habitat does not permit successful reproductive activity (Hayes and Jennings 1988). Breeding adults are often associated with deep still or slow-moving water and dense, shrubby riparian or emergent vegetation (Hayes and Jennings 1988), but frogs have been observed in shallow sections of streams and ponds that are devoid of vegetative cover. Habitats with the highest densities of frogs are deep water ponds with dense stands of overhanging willows (*Salix* sp.) and a fringe of cattails (*Typha latifolia*) between the willow roots and overhanging willow limbs (Jennings 1988; Rathbun *et al.* 1993). The species breeds during the winter and early spring from as early as late November through April and May. Larvae remain in breeding ponds until metamorphosis in the summer months (Storer 1925; Wright and Wright 1949). There is no evidence to suggest that they lay more than one clutch per year like some eastern ranids (Emlen 1977).

Hayes and Tennant (1985) found that most frequent prey groups for adult red-legged frogs were carabid and tenebrionid beetles, water striders (Gerridae), lycosid spiders, and larval neuropterans. Tadpoles probably feed on algae (Jennings *et al.* 1992). Small vertebrates such as Pacific tree frogs (*Pseudacris regilla*) and California mouse (*Peromyscus californicus*) comprised more than 50% of the prey mass taken by larger frogs and were the largest prey items in the Hayes and Tennant (1985) study.

---

[1] The Schaffer *et al.* (2004) genetics study determined that *R. aurora* actually consists of two species, *R. aurora* and *R. draytonii*, whose ranges overlap only in a narrow zone in Mendocino County. *R. aurora* is found to be closely related to *R. cascadae*. Other studies, including an analysis of vocal sacs, have supported separate species status, concluding that *R. aurora* and *R. draytonii* are biologically quite different.

This semi-aquatic species also utilizes non-aquatic habitats for refuge and dispersal. It rests and feeds in riparian vegetation and the moisture and cover of the riparian zone may facilitate dispersal. In non-aquatic habitats, dispersal may be more limited; however, this species has been documented to disperse over a mile under certain conditions. Species has also been documented dispersing through areas with sparse vegetative cover and dispersal patterns are considered to be dependent on habitat availability and environmental conditions (Scott and Rathbun *in litt.* 1998). During periods when water is absent, red-legged frogs may take refuge in moist areas within riparian habitats and small mammal burrows in surrounding upland areas. It may aestivate in small mammal burrows and moist leaf litter up to 98 feet (30 meters) from water in adjacent dense riparian vegetation for up to 77 days (Rathbun *et al.* 1993).

Critical Habitat

On April 13, 2006, critical habitat was designated for the California red-legged frog (71 FR 19244–19346). The only critical habitat unit in Los Angeles County is the 4,321-acre San Francisquito Creek (LOS-1) Unit. This unit is located approximately five miles northeast of the Project area. Three critical habitat units have been designated in Ventura County, including the 6,660-acre Matilija Creek (VEN-1) Unit, the 2,915-acre San Antonio Creek (VEN-2) Unit, and the 8,837-acre Piru Creek (VEN-3) Unit; the closest of these units (Piru Creek) is located approximately seven miles north of the Project area. No designated critical habitat units for the California red-legged frog include any portion of the Project site.

Recovery Plan

The Recovery Plan for the Red-legged Frog (*Rana aurora draytonii*) was published by the USFWS on May 28, 2002 (USFWS 2002D). The recovery strategy for the California red-legged frog consists of four parts: (1) protect existing populations by reducing threats; (2) restore and create habitat that will be protected and managed in perpetuity; (3) survey and monitor populations and conduct research on the biology of and threats to the subspecies; and (4) reestablish populations of the subspecies within its historical range. Therefore, critical habitat is not further addressed in the analysis for the California red-legged frog in this EIS/EIR.

The Santa Clara River Watershed is included in Recovery Unit 7: Northern Transverse Range and Tehachapi Mountains (USFWS 2002D). A goal of the Recovery Plan is to protect the viability of existing populations of the red-legged frog in the recovery units, but recovery actions will focus on identified core areas within the recovery unit that were chosen because they represent viable populations or because they will contribute to habitat connectivity and increase dispersal opportunities. Recovery and delisting will depend on meeting the recovery criteria in all core areas. In Recovery Unit 7, a core area is identified as the Ventura River–Santa Clara River. However, the portion of the Santa Clara River within the Project area is not in the core area and is not directly identified in the Recovery Plan as having a conservation role in the

recovery strategy for the species (USFWS 2002D). Therefore, the Recovery Plan is not further addressed in the analysis for the California red-legged frog in this EIS/EIR.

Threats

Habitat loss and degradation have been primary factors in the decline of the California red-legged frog. Other factors contributing to declining California red-legged frog populations, directly related to urban development, include the introduction and spread of exotic predators (*e.g.*, bullfrog, African clawed-frog, green sunfish, and crayfish) and increases in mesopredators (*e.g.*, raccoons, skunks, and opossums) (Jennings 1988; Jennings and Hayes 1985; Moyle *et al.* 1986; Hayes and Jennings 1986). Additionally, water pollution, in the form of fertilizers, biocides, chlorine, and other pollutants, adversely affect amphibian development, survival, and habitat. Further, exotic plant species (*e.g.*, tamarisk, giant reed, iceplant, and pampas grass) may also degrade California red-legged frog habitat by contributing to altered hydrology, eliminating breeding pools, and restricting access to and quality of upland habitat. Other factors that may adversely affect the species include livestock grazing and recreational activities in riparian areas, and human-related increases in fire frequency (Jennings 1988).

Survey Results

The California red-legged frog has not been observed in the Project area, and conditions generally do not support suitable breeding habitat. If present, California red-legged frogs would be most likely to occur within the following vegetation communities/habitats in the Project area: open water, bulrush–cattail wetland, alluvial scrub, coastal and valley freshwater marsh, southern cottonwood–willow riparian forest, southern willow scrub, river wash, southern coast live oak riparian forest, and tamarisk scrub. Given the intensity of the arroyo toad and other survey efforts, California red-legged frogs would likely have been observed if they occurred within the portion of the Santa Clara River on or near the Project site. While there are no records of California red-legged frog from the Project site in the numerous wildlife surveys conducted since 1992, the species is known in the Project region from verified records upstream and downstream of the Project area. The Project area is within the potential distribution of the California red-legged frog along the Santa Clara River. However, as noted by San Marino Environmental Associates (SMEA 1995A), it probably has a low probability of colonizing the site because of the relatively long distances to extant upstream and downstream locations and of its apparent limited dispersal capabilities. The only critical habitat unit upstream is the San Francisquito Creek (LOS-1) Unit, which is located approximately five miles northeast of the Project area. This distance, coupled with the existing stream conditions in San Francisquito Creek (*i.e.*, dry gaps, absence of flowing water during most of the year), likely limit the potential for this species to disperse through this area.

Potential breeding or summer habitat for the California red-legged frog is absent from the main channel of the Santa Clara River within the eastern portion of the Project site (ENTRIX 2006A,

2006B). California red-legged frogs generally avoid large river channels with widely fluctuating flows, because such habitat usually does not permit reproductive activity (Hayes and Jennings 1988). For example, episodic winter flooding typical of the Santa Clara River may dislodge egg masses. Further, fluctuating water levels before summer typical of the Santa Clara River could kill tadpoles before they could metamorphose. Given these characteristics, other portions of the Santa Clara River within the Project area are also not expected to provide breeding habitat for the species. However, during the late winter and autumn, when California red-legged frogs are most likely to move randomly (USFWS 2002A), the Santa Clara River channel may provide dispersal habitat in the unlikely event that red-legged frogs are present in the Project area. Suitable breeding habitat may exist in some of the small tributaries (such as Salt Creek, Potrero Canyon, and Ayers Canyon) that flow north into the Santa Clara River, within and near the Project boundaries (ENTRIX 2006A). Additionally, Middle Canyon Spring contains relatively deep water in small isolated areas, and could serve as habitat for the California red-legged frog, but this species has not been detected. However, for the purposes of the EIS/EIR impact analysis, it is assumed that the red-legged frog could occur on site. California red-legged frogs are assumed to be present in the following plant communities in the Project area: alluvial scrub, bulrush–cattail wetland, coastal and valley freshwater marsh, river wash, southern coast live oak riparian forest, southern willow scrub, and shrub tamarisk. A total of 785 acres of suitable habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the permanent loss of 62 acres (7.9%) of suitable habitat for California red-legged frog and temporary impacts to 83 acres (**Figure 4.5-54,** Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). Middle Canyon Spring would not be directly affected by the implementation of the RMDP, and the structures to be placed within the River corridor (*i.e.*, bridges and bank stabilization) would not prevent the use of the River corridor by dispersing frogs.

Although a small amount of potential habitat for the California red-legged frog would be permanently lost, and the species has not been documented on site, because this species is becoming increasingly rare, if the species were to occur on site in the future, this habitat loss due to implementation of the RMDP and the SCP could have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in the permanent loss of 43 acres (5.5%) of potential habitat (**Figure 4.5-54,** Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat). Middle Canyon Spring would not be affected by the build-out of the Specific Plan area, and the structures to be placed within the River corridor (*i.e.*, bridges and bank stabilization) would not prevent the use of the River corridor by dispersing frogs.

Although a small amount of potential habitat for the California red-legged frog would be permanently lost, and the species has not been documented on site, because this species is becoming increasingly rare, if the species were to occur on site in the future, this habitat loss due to the build-out of the Specific Plan, VCC, and Entrada planning areas could have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of potential California red-legged frog habitat resulting from implementation of the RMD and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 105 acres (13.4%).

Although a small amount of potential habitat for the California red-legged frog would be permanently lost, and the species has not been documented on site, because this species is becoming increasingly rare, if the species were to occur on site in the future, this combined habitat loss due to the implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas could have a substantial adverse effect

on this species; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The implementation of the RMDP would include the construction of bridges and bank stabilization within areas in which individual California red-legged frogs could occur (most likely during dispersal). Although the potential for impacts is considered very low, should California red-legged frog adults, subadults, tadpoles, or egg masses be present within the disturbance footprint, these activities could result in injury or mortality of California red-legged frog individuals due to direct contact with construction equipment, entombment in burrows, and disturbances to aquatic breeding sites that could disturb egg masses and tadpoles. Implementation of the SCP would not directly impact this species.

There is potential for the direct loss of California red-legged frogs to occur during RMDP-related construction activities. Given its rarity and its status as a federally listed species, the loss of any California red-legged frogs could have a substantial direct adverse effect on this species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

This species has not been detected in the Project area, and the California red-legged frog generally avoids large river channels with widely fluctuating flows because such habitat does not permit successful reproductive activity (Hayes and Jennings 1988). Therefore, the reach of the Santa Clara River in the Project area is not expected to support successful breeding by California red-legged frogs (ENTRIX 2006A, 2006B). The closest known occurrence of this species in the Santa Clara River watershed is located in San Francisquito Creek, approximately five miles northeast of the Project area. There is some potential for non-breeding frogs to occur within the River corridor but their presence is unlikely because of the habitat conditions within the River, the distance from known source populations, and the current barriers to dispersal. Additionally, there is limited potential that breeding and/or non-breeding frogs could occur within Middle Canyon Spring, tributaries that flow north into the Santa Clara River, or other ponded areas in the

Project area. The build-out of the Specific Plan, VCC, and Entrada planning areas would include construction in riparian and upland habitats potentially occupied by the California red-legged frog. Should individuals of the species be present within the disturbance footprint, these activities could result in injury or mortality of California red-legged frog individuals due to direct contact with construction equipment, entombment in burrows, and disturbances to aquatic breeding sites that could disturb egg masses and tadpoles. Therefore, there is potential for the loss of individual California red-legged frogs to occur. Given its rarity and its status as a federally listed species, the loss of California red-legged frogs could have a substantial adverse effect on this species; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Construction activities associated with RMDP facilities and build-out of the Specific Plan, VCC, and Entrada planning areas have the potential to affect California red-legged frogs in the short term in areas adjacent to or downstream of construction zones. Construction activities could result in dispersion of sediments and pollutants from construction sites into the Santa Clara River and affect potentially occurring California red-legged frogs. Hydrologic and water quality-related impacts could include chemical pollution, increased turbidity, excessive sedimentation, flow interruptions, and changes in water temperature due to short-term changes to the active channel morphology. Construction-related vibration could cause individuals to emerge from burrows and other refuge areas, and dust could adversely affect water quality and prey species. These factors could result in injury or mortality of California red-legged frogs and/or the degradation of habitat quality. Implementation of the SCP would not affect this species.

In the long term, use of RMDP facilities, such as bridges over the Santa Clara River, and the occupancy of the Specific Plan, VCC, and Entrada planning areas could result in adverse secondary impacts to California red-legged frogs (if present). Specifically, the proximity of urban development to potential California red-legged frog habitat could result in disruption of nocturnal activities and greater vulnerability to predation by nocturnal predators (such as owls and coyotes) as a result of nighttime lighting; greater vulnerability to predation by pet, stray, and feral cats and dogs as well as other mesopredators; collecting by children; degradation of habitat from invasive plants (*e.g.*, giant reed, tamarisk, and pampas grass) and increased human use (*e.g.*, trampling, trash, and off-road vehicles) and altered fire regimes (likely too frequent fire); and invasion by exotic wildlife species (*e.g.*, Argentine ants, bullfrogs, African clawed frogs, exotic fish, and crayfish). In addition, grazing within the River Corridor SMA could cause habitat degradation. These secondary impacts could have a substantial adverse effect on this species; have the potential to substantially reduce the habitat of the species on site or rangewide;

cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to potential habitat for the California red-legged frog (**Figures 4.5-55** through **4.5-59,** Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 45 acres (5.7%) of permanent loss and 86 acres of temporary loss;
- Alternative 4 – 47 acres (6.0%) of permanent loss and 78 acres of temporary loss;
- Alternative 5 – 50 acres (6.4%) of permanent loss and 93 acres of temporary loss;
- Alternative 6 – 34 acres (4.3%) of permanent loss and 83 acres of temporary loss; and
- Alternative 7 – 13 acres (1.6%) of permanent loss and 58 acres of temporary loss.

For overall direct impacts to potential California red-legged frog habitat, the combined permanent and temporary loss of habitat under Alternatives 3 through 6 would be reduced compared to Alternative 2, which would result in a total of 62 acres (7.9%) of permanent loss and 83 acres of temporary impacts to potential habitat. The substantially greater difference in permanent loss of habitat between Alternative 7 and Alternative 2 is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries and other reductions to the Project footprint under Alternative 7 that would reduce permanent impacts to suitable habitat for the California red-legged frog compared to the other alternatives. Temporary impacts would also be reduced under Alternative 7 compared to Alternative 2.

Although impacts would be reduced compared to Alternative 2 under Alternatives 3 through 6 and substantially reduced under Alternative 7, because this species is rare and federally listed as threatened, the direct permanent and temporary impacts (Loss of Habitat) under Alternatives 3 through 7 would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the California red-legged frog (**Figures 4.5-55** through **4.5-59,** Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat):

- Alternative 3 – 36 acres (4.6%) of permanent loss;
- Alternative 4 – 19 acres (2.4%) of permanent loss;
- Alternative 5 – 16 acres (2.0%) of permanent loss;
- Alternative 6 – 9.0 acres (1.1%) of permanent loss; and
- Alternative 7 – 6.3 acres (0.8%) of permanent loss.

For overall indirect permanent loss of suitable California red-legged frog habitat, Alternatives 3 would be somewhat reduced and Alternatives 4 through 7 would be substantially reduced compared to Alternative 2, which would result in a total of 43 acres (5.5%) of permanent loss. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed and each would have successively smaller development footprints within the Specific Plan and/or Entrada planning areas. Alternative 7 would have the least impact because of the pullback from the Santa Clara River and its tributaries and other changes to the Project footprint under Alternative 7 that would reduce impacts to suitable habitat for the California red-legged frog compared to the other alternatives.

Alternatives 3 through 7 would have reduced indirect permanent impacts to suitable habitat for the California red-legged frog compared to Alternative 2. However, because this species is rare and federally listed as threatened, the indirect permanent impacts (Loss of Habitat) occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the California red-legged frog:

- Alternative 3 – 81 acres (10.3%) of permanent loss;
- Alternative 4 – 66 acres (8.4%) of permanent loss;

- Alternative 5 – 66 acres (8.4%) of permanent loss;
- Alternative 6 – 43 acres (5.5%) of permanent loss; and
- Alternative 7 – 19 acres (2.4%) of permanent loss;

Compared to Alternative 2, which would result in a total of 105 acres (13.4%) of combined direct and indirect permanent impacts, Alternatives 3 through 7 would have substantially reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed and each would have successive reductions in the development footprints in the Specific Plan and/or Entrada planning areas. Alternative 7 would have the least impact because of the pullback of RMDP facilities from the Santa Clara River and its tributaries and other reductions to the Project footprint under Alternative 7 that would result in reduced impacts to suitable habitat for the California red-legged frog compared to the other alternatives.

Alternatives 3 through 7 would have reduced combined direct and indirect permanent impacts to suitable habitat for the California red-legged frog compared to Alternative 2. However, because this species is rare and federally listed as threatened, the combined direct and indirect permanent impacts (Loss of Habitat) occurring as a result of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Impacts to Individuals

The potential for impacts to individual California red-legged frogs as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. However, given its status as a federally listed threatened species, the loss of California red-legged frog adults, juveniles, tadpoles, or egg masses could have a substantial adverse effect on this species. Therefore, impacts to individual California red-legged frogs occurring as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for

Alternative 2 because each alternative has similar short-term impacts from construction activities and long-term effects. Construction activities could result in hydrologic and water quality-related impacts that could include chemical pollution, increased turbidity, excessive sedimentation, flow interruptions, and changes in water temperature due to short-term changes to the active channel morphology. Construction-related vibration could cause individuals to emerge from burrows and other refuge areas, and dust could adversely affect water quality and prey species. These factors could result in injury or mortality of California red-legged frogs and/or the degradation of habitat quality.

In the long term, the proximity of urban development to potential California red-legged frog habitat could result in disruption of nocturnal activities; increased predation by nocturnal predators as a result of nighttime lighting and by pet, stray, and feral cats; collecting by children; degradation of habitat from invasive plants and increased human use (*e.g.*, trampling, trash, and off-road vehicles) and altered fire regimes (likely too frequent fire); and invasion by exotic wildlife species (*e.g.*, Argentine ants, bullfrogs, African clawed frogs, exotic fish, and crayfish). In addition, grazing within the River Corridor SMA could cause habitat degradation.

Therefore, the loss or degradation of suitable habitat and impacts to individual California red-legged frogs due to short-term and long-term secondary impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to California red-legged frog: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

This species has not been detected in the Project area, but has limited potential to occur. If present on site, impacts to individuals, including adults, juveniles, metamorphs, egg masses, and tadpoles, could occur during construction as a result of vegetation clearing and grading and construction activities in breeding pools, including injury and mortality due to direct contact with construction equipment, entombment of hibernating and aestivating individuals, and increased exposure of individuals flushed from burrows or left without protective cover. The applicant will implement several mitigation measures to avoid, minimize, and mitigate impacts to individuals. Pre-construction surveys within the proposed disturbance area and within 1,000 feet of the construction zone and access road will be conducted by a qualified biologist. If detected, no work will be conducted within 500 feet of occupied habitat without concurrence of USFWS. A monitoring plan will prepared and implemented to protect the California red-legged frog, if present, during construction in consultation with and approved by USFWS and CDFG. General procedures included in the monitoring plan to avoid and minimize impacts to California red-legged frog during construction will be implemented, including construction personnel education

for measures to reduce impacts to California red-legged frog, determination of time periods or seasons when construction activities would have the least adverse impacts (*e.g.*, after dispersal), fencing of authorized work areas, daily clearance surveys prior to construction, and relocation of detected California red-legged frog individuals from fenced and unfenced areas to suitable habitat. Several general measures will be implemented to protect wetland habitats, including measures regarding hydrology and water quality, which will reduce impacts to the California red-legged frog. These measures include obtaining pertinent state and federal wetland permits and authorizations prior to construction activities; biological monitoring during any stream diversions; restrictions on construction equipment operating in ponds or flowing water; design of bridges, culverts, and other structures so as not to impair the movement of aquatic species; and protection of water quality from mud, silt, and other pollutants.

The combined permanent loss of suitable habitat for the California red-legged frog resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 19 acres (2.4%) under Alternative 7 to 105 acres (13.4%) under Alternative 2. Because this red-legged frog is rare and federally listed as threatened, this would be a substantial loss of suitable habitat and would reduce the potential size and distribution of any California red-legged frog populations in the Project area. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in approximately 513 acres of suitable habitat for this species being protected in the River Corridor SMA. The Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts in water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area over the long term as a result of the proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County. Conditions within the Santa Clara River would remain similar to baseline conditions, and this habitat is generally considered unsuitable to this species due to the general high level of scour and lack of breeding pools.

With respect to secondary effects, any California red-legged frogs occupying habitat in close proximity to construction zones may be disturbed by construction activities, including ground vibration, dust, and nighttime lighting. Ground vibration could cause frogs to emerge from burrows and expose them to predators and adverse environmental conditions, and increase their chance of injury or mortality from construction equipment and vehicles. Lighting may increase the risk of predation from nocturnal predators, and dust may adversely affect water quality and the insect prey of California red-legged frogs. Potential breeding pools, including downstream pools, could be disturbed during construction by hydrologic alterations and pollutants that impair water quality, thus adversely affecting egg masses and tadpoles. Unsecured trash could attract predators such as crows and ravens. Construction activities within 500 feet of occupied habitat will not be allowed without concurrence of USFWS and thus will help reduce the potential

effects of noise, ground vibration, lighting, and dust. Specific dust suppression measures and the requirement that all lighting will be downcast away from habitat areas will also reduce dust and lighting impacts. Any California red-legged frogs detected emerging due to ground vibration will be relocated by a qualified biologist per the monitoring plan. Trash will be secured during construction activities to reduce the attraction of predators. Several general mitigation measures, as described above, will be implemented to protect on-site and downstream wetland and aquatic habitat quality, and in particular, protection of downstream water quality from mud, silt, and other pollutants. Potential long-term effects of development include increased human activity, including habitat degradation and collection; lighting invasive species, including Argentine ant and invasive plants such as giant reed; pet, stray, and cats and feral dogs; vehicle collisions; and use of pesticides. The River Corridor SMA will provide adequate protected open space that will in large part offset these long-term impacts. Several specific mitigation measures will also be implemented to control human activities in the River Corridor SMA, including restrictions on recreational activities and homeowner education. Pet, stray, and feral cats and dogs will be leashed or otherwise controlled in or adjacent to open space areas. All lighting along the open space-urban interface will be downcast. Pesticides will be controlled through an integrated pest management (IPM) plan. Argentine ant invasions of upland habitats in the open space system will be monitored and controlled to the extent feasible. Implementation of these measures would allow this species to persist on site after development in the River Corridor SMA.

All mitigation measures for the California red-legged frog are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-4 IMPACTS TO INDIVIDUALS – CALIFORNIA RED-LEGGED FROG

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified four mitigation measures that will avoid, minimize, or mitigate the loss of California red-legged frog individuals. These measures require pre-development surveys and permits for impacts that may affect California red-legged frogs and/or their habitat.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that are designed to reduce impacts to California red-legged frog individuals during construction.

BIO-18 states that a qualified biologist shall conduct focused surveys for the California red-legged frog prior to construction, within all construction sites and access roads with the riverbed and all riverbed areas within 1,000 feet of construction sites and access roads. If the California red-legged frog is present, the applicant shall implement measures required by the USFWS Biological Opinion for California red-legged frog that either supplement or supercede these measures.

The following three mitigation measures, BIO-46, BIO-48, and BIO-49, focus primarily on special-status fish, but they generally will also reduce impacts to the California red-legged frog and other semi-aquatic species.

BIO-46 states that, during any stream diversion or culvert installation activity, a qualified biologist(s) shall be present and shall patrol the areas within, upstream, and downstream of the work area. The biologists shall inspect the diversion and inspect for stranded California red-legged frogs.

BIO-48 states that bridges, culverts, and other structures may not impair movement of fish and aquatic life and specifies relative depth requirements for temporary and permanent culverts.

BIO-49 prohibits water containing mud, silt, or other pollutants from entering a flowing stream or being placed in locations subject to normal storm flows.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing harm to or harassment of wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-70 specifies necessary design features and construction notes for construction plans to ensure protection of vegetation communities and special-status plant and aquatic wildlife species

adjacent to construction as well as BMPs for inclusion in the Project SWPPP to avoid impacting special-status species during construction.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to California red-legged frog individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-5 LOSS OF HABITAT – CALIFORNIA RED-LEGGED FROG

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures to mitigate for the loss of suitable habitat for the California red-legged frog. The mitigation measures primarily relate to the establishment and management of a large open space system, with a focus on the River Corridor SMA, which will provide adequate suitable aquatic and terrestrial habitat for the California red-legged frog such that any dispersing individuals or future breeding population could use the Project area.

SP-4.6-1 through SP-4.6-16 and SP-4.6-63 relate to habitat restoration and management of the River Corridor SMA, which has the highest potential in the Project area to support both dispersing individuals and breeding populations of the California red-legged frog in the future. These measures provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to provide potential terrestrial habitat adjacent to the River floodplain and to lessen the impact of the development on the conserved area within the River Corridor SMA. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-21 through SP-4.6-26 and SP-4.6-36 through SP-4.6-42 describe the open space dedication of the River Corridor SMA and the High Country SMA. Although the High Country

SMA has relatively low potential to support breeding habitat for the California red-legged frog because of a lack of adequate hydrology, drainages within this area could be used for overwintering. In combination with the Salt Creek area, these areas will form a large, interconnected open space system that will reduce habitat fragmentation effects (**Figure 4.5-3**).

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional measures to mitigate for the loss of suitable habitat for the California red-legged frog. These measures also address habitat restoration in the River Corridor SMA that will reduce impacts to any future California red-legged frog breeding populations in the River Corridor.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to 2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of habitat for the California red-legged frog would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-6 SECONDARY IMPACTS – CALIFORNIA RED-LEGGED FROG

Significant for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will mitigate for both short-term and long-term secondary impacts to the California red-legged frog resulting from implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas. These mitigation measures address potential impacts to California red-legged frogs and their habitat related to hydrology and water quality, ground vibration, nighttime lighting, inadvertent impacts outside designated construction zones, increased human activity, and cattle grazing.

In order to mitigate impacts from chemical pollutants, increased sedimentation, increased turbidity, changes in flow, and changes in water temperature, SP-4.6-55 and SP-4.6-58 require obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats as well as requiring conformance with all provisions of required NPDES permits and water quality permits required by the RWQCB.

To help mitigate inadvertent habitat impacts and ground vibration, SP-4.6-20 requires that all grading perimeters within the River Corridor SMA shall be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the River Corridor. While this mitigation measure does not address the off-site effects of ground vibration resulting from construction in the designated construction zone, it does minimize inadvertent effects by limiting the work to the designated area.

In order to mitigate impacts from nighttime lighting, SP-4.6-56 requires that all lighting along perimeter areas be downcast luminaries with light patterns directed away from natural areas.

In order to mitigate impacts from increased short-term human activity, SP-4.6-53 and SP-4.6-59, described above, will be implemented.

Mitigation measures for impacts resulting from increased human activity and related use of RMDP facilities such as trails and long-term occupation of the Specific Plan, VCC, and Entrada planning areas include measures related to preservation and habitat management of the River Corridor SMA, including SP-4.6-1 through SP-4.6-16, SP-4.6-18, SP-4.6-19, and SP-4.6-63. These mitigation measures are summarized above.

In addition, impacts resulting from public use of the River Corridor SMA, including trampling and litter, will be controlled by SP-4.6-17, which states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats. SP-4.6-24 also restricts recreational use to the established trail system.

To control cattle grazing, SP-4.6-12 states that grazing shall be removed from the River Corridor SMA except as permitted as a long-term resource management activity, SP-4.6-24 states that the River Corridor SMA conservation and public access easement shall prohibit grazing and agriculture, and SP-4.6-27 requires removal of grazing from the High Country SMA except for long-term resource management.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures that address potential short-term and long-term secondary effects to the California red-legged frog, including construction-related impacts such as noise and ground vibration; lighting; inadvertent loss of habitat; introduction of disease; attraction of predators (*e.g.*, crows and ravens); hydrology and water quality; fugitive dust; increased human activity; pet, stray, and feral cats and dogs; invasive plant and animal species; and use of pesticides.

BIO-18 will reduce construction-related secondary impacts such as noise, ground vibration, lighting, and inadvertent impacts to habitat by not allowing work within 500 feet of occupied habitat until the applicant provides concurrence from the USFWS to CDFG and Corps. Occupied habitat will be fenced to prevent equipment and vehicles from straying outside the designated construction zone. All trash will be secured so as not to attract predators to the construction area. The monitoring biologist(s) will follow the fieldwork code of practices developed by the Declining Amphibian Populations Task Force to ensure that diseases are not introduced to the construction area and surrounding habitat. The applicant shall implement measures required by the USFWS Biological Opinion for California red-legged frog that either supplement or supercede these measures.

In order to mitigate impacts from chemical pollution, increased sedimentation, increased turbidity, changes in flow, and changes in water temperature, BIO-46, BIO-48, BIO-49, and BIO-70, as summarized above, will be implemented. In addition, BIO-44, BIO-45, BIO-47, BIO-74, and BIO-77 will be implemented.

BIO-44 requires temporary bridges, culverts, or other feasible methods of providing access across the Santa Clara River. A Stream Crossing and Diversion Plan will be prepared that includes a description of diversion measures, such as berms, inflatable dams, sand bags, or other approved materials.

BIO-45 requires construction of bypass channels when the active wetted channel is within the work zone, in accordance with BIO-44. Equipment shall not be operated in areas of ponded or flowing water unless authorized by CDFG/USFWS. In addition, BIO-45, BIO-74, and BIO-77 will be implemented.

BIO-47 requires that slow moving water habitats shall be constructed upstream and downstream of any river crossing or bridge construction area that will provide refuge for California red-legged frog during construction.

BIO-74 requires installation of temporary orange fencing and prohibitive signage around the Middle Canyon Spring prior to construction within 200 feet of the spring and, if applicable, within 100 feet of flowing water in the Middle Canyon drainage. Permanent fencing and signage shall be erected along the bordering subdivision tract following construction. A qualified

biologist will be present to monitor construction activities within 200 feet of the spring and, if applicable, around the Middle Canyon drainage within 100 feet of flowing water. Any upslope runoff from construction areas will be directed away from the Middle Canyon Spring. No trail shall be constructed that passes within 100 feet of the Middle Canyon Spring.

BIO-77 requires preparation of a plan and measures to be implemented by the applicant specifically to maintain the populations of the undescribed snail and sunflower species, but these measures are also applicable to the California red-legged frog. The plan will provide guidelines for collecting data on existing site conditions; developing a construction monitoring program and a post-development monitoring program; developing threshold parameters that activate adaptive management measures for water quality and water quantity issues; excluding unauthorized entry into the spring; and contingency measures. The plan shall be subject to the approval of CDFG prior to disturbance within 100 feet of flowing water in the Middle Canyon drainage and/or 200 feet of Middle Canyon Spring.

In order to mitigate impacts from human activity (short term and long term), collection, and pet, stray, and feral cats and dogs and other mesopredators, BIO-1 through BIO-16, as summarized above, will be implemented. In addition, BIO-19, BIO-63, BIO-64, BIO-69, and BIO-73 will be implemented.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126. This mitigation measure provides additional potential upland habitat for the California red-legged that will be protected from adverse effects associated with an increased human population in the region.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-64 will be implemented to prevent the pollution of suitable breeding habitat by pesticides and requires preparation of an IPM plan addressing the use of pesticides on site prior to the issuance of building permits.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-71 will be implemented to control for construction-related dust impacts to special-status species. Dust control shall comply with SCAQMD Rule 403d (SCAQMD 2005). Where determined necessary by a qualified biologist, a screening fence (*i.e.*, a six-foot-high chain link fence with green fabric up to a height of five feet) shall be installed to protect special-status species locations.

BIO-72, BIO-80, BIO-85 and BIO-87 will mitigate impacts from non-native invasive plant and animal species that could degrade California red-legged frog habitat and directly affect individuals, including adults, juveniles, tadpoles, and egg masses.

BIO-72 specifies that plant palettes proposed for use within 100 feet of native vegetation communities shall be reviewed to ensure that the proposed plants will not naturalize and require maintenance or cause vegetation community degradation. Container plants for use within 100 feet of the open space areas shall be inspected for pests and disease. Invasive landscape plants shall not be used within 100 feet of native vegetation communities. Plant palettes shall include non-invasive species that do not require high irrigation rates. Except as required for fuel modification, perimeter landscaping irrigation shall be temporary.

BIO-80 states that the Project applicant shall retain a qualified biologist to develop and implement an Eradication Plan for bullfrog, African clawed frog, and crayfish. Following construction, monitoring shall be conducted at sentinel locations along the River Corridor SMA (and other potential habitat areas) annually for five years. After five years, monitoring shall be conducted bi-annually for 50 years.

BIO-85 lists the following project design features and management measures to prevent invasion of Argentine ants into the spineflower preserves: (1) providing "dry zones" between urban development and spineflower populations; (2) ensuring that landscape container plants installed within 200 feet of preserves are ant free; (3) maintaining natural hydrological conditions in the preserves; and (4) using drought-resistant plants in FMZs and minimizing irrigation to the extent feasible.

BIO-87 requires quarterly monitoring for Argentine ants along the urban–open space interface where invasions could occur following the completion and occupancy of a development area. If Argentine ants are detected, direct control measures will be implemented immediately to help prevent the invasion from worsening. Monitoring and control of Argentine ants would occur for a 50-year period.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to California red-legged frog and its habitat would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

SOUTHERN STEELHEAD (FE)

Life History

The southern steelhead (*Oncorhynchus mykiss*) was listed as endangered under the federal Endangered Species Act (ESA) on August 18, 1997. Southern steelhead and rainbow trout represent two life history patterns of the same species. The former represents anadromy and the latter represents freshwater residency. It is common to find populations exhibiting both life history strategies within the same river system. Fish that exhibit one life history strategy can produce offspring that exhibit the other strategy (62 FR 43937–43954). Southern steelhead are lightly to heavily spotted with small black spots on a lighter background; the dorsal, caudal, and adipose fins have these spots as well. Juvenile and larger freshwater resident fish have a red to pink stripe down the mid-sides, hence the name for the freshwater populations. The sea run fish are larger, lack the pink stripe, and present an overall silvery appearance with a "steely" blue-grey color dorsally. The inside of the mouth is entirely white in contrast to the other Pacific salmonid species, and they have a stronger tail stock and smaller anal fin than the other native Pacific salmon. The adipose fin separates them from all other native freshwater fish in anadromous streams in coastal southern California (Moyle 2002).

The range of the southern steelhead is from the Santa Maria River along the San Luis Obispo–Santa Barbara County line in the north to the Tijuana River just north of the United States–Mexico border in the south. Their historical range within many of these coastal streams was limited by natural barriers, above which no known southern California populations of native rainbow trout or steelhead previously existed. Definitive records of southern steelhead are not available for many of the small coastal streams within the Southern California Evolutionarily Significant Unit (ESU); however, it is believed that most of the streams were inhabited by southern steelhead. The distribution of southern steelhead within the ocean is not well known, but some evidence indicates that they remain relatively close to the coast and even near the mouths of their natal streams, which contrasts with other Pacific salmonid species that range widely in the ocean (NMFS 2007).

Within the last decade, the anadromous southern steelhead has been recorded in the following watersheds:

- Santa Barbara County – the Santa Maria River, Santa Ynez River, Gaviota Creek, Arroyo Honda, Mission Creek, and Carpinteria Creek;
- Ventura County – the Ventura River and Santa Clara River;
- Los Angeles County – Malibu Creek and Topanga Creek;
- Orange County – San Juan Creek; and
- San Diego County – San Mateo Creek.

Within the Santa Clara River drainage, southern steelhead historically inhabited Piru Creek, Sespe Creek, Santa Paula Creek, Hopper Creek, and possibly Pole Creek (Titus *et al.* n.d.). Presently, southern steelhead occur in the Santa Clara River Watershed in Piru Creek between the confluence with the Santa Clara River and Santa Felicia Dam, in Sespe Creek, in Santa Paula Creek, and possibly in Hopper and Pole Creeks (Stoeker and Kelly 2005). There is no historical record of steelhead use of the Santa Clara River or tributaries upstream of Piru Creek and the Dry Gap approximately five miles downstream of the Project area.

Migration and life history patterns of southern steelhead depend on rainfall and streamflow. In the highly variable conditions of the watersheds along the south central California coast, it is presumed to be common for one form to decline to extremely low numbers in some years. In most southern California streams, including the Santa Clara River, a sandbar is present at the mouth of the estuary during periods of low river flow that may block migration from the ocean. Adult steelhead congregate in the Pacific Ocean off the mouth of the River and migrate upstream after the sandbar is breached (Shapovalov and Taft 1954) from seasonal tidal influences and/or when triggered by rising streamflows from storm events (Moyle 2002).

Steelhead in the Santa Clara River are presumed to be adapted to utilize winter freshets (a rise or overflowing of a stream resulting from heavy rain or snow melt) as a means to move from the sea to the upper areas of the watershed. These winter freshets typically have provided enough surface flow to break through the sandbar that builds up at the River–estuary interface during the low flow summer months. In the Santa Ynez River, the majority of the upstream migration is believed to have occurred from January through March before the construction of Bradbury Dam (Shapovalov and Taft 1954). More recently, adult steelhead have been observed in the lower Santa Clara River and a subset of Ventura County tributaries in February, March, and early April (Puckett and Villa 1985; ENTRIX 1994, 1995, 1996, 1998, 1999).

Downstream migration of juveniles usually occurs between March and June (Shapovalov and Taft 1954). In southern California, steelhead typically migrate to the ocean as one- or two-year olds (Moore 1980; ENTRIX 1994, 1995, 1996). Outmigrating steelhead in the Santa Clara River have been observed from January through early June, but the majority of steelhead smolt emigrate during the period from March through early May, and the timing of migration is strongly dependent on streamflows (ENTRIX 2000).

Steelhead in the ocean feed on a variety of pelagic organisms, primarily anchovies and crustaceans. In streams, they overwhelmingly feed on aquatic insects in both the benthos and stream drift. They also consume non-insects, like amphipods, isopods, oligochaete worms, and terrestrial insects that fall into the stream, if available. Larger fish in freshwater streams will also take fish, such as sculpin, tidewater gobies, and small minnows and suckers. Larger juveniles in lagoons will feed on mysid shrimp, amphipods, and isopods in addition to a smaller variety of insects available in lagoons (Moyle 2002).

In streams, steelhead prefer habitat consisting of relatively cool, well-oxygenated water with adequate depth and cover. Temperature tolerances and preferences of steelhead vary among life stages. Eggs tend to experience mortality at temperatures in excess of 55° F (13.3° C) (McEwan and Jackson 1996). At temperatures greater than 70° F (21.1° C), steelhead appear to have difficulty obtaining sufficient oxygen from the water (McEwan and Jackson 1996). However, Carpanzano (1996) found trout living in Sespe Creek with a water temperature of 82.4º F (28º C). Cover in the way of gravel, cobble, boulder, undercut banks, large and small woody debris, and overhanging vegetation is important for survival.

Steelhead require relatively clean unconsolidated gravel and cobble for spawning. Females excavate oval nests and lay their eggs while one or more attending males fertilize the eggs as they fall among the gravel. Unlike other Pacific salmonid species, steelhead can survive the spawning activity and return to reproduce multiple times. The eggs hatch within three to four weeks, but the alevins (yolk-sac fry) cannot swim since they still have a large yolk attached. The alevins remain in the gravel for two additional weeks and then emerge from the gravel when their yolk is used up. At this point, the alevins become free swimming juveniles. The juveniles spend one to two years in freshwater and reach five to 10 inches in length before attempting to leave for the ocean (Moyle 2002). Fish that descend to larger river habitats or coastal lagoons often attain larger sizes than stream-reared fish. It has been shown in the Santa Cruz, California area that these larger fish survive much better in the ocean than the smaller fish. After their first year of life, steelhead may undergo physiological and morphological changes enabling the fish to survive in a marine environment. These smolts then migrate to the ocean, typically from March to May (Moyle 2002). The steelhead spend two to three years in the ocean and can grow to approximately 35 inches in length and weigh up to 22 pounds, although most fish are smaller (Moyle 2002). Studies of central California fish indicate that most fish return to their natal stream, but some fish do stray to other streams. This aspect of southern California populations is little studied and is an area of active current research.

In addition to impacts to individuals, the primary threats to steelhead include loss of important portions of habitat range and deterioration of habitats due to artificial barriers that limit upstream migration, diversion of water from natural channels, and introduction of non-native species. The following provides a brief summary of the threats to southern steelhead based on the five listing factors that are used to assess species for listing as threatened or endangered under the federal ESA: (1) alteration of flow regimes from construction of dams and diversions; (2) decreased water quality (particularly higher water temperatures); (3) recreational fishing; (4) predation from birds and other fishes; and (5) competition and introduction of disease from trout and exotic species such as channel catfish, black bullhead, green sunfish, and largemouth bass.

Critical Habitat

The southern steelhead was listed as endangered under the federal ESA in 1997 in the Southern California ESU that extends from the Santa Maria River in the north southward to Malibu Creek without critical habitat (62 FR 43937–43954). On May 1, 2002, the range of the Southern California ESU was extended south to the United States–Mexico Border (67 FR 21586–21598). In 2005, the final critical habitat designation for the Southern California ESU was determined (70 FR 37159–37204). On January 5, 2006, the federal endangered status of the southern steelhead was re-affirmed for 10 Distinct Population Segments (DPS) of West Coast Steelhead (71 FR 834) and, in September 2007, a Federal Recovery Outline for the DPS of southern steelhead was released (NMFS 2007).

In the Santa Clara River Watershed, designated critical habitat includes the Santa Clara River and its tributaries from Piru Creek (below Santa Felicia Dam) to the Santa Clara River confluence and downstream to the Pacific Ocean. The upstream extent of designated critical habitat is approximately five miles downstream of the Project area in Ventura County, California. In 2000, the National Marine Fisheries Service (NMFS) issued a letter to the Corps clarifying their designation of critical habitat in the Santa Clara River Watershed as follows (Lecky 2000):

> *Currently available information [also] indicates that the Santa Clara River basin upstream from its confluence with Piru Creek is unlikely to be occupied or accessible to steelhead and, therefore, is not currently considered by NMFS to be part of the critical habitat designation for this ESU.*

Recovery Plan

Presently, a Recovery Plan required by the federal ESA has not been published. However, a Southern California ESU recovery team has been formed and is currently working on a draft Recovery Plan for southern steelhead within the Santa Clara River and the Southern California ESU. In September 2007, a Federal Recovery Outline for the DPS of southern steelhead was released (NMFS 2007).

Survey Results

In 2004 and 2005, reconnaissance surveys were conducted along the Santa Clara River and tributary drainages within the Specific Plan area of the RMDP. The objectives of the survey were to characterize habitat and assess presence/absence of various fish species through visual observations and periodic dip net/seine sampling (ENTRIX 2009). The habitat assessment was conducted utilizing a modified level-two version of CDFG protocols presented in the California Salmonid Stream Habitat Restoration Manual (ENTRIX 2009). The protocol was modified to capture habitat attributes related to the target fish species rather than salmonids exclusively. The

fish sampling was conducted utilizing dip nets (four feet long overall, opening 16 by 12 inches with one-eighth-inch mesh) and/or a small seine (10 by four feet with one-eighth-inch mesh) and visual estimates. The surveys were conducted within the Newhall Ranch reach of the Santa Clara River from the confluence of Salt Canyon in the west to the confluence of Middle Canyon in the east. In addition, the surveys included the following tributary drainages: Salt Canyon, Potrero Canyon, Long Canyon, San Martinez Grande Canyon, Chiquito Canyon, Castaic Creek, Humble Canyon, Lion Canyon, and Middle Canyon. Southern steelhead were not observed or collected in any of the surveyed areas. In the late spring of 2007, ENTRIX conducted an assessment of aquatic habitat conditions and identified potential physical migration barriers present in these tributary drainages (ENTRIX 2009). In the entire Project area, there is only one tributary reach (approximately 8,855 linear feet) of perennial habitat in Potrero Canyon that could possibly support any form of steelhead spawning or rearing activity. Aquatic habitat conditions within the reach where patchy small pools are very shallow are marginal for supporting any fish species, the deepest being approximately 30 centimeters deep. However, a culvert at the lowermost portion of the reach and a large bedrock headcut at the upstream end present significant barriers to upstream migration. Upstream of this reach in Potrero Canyon, conditions were classified as intermittent and do support any aquatic habitat suitable for fish.

In 2005, ENTRIX's quantitative habitat surveys of the Santa Clara River concluded that the Project reach channel has very low-gradient runs and riffles and is dominated by sandy substrate with little or no riparian canopy along the flowing stream (ENTRIX 2009). It is not expected that steelhead could successfully spawn in this reach due to inadequate substrate material (*e.g.*, lack of gravel for redd development) and sub-optimum water quality conditions related to wastewater outflows from upstream of the Project reach. The River habitat for steelhead also lacks requisite channel structure and pool habitat necessary to support rearing. If steelhead could migrate into the Project reach, this species would face significant challenges in successfully completing its life history cycle due to poor instream River habitat conditions and the absence of perennial tributary habitat for spawning and rearing. Therefore, this analysis has been conducted under the assumption that steelhead and their habitat are not present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, where no project will be constructed (No Project/No Action), southern steelhead and suitable habitat would not be impacted. The effects of continued operation of agricultural and oil and gas production activities within the Project area would not change any elements of southern steelhead life history or requisite habitat conditions downstream within the Santa Clara River. If Alternative 1 were selected, and none of the other build alternatives were implemented, there would not be any impacts to southern steelhead migration, spawning, or rearing activities downstream in the Santa Clara River.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

No historical records exist for southern steelhead in the Santa Clara River or tributaries upstream of the confluence of Piru Creek (Titus *et al.* n.d.), and the Project area is not included in the federal critical habitat designation for Southern California ESU steelhead, whereby NMFS considers natural barriers and specific dams within the historical range of each ESU to be the upstream limit of a critical habitat designation (65 FR 7764). Appropriate habitat to support southern steelhead life history, such as spawning and rearing, is not present with the RMDP and SCP project boundaries.

Implementation of the RMDP would include 32,334 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch); the construction of bridges at Potrero Canyon, Long Canyon and Commerce Center Drive; and a Newhall Ranch Water Reclamation Plant (WRP) outfall in the Santa Clara River (**Figures 4.5-33-A1** through **4.5-33-D2**). The placement of bridge piers would be located within the Santa Clara River floodplain. This floodplain ranges in width from 980 to 1,550 feet at the bridge crossings, and bridge footings would have the potential to occur in flowing portions of the River, depending on stream hydrology. For example, the Potrero Canyon Bridge includes approximately 15 piers within the floodplain. During any given storm event, the number of piers subject to inundation may range from a single pier, to all of the piers. However, during summer low flows, the maximum number of piers to likely be in contact with the wetted channel would be two piers per bridge crossing. This would result in the direct loss of aquatic habitat in the Santa Clara River. While the placement of bridge footings would result in the loss of River channel, the large width and hydrology of the River would maintain the formation of natural channels suitable for this species.

ENTRIX (2009) evaluated the long-term effects of these facilities on fish habitat and concluded that no significant effects would occur because the general morphology of the Santa Clara River, adjacent rearing habitat, and high-flow riparian refugia would not be substantially altered. Parameters evaluated included potential changes in floodplain width, backwater refuge habitat (zero to two feet per second (fps) flow) area, and water velocity, and changes were evaluated during various theoretical flood frequency events including 20- and 100-year occurrences (**Figures 4.5-61a** and **4.5-61b**). Since steelhead do not utilize or otherwise fulfill their life history requirements within the Project reach, RMDP direct permanent impacts to aquatic habitat would be less than significant.

Although no substantial permanent impacts to fish habitat would occur through implementation of the RMDP, the Project would temporarily affect habitat when construction occurs directly in aquatic habitat, such as the active stream channel. Bridge construction, in particular, could directly affect aquatic habitat occupied by fish through disturbance within the flowing stream, stream diversion, and dewatering when construction is occurring within the River corridor. However, impacts to aquatic habitat in the Project reach of the Santa Clara River would be less than significant because steelhead is not expected to occur in the Project area and the aquatic habitat present does not support requisite habitat conditions for steelhead spawning and rearing.

Implementation of the RMDP would not result in the significant alteration of stream hydrology or limit access to refugia during storm events. Implementation of the RMDP would not substantially affect fish habitat; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be less than significant.

Indirect Permanent Impacts

As described above, RMDP impacts would occur to aquatic habitat in the Project reach of the Santa Clara River. However, appropriate habitat to support southern steelhead life history, such as spawning and rearing, is not present. Therefore, build-out of the Specific Plan, VCC, and Entrada planning areas will not impact aquatic habitat, including that for southern steelhead, since steelhead utilization of the Project area is not expected to occur and requisite habitat conditions for steelhead spawning and rearing are not present.

Project build-out would not have a substantial adverse effect on the population or habitat; substantially interfere with the movement of southern steelhead; have the potential to substantially reduce the habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Impacts to aquatic habitat would not occur as a result of the build-out of the Specific Plan, VCC, or Entrada planning areas; therefore, no impacts to southern steelhead are expected to occur.

Combined Direct and Indirect Permanent Impacts

Aquatic habitat within the RMDP site does not support steelhead life history and no utilization has been documented within the Project reach of the Santa Clara River nor is any utilization expected to occur in the future. Neither implementation of the RMDP nor build-out of the Specific Plan, VCC, and Entrada planning areas would result in

permanent impacts that could have a substantial adverse effect on the species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Therefore, the impacts to aquatic habitat within the Project reach would be less than significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

No historical records exist for southern steelhead in the Santa Clara River or tributaries upstream of the confluence of Piru Creek (Titus *et al.* n.d.), and the Project area is not included in the federal critical habitat designation for Southern California ESU steelhead, whereby NMFS considers natural barriers and specific dams within the historical range of each ESU to be the upstream limit of a critical habitat designation (65 FR 7764). The Project reach of the Santa Clara River does not include requisite aquatic habitat to support steelhead life history and no utilization has been documented within the Project reach of the Santa Clara River nor is any utilization expected to occur in the future. A recognized, natural barrier to fish migration within the Santa Clara River exists downstream of the Project area and upstream of the Piru Creek confluence in the form of an ephemeral reach of the River that is referred to as the "Dry Gap." The Dry Gap consists of an area downstream of the Los Angeles County/Ventura County line where surface flows in the River are lost to the Piru groundwater basin. Additionally, NMFS has indicated that the Santa Clara River basin upstream of the Piru Creek confluence is unlikely to be occupied by or accessible to steelhead (Lecky 2000).

Implementation of the Project would require the construction of bridges and bank stabilization within the River corridor. Due to the absence of southern steelhead and their habitat, it is unlikely that implementation would result in physical impacts to steelhead in the Project area. However, it is possible that over the 20-year course of the Project a vagrant steelhead or rainbow trout could be found during surveys or fish exclusion activities prior to construction.

With implementation of the RMDP, direct permanent and temporary impacts will not substantially interfere with the movement of the species; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be less than significant.

Indirect Permanent Impacts

As described above, build-out of the Specific Plan, VCC, and Entrada planning areas does not have potential to impact southern steelhead individuals within the Project reach because no build-out-related impacts to aquatic habitat would occur in the Santa Clara River where fish species would be present. Impacts to southern steelhead individuals are not expected as a result of the build-out of the Specific Plan, VCC, or Entrada planning areas. Project build-out would not have a substantial adverse effect on the population or habitat; substantially interfere with the movement of southern steelhead; have the potential to substantially reduce the habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Accordingly, build-out of the Specific Plan, VCC, or Entrada planning areas would not result in indirect impacts to southern steelhead individuals because steelhead are not expected to occur on site.

Secondary Impacts

Although southern steelhead are not present in the Santa Clara River or tributaries within the Project area and the Project area is not included the federal critical habitat designation for Southern California ESU steelhead (65 FR 7764), the Project has the potential to affect fish species and habitat downstream of the Project through short-term or long-term hydrologic, geomorphic, or water quality alterations of the River.

Implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas could result in both short-term secondary effects during construction and long-term effects due to use of RMDP facilities and build-out of the Project area. Because steelhead are not expected to be present within the Project reach of the Santa Clara River, it is unlikely that short- or long-term secondary impacts would occur. In addition, these impacts are unlikely to affect the downstream populations of steelhead within the Santa Clara River basin. Implementation of the SCP would not result in secondary impacts to this species.

Short-term construction-related effects include hydrologic and water quality effects, such as sedimentation, increased turbidity, temperature, or the introduction of other pollutants. It is unlikely that these short-term impacts could affect steelhead in the Santa Clara River in downstream populations.

Long-term effects associated with operation of RMDP facilities and build-out of the Project area due to potential physical changes in the River and increased discharges include alterations in base flows, timing and duration of flood flows, biochemical changes, condition and composition of the substrate, aquatic and riparian vegetation (including exotic species), and water temperatures as well as increased pollutants from irrigation runoff and increased runoff from

roadways. Additional secondary impacts associated with increased human presence include incidental litter and trash from recreation activity; impacts such as fecal material from pet, stray, and feral cats and dogs entering the aquatic system; and increased predation by exotic predators, such as bullfrogs and non-native fish. Steelhead are not known use the Project reach, nor are they expected to in the future; therefore, potential long-term secondary impacts would be less than significant.

Following build-out of the Specific Plan area, the physical changes to the River corridor and surrounding watershed could affect fish species and habitat downstream of the Project through long-term hydrologic, geomorphic, or water quality alterations of the River. The Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area over the long term as a result of the proposed Project improvements. Under Alternative 2, build-out will not appreciably alter the existing sediment transport regime (less than a 0.25% decrease in average annual sediment supply/delivery to the Santa Clara River). Therefore, channel morphology and substrate composition conditions downstream that support steelhead migration in Ventura County will not be affected. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County. The PACE (2009) study determined that the River would still retain sufficient width to allow natural fluvial processes to continue. As a result, the mosaic of habitats in downstream portions of the River that support various special-status fish species would be maintained and the populations of the species within and immediately adjacent to the River corridor would not be substantially affected.

Additionally, although the Newhall Ranch WRP will be a near-zero discharge facility, limited discharge from the WRP to the Santa Clara River will occur during the winter months. Depending upon the nature and extent of these changes, it is possible that southern steelhead present downstream of the Project area and downstream of the Dry Gap (within federally designated critical habitat for the Southern California ESU steelhead) could be affected by alterations in the River's base flow, timing and duration of flood flows, condition and composition of the substrate, and presence of aquatic and riparian vegetation, on the occasions when connectivity through the Dry Gap occurs. If the discharge from the Newhall Ranch WRP substantially lengthens the duration of seasonal flow in the "Dry Gap" and cause steelhead to intermittently migrate further upstream into the Project reach, it would be considered a significant secondary impact of the Project because requisite spawning and rearing habitat is unavailable. Based on an analysis of post-development conditions within the Dry Gap (GSI Water Solutions 2008), it was determined that the future WRP discharge will not affect the seasonality (*i.e.*, ephemeral nature) of flows through the Dry Gap; therefore, the impact would be less than significant. In addition, these potential changes in hydrology are not substantial and steelhead migration downstream of the Dry Gap would not be affected.

These short-term and long-term secondary impacts would not have a substantial adverse effect on the southern steelhead; substantially interfere with the movement of the species; reduce the species' habitat; or restrict the range of the species (significance criteria 1, 4, and 7). Secondary impacts would be less than significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Overall, implementation of the RMDP under Alternatives 3 through 7 would have similar types of impacts to aquatic habitat for fish in the Santa Clara River corridor to those described above for Alternative 2 (**Figures 4.5-34-A1** through **4.5-38-D2**). Although no substantial permanent impacts to fish habitat would occur through implementation of the RMDP under Alternatives 3 through 7, the Project has the potential to temporarily affect habitat when construction occurs directly in aquatic habitat, such as the active stream channel. Buried bank stabilization would be installed at the riparian–upland interface under all the alternatives, although under Alternative 7 it would be outside the 100-year floodplain and thus would have a substantially reduced risk of temporary impacts to fish habitat. Bridge construction, in particular, would directly affect aquatic habitat through direct disturbance to the flowing stream, stream diversion, and dewatering when construction is occurring within the River corridor as previously described for Alternative 2. Three bridges would be constructed under Alternative 2. Bridges would also be constructed under Alternatives 3 through 7: two under Alternatives 3, 4, and 6; three under Alternative 5; and one under Alternative 7 (see **Table 4.5-23**, Key Components of Alternatives, for details). Thus, Alternatives 3, 4, 6, and 7 would have relatively reduced temporary impacts from bridge construction compared to Alternatives 2 and 5.

As described previously for Alternative 2, aquatic habitat does not support steelhead life history and no utilization has been documented within the Project reach of the Santa Clara River nor is any utilization expected to occur in the future. In addition, numerous measures protective of fish habitat have already been incorporated, which would also be protective of steelhead. Therefore, the impacts to aquatic habitat within the Project reach would be less than significant.

ENTRIX (2009) conducted a study of Project-related hydrologic changes in the Santa Clara River and tributaries and their potential effects on fish species for Alternatives 3, 4, 5, 6, and 7. Parameters evaluated included potential changes in floodplain width, floodplain refugia (zero to two fps flow) area, and water velocity, and changes were evaluated during various theoretical flood frequency events including five-, 10-, 20-, 50-, and 100-year occurrences. **Figures 4.5-62a** through **4.5-65b** show the range of floodplain

effects for the 20- and 100-year flood events. The following summarizes the results of this analysis.

Alternatives 3 and 4

Implementation of the RMDP within the Project reach of the Santa Clara River would include 31,857 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch; the construction of bridges at Long Canyon and Commerce Center Drive; and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-62a** and **4.5-62b**). Alternatives 3 and 4 construct one less bridge (Potrero Canyon Road) than Alternative 2, but the direct impacts from construction would be similar to Alternative 2. Direct impacts from construction would be the same with regard to steelhead habitat and therefore, would be less than significant since steelhead have not and are not expected to use the Project reach of the Santa Clara River because requisite habitat to complete their life history is not present.

Alternative 5

Implementation of the RMDP between Salt Creek and Middle Canyon would include 32,334 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch); the construction of bridges at Potrero Canyon, Long Canyon, and Commerce Center Drive; and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-63a** and **4.5-63b**). Alternative 5 bridge construction (three bridges) would be similar to Alternative 2, and the direct impacts from construction would be the same with regard to steelhead habitat. Therefore, these impacts would be less than significant since steelhead have not and are not expected to use the Project reach of the Santa Clara River because requisite habitat to complete their life history is not present.

Alternative 6

Implementation of the RMDP between Salt Creek and Middle Canyon would include 29,293 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch); the construction of bridges at Potrero Canyon and Long Canyon; and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-64a** and **4.5-64b**). Alternative 6 constructs one less bridge (Commerce Center Drive) than Alternative 2. However, the direct impacts from construction would be similar to Alternative 2 and the direct impacts from construction would be the same with regard to steelhead habitat. Therefore, these impacts would be

less than significant since steelhead have not and are not expected to use the Project reach of the Santa Clara River because requisite habitat to complete their life history is not present.

Alternative 7

Implementation of the RMDP between Salt Creek and Middle Canyon would include the construction of one bridge at Long Canyon (with spans removed from the 100-year floodplain); the grading and conversion of 13,956 linear feet of ephemeral drainages to buried storm drains; and construction of a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-65a and 4.5-65b**). Bank protection would be removed from the 100-year floodplain and built in upland areas. All jurisdictional streams and wetlands in the Santa Clara River, Potrero Canyon, Chiquito Canyon, and San Martinez Grande Canyon drainages would be preserved or avoided except where bridges are built to facilitate road crossings.

Alternative 7 constructs two less bridges (Potrero Canyon Road and Commerce Center Drive) than Alternative 2. However, the direct impacts from construction would be similar to Alternative 2, and the direct impacts from construction would be the same with regard to steelhead habitat. Therefore, these impacts would be less than significant since steelhead have not and are not expected to use the Project reach of the Santa Clara River because requisite habitat to complete their life history is not present.

Indirect Permanent Impacts

As described above, RMDP impacts would occur to aquatic habitat in the Project reach of the Santa Clara River. However, appropriate habitat to support southern steelhead life history, such as spawning and rearing, is not present. Therefore, Alternative 3, 4, 5, 6, and 7 build-out scenarios for the Specific Plan, VCC, and Entrada planning areas will not impact southern steelhead habitat since steelhead utilization of the Project area is not expected to occur. Therefore, indirect impacts to aquatic habitat would not occur.

Impacts to habitat for southern steelhead are not expected to occur as a result of the build-out of the Specific Plan, VCC, or Entrada planning areas. Project build-out would not have a substantial adverse effect on the population or habitat; substantially interfere with the movement of southern steelhead; have the potential to substantially reduce the habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7).

Combined Direct and Indirect Permanent Impacts

Aquatic habitat does not support steelhead life history and no utilization has been documented within the Project reach of the Santa Clara River nor is any utilization expected to occur in the future. Neither implementation of the RMDP nor build-out of the Specific Plan, VCC, and Entrada planning areas would result in permanent impacts that could have a substantial adverse effect on the species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Therefore, the impacts of Alternatives 3, 4, 5, 6, and 7 to aquatic habitat within the Project reach would be less than significant.

Impacts to Individuals

Due to the absence of southern steelhead and their habitat, it is unlikely that implementation of the RMDP or build-out of the Specific Plan, VCC, and Entrada planning areas would result in physical impacts to steelhead in the Project area. Implementation of the Project would require the construction of bridges and bank stabilization within the River corridor. Due to the absence of southern steelhead and their habitat, it is unlikely that implementation would result in physical impacts to steelhead in the Project area. However, it is possible that over the 20 year course of the Project, a vagrant steelhead or rainbow trout could be found during surveys or fish exclusion activities prior to construction.

With implementation of the RMDP under Alternatives 3 through 7, direct permanent and temporary impacts would not substantially interfere with the movement of the species; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be less than significant.

Secondary Impacts

Because potential secondary impacts under Alternatives 3 through 7 would be similar or less than Alternative 2, short-term and long-term secondary impacts that could occur under Alternatives 3 through 7 will not have a substantial adverse effect on the southern steelhead; substantially interfere with the movement of the species; reduce the species' habitat; or restrict the range of the species (significance criteria 1, 4, and 7). Secondary impacts would be less than significant.

Mitigation Strategy and Summary

Southern steelhead would not be subject to significant direct, indirect, or secondary impacts by the proposed Project because this species is not expected to occur in the Project area and the requisite habitat features to support spawning and rearing are not present on site; therefore, no mitigation is required for this species. Although no mitigation is required, in the unlikely event that a vagrant southern steelhead occurred in the Project area, potential impacts would be reduced by previously incorporated Mitigation Measures SP-4.6-53 and SP-4.6-59, which state that, at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

As this fish is associated with riparian areas, southern steelhead could also benefit from previously incorporated measures SP-4.6-1 through SP-4.6-16 and SP-4.6-18 through SP-4.6-26, which dedicate the River Corridor SMA and set requirements for restoration and enhancement of riparian vegetation, removal of grazing, and establishment of a transition area between developed areas and the River Corridor SMA, which will avoid and minimize downstream impacts to water quality.

Any potential impacts to vagrant southern steelhead would also be reduced by implementation of previously incorporated Mitigation Measures SP-4.6-44, SP-4.6-57, and SP-4.6-58. SP-4.6-44 requires that drainages with flows greater than 2,000 cubic feet per second have soft bottoms. Bank protection will be of ungrouted rock or buried bank stabilization, as described in **Subsection 2.5.2.a**, except at bridge crossings and other areas where public health and safety considerations require concrete or other stabilization. SP-4.6-57 requires that, where bridge construction is proposed and water flow would be temporarily diverted, blocking nets and seines be used to control and remove fish from the area of activity. All fish captured during this operation would be stored in tubs and returned unharmed back to the River after construction activities were complete. SP-4.6-58 requires that in order to limit impacts to water quality, the Specific Plan shall conform to all provisions of required National Pollutant Discharge Elimination System (NPDES) permits and water quality permits that would be required by the State of California Regional Water Quality Control Board.

This EIS/EIR recommends several mitigation measures that would reduce impacts to vagrant southern steelhead. These mitigation measures include coordination with the USFWS and CDFG, channel diversion requirements, biological monitoring, avoidance of flowing water, design guidelines for bridges and culverts, and other BMPs. Additional mitigation measures are specified in other sections of the EIS/EIR that address water quality, riparian vegetation scour,

and sedimentation. Specifically, Mitigation Measure WQ-1 in **Section 4.4,** Water Quality, and Mitigation Measures GRR-1 through GRR-7 in **Section 4.2**, Geomorphology and Riparian Resources, provide additional measures to reduce the impacts to southern steelhead individuals. These mitigation measures include implementation of Project BMPs (including runoff control, conservation of natural areas, minimization of stormwater runoff pollutants of concern, prevention of slope and channel erosion, and education and signage to discourage illegal dumping to the storm drains), and other measures to minimize impacts to riparian resources and geomorphology (peak storm flow control, bridge span and clearance guidelines, maintenance minimization, channel design to minimize erosion potential, sediment and debris control, reintroduction of sediments for beach replenishment, and a Geomorphology Monitoring and Management Plan).

Potential impacts to vagrant southern steelhead could be reduced by mitigation measures that protect and exclude fish from construction areas. BIO-43 provides for the biological surveys of aquatic habitats within 300 feet of construction sites and access roads for the presence of special-status fishes at least 10 days prior to commencing construction, unless fish spawn has occurred or juvenile fishes are present; then construction activities would be suspended. BIO-44 requires that temporary crossings or access across the River be constructed outside of the winter season and not during spring periods when fish spawning is occurring, and be consistent with a Stream Crossing and Diversion Plan that outlines the following: the timing and methods for pre-construction fish surveys; a detailed description of the diversion methods; fish exclusion techniques; methods to maintain fish passage; channel habitat enhancement design; fish stranding surveys; and the techniques for the removal of temporary crossings prior to winter storm flows. BIO-45 defines the timing and design of stream diversion bypass channels and dewatering activities and related restrictions to ensure proper construction, operation, and abandonment diversion or dewatering will occur. BIO-46 requires that a qualified biologist inspect diversion or dewatering activities for stranded fish or other aquatic organisms. BIO-47 provides for the construction of additional slow moving water habitats upstream and downstream of any river crossing or bridge construction area to provide refuge for special status fishes during construction. BIO-48 requires the design and installation of bridges, culverts, or other structures to not impair the movement of fish and aquatic life and provisions for a low flow channel where velocities are less than two fps to allow fish passage.

Potential impacts to vagrant southern steelhead could also be reduced by mitigation measures that minimize impacts related to water quality and dust. BIO-49 requires that pollutants from construction activities not be allowed to enter a flowing stream or be placed in locations that may be subjected to storm flows. BIO-63 will be implemented to mitigate impacts by pet, stray, and feral cats and dogs, such as fecal material entering the aquatic system. This measure requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed

control of stray and feral cats and dogs in open space areas. BIO-70 provides for construction plans that will include erosion control plans and dust control plans, specifications, and details, along with an overall Project SWPPP. Together, these documents shall include measures to ensure that impacts (*e.g.*, the introduction of chemical pollutants, exposure to fugitive dust, contact with polluted runoff, and changes in hydrology) to vegetation communities and special-status plant species are avoided or minimized during construction. BIO-71 requires that development areas have dust control measures implemented and maintained to prevent dust from impacting vegetation communities and aquatic wildlife species. Dust control plans shall be prepared prior to initiation of construction activities and shall comply with SCAQMD Rule 403 (SCAQMD 2005).

Finally, potential impacts to vagrant southern steelhead by non-native predators could be reduced by BIO-80, which states that the Project applicant shall retain a qualified biologist to develop and implement an Eradication Plan for bullfrog, African clawed frog, and crayfish. Following construction, monitoring shall be conducted at sentinel locations along the River Corridor SMA (and other potential habitat areas) annually for five years. After five years, monitoring shall be conducted bi-annually for 50 years.

INTENTIONALLY LEFT BLANK

UNARMORED THREESPINE STICKLEBACK (FE, CE, CFP)

Life History

The unarmored threespine stickleback (*Gasterosteus aculeatus williamsoni*) is listed as both state- and federally endangered and is a California Fully Protected species. Although originally widespread throughout the Los Angeles Basin, the unarmored threespine stickleback is currently found in few locations which are all situated outside of the Los Angeles River basin (Swift *et al.* 1993). The unarmored threespine stickleback is a known resident species in the Santa Clara River throughout the Project reach, and the RMDP site is within the Del Valle zone of the designated essential habitat for this species (**Figure 4.5-60**, Habitat in RMDP/SCP for Unarmored Threespine Stickleback).

The unarmored threespine stickleback is a small territorial fish that can grow up to a maximum of approximately four inches in length (CDFG 2000). There are numerous subspecies and morphs of threespine stickleback (*G. aculeatus*) found throughout the Northern Hemisphere, and these are thought to represent a superspecies[1] whose ancestral form is the completely plated morph inhabiting marine waters and some freshwaters (Moyle 2002; McPhail 2007; Östlund-Nilsson *et al.* 2007). Threespine sticklebacks lack scales that are common to other fish, and they are related to pipefish and seahorses (ITIS 2007). Their spines and plating are thought to provide protection against piscivorous fish, such as salmonids, by disrupting the capture biomechanics of the predator's jaws, inhibiting capture, and providing increased opportunities for escape (Reimchen 1992, 2000). Studies of threespine stickleback systematics suggest that reduction of plating is a common convergent morphological change in freshwater populations; many such populations colonized inland streams and lakes after the Pleistocene (ice-age) glacial retreat (O'Reilly *et al.* 1993; Orti *et al.* 1994). The USFWS (1985) notes that the unarmored threespine stickleback can be found in all areas of streams, but they prefer slow-moving and standing water or locations behind obstructions, at the edge of streams, or in vegetation in faster moving water. Similar to other threespine stickleback species, male unarmored threespine sticklebacks create a nest in slow-moving water, by gluing together bits of vegetation, such as grass and sticks, using a kidney-secreted protein, and will vigorously defend the established nest territory. After egg fertilization, the male will care for and protect the eggs until the young leave. The male unarmored threespine stickleback will fan the eggs with his pectoral fins, helping to ensure proper development of the embryos. The amount of suitable breeding habitat may be a limiting factor in the population of the unarmored threespine stickleback (CDFG 2000). The unarmored threespine stickleback lives for about one year, and few if any survive to breed again (USFWS 1985; ESIS 1998).

[1] A superspecies is a set of closely related species.

Critical Habitat

On November 17, 1980, the USFWS proposed designating approximately 51 kilometers (31.7 miles) of streams in Los Angeles and Santa Barbara counties as critical habitat for the unarmored threespine stickleback (45 FR 76012). The proposed critical habitat included three stream zones of the upper Santa Clara River, including the Del Valle zone, the San Francisquito zone, and the Soledad Canyon zone. The Del Valle zone includes the Project area and runs from the confluence with San Martinez Grande Canyon upstream to the I-5 Bridge. On September 17, 2002, the USFWS determined that a designation of critical habitat for unarmored threespine stickleback should not be made because the initial federal listing was in 1970 under the Endangered Species Conservation Act of 1969, the predecessor of the Endangered Species Act of 1973 (67 FR 58850–58582). The Endangered Species Conservation Act did not have a critical habitat designation requirement. A lawsuit brought by the Center for Biological Diversity (CBD) resulted in a decision by the Ninth Circuit Court of Appeals in 2006 upholding the USFWS decision to not designate critical habitat for unarmored threespine stickleback.

Because there is no critical habitat designation in the Project area, critical habitat is not further addressed in the unarmored threespine stickleback analysis in this EIS/EIR.

Recovery Plan

The Unarmored Threespine Stickleback Recovery Plan (Revised) was published by the USFWS on December 26, 1985 (USFWS 1985). The recovery strategy for the unarmored threespine stickleback consists of five parts: (1) restore and maintain essential habitat at optimum conditions; (2) restore and maintain populations at optimum conditions; (3) determine life history and obtain needed ecological and genetic information; (4) inform the public of the species' status and recovery effort; and (5) utilize laws and regulations to protect fish and habitat. The Recovery Plan designated three areas as very important for the survival and recovery of the species: (1) two disjunct reaches of the Santa Clara River in Los Angeles County; (2) a short reach of San Francisquito Canyon; and (3) and the lowermost 8.4 miles in San Antonio Creek in Santa Barbara County. One of the reaches in the Santa Clara River is the area from San Martinez Grande Canyon upstream to the I-5 Bridge, which runs through the Project area and is the same area proposed as critical habitat (45 FR 76012).

Survey Results

ENTRIX (2009) conducted surveys for the unarmored threespine stickleback in 2004 and 2005 within the Newhall Ranch reach. ENTRIX (2009) surveyed for unarmored threespine stickleback habitat by targeting habitat attributes between Salt Creek Canyon and The Old Road Bridge. The survey recorded habitat type, length and mean width, mean and maximum depth, substrate composition, water and air temperature, and percent edgewater vegetation.

The unarmored threespine stickleback was observed during surveys within the Santa Clara River portion of the Specific Plan area in 1988, 1995, 2000, 2002–2005, and 2007 (Aquatic Consulting Services 2002A, 2002B, 2002C, 2002D; ENTRIX 2009; Haglund 1989; SMEA 1995, 2000; Impact Sciences 2003A, 2003B, 2003C).

Because the unarmored threespine stickleback is confined to perennial aquatic habitat in the Santa Clara River, which comprises a small portion of the wetland/riparian habitat in the River and has high temporal variability, suitable aquatic habitat was not quantified for the purpose of the impact analysis in this EIS/EIR. The presence of unarmored threespine stickleback is quite variable (ranging from rare or absent in certain reaches of the River, to locally abundant in any given year) in the Project reach in sections of the Santa Clara River, but the species is assumed to be present for this analysis.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the proposed RMDP could result in permanent physical changes to the Santa Clara River corridor and surrounding watershed that could affect suitable unarmored threespine stickleback habitat, including hydrology and fluvial processes. Implementation of the SCP would not directly affect this species.

Habitat variables evaluated by ENTRIX (2009) included potential changes in floodplain width, backwater refuge habitat area (flood condition aquatic refugia), and water velocity during various theoretical flood frequency events. ENTRIX (2009) conducted a study of Project-related hydrologic changes in the Santa Clara River and tributaries and their potential effects on the unarmored threespine stickleback. Parameters evaluated included potential changes in floodplain width, backwater refuge habitat (zero to two feet per second (fps) flow) area, and water velocity, and changes were evaluated during various theoretical flood frequency events including 20- and 100-year occurrences (**Figures 4.5-61a** and **4.5-61b**). The following summarizes the results of this analysis.

Implementation of the RMDP between Salt Creek and Middle Canyon would include 32,334 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch); the construction of bridges at Potrero Canyon, Long Canyon, and Commerce Center Drive; and a Newhall Ranch Water Reclamation Plant (WRP) outfall in the Santa Clara River (**Figures 4.5-33-A1** through **4.5-33-D2**). The placement of bridge piers would be located within the Santa Clara River floodplain. This floodplain ranges in width from 980 to 1,550 feet at the bridge crossings, and bridge footings would have the potential to occur in flowing portions of the River depending on stream hydrology. For example, the Potrero Canyon Bridge includes approximately 15 piers within the floodplain. During any given storm event, the number of piers subject to inundation may range from a single pier to all of the piers. However, during summer low flows, the maximum number of piers to likely be in contact with the wetted channel would be two piers per bridge crossing. This would result in the direct loss of habitat occupied by stickleback. While the placement of bridge footings would result in the loss of River channel, the large width and hydrology of the River would maintain the formation of natural channels to support this species. Therefore, this permanent loss of habitat due to bridge footings would be adverse but not significant.

The primary effect of construction within the River channel is the alteration of natural stream hydrology and the quantity of stickleback habitat available. The ENTRIX report (2009) analyzed the hydrologic effects of the Project on the Santa Clara River for impacts to potential unarmored threespine stickleback habitat. Based on an evaluation of velocity tolerance studies of stickleback fishes, ENTRIX inferred that unarmored threespine stickleback in the Santa Clara River require flood refugia velocities of two fps or less in natural river floodplain in order to avoid being washed downstream during flood events (ENTRIX 2009). Areas maintaining velocities less than or equal to two fps would provide refuge during storm events. Under existing conditions (dry and wet season conditions), most of the wetted channel of the Santa Clara River supports flows greater than two fps. In the Project area, stickleback tend to be associated with flow velocities less than two fps in areas along the margin of the river and backwater areas outside of the higher velocity portions of the wetted channel.

At the five- and 10-year flood events, frequency hydraulic modeling shows that there would be an increase in available area with less than two fps velocity of 1.3 acres and 5.5 acres, respectively, for the unarmored threespine stickleback. During the 20-, 50-, and 100-year events, there is a decrease in habitat with less than two fps velocity at 12.5 acres, 11.1 acres, and 8.9 acres, respectively. The decrease is not expected to be significant, as the area lost during these flood events is in terraced agricultural land that is not suitable floodplain refugia habitat for the unarmored threespine stickleback. Suitable

floodplain refugia requires microhabitat elements, such as vegetative cover, substrate, and stream topography (ENTRIX 2009). Agricultural land is not considered as refuge, as it presents a greater threat to fish stranding during high flood events. The ENTRIX report further indicates that the alteration of the stream hydrology would not result in significant impacts related to stickleback access to floodplain refugia during flood events, since the general morphology of the Santa Clara River, adjacent rearing habitat, and high-flow floodplain refugia would not be substantially altered. This is illustrated on **Figures 4.5-61a** and **4.5-61b,** which indicate stream flow areas with less than two fps during the 20- and 100-year flood events, respectively (see entire set of graphics in ENTRIX 2009 report, Appendix 4.5).

Implementation of the RMDP between Salt Creek and Middle Canyon would include buried bank stabilization along the upland–riparian interface along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch), the construction of bridges at Potrero Canyon, Long Canyon, and Commerce Center Drive, and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-33-A1** through **4.5-33-D2**). ENTRIX (2009) evaluated the long-term effects of these facilities on unarmored threespine stickleback habitat and concluded that no significant effects to unarmored threespine stickleback habitat would occur because the general morphology of the Santa Clara River, adjacent rearing habitat, and high-flow riparian refugia would not be substantially altered.

There also would be no impacts to unarmored threespine stickleback habitat resulting from modifications to tributaries to the Santa Clara River due to the absence of unarmored threespine stickleback. Most of the tributaries do not support perennial flows, and none of the tributaries have surface water connectivity with the Santa Clara River, except for Middle and Potrero canyons, which although they contain perennial flow, they have substantial blockages (bedrock headcuts or cascades) that are impassable to fish (ENTRIX 2009).

Although no substantial permanent impacts to unarmored threespine stickleback habitat would occur through implementation of the RMDP, the Project would temporarily affect habitat when construction occurs directly in aquatic habitat, such as the active stream channel. Bridge construction, in particular, could directly affect aquatic habitat occupied by unarmored threespine stickleback through direct impacts to the flowing stream, stream diversion, and dewatering when construction is occurring within the River corridor. Direct impacts from temporary construction would be significant absent mitigation primarily due to permanent and temporary disturbance to aquatic habitat from construction of RMDP facilities within the Santa Clara River.

With implementation of the RMDP direct temporary impacts would substantially affect unarmored threespine stickleback habitat; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct temporary impacts (Loss of Habitat) would be significant, absent mitigation. Implementation of the RMDP would not result in the significant alteration to stream hydrology or limit access to refugia during storm events and, therefore, direct permanent impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

Because the distribution of this species within the Project area is limited to aquatic habitats within the Santa Clara River, construction activities associated with build-out of the Specific Plan, VCC, and Entrada planning areas do not have potential to harm or eliminate occupied unarmored threespine stickleback habitat because all activities would be outside the River corridor. Project build-out would not have a substantial adverse effect on the unarmored threespine stickleback habitat; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would not be significant because no impacts are expected to occur as a result of Specific Plan build out and development outside of the River and aquatic habitat.

Combined Direct and Indirect Permanent Impacts

Only RMDP-related impacts would result in permanent impacts to suitable habitat for this species, and these impacts would be adverse but not significant. Neither implementation of the RMDP nor build-out of the Specific Plan, VCC, and Entrada planning areas would result in permanent impacts that could have a substantial adverse effect on the species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Therefore, the combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

The presence of unarmored threespine stickleback is quite variable (ranging from rare or absent in certain reaches of the River, to locally abundant in any given year) in the Project reach, and the species is generally assumed to be present for this analysis. Implementation of the RMDP, including construction of buried bank structures and bridges, could adversely affect individual unarmored threespine sticklebacks during construction work within the River. The potential for impacts from installation of these structures is increased as the construction is planned for marginal areas of the riparian zone and because this species is known to use lateral backwater refuge habitat and aquatic environments of emergent, fringe vegetation. Direct impacts to the species may occur during construction of RMDP components during the following anticipated activities:

- Stream diversion and/or species exclusion;
- unauthorized entry of construction equipment into ponded or flowing water;
- placement of fill in occupied waters;
- construction dewatering activities;
- discharge of pollutants, including silt, sediment, fresh concrete, trash/debris, and petroleum or other deleterious materials or pollutants, and/or;
- unauthorized personnel entry into occupied waters.

These activities could result in the following impacts:

- inadvertently directing fish to unsuitable habitats, blocking fish passage, stranding of fish in unsuitable habitat, or directing fish into unsuitable flow regimes;
- causing water quality conditions unsuitable for the fish survival;
- direct mechanical crushing or entombment of fish;
- unauthorized collection of individuals and/or physical disturbance of river edge habitats

Implementation of the SCP would not directly impact this species within the Project reach or downstream. Implementation of the RMDP could have direct substantial adverse effects on the unarmored threespine stickleback, interfere with the movement of the species, and substantially reduce the number of the species (significance criteria 1, 4,

and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

Because the distribution of this species within the Project area is limited to aquatic habitats within the Santa Clara River corridor, build-out of the Specific Plan, VCC, and Entrada planning areas would not result in the impacts to unarmored threespine stickleback individuals. Project build-out would not have a substantial adverse effect on the unarmored threespine stickleback; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Impacts to Individuals) would not be significant because physical on-site impacts are not expected to occur due to Specific Plan build-out.

Secondary Impacts

Implementation of the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas could result in both short-term secondary effects during construction and long-term effects due to use of RMDP facilities and build-out of the Project area. These impacts could affect the unarmored threespine stickleback along the Santa Clara River corridor within the Project area and in downstream populations. Implementation of the SCP would not result in secondary impacts to this species.

Short-term construction-related effects include hydrologic and water quality effects. These short-term impacts could affect unarmored threespine stickleback in the Santa Clara River within the Project area and in downstream populations.

Long-term effects associated with operation of RMDP facilities and build-out of the Project area due to potential physical changes in the River and increased discharges include alterations in base flows; timing and duration of flood flows; biochemical changes; condition and composition of the substrate; aquatic and riparian vegetation (including exotic species); water temperatures; increased pollutants from irrigation runoff; and increased runoff from roadways. Additional secondary impacts associated with increased human presence include incidental litter and trash from recreation activity; impacts such as fecal material from pet, stray, and feral cats and dogs entering the aquatic system; and increased predation by exotic predators, such as bullfrogs and non-native fish.

These short-term and long-term secondary impacts could have a substantial adverse effect on the unarmored threespine stickleback; substantially interfere with the movement of the species;

reduce the species' habitat; or restrict the range of the species (significance criteria 1, 4, and 7). Secondary impacts would be significant, absent mitigation.

Following build-out of the Specific Plan areas, the physical changes to the River corridor and surrounding watershed could affect fish species and habitat downstream of the Project through short- or long-term hydrologic, geomorphic, or water quality alterations of the River. Newhall Ranch WRP will be a near-zero discharge facility. Limited discharge from the WRP to the Santa Clara River is only to occur during the winter months. Of primary concern is the potential that the partially armored subspecies of threespine stickleback present downstream of the Project area and downstream of the Dry Gap could have access to the Project area and could hybridize with unarmored threespine stickleback by alterations in the river's base flow or changes to the seasonality or connectivity through the Dry Gap. During periods when connectivity between these two populations occurs, flows are of a sufficient velocity to prevent upstream passage and migration of partially-armored threespine stickleback. If the discharge from the Newhall Ranch WRP creates conditions that allow partially-armored threespine stickleback to migrate further upstream into the Project reach, it would be considered a significant secondary impact of the Project due to the potential for genetic introgression into the unarmored threespine stickleback population in the Project reach. Based on an analysis of post-development conditions within the Dry Gap (GSI Water Solutions, 2008), it was determined that the future WRP discharge will not affect the seasonality (*i.e.*, ephemeral nature) or duration of flows through the Dry Gap. Therefore, secondary impacts to unarmored threespine stickleback from genetic introgression are not expected to occur and are considered less than significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Overall, implementation of the RMDP under Alternatives 3 through 7 would have similar types of impacts to unarmored threespine stickleback habitat in the Santa Clara River corridor to those described above for Alternative 2 (**Figures 4.5-34-A1** through **4.5-38-D2**). Although no substantial permanent impacts to unarmored threespine stickleback habitat would occur through implementation of the RMDP under Alternatives 3 through 7, the Project has the potential to temporarily affect habitat when construction occurs directly in aquatic habitat, such as the active stream channel. Buried bank stabilization would be installed at the riparian–upland interface under all the alternatives, although under Alternative 7 it would be outside the 100-year floodplain and thus would have a substantially reduced risk of temporary impacts to unarmored threespine stickleback habitat. Bridge construction, in particular, would directly affect aquatic habitat occupied by unarmored threespine stickleback through direct impacts to the flowing stream, stream diversion, and dewatering when construction is occurring within the River corridor as

previously described for Alternative 2. Three bridges would be constructed under Alternative 2. Bridges would also be constructed under Alternatives 3 through 7: two under Alternatives 3, 4, and 6; three under Alternative 5; and one under Alternative 7 (see **Table 4.5-23**, Key Components of Alternatives, for details). Thus, Alternatives 3, 4, 6, and 7 would have relatively reduced temporary impacts from bridge construction compared to Alternatives 2 and 5.

As described previously for Alternative 2, direct impacts from construction would be significant absent mitigation primarily due to permanent and temporary disturbance to aquatic habitat from construction of RMDP facilities within the Santa Clara River.

ENTRIX (2009) conducted a study of Project-related hydrologic changes in the Santa Clara River and tributaries and their potential effects on the unarmored threespine stickleback for Alternatives 3, 4, 5, 6, and 7. Parameters evaluated included potential changes in floodplain width, floodplain refugia (zero to two fps flow) area, and water velocity, and changes were evaluated during various theoretical flood frequency events including five-, 10-, 20-, 50-, and 100-year occurrences. **Figures 4.5-62a** through **4.5-65b** show the range of floodplain effects for the 20- and 100-year flood events. The following summarizes the results of this analysis.

Alternatives 3 and 4

Implementation of the RMDP within the Project reach of the Santa Clara River would include 31,857 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch; the construction of bridges at Long Canyon and Commerce Center Drive; and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-62a** and **4.5-62b**). The ENTRIX report (2009) indicates that there would be the following impacts to potential unarmored threespine stickleback floodplain refugia. At the five- and 10-year flood events, frequency hydraulic modeling shows that there would be an increase in available refugia of 2.1 acres and 8.9 acres, respectively, for the unarmored threespine stickleback with less than two fps flow. During the 20-, 50-, and 100-year events, there is a decrease in refugia with less than two fps flow at 7.3 acres, 5.3 acres, and 5.7 acres, respectively. The decrease in refugia is not expected to be significant as the area lost during these flood events is in terraced agricultural land that is not suitable floodplain refugia for the unarmored threespine stickleback (ENTRIX 2009). The ENTRIX report (2009) further indicates that accessible floodplain refugia, would not be substantially altered, and therefore, any impact would be less than significant.

Alternatives 3 and 4 construct one less bridge (Potrero Canyon Road) than Alternative 2; however, the direct temporary impacts to habitat from construction would be similar to Alternative 2, and therefore would be significant absent mitigation.

Alternative 5

Implementation of the RMDP between Salt Creek and Middle Canyon would include 32,334 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch); the construction of bridges at Potrero Canyon, Long Canyon and Commerce Center Drive; and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-63a** and **4.5-63b**). The ENTRIX report (2009) indicates that there would be the following impacts to potential unarmored threespine stickleback habitat (zero to two fps flow). At the five- and 10-year flood events, frequency hydraulic modeling shows that there would be an increase in available habitat of 1.3 acres and 5.5 acres, respectively, for the unarmored threespine stickleback with less than two fps flow. During the 20-, 50-, and 100-year events, there is a decrease in habitat with less than two fps flow at 12.5 acres, 11.1 acres, and 8.9 acres, respectively. The decrease in habitat is not expected to be significant as the habitat lost during these flood events is in terraced agricultural land that is not suitable habitat for the unarmored threespine stickleback (ENTRIX 2009). The ENTRIX report (2009) further indicates that accessible floodplain refugia would not be substantially altered, and therefore, any impact would be less than significant.

Three bridges would be constructed under Alternative 5. The direct temporary impacts to habitat from construction would be similar to Alternative 2, and therefore would be significant absent mitigation.

Alternative 6

Implementation of the RMDP between Salt Creek and Middle Canyon would include 29,293 linear feet of buried bank stabilization in upland and riparian areas, along the mainstem of the Santa Clara River (approximately one-half of the north bank and one-third of the south bank of the Santa Clara River within Newhall Ranch); the construction of bridges at Potrero Canyon and Long Canyon; and a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-64a** and **4.5-64b**). The ENTRIX report (2009) indicates that there would be the following impacts to potential unarmored threespine stickleback habitat (zero to two fps flow). At the five- and 10-year flood events, frequency hydraulic modeling shows that there would be an increase in available habitat of 1.3 acres and 10.7 acres, respectively, for the unarmored threespine stickleback with less than two fps flow. During the 20-, 50-, and 100-year events there is a decrease in habitat with less than two fps flow at 7.0 acres, 4.6 acres, and 2.6 acres, respectively. The decrease in

habitat is not expected to be significant as the habitat lost during these flood events is in terraced agricultural land that is not suitable habitat for the unarmored threespine stickleback (ENTRIX 2009). The ENTRIX report (2009) further indicates that there would be no impacts from the installation of these Project components, since the general morphology of the Santa Clara River, adjacent rearing habitat, and high-flow riparian refugia would not be substantially altered. The ENTRIX report (2009) further indicates that accessible floodplain refugia would not be substantially altered, and therefore, any impact would be less than significant.

Alternatives 6 constructs one less bridge (Commerce Center Drive) than Alternative 2; however, the direct temporary impacts to habitat from construction would be similar to Alternative 2, and therefore would be significant absent mitigation.

Alternative 7

Implementation of the RMDP between Salt Creek and Middle Canyon would include the construction of one bridge at Long Canyon (with spans removed from the 100-year floodplain); the grading and conversion of 13,956 linear feet of ephemeral drainages to buried storm drains; and construction of a Newhall Ranch WRP outfall in the Santa Clara River (**Figures 4.5-65a and 4.5-65b**). Bank protection would be removed from the 100-year floodplain and built in upland areas. All jurisdictional streams and wetlands in the Santa Clara River, Potrero Canyon, Chiquito Canyon, and San Martinez Grande Canyon drainages would be preserved or avoided except where bridges are built to facilitate road crossings. The ENTRIX report (2009) indicates that there would be the following impacts to potential unarmored threespine stickleback habitat. The model predicts a projected increase of available refuge habitat (less flow during the five-, 10-, 20-, 50-, and 100-year flood events. The amount of available habitat would be 2.0, 13.3, 22.5, 41.7, and 25.2 acres, respectively. The ENTRIX report (2009) further indicates that there would be no impacts from the installation of these Project components, since the general morphology of the Santa Clara River, adjacent rearing habitat, and high-flow riparian refugia would not be substantially altered.

Alternatives 7 constructs two less bridges (Potrero Canyon Road and Commerce Center Drive) than Alternative 2; however, the direct temporary impacts to habitat from construction would be similar to Alternative 2, and therefore would be significant absent mitigation.

While implementation of the RMDP under Alternatives 3 through 7 would not have a substantial permanent adverse effect, temporary impacts could substantially affect unarmored threespine stickleback; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species; or

substantially reduce the number or restrict the range of the species. Direct permanent impacts (Loss of Habitat) under Alternatives 3 through 7 would not be significant because no impacts would occur but direct temporary impacts (Loss of Habitat) would be significant, absent mitigation.

Indirect Permanent Impacts

The unarmored threespine stickleback within the Project area is limited to aquatic habitats within the Santa Clara River. As with Alternative 2, construction activities associated with build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas do not have the potential to harm or eliminate occupied unarmored threespine stickleback habitat because all activities would be outside the River corridor. Project build-out would not have a substantial adverse effect on the unarmored threespine stickleback; substantially interfere with the movement of the species; have the potential to substantially reduce the species' habitat; cause the population to drop below self-sustaining levels; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Indirect permanent impacts (Loss of Habitat) under Alternatives 3 through 7 would not be significant because no impacts are expected to occur.

Combined Direct and Indirect Permanent Impacts

For Alternatives 3 through 7, only RMDP-related impacts would result in permanent impacts to suitable habitat for this species, and these impacts are considered to be adverse but not significant. Neither implementation of the RMDP nor build-out of the Specific Plan, VCC, and Entrada planning areas would result in permanent impacts that could have a substantial adverse effect on the species; interfere substantially with the movement of the species or impede the use of nursery sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Therefore, the combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Similar to Alternative 2, implementation of the RMDP would require the construction of bridges and bank stabilization within the River corridor, although the number of bridges varies among the alternatives and bank stabilization under Alternative 7 would be constructed outside the 100-year floodplain, resulting in reduced risk of temporary impacts to unarmored threespine stickleback habitat under this alternative. Implementation of the RMDP under Alternatives 3 through 7 may result in impacts to unarmored threespine stickleback individuals if construction

occurs during River flows adequate to support this species in work zones in occupied habitat or if construction causes interruptions in water flows. Implementation of the SCP would not directly impact this species.

Implementation of the RMDP under Alternatives 3 through 7 could have a direct substantial adverse effect on the unarmored threespine stickleback; interfere with the movement of the species; or substantially reduce the number of the species. Direct impacts to individuals under Alternatives 3 through 7 would be significant, absent mitigation.

Implementation of build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7, would not result in indirect impacts to individuals.

Secondary Impacts

The potential short-term and long-term secondary impacts to the unarmored threespine stickleback and its habitat under Alternatives 3 through 7 would be similar to those described above for Alternative 2.

Short-term construction-related effects include hydrologic and water quality effects, as described above, that could affect unarmored threespine stickleback in the Santa Clara River within the Project area and in downstream populations.

Long-term effects associated with operation of RMDP facilities and build-out of the Project area could occur due to potential physical changes in the River and increased discharges and could affect base flows and flood flows and induce biochemical, substrate, temperature, and vegetative changes. Increased human activity could increase litter and trash, and fecal material from pet, stray, and feral cats and dogs may enter the aquatic system. In addition, increased predation by exotic predators, such as bullfrogs and non-native fish, may occur.

These short-term and long-term secondary impacts could have a substantial adverse effect on the unarmored threespine stickleback; substantially interfere with the movement of the species; reduce the species' habitat; or restrict the range of the species. Secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Following build-out of the Specific Plan areas, the physical changes to the River Corridor and surrounding watershed could affect fish species and habitat downstream of the Project through short- or long-term hydrologic, geomorphic, or water quality alterations of the River. Newhall Ranch WRP will be a near-zero discharge facility. Limited discharge from the WRP to the Santa Clara River is only to occur during the winter months. Of primary concern is the potential that the partially armored species of threespine stickleback present downstream of the Project area and downstream of the Dry Gap could have access to the Project area and could hybridize with unarmored threespine stickleback by alterations in the river's base flow or changes to the

seasonality or connectivity through the Dry Gap. During periods when connectivity between these two populations occurs, flows are of a sufficient velocity to prevent upstream passage and migration of partially armored threespine stickleback. If the discharge from the Newhall Ranch WRP creates conditions that allow partially armored threespine stickleback to migrate further upstream into the Project reach, it would be considered a significant secondary impact of the Project due to the potential for genetic introgression into the unarmored threespine stickleback population in the Project reach. Based on an analysis of post-development conditions within the Dry Gap (GSI Water Solutions 2008), it was determined that the future WRP discharge will not affect the seasonality (*i.e.* ephemeral nature) or duration of flows through the Dry Gap. Therefore, secondary impacts to unarmored threespine stickleback from genetic introgression are not expected to occur and would be less than significant.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to unarmored threespine stickleback: (1) impacts to individuals; (2) loss of suitable habitat; and (3) secondary impacts to individuals and suitable habitat outside the Project footprint.

The mitigation required by the Newhall Ranch Specific Plan Program EIR and the mitigation measures recommended by this EIS/EIR combined will avoid or substantially lessen impacts to unarmored threespine stickleback individuals. To avoid or substantially lessen impacts to unarmored threespine stickleback, protective measures will be implemented, such as pre-construction surveys, biological monitoring, exclusion of the species from construction areas using temporary diversion channels, and protection of habitat through facilities design guidelines and BMPs, which will avoid or substantially lessen impacts to unarmored threespine stickleback individuals.

Impacts to individuals, including adults and fry (juvenile fish), could occur during construction as a result of heavy equipment operation for access and grading, or during diversion of Santa Clara River flows. The Project incorporates numerous elements to avoid or substantially lessen potential impacts to individuals, such as injury or mortality, which would come as a result of direct contact with construction equipment or as an outcome of modification of River habitat, such as flow diversion activities. These measures include pre-construction surveys for any construction activity within 300 feet of River habitat to assure that stickleback are avoided or excluded, particularly during the sensitive periods such as spawning or when fry are present. These measures also specify the methods to be used for excluded stickleback, as well as how temporary diversion channels will be constructed to assure that adequate rearing habitat is present for stickleback during construction. These measures also employ provisions for constructing permanent and temporary stream crossings in the Santa Clara River in a manner that will allow for unimpeded movement upstream and downstream. Numerous water quality measures, such as construction stormwater BMPs (*e.g.*, silt fencing, erosion control materials,

sediment basins) and the installation of water quality treatment facilities are also included to minimize impacts from pollutants related to storm runoff during storm events.

The mitigation required by the Newhall Ranch Specific Plan Program EIR and the mitigation measures recommended by this EIS/EIR will reduce temporary impacts to unarmored threespine stickleback habitat through facilities design requirements, which will avoid and minimize impacts to habitat, and conformance with state and federal permits to protect water quality.

The vast majority of stickleback habitat in Project reach of the Santa Clara River will be preserved under all of the alternatives. Stickleback habitat will be impacted through the construction of RMDP facilities, by bridge pier or column footings in particular. It is estimated that one to two pier or column footings would affect stickleback habitat at each of the three Santa Clara River bridge crossings (Commerce Center Drive, Long Canyon Road, Potrero Canyon Road) depending on the location of the active channel. The wetted channel of the River is typically between 30 and 50 feet wide, while the river floodplain ranges between 1,000 and 2,000 feet wide. The spacing between piers and columns will be 100 feet, thus approximately one to two pier or column footings per bridge could be placed in the flow of the River and affect stickleback habitat. Because River flow will deflect off of these structures and will become realigned, stickleback habitat will become re-established after bridge construction is completed. Temporary diversion for the construction of piers and columns will include the establishment of additional habitat downstream to allow for necessary stickleback spawning, rearing, and/or oversummering. Bank stabilization features (buried soil cement, rock riprap, or gunite lining) will impact stickleback habitat through floodplain alterations caused by changes to flood flows through the Project area. Under severe flood conditions, stickleback will seek slow-moving floodplain areas as refugia from high velocity conditions. Although bank stabilization features will sometimes constrict flows through the Project reach, the amount of available flood refugia present during these events is adequate to protect stickleback from being flushed out of the Project area.

The mitigation required by the Newhall Ranch Specific Plan Program EIR and the mitigation measures recommended by this EIS/EIR combined will avoid or substantially lessen secondary impacts on the unarmored threespine stickleback and its habitat. Impacts such as increased chemical pollutants, sedimentation, and increased human activity will be mitigated by measures such as the protection and management of the River Corridor SMA, creation of buffer areas between the River Corridor SMA and development, water quality requirements, and restrictions on public access. In addition, the technical studies conducted by ENTRIX (2009) concluded that suitable unarmored threespine stickleback habitat would not be significantly affected by the RMDP and build-out of the Specific Plan, VCC, and Entrada planning areas under any of the alternatives. Further, the Flood Hydraulics Impacts Assessment (PACE 2009) found that there would be no significant impacts to water flows, velocities, depth, sedimentation, or floodplain and channel conditions downstream of the Project area over the long term as a result of the

proposed Project improvements. These hydrologic effects were also found to be insufficient to alter the amount, location, and nature of aquatic and riparian habitats within the Project area and downstream into Ventura County. The PACE study determined that the River would still retain sufficient width to allow natural fluvial processes to continue. As a result, the mosaic of habitats in the River that support various special-status fish species would be maintained and the populations of the species within and immediately adjacent to the River corridor would not be substantially affected.

Additionally, following build-out of the Specific Plan areas, the physical changes to the River corridor and surrounding watershed could affect fish species and habitat downstream of the Project through short- or long-term hydrologic, geomorphic, or water quality alterations of the river. Newhall Ranch WRP will be a near-zero discharge facility, and only limited discharge from the WRP to the Santa Clara River will occur during the winter months. If the discharge from the Newhall Ranch WRP substantially lengthens the duration of seasonal river connectivity in the "Dry Gap" and causes partially-armored threespine stickleback to intermittently migrate further upstream into the Project reach, it would be considered a significant secondary impact of the Project due to the potential for genetic introgression into the unarmored threespine stickleback population in the Project reach. Based on an analysis of post-development conditions within the Dry Gap (GSI Water Solutions, 2008), it was determined that the future WRP discharge will not affect the seasonality (*i.e.*, ephemeral nature) of flows through the Dry Gap and genetic introgression effects are not anticipated. Since the greatest threat to the genetic integrity of unarmored threespine stickleback is introgression resulting from intermittent migration of downstream partially-armored threespine stickleback populations, the maintenance of ephemeral conditions in the Dry Gap creates an essential natural geographic barrier that prevents unarmored threespine stickleback populations upstream from hybridizing and the loss of the species' genetic integrity.

All mitigation measures listed below are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-7 IMPACTS TO INDIVIDUALS – UNARMORED THREESPINE STICKLEBACK

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the impacts to unarmored threespine stickleback through facilities design requirements, pre-development surveys, consultation with USFWS, and conformance with state and federal permits related to wetlands and water quality.

SP-4.6-44 requires that drainages with flows greater than 2,000 cfs have soft bottoms. Bank protection will be of ungrouted rock or buried bank stabilization, except at bridge crossings and other areas where public health and safety considerations require concrete or other stabilization.

SP-4.6-53 requires updated surveys for special-status plants, animals, and vegetation communities as determined necessary by the County whenever construction maps are submitted. Based on the results of the surveys, additional conditions and mitigation measures may be required.

SP-4.6-54 requires that prior to development within or disturbance to occupied unarmored threespine stickleback habitat, a formal consultation with the USFWS shall occur.

SP-4.6-55 obtaining all pertinent state and federal permits prior to impacts to wetlands or other sensitive habitats.

SP-4.6-57 requires that, where bridge construction is proposed and water flow will be temporarily diverted, blocking nets and seines be used to control and remove fish from the area of activity. All fish captured during this operation will be stored in tubs and returned unharmed to the river after construction activities are complete.

SP-4.6-58 requires that in order to limit impacts to water quality, the Specific Plan shall conform to all provisions of required NPDES permits and water quality permits required by the RWQCB.

SP-4.6-59 requires consultations with the County of Los Angeles and CDFG before surveys, after surveys, at subdivision map approval, and prior to development or disturbance to habitats occupied by special-status species. Based on the results the consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends several additional mitigation measures that will mitigate the impacts to unarmored threespine stickleback individuals. These mitigation measures include pre-development focused surveys for the unarmored threespine stickleback, coordination with the USFWS and CDFG, channel diversion requirements, biological monitoring, avoidance of flowing water, design guidelines for bridges and culverts, and other BMPs. Additional mitigation measures are specified in other sections of the EIS/EIR that address water quality, riparian vegetation scour, and sedimentation. Specifically, Mitigation Measure WQ-1 in **Section 4.4,** Water Quality, and Mitigation Measures GRR-1 through GRR-7 in **Section 4.2**, Geomorphology and Riparian Resources, provide additional measures to reduce the impacts to unarmored threespine stickleback individuals. These mitigation measures include implementation of Project BMPs (including runoff control, conservation of natural areas, minimization of stormwater runoff pollutants of concern, prevention of slope and channel erosion, and education and signage

to discourage illegal dumping to the storm drains), and other measures to minimize impacts to riparian resources and geomorphology (peak storm flow control, bridge span and clearance guidelines, maintenance minimization, channel design to minimize erosion potential, sediment and debris control, reintroduction of sediments for beach replenishment, and a Geomorphology Monitoring and Management Plan).

BIO-43 provides for the biological surveying of aquatic habitats within 300 feet of construction sites and access roads for the presence of special-status fishes, at least 10 days prior to commencing construction, unless fish spawn has occurred or juvenile fishes are present; in which case, construction activities would be suspended. BIO-44 requires that temporary crossings or access across the River be constructed outside of the winter season and not during spring periods when fish spawning is occurring, and be consistent with a Stream Crossing and Diversion Plan that outlines the following: the timing and methods for pre-construction fish surveys, a detailed description of the diversion methods, fish exclusion techniques, methods to maintain fish passage, channel habitat enhancement design, fish stranding surveys, and the techniques for the removal of temporary crossings prior to winter storm flows.

BIO-45 defines the timing and design of stream diversion bypass channels and dewatering activities and related restrictions to ensure that proper construction, operation, and abandonment diversion or dewatering will occur.

BIO-46 requires that a qualified biologist will inspect diversion or dewatering activities for stranded fish or other aquatic organisms.

BIO-47 provides for the construction of additional slow moving water habitats upstream and downstream of any river crossing or bridge construction area, to provide refuge for special-status fishes during construction.

BIO-48 requires the design and installation of bridges, culverts, or other structures to not impair the movement of fish and aquatic life, and requires provisions for a low flow channel where velocities are less than 2 fps to allow fish passage.

BIO-49 requires that pollutants from construction activities not be allowed to enter a flowing stream or be placed in locations that may be subjected to storm flows.

BIO-70 provides for construction plans that will include erosion control plans and dust control plans, specifications, and details, along with an overall Project SWPPP. Together, these documents shall include measures to ensure that impacts (*e.g.*, the introduction of chemical pollutants, exposure to fugitive dust, contact with polluted runoff, and changes in hydrology) to vegetation communities and special-status plant species are avoided or minimized during construction.

BIO-71 requires that development areas have dust control measures implemented and maintained to prevent dust from impacting vegetation communities and aquatic wildlife species. Dust control plans shall be prepared prior to initiation of construction activities and shall comply with SCAQMD Rule 403 (SCAQMD 2005).

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to unarmored threespine stickleback individuals would be less than significant for Alternatives 2, 3, 4, 5, 6, and 7. .

IMPACT 4.5-8 LOSS OF HABITAT – UNARMORED THREESPINE STICKLEBACK

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures that will mitigate the temporary loss of habitat for unarmored threespine stickleback through RMDP facilities design requirements, consultation with the USFWS, and conformance with federal and state permits to protect water quality.

SP-4.6-44, SP-4.6-54, SP-4.6-55, and SP-4.6-58, as described above, will be implemented to mitigate impacts related to unarmored threespine stickleback through facilities design requirements, consultation with USFWS, and conformance with state and federal permits related to wetlands and water quality.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the temporary loss of habitat for the unarmored threespine stickleback. These measures refer to stream diversions, BMPs, and facilities design. Additional mitigation measures are specified in other sections of the EIS/EIR that address water quality, riparian vegetation scour, and sedimentation as described above (Mitigation Measures WQ-1 and GRR-1 through GRR-7). These mitigation measures include implementation of Project BMPs and other measures to minimize impacts to riparian resources and geomorphology.

BIO-45, BIO-47 through BIO-49, BIO-70, and BIO-71, as described above, will be implemented to mitigate impacts from chemical pollution, increased sedimentation, increased turbidity, changes in flow, changes in water temperature, and dust.

Finding of Significance for Loss of Habitat After Mitigation

Permanent impacts (Loss of Habitat) would not be significant because impacts will be predominantly outside of the stream channel and be limited with respect to aquatic habitat. After mitigation, temporary impacts to unarmored threespine stickleback habitat would be less than significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-9 SECONDARY IMPACTS – UNARMORED THREESPINE STICKLEBACK

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures to mitigate for both short-term secondary impacts to the unarmored threespine stickleback, such as altered hydrology and water quality, and long-term secondary impacts, such as potential physical changes in the River; altered base and flood flows; biochemical, substrate, and temperature alterations; vegetative changes, such as invasive plant species; increased human activity; and impacts from fecal material from pet, stray, and feral cats and dogs.

Most importantly, the River Corridor SMA will be protected and managed to preserve aquatic and riparian resources, including the unarmored threespine stickleback and its habitat, through a series of mitigation measures. SP-4.6-1 through SP-4.6-16 and SP-4.6-63 address habitat restoration in the River Corridor SMA and provide requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc*.) for the revegetation, restoration, and/or enhancement of the riparian areas within the River Corridor SMA. Guidelines are provided for exotics control, temporary irrigation, mitigation banking, annual reporting to the state and/or federal permitting agency, and 1:1 replacement of riparian resources.

SP-4.6-17 states that hiking and biking within the River Corridor SMA shall be limited to the River trail system. Trail access shall be limited to daytime use. No hunting, fishing, motor or off-trail bike riding, or pets shall be allowed. The trail system shall be designed to minimize impacts to native habitats, including aquatic habitats used by the unarmored threespine stickleback.

SP-4.6-18 and SP-4.6-19 describe design requirements for transition areas between the River Corridor SMA and development to lessen the impact of the development on the conserved area. These measures will provide a buffer between human activity and aquatic habitats supporting the unarmored threespine stickleback. Transition areas may be composed of Open Area, natural or revegetated manufactured slopes, other planted areas, bank areas, and trails. Transition areas shall be located where there is no steep grade separation, native riparian plants shall be

incorporated into landscaping where feasible, roads and bridges shall be designed to discourage public access to the River Corridor SMA, and a minimum 100-foot-wide buffer shall be provided between top river-side bank stabilization and development.

SP-4.6-20 requires that all grading perimeters within the River Corridor SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian resources (including aquatic habitats) outside the grading area in the River Corridor SMA.

SP-4.6-21 through SP-4.6-26 describe the open space dedication of the River Corridor SMA.

SP-4.6-27 prohibits grazing in the River Corridor SMA except as a long-term resource management activity. Controls on grazing will help protect water quality in aquatic habitats used by the unarmored threespine stickleback.

In addition, SP-4.6-44 (drainage design), SP-4.6-55 (state and federal wetlands permits), and SP-4.6-58 (NPDES/RWQCB permits), as described above, will be implemented to protect natural flows and water quality, and SP-4.6-54 will require formal consultation with USFWS prior to impacts.

Measures Recommended by EIS/EIR

This EIS/EIR recommends additional mitigation measures to mitigate for secondary impacts to unarmored threespine stickleback, including short-term impacts to hydrology and water quality and long-term impacts, such as effects on movement; increased human activity; fecal material from pet, stray, and feral cats and dogs; habitat degradation by exotic plants; and increased predation by exotic predators. Additional mitigation measures are specified in other sections of the EIS/EIR that address water quality, riparian vegetation scour, and sedimentation as described above (Mitigation Measures WQ-1 and GRR-1 through GRR-7). These mitigation measures include implementation of Project BMPs and other measures to minimize impacts to riparian resources and geomorphology.

BIO-1 through BIO-16 include requirements for the development of conceptual wetlands mitigation plans (including planting palettes, assessment of functions and values, mitigation ratios, monitoring methods, success criteria, corrective measures, *etc.*) for the revegetation, restoration, and/or enhancement of the riparian areas within the Project site. Guidelines are provided for the replacement of native riparian trees, exotics control, temporary irrigation, "in-lieu fees," mitigation banking, passive restoration using native mulch, minimization of temporary impacts, annual reporting to the Corps and CDFG, and sub-notification letter requirements. CDFG jurisdictional riparian habitat meeting success criteria (for permanent impacts) two years or more prior to construction impact: for all vegetation communities = 1:1 ratio. Attainment of success criteria less than two years in advance of impact: low reach value communities = 1:1 to

2:1 ratios; moderate reach value communities = 1:1 to 3:1 ratios; high reach value communities = 1:1 to 4:1 ratios. Although these measures primarily refer to riparian habitats, the riparian/aquatic communities in the River Corridor SMA will be addressed comprehensively in a manner that protects and enhances habitat for the unarmored threespine stickleback, including management of invasive species, such as giant reed.

BIO-45, BIO-47 through BIO-49, BIO-70, and BIO-71, as described above, will be implemented to mitigate impacts from chemical pollution, increased sedimentation, increased turbidity, changes in flow, changes in water temperature, and dust.

BIO-63 will be implemented to mitigate impacts by pet, stray, and feral cats and dogs, such as fecal material entering the aquatic system. This measure requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-73 requires permanent fencing along all trails that pass through the River Corridor SMA to minimize impacts to protected vegetation communities and special-status plant and wildlife species due to increased human presence.

BIO-80 states that the Project applicant shall retain a qualified biologist to develop and implement an Eradication Plan for bullfrog, African clawed frog, and crayfish. Following construction, monitoring shall be conducted at sentinel locations along the River Corridor SMA (and other potential habitat areas) annually for five years. After five years, monitoring shall be conducted bi-annually for 50 years.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, secondary impacts to the unarmored threespine stickleback and its habitat would be less than significant for Alternatives 2, 3, 4, 5, 6, and 7.

INTENTIONALLY LEFT BLANK

AMERICAN PEREGRINE FALCON (BCC, CE, CFP)

Life History

The peregrine falcon (*Falco peregrinus*) is listed as state endangered and is a California Fully Protected species. On October 11, 2007, the California Fish and Game Commission designated the American peregrine falcon (*F. p. anatum*) as a candidate for delisting under CESA (California Regulatory Notice Register 2007).

The peregrine falcon has a worldwide distribution that is more extensive than that of any other bird. The only regions this species does not occupy as a breeder are the Amazon Basin, the Sahara Desert, most of the steppes of central and eastern Asia, and Antarctica. In North America, the peregrine falcon breeds from Alaska to Labrador, southward to Baja California and other parts of northern Mexico, and east across central Arizona through Alabama. Its distribution is patchy in North America, and populations in the eastern United States are still chiefly in urban areas (AOU 1998; White *et al.* 2002). The distribution is likely to change as the species reoccupies areas from which it was formerly extirpated (White *et al.* 2002). The former breeding range also included Ontario, southern Quebec, the Canadian Maritime Provinces, and all of the eastern United States south to northern Georgia. In the Americas, the species winters from southern Alaska to Tierra del Fuego in southernmost South America (AOU 1998). There are 19 subspecies of peregrine falcons, three of which occur in North America (White *et al.* 2002). This account addresses only the American subspecies, *F. p. anatum*.

In California, the American peregrine falcon is an uncommon breeder or winter migrant throughout much of the state. It is absent from desert areas (Zeiner *et al.* 1990A). Active nests have been documented along the coast north of Santa Barbara, in the Sierra Nevada, and in other mountains of northern California. As a transient species, the American peregrine falcon may occur almost anywhere that suitable habitat is present (Garrett and Dunn 1981).

Peregrine falcons in general use a large variety of open habitats for foraging, including tundra, marshes, seacoasts, savannahs, grasslands, meadows, open woodlands, and agricultural areas. Sites are often located near rivers or lakes (AOU 1998; Brown 1999; Snyder 1991). Riparian areas, as well as coastal and inland wetlands, are also important habitats year-round for this species. The species breeds mostly in woodland, forest, and coastal habitats (Zeiner *et al.* 1990A; Brown 1999). Within southern California, American peregrine falcons are primarily found at coastal estuaries and inland oases during migration periods and during the winter months (Garrett and Dunn 1981). The high mobility, extensive hunting areas, remote nest sites, and preferences of individual pairs make it difficult to identify what might be typical peregrine falcon habitat (USFWS 1984), and no particular terrestrial biome appears to be preferred over others (White *et al.* 2002).

The diet of the American peregrine falcon primarily consists of birds that, while most are pigeon-sized, can be as small as hummingbirds or as large as small geese (White *et al.* 2002). Other prey species include jays, flickers, meadowlarks, starlings, woodpeckers, shorebirds, and other readily available birds. The American peregrine falcon may feed on large numbers of rodents when present (Brown 1999).

Breeding requires cliffs or suitable surrogates that are close to preferred foraging areas. Nests are typically located in cliffs between 50 and 200 meters (164 to 656 feet) tall that are prominent in the landscape. American peregrine falcons have also been known to nest in trees and on small outcrops. Tall buildings, bridges, or other tall man-made structures are also suitable for nesting (White *et al.* 2002). The nest site usually provides a panoramic view of open country and often overlooks water. It is always associated with an abundance of avian prey, even in an urban setting. A cliff or building nest site may be used for many years (Brown 1999). The nest site itself usually consists of a rounded depression or scrape with accumulated debris that is occasionally lined with grass (Call 1978). Higher-quality nest sites confer greater protection from the elements and have greater breeding success (Olsen and Olsen 1989).

The American peregrine falcon was formerly critically endangered after populations declined drastically between 1950 and 1970. The principal cause of the American peregrine falcon population decline was the use of organochlorine pesticides, especially DDT and its metabolite DDE, which interfered with their calcium metabolism and resulted in eggs with thin shells that were easily broken (USFWS 2003). Nesting sites also have been abandoned due to human encroachment or increased levels of nearby activity (Hickey 1969; Bond 1946), although this did not contribute significantly to historical population declines. In recent years, the peregrine falcon population in the United States has been increasing and the species is re-occupying areas from which it was previously extirpated (White *et al.* 2002). However, increases in human activity and other urban-related effects, including pesticides, which may cause secondary poisoning or reduce prey abundance, may have local effects on nesting and foraging behavior.

Survey Results

Avian surveys were conducted in the riparian areas of the Santa Clara River and Castaic Creek from 1988 through 2008 (see **Table 4.5-6**). Additional avian surveys were conducted by Bloom Biological, Inc. throughout upland areas the Project area in 2007 and 2008 (Bloom Biological 2007A, 2008). One American peregrine falcon was observed hunting along the Santa Clara River corridor near the Grapevine Mesa area within the Newhall Ranch Specific Plan area by Guthrie in July 2000 (Guthrie 2000C), and an adult male was observed hunting over the Wolcott agricultural field by Bloom Biological, Inc. in late December 2007 (Bloom Biological 2008). No other occurrences of this species have been documented on site during annual bird surveys between 1988 and 2008. American peregrine falcons have never been documented nesting in the Project area. This species is sensitive to human disturbance and usually nests in areas that are

remote from human activities, such as cliffs, although tall buildings, bridges, or other tall man-made structures are also suitable for nesting if they are protected from human disturbance. Such features that would be suitable for nesting by the peregrine falcon are absent in the Project area; therefore it is not expected to nest on site.

Guthrie's surveys were focused on riparian habitats and coastal scrub habitats, but the American peregrine falcon also uses open habitats, such as grassland and agricultural areas, as observed by Bloom Biological, Inc. Bulrush–cattail wetland, cismontane alkali marsh, open water, California annual grassland, purple needlegrass, and agriculture areas are suitable foraging habitat for the American peregrine falcon in the Project area. A total of 3,937 acres of suitable foraging habitat is present in the Project area.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

A total of 150 acres of suitable foraging habitat would be permanently lost through implementation of the RMDP and the SCP, representing 3.8% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat, and **Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat). A total of 77 acres of suitable foraging habitat would be temporarily impacted. Suitable nesting habitat for the American peregrine falcon is not present within the RMDP area.

Because this species is a transient visitor to the site and only known to forage on site and uses a large variety of habitats for foraging, and because the construction of RMDP facilities would be phased over a long period of time, thousands of acres of suitable foraging habitat in the Project vicinity would be available for this species at any given time. Therefore, the permanent and temporary loss of foraging habitat as a result of implementation of the RMDP and the SCP would not have a substantial direct adverse effect on this species; have the potential to substantially reduce the habitat of the species

on site or rangewide; interfere with the movement of the species between important habitat areas or impede the use of native nursery sites (nests); cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 2,191 acres of suitable foraging habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 55.7% of these habitats on site (**Figure 4.5-54**, Alternative 2 Impacts to Riparian/Wetland Wildlife Habitat, and **Figure 4.5-66**, Alternative 2 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat). Suitable nesting habitat for the American peregrine falcon is not present within the Project area.

A relatively large amount and percentage of suitable on-site foraging habitat for the American peregrine falcon would be permanently lost as a result of build-out of the Specific Plan, VCC, and Entrada planning areas. This species has not been documented to nest on site, but American peregrine falcons have been observed foraging during winter months and migration periods. Wintering and migrating American peregrine falcons use open habitats throughout the state and become somewhat nomadic during the non-breeding period in the southern portion of the state and are not restricted to any one migration route or wintering habitat area. Large areas of the River corridor will remain as open space and provide foraging habitat for this species. For these reasons, the loss of wintering and migratory foraging habitat, while adverse, would not have a substantial adverse effect on this species; would not cause the species population to drop below self-sustaining levels on site or rangewide; would not interfere substantially with the movement of the species between important habitat areas; would not threaten to eliminate the species on site or rangewide; and would not substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable foraging habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 2,342 acres (59.5%). A large amount and percentage of suitable on-site foraging habitat for the American peregrine falcon would be permanently lost as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas. Although this species has not been documented to nest on site, isolated occurrences of American peregrine

falcons have been observed foraging during winter months and migration. Large areas of the River corridor will remain as open space and provide foraging habitat for this species. Thus, the combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because American peregrine falcons are highly mobile, it is extremely unlikely that RMDP-related construction/grading activities would result in injury or mortality of individuals occupying this habitat during construction and/or grading activities. This species has not been observed nesting on site, and suitable nesting habitat for this species is limited in the RMDP area, primarily in the Santa Clara River corridor. Therefore, RMDP-related construction/grading activities would not result in direct mortality of individuals or destruction of nests. However, some individuals and their prey (*e.g.*, waterfowl) may be inhibited from foraging in areas near construction activities, resulting in a potential adverse effect on foraging behavior. Implementation of the SCP would not directly impact this species.

The American peregrine falcon is known to forage on site, but has not been documented to nest on site. Construction/grading activities associated with implementation of the RMDP would not result in a substantial direct adverse effect on this species; would not have the potential to substantially reduce the habitat of the species on site or rangewide; would not interfere with the movement of the species between important habitat areas; would not cause the species population to drop below self-sustaining levels on site or rangewide; would not threaten to eliminate the species on site or rangewide; and would not substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts to foraging individuals (Impacts to Individuals) would be adverse but not significant. .

Indirect Permanent Impacts

Because American peregrine falcons are highly mobile, it is extremely unlikely that construction/grading activities associated with build-out of the Specific Plan, VCC, and Entrada planning areas would result in injury or mortality of individuals occupying this habitat. In addition, because no suitable nesting habitat for the species exists within these areas, construction/grading activities would not result in mortality of individuals or destruction of nests. However, some individuals and their prey (*e.g.*, waterfowl) may be inhibited from foraging in areas near construction activities, resulting in a potential adverse effect on foraging behavior.

The American peregrine falcon is known to forage on site, but has not been documented to nest on site. Construction/grading activities would not have a substantial adverse effect on this species; would not cause the species population to drop below self-sustaining levels on site or rangewide; would not interfere with the movement of the species between important habitat areas; would not threaten to eliminate the species on site or rangewide; and would not substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts to foraging individuals (Impacts to Individuals) would be adverse but not significant.

Secondary Impacts

In the short term, construction-related impacts, such as noise, dust, nighttime lighting, and increased human activity, associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas could inhibit foraging by the American peregrine falcon, either directly or indirectly (by affecting its prey species). Because this species is not expected to nest within the Project area due to limited suitable nesting habitat and avoidance of human activities, nesting would not be affected. Potential long-term secondary impacts to foraging may occur due to increased human activity in the area and use of pesticides. Although the species uses the Project area for foraging, large areas of the River corridor will be preserved in addition to substantial open areas adjacent to the River corridor, these potential short-term and long-term secondary impacts would not have a substantial adverse effect on this species; cause the species population to drop below self-sustaining levels on site or rangewide; interfere substantially with the movement of the species between important habitat areas; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Short-term and long-term secondary impacts would be adverse but not significant.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable foraging habitat for the American peregrine falcon (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat, and **Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 133 acres (3.4%) of permanent loss and 108 acres of temporary loss;

- Alternative 4 – 122 acres (3.1%) of permanent loss and 118 acres of temporary loss;
- Alternative 5 – 157 acres (4.0%) of permanent loss and 100 acres of temporary loss;
- Alternative 6 – 154 acres (3.9%) of permanent loss and 107 acres of temporary loss; and
- Alternative 7 – 68 acres (1.7%) of permanent loss and 345 acres of temporary loss.

Compared to Alternative 2, which would result in 150 acres (3.8%) of permanent foraging habitat loss and 77 acres of temporary impacts, the permanent loss of habitat under Alternatives 3 and 4 would be somewhat reduced, under Alternative 5 would be marginally greater, under Alternative 6 would not be substantially greater, and under Alternative 7 would be substantially reduced. Alternatives 3 through 7 would have greater temporary impacts, with Alternative 7 substantially greater than the other alternatives. The difference between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries as well as other reductions to the Project footprint under Alternative 7 that would result in substantially reduced permanent impacts and relatively greater temporary impacts to suitable foraging habitat for the American peregrine falcon compared to the other alternatives.

Because the overall loss of foraging habitat resulting from implementation of the RMDP and the SCP under Alternatives 3 through 7 would be similar in magnitude or reduced compared to the overall habitat loss under Alternative 2, the impacts under these alternatives would be adverse but not significant.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable foraging habitat for the American peregrine falcon (**Figures 4.5-55** through **4.5-59**, Alternatives 3 through 7 Impacts to Riparian/Wetland Wildlife Habitat, and **Figures 4.5-67** through **4.5-71**, Alternatives 3 through 7 Impacts to Grassland, Agriculture, and Disturbed Land Wildlife Habitat):

- Alternative 3 – 2,086 acres (53.0%) of permanent loss;
- Alternative 4 – 2,010 acres (51.0%) of permanent loss;
- Alternative 5 – 1,974 acres (49.4%) of permanent loss;

- Alternative 6 – 1,845 acres (46.9%) of permanent loss; and
- Alternative 7 – 1,503 acres (38.2%) of permanent loss.

Compared to Alternative 2, which would result in 2,191 acres (55.6%) of permanent loss of foraging habitat, Alternatives 3 through 7 would have reduced impacts. Alternatives 4 through 7 would impact relatively fewer acres than Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions in the development footprints for the Specific Plan and Entrada planning areas under Alternatives 4 through 7, and there would be additional pullbacks from the Santa Clara River and its tributaries and other changes in the Project footprint under Alternative 7 that would reduce impacts to suitable habitat for the American peregrine falcon compared to the other alternatives.

Because the overall permanent loss of habitat from build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar or somewhat reduced compared to the overall habitat loss under Alternative 2, the impacts under these alternatives would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable foraging habitat for American peregrine falcon:

- Alternative 3 – 2,219 acres (56.4%) of permanent loss;
- Alternative 4 – 2,133 acres (54.2%) of permanent loss;
- Alternative 5 – 2,104 acres (54.4%) of permanent loss;
- Alternative 6 – 1,999 acres (50.8%) of permanent loss; and
- Alternative 7 – 1,571 acres (39.9%) of permanent loss.

Compared to Alternative 2, which would result in 2,342 acres (59.5%) of combined direct and indirect permanent loss of foraging habitat, Alternatives 3 through 7 would have reduced impacts for the same reasons as described above in the discussions of direct and indirect impacts. Alternatives 4 through 7 would have reduced impacts compared to Alternative 3 because VCC would not be constructed under these alternatives. There would also be successive reductions Project footprint for the Specific Plan and Entrada planning areas under Alternatives 4 through 7 and there would be additional pullbacks from the Santa Clara River and its tributaries and other Project footprint reductions under Alternative 7 that would result in reduced impacts to suitable habitat for the American

peregrine falcon compared to the other alternatives. For the reasons described above for indirect impacts under Alternatives 3 through 7, the combined direct and indirect permanent impacts to foraging habitat for the American peregrine falcon as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would not have a substantial adverse affect on this species; therefore, the impacts under Alternatives 3 through 7 would be adverse but not significant.

Impacts to Individuals

The potential for impacts to American peregrine falcon individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would not be substantially different than under Alternative 2. Because this species does not nest on site, construction/ grading activities would not result in injury or mortality of individuals or destruction of nests. However, some individuals and their prey (*e.g.*, waterfowl) may be inhibited from foraging in areas near construction activities, resulting in a potential adverse effect on foraging behavior. Although the American peregrine falcon forages on site, substantial undeveloped open space will be preserved in the River corridor and open areas adjacent to the River corridor. Construction/grading activities would not have a substantial adverse effect and, therefore, impacts to individuals under Alternatives 3 through 7 would adverse but not significant.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative has similar impacts due to short-term construction-related activities (noise, dust, and increased human activity) and long-term effects due to urban development, including increased human activity and pesticides. Although the American peregrine falcon forages on site, substantial undeveloped open space will be preserved in the River corridor and open areas adjacent to the River corridor, these potential short-term and long-term secondary impacts would not have a substantial adverse effect on this species; therefore, short-term and long-term secondary impacts under Alternatives 3 through 7 would be adverse but not significant.

Mitigation Strategy and Summary

Although no mitigation is required for impacts to American peregrine falcon individuals and habitat because impacts were determined to be adverse but not significant, several mitigation measures will be implemented for other impacts to biological resources that will further reduce impacts to this species. These mitigation measures include habitat preservation, restoration,

enhancement, and management of the River Corridor SMA, High Country SMA, and Salt Creek area—areas that will form a large, contiguous open space system totaling approximately 6,300 acres comprised of riparian and upland habitats that provide foraging habitat for American peregrine falcon. This set-aside also will reduce short-term and long-term secondary effects, such as increased noise, lighting, and increased human activity because birds would have substantial alternative habitat in which to forage. In addition, short-term construction impacts would be reduced through biological monitoring and controls on nighttime lighting. Long-term effects such as potential secondary poisoning from pesticides would be controlled through an integrated pest management (IPM) plan and all lighting near open space areas would be downcast.

CALIFORNIA CONDOR (FE, CE, CFP)

Life History

The California condor (*Gymnogyps californianus*) is listed as both state- and federally endangered and is a California Fully Protected species. The southern California population of the California condor is largely confined to the semi-arid, rugged mountain ranges surrounding the southern San Joaquin Valley, including the Coast Ranges from Santa Clara County south to Los Angeles County, the Transverse Ranges, Tehachapi Mountains, and southern Sierra Nevada (Zeiner *et al.* 1990A). The California condor has also historically occurred in northern Baja California, Mexico; northern California; Oregon; Washington; and south British Columbia, Canada in the early nineteenth century (Harris 1941; Koford 1953; Wilbur 1978; Kiff 2000; Snyder and Snyder 2000). Elevations of recent nest sites varied from approximately 600 to 1,830 meters (1,969 to 6,004 feet) AMSL. Prior to all California condors being removed from the wild for captive breeding in the late 1980s, nonbreeding California condors often moved north to Kern and Tulare counties in April and returned south in September to winter in the Tehachapi Mountains, Mount Pinos, and Ventura and Santa Barbara counties (Zeiner *et al.* 1990A). Since that time, California condors have been reintroduced into suitable habitat in eastern Ventura County as well as in the Ventana Wilderness area along the coast south of San Francisco.

California condors require vast expanses of open savannah, grasslands, and foothill chaparral, with cliffs, large trees, and snags for roosting and nesting (Zeiner *et al.* 1990A). As opportunistic scavengers, California condors travel up to 225 kilometers (140 miles) per day (Koford 1953; Wilbur 1978; Meretsky and Snyder 1992; Snyder and Snyder 2000). The California condor requires an adequate food supply, open habitat in which food can readily be found and accessed, and reliable air movements that allow extended soaring flight (Snyder and Schmitt 2002). Most foraging has been documented in grasslands and oak woodlands, where individuals can easily launch into flight from nearly any location by running downhill, and where winds deflected by topographic relief usually provide the uplift necessary for extended flight (Snyder and Schmitt 2002). Most California condors forage within 50 to 70 kilometers (31 to 43 miles) of nesting areas, with core foraging areas ranging around 2,500 to 2,800 square kilometers (1,553 to 1,740 miles). This wide-ranging foraging area appears to be an adaptation to unpredictable food supplies. Most remaining California condors in the 1970s and 1980s were familiar with the primary foraging areas, which consisted of an area of 7,000 square kilometers (4,350 miles) in the foothills of the southern San Joaquin Valley and auxiliary valleys in San Luis Obispo, Santa Barbara, Kern, and Tulare counties (Meretsky and Snyder 1992). After 1982, most visual sightings of foraging occurred in the Elkhorn Hills/Cuyama Valley/Carrizo Plain complex and in the foothills of the southern San Joaquin Valley (Meretsky and Snyder 1992).

The California condor primarily feeds on mammalian carrion, although remains of reptiles and birds have been occasionally found within nests (Collins *et al.* 2000). California condors are scavengers of fresh medium- to large-sized carcasses, such as sheep, cattle, deer, and elk (Koford 1953; Snyder and Snyder 2000; Collins *et al.* 2000). California condors are not known to feed on vehicle-killed animals, but in recent years, hunter-shot mule deer, shot or poisoned coyotes, and ground squirrels were consumed when available (Snyder and Schmitt 2002).

California condors typically breed annually but frequently breed less often. Observations of new pair formations have been observed in late fall and early winter (Snyder and Schmitt 2002). Once pairs have been formed, the California condors stay together year round for multiple years. California condors lay only one egg; this can occur from the last week of January through the first week of April, with an incubation period averaging 57 days. The hatching of the eggs ranges between the last week of March and the first week of June. The chicks are tended by both parents until the chicks are fledged, which occurs five and a half to six months after hatching. The chicks are fully dependent on their parents for approximately another six months, ending roughly a year after hatching, from early March to mid-May (Snyder and Schmitt 2002).

Critical Habitat

Critical habitat for the California condor was designated by the USFWS on September 22, 1977 (42 FR 47840–47845). Critical habitat was not designated for the Project area. The nearest critical habitat area is the Sespe–Piru Condor Area. Because there is no critical habitat designation for the Project area, critical habitat is not further addressed in the California condor analysis in this EIS/EIR.

Recovery Plan

The California Condor Recovery Plan was published by the USFWS on February 26, 1980 (USFWS 1980). The Recovery Plan identified several objectives to meet the overall objective of stopping the decline of the species and increasing the population to a secure level: (1) reduce mortality to the lowest level possible; (2) substantially increase productivity (*i.e.*, reproductive success); (3) retain adequate nesting, roosting, and feeding habitat for each subpopulation; and (4) include habitat for future growth and expansion of each subpopulation. A series of geography-specific activities was identified in the Recovery Plan. The nearest activity area relative to the Project area is the Sespe–Piru Condor Area. Because no recovery activities were identified for the Project area and nearby vicinity, the Recovery Plan is not further addressed in the California condor analysis in this EIS/EIR.

Threats

The total population of the California condor in the early 1980s was estimated to be fewer than 20 individuals (Ogden 1982), and by the mid-1980s, wild California condors were being trapped

for captive breeding purposes. Snyder and Schmitt (2002) suggested that lead poisoning was likely the most important cause of the recent decline of the species, and it appears to be a continuing problem for reestablishing viable wild populations. Meretsky *et al.* (2000, 2001) confirmed the threat of lead poisoning in birds released to the wild in Arizona and California, with five deaths attributable to lead and a total of 16 emergency chelations of acutely poisoned birds occurring through September 2000. Other sources of mortality of released birds through 2000 include collisions, poisoning due to ingestion of antifreeze, drowning, and shooting (Snyder and Schmitt 2002). It has been observed that individuals landing in human-altered environments (including parking lots or buildings) had had inappropriate familiarity (imprinting) with humans while in captivity prior to release. An increase in power lines and utility poles, which can result in collisions and electrocution; microtrash (*e.g.*, bottle caps, pull tabs, broken glass, cigarette butts, small plastic items, lead bullets, and shell casings, which condors can ingest); long-term habitat degradation; and contaminants other than lead and antifreeze also have the potential to affect individuals.

Survey Results

Surveys for the California condor were included as part of other raptor and avian species surveys that were conducted along the Santa Clara River and throughout upland areas of the Project area (Bloom Biological 2007A, 2008). While California condor foraging flights have been known to take individuals over the Santa Clarita Valley, these flights are generally at high altitudes. A reliable source of updrafts and thermals appears to be lacking in the Project area. Until April 2008, California condors had not been known to nest or land within the Project area within the last 25 years (Bloom Biological 2007A, 2008). In April 2008, a California condor was observed feeding on a dead calf in a Potrero side canyon by wildlife biologist Chris Niemela (Carpenter 2008) (**Figure 4.5-5**, Listed and California Fully Protected Wildlife Species Occurrences). The USFWS also provided information to Bloom that California condors fitted with GPS transmitters had landed on Newhall Ranch on several days from April through July 2008 (Root 2008). In January 2009, up to five California condors were detected feeding on a dead calf in the middle section of Potrero Canyon south of Potrero Mesa between January 27 and 30 (Niemela 2009). A follow-up visit by Chris Niemela was conducted at the request of the USFWS to photodocument the calf carcass and site where the feeding occurred. No other mention of California condor observations have been made during numerous other plant and wildlife surveys conducted over the past 30 years within various portions of the Project area.

The California condor requires habitat that contains an adequate food supply (carrion), open space areas, and reliable winds and air movement to allow for long-duration soaring during foraging. Nest habitat typically includes cliff faces and, occasionally, large tree snags with cavities. Condors are not expected to nest in the Project area due to the general lack of adequate nesting habitat and likely only opportunistically forage in the Project area. In general, the Project area does not support significant populations of large mammals across the broad

landscape area. Because this species has the potential to periodically land anywhere within the Project area where carrion is present, suitable nesting and foraging habitat was not quantified for this EIS/EIR.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

There is little suitable foraging and nesting habitat for California condor within the Project area due to the lack of adequate prey. Some suitable foraging habitat is present in the upper regions of the High Country SMA and Salt Creek area where prey can occur, but these areas would not be affected by implementation of the RMDP and the SCP.

Condors have been observed on two separate occasions since April 2008 in the Potrero Canyon area. Condors were observed feeding on dead calves in both instances. In addition, several radio-tagged condors were recorded landing on Newhall Ranch (Root 2008). However, due to the general lack of prey and limited foraging opportunities within the RMDP area, construction and/or grading activities associated with development of the RMDP would not have a substantial direct adverse effect on habitat of this species; impede the use of nest sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

As stated above for direct permanent and temporary impacts to loss of habitat, there is limited nesting habitat and foraging opportunities for California condor within the Project area that would be developed. Suitable foraging habitat is present in the High Country

SMA and Salt Creek area, but these areas would not be affected by build-out of the Specific Plan, VCC, or Entrada planning areas. These areas where suitable foraging habitat is present support mule deer and other prey items.

Due to the lack of prey and limited foraging opportunities within the Project area, the permanent loss of vegetation within the Specific Plan, VCC, and Entrada planning areas is not expected to substantially reduce suitable habitat for the California condor. Condors forage over vast areas, and large expanses of open space remain in the Project area. In addition, condors that occur in the region are feeding primarily on carrion at USFWS-managed feeding stations in the Los Padres National Forest. However, condors are increasing their current range and moving into areas not recently inhabited by this species. Therefore, build-out of these areas would not have a substantial adverse effect on the habitat of this species; impede the use of nest sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Combined Direct and Indirect Permanent Impacts

As stated above for direct and indirect permanent impacts to loss of habitat, there is little suitable nesting habitat and there are limited foraging opportunities for California condor within the Project area (developed area). Some suitable foraging habitat is present in the High Country SMA and Salt Creek area, but these areas would not be affected by build-out of the Specific Plan, VCC, or Entrada planning areas. Therefore, the combined direct and indirect permanent impact to vegetation communities would not have a substantial adverse effect on the habitat of this species; impede the use of nest sites; have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Combined direct and indirect permanent impacts (Loss of Habitat) would be adverse but not significant.

Impacts to Individuals

Direct Permanent and Temporary Impacts

California condors have recently been observed foraging in the Project area in Potrero Canyon. However, the species is not expected to roost or nest due to lack of suitable habitat. Roost sites have not been observed in the Project area. Condors often return to traditional sites for perching and roosting and, if present, would likely have been

detected. Traditional roost sites include cliffs and large trees and snags (roost trees are often conifer snags 40 to 70 feet tall), often near feeding and nesting areas. These areas are generally absent from the Project area, although some potential roost area occurs in the High Country SMA. Although they can sporadically forage in areas affected by the RMDP, it is highly unlikely that activities associated with implementation of the RMDP would result in direct injury or mortality of individual California condors. Construction debris, litter, leaking equipment, or road kill can attract this species to the proposed Project. This could subject condors to strikes by construction vehicles. Condors are curious birds and have been documented in close association with oil pumps and human activity on the Los Padres National Forest. During cleanup activities at trash sites, condors have been observed sitting on guard rails adjacent to the cleanup activities. Adverse effects to condors have also been documented by the animal's collection of microtrash (*i.e.*, broken glass, paper and plastic waste, small pieces of metal). This waste is often brought back to nest sites where young birds ingest the material. This can lead to mortality of young birds. Ethylene glycol, a component in antifreeze and petroleum products can also be ingested by condors, which could result in injury or mortality.

While there is the potential for injury or mortality to condor individuals from Project activities, this potential is considered to be extremely low due to the generally sporadic occurrence on site. Implementation of the SCP would not directly impact this species. If an individual were injured or killed, this would be a substantial adverse effect (significance criterion 1). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

As with the RMDP and the SCP, it is highly unlikely that activities associated with build-out of the Specific Plan, VCC, and Entrada planning areas would result in direct injury or mortality of individual California condors. However, as described above, construction activities could attract condors, exposing them to potential risks such as vehicle strikes and ingestion of microtrash and pollutants that could cause injury or mortality. Foraging behavior also can be affected; however, not substantially, because of this species' infrequent use of the site. If an individual were injured or killed, this would be a substantial adverse effect (significance criterion 1). Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term construction-related secondary impacts that could affect California condors behaviorally and physically include noise, harassment by humans, and ingestion of contaminants, trash, and/or debris associated with construction sites. Ingestion of contaminants could result in injury or mortality, as described above.

Over time, as more condors are released into the wild in the Sespe Wilderness area to the northwest of the Project area and as these birds continue to forage over large distances in the region, individuals are expected to occasionally forage over suitable habitat within and adjacent to build-out areas, as evidenced by the single observation of a feeding condor in April 2008 in a Potrero side canyon (Carpenter 2008) and other documented landings in the Project area (Root 2008). Long-term secondary impacts associated with the development include phone towers, power lines, and utility poles, which could increase the potential for collisions; increased microtrash within residential and commercial areas, and potentially areas used for recreation, which has been known to attract and be ingested by California condors, causing sickness or mortality; and the presence of various contaminants, such as antifreeze, which have been known to be ingested by California condors, causing sickness or mortality. Increased human and pet activity in open space areas can result in inadvertent harassment of California condors and increased access to remote parts of the High Country SMA through road improvements or during construction activities can result in increased human presence, illicit shooting, or hunting. In addition, termination of cattle grazing in open space areas (except for the purpose of resource management) would reduce potential prey. These short-term and long-term secondary impacts can result in physical impacts to individuals (*i.e.*, sickness or mortality) and/or inhibit the California condor from foraging in the Project region, resulting in a substantially adverse effect on the species and/or reduction in suitable range for the California condor in the Project area (significance criteria 4 and 7). These short-term and long-term secondary impacts would be significant, absent mitigation.

It was noted above that termination of cattle grazing in open space areas (except for the purpose of resource management) would reduce potential prey, but that this would not be a substantially adverse effect because foraging by condors on site is occasional.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Generally, Alternatives 3 through 7 would have similar to fewer impacts to vegetation communities compared to Alternative 2. The outer boundaries of the Project footprints of these alternatives also would be similar or reduced compared to Alternative 2. None of the other alternatives would affect the upper regions of the High Country SMA and Salt Creek areas that can support foraging by the California condor. For these reasons, Alternatives 3 through 7 would have similar potential for loss of foraging and nesting habitat for the California condor as Alternative 2. The direct permanent and temporary impacts to habitat resulting from implementation of the RMDP and the SCP; indirect permanent impacts to habitat resulting from implementation of the Specific Plan, VCC, and Entrada planning areas; and combined direct and indirect permanent impacts to habitat, therefore, would be adverse but not significant for Alternatives 3 through 7.

Impacts to Individuals

As with Alternative 2, it is highly unlikely that activities associated with implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas possibly could result in direct injury or mortality of individual California condors under Alternatives 3 through 7. However, as described above, construction activities could attract condors, exposing them to potential risks such as vehicle strikes and ingestion of microtrash and pollutants that could cause injury or mortality. Foraging behavior also can be affected; however, not substantially, because of this species' infrequent use of the site. If an individual were injured or killed, this would be a substantial adverse effect (significance criterion 1). Impacts to individuals would be significant, absent mitigation.

Secondary Impacts

Similar to Alternative 2, short-term construction-related secondary impacts, such as noise and increased human activity, are unlikely to affect the California condor under Alternatives 3 through 7. However, condors can be attracted to construction sites, where ingestion of microtrash or contaminants could result in injury or mortality, as described above. Long-term secondary effects due to build-out of the Specific Plan, VCC, and Entrada planning areas, would be the same as those under Alternative 2 and can include increased collisions with power lines and utility poles, and potentially electrocution; ingestion of microtrash and contaminants such as antifreeze; increased human and pet activity; and loss of potential prey due to termination of cattle grazing (except for the purpose of resource management). These short-term and long-term secondary impacts can result in physical impacts to individuals and/or inhibit the California condor from foraging in the Project region, resulting in a substantially adverse affect on the species and/or reduction in suitable range for the California condor in the Project area. These short-term and long-term secondary impacts would be significant, absent mitigation, under Alternatives 3 through 7.

It was noted above that termination of cattle grazing in open space areas (except for the purpose of resource management) would reduce potential prey, but that this would not be a substantially adverse effect because foraging by condors on site is only occasional.

Mitigation Strategy and Summary

The Project would result in two significant impacts to the California condor, absent mitigation: (1) direct and indirect impacts to individuals during constructions; and (2) long-term secondary impacts to individuals.

Until recently, condors have not been detected landing in the Project area. There are two observations of condors foraging on dead cattle in the Project and several birds have been recorded landing in the Project area since 2008. Therefore, condors are expected to sporadically

forage in the Project area when carrion (*i.e.*, dead cattle or large wildlife) are present. Because this species has been detected, impacts to individuals could occur during construction activities. Construction debris, litter, leaking equipment, or road kill can attract this species to the proposed Project. This could subject condors to strikes by construction vehicles and increase the risk that they could ingest microtrash and contaminants, which could result in injury or mortality. Condors are curious birds and have been documented in close association with oil pumps and human activity on the Los Padres National Forest. During microtrash cleanup activities on U.S. Forest Service lands, condors have been observed sitting on guard rails adjacent to the cleanup activities. Adverse effects to condors have also been documented by the animal's collection of microtrash (*i.e.*, broken glass, paper and plastic waste, small pieces of metal). In addition to potential impacts to adult birds, this waste is often brought back to nest sites where young birds could ingest the material, which could result in injury or mortality. Ethylene glycol, a component in antifreeze and petroleum products can also be ingested by condors, which could result in injury or mortality. To reduce or avoid potential effects to this species, the applicant shall implement measures during construction to monitor for the presence of birds, and collect all litter, small items, vehicle fluids, and food waste from the Project area on a daily basis. Workers will be trained on the issue of microtrash—what it is, its potential effects on California condors, and how to avoid the deposition of microtrash. In the event California condors are observed landing in the construction area, all work activities shall be suspended until the bird has left the area. Long-term development-related secondary impacts include an increased potential for collisions with phone towers, power lines, and utility poles, which could result in physical injury or death as a result of the collision or from electrocution. As noted above, ingestion of microtrash and contaminants such as antifreeze can cause sickness or mortality. Increased human and pet activity in open space areas can result in inadvertent harassment of California condors. These long-term secondary impacts will be avoided and minimized through several mitigation measures. Generally, protection, restoration and enhancement, and management habitat in the High Country SMA and Salt Creek area will provide California condors with a large tract (5,720 acres) of relatively undisturbed habitat suitable for foraging. Limited recreational usage and access restrictions within the High Country SMA, control of pets in or near open space areas, trail signage, and homeowner education regarding special-status resources in preserved natural habitat areas will help protect California condors foraging in the High Country SMA and Salt Creek area. Installation of new or relocation of existing phone and cell towers, power lines, and utility poles in the High Country SMA and Salt Creek area will be coordinated with CDFG and structures will be designed in accordance with Avian Power Line Interaction Committee (APLIC 2006) guidelines and operated with anti-perching devices to help reduce collisions and electrocutions of California condors.

The specific mitigation measures for the California condor are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-10 IMPACTS TO INDIVIDUALS – CALIFORNIA CONDOR

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR did not identify mitigation measures to avoid or reduce impacts to individuals.

Measures Recommended by EIS/EIR

In order to minimize impacts to individuals during construction, BIO-82 will be implemented. This measure requires the applicant to retain a qualified biologist with knowledge of California condors to monitor construction activities within the Project area. The resumes of the proposed biologist(s) will be provided to CDFG for concurrence. This biologist(s) will be referred to as the authorized biologist hereafter. During clearing and grubbing of construction areas, the qualified biologist shall be present at all times. During mass grading, construction sites shall be monitored on a daily basis. The authorized biologist will have the authority to stop all activities until appropriate corrective measures have been completed. If condors are observed landing in the Project area, the applicant shall avoid further construction within 500 feet of the sighting until the animals have left the area, or as otherwise authorized by CDFG and USFWS. All condor sightings in the Project area will be reported to CDFG and USFWS within 24 hours of the sighting. Should condors be found roosting within 0.5 mile of the construction area, no construction activity shall occur between one hour before sunset to one hour after sunrise, or until the condors leave the area, or as otherwise directed by USFWS. Should condors be found nesting within 1.5 miles of the construction area, no construction activity will occur until further authorization occurs from CDFG and USFWS. The applicant shall collect all litter, small items, vehicle fluids, and food waste from the Project area on a daily basis. Workers will be trained on the issue of microtrash—what it is, its potential effects to California condors, and how to avoid the deposition of microtrash.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to individual California condor would be less than significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-11 SECONDARY IMPACTS – CALIFORNIA CONDOR

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified several mitigation measures that will help offset and reduce potential long-term secondary effects on the California condor. These mitigation measures include protection, restoration and enhancement, and management of habitat in the High Country SMA that can be used as foraging habitat by the California condor, restrictions and limitations on development adjacent to the High Country SMA, and restrictions and limitations on human activity in this area.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access, and grazing within the River Corridor SMA.

SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

SP-4.6-33 permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

Measures Recommended by EIS/EIR

The EIS/EIR recommends the following additional mitigation measures that will help offset and reduce potential long-term secondary effects on the California condor. These mitigation measures include protection, restoration and enhancement, and management of habitat in the Salt Creek area that can be used as foraging habitat by the California condor and provide restrictions and limitations on utilities.

BIO-19 through BIO-21 refer to habitat protection, restoration and enhancement, and management in the 1,518-acre Salt Creek area in conjunction with the 4,205-acre High Country SMA.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active

intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas, specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

BIO-81 and BIO-82 will be implemented to mitigate for the impacts from phone towers, power lines, and utility poles as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas. BIO-81 requires the installation/relocation of phone and cell towers and utility poles in the High Country SMA and Salt Creek area to be coordinated with CDFG. The Project applicant shall install utility poles, phone towers, and cell towers in conformance with APLIC standards for collision-reducing techniques.

BIO-82 specifies anti-perching devices to deter California condors and other raptors from perching on all surfaces of new antennae and phone/utility towers. Antennae and towers shall be kept clean of debris, such as cable, trash, and construction materials. BIO-82, as described above, includes construction monitoring measures to avoid injury or mortality of individuals.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, the long-term secondary impacts to the California condor would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

GOLDEN EAGLE (NESTING AND WINTERING) (BCC, WL, CFP)

Life History

The golden eagle (*Aquila chrysaetos*) is a California Fully Protected species, and has a holarctic (northern parts of the both the Old World and New World) distribution, extending as far south as north Africa, Arabia, the Himalayas, North America, and Mexico. It is a partial migrant within this distribution, with the northern breeding birds migrating south in winter and those in more temperate climates remaining within breeding territories year round (Brown and Amadon 1968). In North America, this species breeds locally from northern Alaska eastward to Labrador and southward to northern Baja California and northern Mexico. The species winters from southern Alaska and southern Canada southward through the breeding range. The golden eagle ranges from sea level up to 3,833 meters (11,500 feet) AMSL (Grinnell and Miller 1944).

The golden eagle requires rolling foothills, mountain terrain, and wide arid plateaus deeply cut by streams and canyons, open mountain slopes and cliffs, and rock outcrops (Zeiner *et al.* 1990A). In central California, the golden eagle nests primarily in open grasslands and oak savannahs and, to a lesser degree, in oak woodlands and open shrublands (Hunt *et al.* 1995, 1999). During spring and fall migration in the western United States and Canada, the golden eagle prefers wetlands, agricultural areas, and grassy foothills (Dekker 1985). The winter range in the western United States includes open habitats with native vegetation and the golden eagle avoids urban, agricultural, and heavily forested areas (Millsap 1981; Fischer *et al.* 1984; Craig *et al.* 1986; Marzluff *et al.* 1997B). The golden eagle also uses sagebrush communities, riparian areas, grasslands, and rolling oak savannahs as habitat (Knight *et al.* 1979; Fischer *et al.* 1984; Hayden 1984; Estep and Sculley 1989).

The food supply for this species includes medium to large mammals such as rabbits, hares, and squirrels, and it will also feed on reptiles, birds, and sometimes carrion (Olendorff 1976; Johnsgard 1990).

Golden eagles breed from late January through August with peak breeding occurring in March through July. Nest construction in southern California occurs in fall and continues through winter (Dixon 1937). This species nests on cliffs with canyons and escarpments and in large trees (generally occurring in open habitats) and is primarily restricted to rugged, mountainous country (Garrett and Dunn 1981; Johnsgard 1990). It is common for the golden eagle to use alternate nest sites, and old nests are reused. The nests are large platforms composed of sticks, twigs, and greenery that are often three meters (10 feet) across and one meter (three feet) high (Zeiner *et al.* 1990A). This species has a clutch size of one to three eggs that have an incubation time of 43 to 45 days (Beebe 1974).

The golden eagle was formerly considered common within suitable habitats in California (Grinnell and Miller 1944) and is now considered an uncommon resident throughout California

(Garrett and Dunn 1981). A major threat to this species is human disturbance in the form of habitat loss as well as human development and activity adjacent to golden eagle habitat. Accidental deaths attributed to increased development include collisions with vehicles, power lines, and other structures; electrocution; hunting; and poisoning (Franson *et al.* 1995). Golden eagles avoid developed areas; the golden eagle population in California has undergone a decline within the past century due to a decrease in open habitats (Grinnell and Miller 1944). If nests are disturbed by humans, abandonment of these nests in early incubation will typically occur (Thelander 1974), thereby threatening the species' reproductive success.

Survey Results

Surveys for upland bird species have been conducted throughout the Project area and in nearby areas between 1995 and 2008. Areas near the Project area that have been surveyed for upland bird species include the Legacy Village area adjacent to the Project area on the south and east (Guthrie 2004C), the Castaic Junction area just north of the Entrada planning area (Guthrie 2004F, 2004I), the Riverpark site (now referred to as River Village) upstream of the Specific Plan area (Compliance Biology 2003A), and upland areas upstream of the VCC planning area, including the Castaic Mesa area (PCR 1998; Compliance Biology 2006A, 2006D).

On site, this species has been occasionally observed during the annual bird surveys conducted from 1988 through 2008 along the Santa Clara River within the riparian scrub and woodland habitat (Guthrie 1993A, 2000B, 2004H, 2006A; Labinger *et al.* 1997A; Bloom Biological 2007A, 2008). Off site, they were also observed along the Santa Clara River east and west of the Project site (Guthrie 1993A, 1997A, 2004F, 2006A; Labinger *et al.* 1997A). In winter 2008, one juvenile and one pair was seen in upper Potrero Canyon and it is believed that this is likely a resident pair, but no nest site has been identified to date (Bloom Biological 2008). In the fall of 2008, two golden eagles were observed resting on a rugged outcrop in the upper portion of the Salt Creek area in Ventura County (Bedford 2009). The golden eagle has not been observed within the VCC planning area. While no nesting has been observed in the Project area, suitable nesting and foraging habitat is present within the RMDP area; Salt Creek; and the Specific Plan, VCC, and Entrada planning areas. Nesting habitat in the Project area, which may also be used for foraging for this species, includes upland woodlands (mixed oak woodland, coast live oak woodland, and valley oak/grass). There is a total of 1,388 acres of suitable nesting and foraging habitat in the Project area. Suitable habitat for foraging only for this species is very broad, and includes all open scrub vegetation communities (alluvial scrub, arrow weed scrub, big sagebrush scrub, California sagebrush scrub, California sagebrush (*Artemisia californica*), California sagebrush–California buckwheat scrub, and *Eriodictyon* scrub), grasslands (California annual grassland, purple needlegrass, and valley oak/grass), agriculture, and disturbed land. A total of 8,827 acres of suitable foraging habitat only is present in the Project area. The combined suitable nesting and/or foraging habitat in the Project area totals 10,215 acres.

Impacts

ALTERNATIVE 1 (No Action/No Project)

Under Alternative 1, the proposed RMDP and SCP would not be approved and implemented and the previously approved Specific Plan and VCC developments and the planned development of Entrada would not go forward. There would be no foreseeable change in existing land use practices. Oil and gas production, grazing, and agricultural operations would continue under Alternative 1. Please see **Subsection 4.5.5.2.2** for detailed analysis.

ALTERNATIVE 2

Loss of Habitat

Direct Permanent and Temporary Impacts

Although there is suitable nesting habitat in the RMDP area (oak woodlands and oak/grass) in the RMDP area, the golden eagle has not been documented to nest within areas subject to disturbance. For the purpose of this analysis, however, it is assumed that the probability of the golden eagle nesting in the RMDP disturbance area is low, but that nesting could occur in suitable habitat. The golden eagle has been observed foraging in the more open/upland habitats beyond the RMDP.

A total of 270 acres of suitable nesting and/or foraging habitat would be permanently lost through implementation of the RMDP and the SCP, representing 2.6% of these habitats on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats). Of these impacts, 8.5 acres are nesting and foraging habitat (*i.e.*, habitat suitable for both nesting and foraging, including upland oak woodland and oak/grass), representing 0.6% of this habitat on site. The remaining 262 acres of impact are foraging habitat only (*i.e.*, habitat suitable only for foraging, including scrubs, chaparral, agriculture, and disturbed lands), representing 3.0% of this habitat on site. A total of 105 acres of suitable nesting and/or foraging habitat would be temporarily impacted, of which 1.3 acres are nesting and foraging habitat and 103 acres are foraging habitat only.

Because the golden eagle is still a wide-ranging species and uses a variety of habitats for nesting and foraging, and because the construction of RMDP facilities would be phased over a long period of time, thousands of acres of suitable nesting and foraging habitat in the High Country SMA, Salt Creek area, and River Corridor SMA would be available for this species at any given time. The overall loss of 2.6% of nesting and/or foraging habitat, including the loss of 0.6% of nesting and foraging habitat and 3.0% of foraging habitat only within the RMDP and the direct permanent and temporary loss of habitat that would occur as a result of construction/grading activities associated with the RMDP

therefore would not have a substantial direct adverse effect on this species; interfere substantially with the movement of the species between important habitat areas or impede the use of native nursery sites (nests); have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant.

Indirect Permanent Impacts

A total of 4,310 acres of suitable nesting and/or foraging habitat would be permanently lost through build-out of the Specific Plan, VCC, and Entrada planning areas, representing 42.2% of these habitats on site (**Figure 4.5-72**, Alternative 2 Impacts to General Wildlife Habitats). Of these impacts, 81 acres are nesting and foraging habitat, representing 5.8% of this habitat on site. The remaining 4,229 acres of impact are foraging habitat only, representing 47.9% of this habitat on site.

Golden eagles have been observed within the Project area, and although nesting has not been documented in areas subject to disturbance, suitable nesting habitat exists within the Project area and it is assumed that nesting could occur for the purpose of this analysis. The permanent loss of 42.2% of the suitable nesting and/or foraging habitat, including 5.8% of nesting and foraging habitat and 47.9% of foraging habitat only, as a result of build-out of the Specific Plan, VCC, and Entrada planning areas would have a substantial adverse effect on this species; interfere with the movement of the species between important habitat areas or impede the use of native nursery sites (nests); have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7), absent mitigation. Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent loss of suitable nesting and/or foraging habitat resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC, and Entrada planning areas would total 4,580 acres (44.8%). Of these impacts, 89 acres are nesting and foraging habitat, representing 6.4% of this habitat on site. The remaining 4,490 acres of impact are foraging habitat only, representing 50.9% of this habitat on site.

The overall loss of 44.8% of nesting and/or foraging habitat, including 6.4% of foraging and nesting habitat and 50.9% of foraging habitat only, would be a substantial habitat loss on site. This impact would be considered a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7), absent mitigation. The combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation.

Impacts to Individuals

Direct Permanent and Temporary Impacts

Because golden eagles are highly mobile, it is extremely unlikely that RMDP-related construction activities would result in mortality of adults and juveniles foraging within the RMDP area. This species has not been documented nesting within the RMDP area subject to disturbance. However, suitable nesting habitat (oak woodlands and oak/grass) is present in the RMDP area, and it is assumed that nesting could occur. If nesting occurred, construction and/or grading activities associated with the proposed RMDP could result in destruction of young or eggs in active nests of this species if such activities occurred during the nesting season. Implementation of the SCP would not directly impact this species. If nests were disturbed, implementation of the RMDP would have a substantial direct adverse effect on this species; interfere substantially with the movement of the species between important habitat areas or impede the use of native nursery sites (nests); have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7). Direct permanent and temporary impacts (Impacts to Individuals) would be significant, absent mitigation.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC, and Entrada planning areas would result in the loss of suitable nesting habitat for this species; thus, absent mitigation, construction and/or grading activities occurring during the nesting season could inadvertently destroy active nests of this species, resulting in the loss of eggs and/or young.

Although golden eagles are highly mobile, due to the size of the Specific Plan, VCC, and Entrada planning areas, injury to or mortality of individual birds, specifically loss of

young and/or eggs during construction/grading activities as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas, would have a substantial adverse effect on a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7), absent mitigation. Indirect permanent impacts (Impacts to Individuals) would be significant, absent mitigation.

Secondary Impacts

Short-term secondary impacts associated with construction include noise, nighttime lighting, and human activity. If construction occurs during the nesting season, these impacts may decrease reproductive success by causing adults to abandon nests.

Long-term development-related impacts include an increased potential for collisions with phone towers, power lines, and utility poles, resulting in physical injury or death as a result of the collision or from electrocution. Reproductive success also could be affected by increased noise; lighting; pesticides that may cause secondary poisoning and loss of prey; human disturbances of nest sites; and pet, stray, and feral cats and dogs. Urban development may also increase the potential for fragmentation and would likely restrict any use of habitat within the development area.

Both these short-term and long-term secondary impacts would have a substantial adverse effect on this species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species (significance criteria 1, 4, and 7), absent mitigation. Short-term and long-term secondary impacts would be significant, absent mitigation.

ALTERNATIVES 3 THROUGH 7

Loss of Habitat

Direct Permanent and Temporary Impacts

Implementation of the RMDP and the SCP would result in the following direct permanent and temporary impacts to suitable nesting and/or foraging habitat for the golden eagle (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 250 acres (2.4%) permanent loss and 147 acres of temporary loss of nesting and/or foraging habitat, including
  - 8.7 acres (0.6%) of permanent loss and 1.3 acres of temporary loss of nesting and foraging habitat
  - 241 acres (2.7%) of permanent loss and 146 acres of temporary loss of foraging habitat only;
- Alternative 4 – 231 acres (1.4%) permanent loss and 154 acres of temporary loss of nesting and/or foraging habitat, including
  - 8.2 acres (0.6%) of permanent loss and 1.3 acres of temporary loss of nesting and foraging habitat
  - 223 acres (2.5%) of permanent loss and 153 acres of temporary loss of foraging habitat only;
- Alternative 5 – 295 acres (2.9%) permanent loss and 133 acres of temporary loss of nesting and/or foraging habitat, including
  - 12 acres (0.9%) of permanent loss and 1.3 acres of temporary loss of nesting and foraging habitat
  - 283 acres (3.2%) of permanent loss and 132 acres of temporary loss of foraging habitat only;
- Alternative 6 – 290 acres (2.8%) permanent loss and 149 acres of temporary loss of nesting and/or foraging habitat, including
  - 18 acres (1.3%) of permanent loss and 1.2 acres of temporary loss of nesting and foraging habitat
  - 272 acres (3.1%) of permanent loss and 148 acres of temporary loss of foraging habitat only; and
- Alternative 7 – 134 acres (1.3%) permanent loss and 484 acres of temporary loss of nesting and/or foraging habitat, including
  - 4.8 acres (0.3%) of permanent loss and 13 acres of temporary loss of nesting and foraging habitat
  - 129 acres (1.5%) of permanent loss and 471 acres of temporary loss of foraging habitat only.

Compared to Alternative 2 for nesting and/or foraging habitat, which would result in 270 acres (2.6%) of permanent loss and 105 acres of temporary impacts, Alternative 3 would have marginally reduced permanent impacts, Alternatives 5 and 6 would have marginally to somewhat increased permanent impacts, and Alternatives 4 and 7 would have

substantially reduced permanent impacts. Alternatives 3 through 6 would have somewhat increased temporary impacts and Alternative 7 would have substantially increased temporary impacts, primarily due to increased temporary impacts along Potrero and Long canyons compared to the other alternatives. For permanent loss of nesting and foraging habitat, compared to Alternative 2, which would have 8.5 acres (0.6%) of permanent impact, Alternatives 3 and 4 impacts would not be substantially different, Alternatives 5 and 6 would have somewhat higher impacts, and Alternative 7 would have somewhat reduced impacts. For temporary impacts to nesting and foraging habitat, compared to Alternative 2, which would result in 1.3 acres of temporary loss, Alternatives 3 through 6 would not have substantially different impacts and Alternative 7 would have substantially higher impacts. Compared to Alternative 2 for permanent loss of foraging habitat only, which would result in 262 acres (3.0%) of permanent loss, Alternatives 3 and 4 would have somewhat reduced impacts, Alternatives 5 and 6 would have marginally higher impacts, and Alternative 7 would have substantially reduced impacts. For temporary impacts to foraging habitat only, compared to Alternative 2, which would result in 103 acres of temporary loss, Alternatives 3 through 7 would have higher impacts, with Alternatives 3 through 6 resulting in somewhat higher and Alternative 7 resulting in substantially higher impacts.

The relatively greater difference in impacts between Alternative 7 and the other alternatives is primarily due to the pullback of RMDP facilities from the Santa Clara River and its tributaries, which would result in substantially fewer permanent impacts and relatively more temporary impacts.

As noted for Alternative 2, although suitable nesting habitat is present in the RMDP area, the probability that the golden eagle would nest on site is considered to be low, but it could occur. The golden eagle does forage on site in the more open upland habitats beyond the RMDP area. Because the golden eagle is still a wide-ranging species and uses a variety of habitats for nesting and foraging, because the construction of RMDP facilities would be phased over a long period of time, and because thousands of acres of habitat in the High Country SMA, Salt Creek area, and River Corridor SMA would be available at any given time during construction, the overall permanent loss of nesting and/or foraging habitat (ranging from 1.3% to 2.9%) and temporary impacts within the RMDP area would not have a substantial direct adverse effect on this species; interfere substantially with the movement of the species between important habitat areas or impede the use of native nursery sites (nests); have the potential to substantially reduce the habitat of the species on site or rangewide; cause the species to drop below self-sustaining levels on site or rangewide; threaten to eliminate the species on site or rangewide; or substantially reduce the number or restrict the range of the species. Direct permanent and temporary impacts (Loss of Habitat) would be adverse but not significant under Alternatives 3 through 7.

Indirect Permanent Impacts

Build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following indirect permanent impacts to suitable habitat for the golden eagle (**Figures 4.5-73** through **4.5-77**, Alternatives 3 through 7 Impacts to General Wildlife Habitats):

- Alternative 3 – 4,075 acres (39.9%) permanent loss of nesting and/or foraging habitat, including
  - 62 acres (4.5%) of permanent loss of nesting and foraging habitat
  - 4,013 acres (45.5%) of permanent loss of foraging habitat only;
- Alternative 4 – 3,897 acres (38.2%) permanent loss of nesting and/or foraging habitat, including
  - 61 acres (4.4%) of permanent loss of nesting and foraging habitat
  - 3,836 acres (43.4%) of permanent loss of foraging habitat only;
- Alternative 5 – 3,797 acres (37.2%) permanent loss of nesting and/or foraging habitat, including
  - 62 acres (4.5%) of permanent loss of nesting and foraging habitat
  - 3,735 acres (42.3%) of permanent loss of foraging habitat only;
- Alternative 6 – 3,382 acres (33.1%) permanent loss of nesting and/or foraging habitat, including
  - 40 acres (2.9%) of permanent loss of nesting and foraging habitat
  - 3,342 acres (37.9%) of permanent loss of foraging habitat only; and
- Alternative 7 – 2,879 acres (28.2%) permanent loss of nesting and/or foraging habitat, including
  - 41 acres (3.0%) of permanent loss of nesting and foraging habitat
  - 2,838 acres (33.7%) of permanent loss of foraging habitat only.

Compared to Alternative 2 for nesting/and or foraging habitat, which would result in 4,310 acres (42.2%) of permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. This general pattern is similar for permanent impacts to nesting and foraging habitat. Compared to Alternative 2, which would result in 81 acres (5.8%) of permanent loss of nesting and foraging habitat, Alternatives 3 through 7 would have reduced impacts. Compared to Alternative 2 for permanent loss of foraging habitat only, which would result in 4,229 acres (47.9%) of permanent loss, Alternatives 3 through 6 would have reduced impacts. Overall for nesting and/or foraging habitat, Alternatives 4

through 7 would have fewer impacts than Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, and each would successively fewer impacts due to other differences in the Project footprints. Alternative 7 would have the least amount of impact due to pullbacks from the Santa Clara River and its tributaries.

Although Alternatives 3 through 7 would have reduced impacts compared to Alternative 2, all would result in impacts to nesting and foraging habitat and substantial impacts to foraging habitat only. These impacts would have a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species, absent mitigation. Indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Combined Direct and Indirect Permanent Impacts

The combined direct and indirect permanent impacts resulting from implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas would result in the following impacts to suitable habitat for the golden eagle:

- Alternative 3 – 4,324 acres (42.3%) permanent loss of nesting and/or foraging habitat, including
  - 71 acres (5.1%) of permanent loss of nesting and foraging habitat
  - 4,253 acres (48.2%) of permanent loss of foraging habitat only;
- Alternative 4 – 4,128 acres (40.4%) permanent loss of nesting and/or foraging habitat, including
  - 69 acres (5.0%) of permanent loss of nesting and foraging habitat
  - 4,059 acres (46.0%) of permanent loss of foraging habitat only;
- Alternative 5 – 4,092 acres (40.1%) permanent loss of nesting and/or foraging habitat, including
  - 74 acres (5.3%) of permanent loss of nesting and foraging habitat
  - 4,018 acres (45.5%) of permanent loss of foraging habitat only;

- Alternative 6 – 3,672 acres (35.9%) permanent loss of nesting and/or foraging habitat, including
  - 58 acres (4.2%) of permanent loss of nesting and foraging habitat
  - 3,614 acres (40.1%) of permanent loss of foraging habitat only; and
- Alternative 7 – 3,013 acres (29.5%) permanent loss of nesting and/or foraging habitat, including
  - 46 acres (3.3%) of permanent loss of nesting and foraging habitat
  - 2,967 acres (33.6%) of permanent loss of foraging habitat only.

Compared to Alternative 2 for nesting/and or foraging habitat, which would result in 4,580 acres (44.8%) of combined direct and indirect permanent loss of habitat, Alternatives 3 through 7 would have reduced impacts. This general pattern is similar for permanent impacts to nesting and foraging habitat. Compared to Alternative 2, which would result in 89 acres (6.4%) of combined direct and indirect permanent loss of nesting and foraging habitat, Alternatives 3 through 7 would have reduced impacts. Compared to Alternative 2 for the combined direct and indirect permanent loss of foraging habitat only, which would result in 4,490 acres (50.9%) of permanent loss, Alternatives 3 through 6 would have reduced impacts. Overall for nesting and/or foraging habitat, Alternatives 4 through 7 would have fewer combined direct and indirect permanent impacts than Alternative 3 because VCC would not be constructed under Alternatives 4 through 7, and each would have successively fewer impacts due to other differences in the Project footprints. Alternative 7 would have the least amount of impact due to pullbacks from the Santa Clara River and its tributaries and other differences in the Project footprint.

Although Alternatives 3 through 7 would have reduced combined direct and indirect permanent impacts compared to Alternative 2, all would result in impacts to nesting and foraging habitat and substantial impacts to foraging habitat only. These combined direct and indirect permanent impacts would have a substantial adverse effect on the habitat of a special-status species; would impede the use of a native wildlife nursery site; would have the potential to substantially reduce the habitat of the species on site or rangewide; would potentially cause the species to drop below self-sustaining levels on site or rangewide; would threaten to eliminate the species on site or rangewide; or would substantially reduce the number or restrict the range of the species, absent mitigation. Combined direct and indirect permanent impacts (Loss of Habitat) would be significant, absent mitigation, under Alternatives 3 through 7.

Impacts to Individuals

The potential for impacts to golden eagle individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be similar to Alternative 2, although the relative risk of this impact would decrease proportionally with decreases in the size of the Project footprint under the different alternatives. Although nesting has not been documented in the Project area subject to disturbance and the potential for nesting is considered to be low, it is assumed that nesting could occur because suitable nesting habitat is present on site. If nesting occurred, construction/grading activities could result in loss of eggs or young where the golden eagles are nesting, absent mitigation. The loss of or harm to golden eagle individuals as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 would be significant, absent mitigation.

Secondary Impacts

Short-term and long-term secondary impacts could occur as a result of implementation of the RMDP and the SCP and build-out of the Specific Plan, VCC (Alternative 3 only), and Entrada planning areas under Alternatives 3 through 7 and would be similar to those presented above for Alternative 2 because each alternative would have similar short-term construction activities and long-term effects.

Short-term effects include construction-related noise, lighting, and disturbance from human activity that could cause nest abandonment. Urban development could result in long-term secondary impacts, such as increased collisions with phone towers, power lines, and utility poles, resulting in injury or death from the collision or electrocution. A decline in reproductive success could occur due to increased noise; lighting; pesticides that may cause secondary poisoning and loss of prey; human disturbance of nest sites; and pet, stray, and feral cats and dogs. Habitat fragmentation would likely restrict any use of habitat within the development area.

These short-term and long-term secondary impacts therefore may interfere with the movement of this species on site, impede use of nursery sites, or substantially reduce the number of this species or cause the species to drop below self-sustaining levels, absent mitigation. Short-term and long-term secondary impacts under Alternatives 3 through 7 would be significant, absent mitigation.

Mitigation Strategy and Summary

The Project would result in three types of significant impacts to golden eagle: (1) impacts to individuals; (2) loss of suitable nesting and/or foraging habitat; and (3) secondary impacts to individuals and suitable nesting and/or foraging habitat outside the Project footprint.

Although nesting by golden eagles has not been documented for areas that would be subject to disturbance as result of implementation of the RMDP or build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas, suitable nesting habitat (oak woodlands and oak/grass) is present on site and it is assumed for the purpose of this analysis that nesting could occur. Impacts to individuals could occur if active nests are disturbed during construction, including destruction of nests and loss of eggs and/or fledglings, or abandonment of nests as a result of human activity and noise. In order to avoid, minimize, and mitigate these impacts, the applicant will conduct pre-construction surveys for active nest sites and postpone work within 500 feet of any active nest until young have fledged.

The combined permanent loss of nesting and/or foraging habitat resulting from implementation of the RMDP and build-out of the Specific Plan, VCC (Alternatives 2 and 3 only), and Entrada planning areas would range from 3,013 acres (29.5%) under Alternative 7 to 4,580 acres (44.8%) under Alternative 2. This would be a substantial loss of suitable foraging and/or nesting habitat. Although the golden eagle has not been documented to nest in the Project disturbance area, in the winter of 2008, one juvenile and one pair was seen in upper Potrero Canyon and it is believed that this is likely a resident pair, but no nest site has been identified to date. Therefore, the loss of foraging habitat will alter its foraging behavior on site. The combined Newhall Ranch Specific Plan Program EIR mitigation measures and additional mitigation measures recommended by this EIS/EIR will result in a large, permanent open space system that will provide suitable nesting and/or foraging habitat to support the golden eagle in the Project vicinity. Implementation of these mitigation measures will result in protection and management of approximately 4,068 acres of suitable nesting and/or foraging habitat for the golden eagle in three main interconnected areas: the River Corridor SMA, the High Country SMA, and the Salt Creek area (**Figure 4.5-3**).

With regard to secondary effects, any nesting activities by the golden eagle could be adversely affected in the short term by increased human activity and noise if construction occurred during the nesting season. Nighttime lighting may cause adults to abandon nests due to stress and disruption of normal behavioral patterns, and nests may also be more vulnerable to nocturnal predators. These short-term construction-related secondary impacts will be minimized by conducting a survey to determine if active nests are present in the disturbance zone or within 500 feet and by retaining a qualified biologist during all grading and construction activities. Long-term development-related impacts include an increased potential for collisions with phone towers, power lines, and utility poles, resulting in physical injury or death as a result of the collision or from electrocution. Reproductive success also could be affected by increased noise; lighting; pesticides that may cause secondary poisoning and loss of prey; human disturbances of nest sites; and pet, stray, and feral cats and dogs. These long-term secondary impacts will be minimized through several mitigation measures. Protection, restoration and enhancement, and management of nesting and/or foraging habitat in the High Country SMA and Salt Creek area will provide golden eagles with relatively undisturbed habitat for foraging and potentially

nesting, especially in the remote portions of the High Country SMA. Lighting restrictions along the perimeter of natural areas would help reduce impacts to potential nest sites. Limited recreational usage and access restrictions within the High Country SMA, control of pet, stray, and feral cats and dogs in or near open space areas, trail signage, and homeowner education regarding special-status resources in preserved natural habitat areas will help protect golden eagles during foraging activities and potential nest sites. Controls on pesticides (including rodenticides) will reduce the chance of accidental poisoning and potential loss of prey. Installation of new or relocation of existing phone and cell towers, power lines, and utility poles in the High Country SMA and Salt Creek area will be coordinated with CDFG and structures will be designed in accordance with Avian Power Line Interaction Committee (APLIC 2006) guidelines and operated with anti-perching devices to help reduce collisions and electrocutions of golden eagles.

The specific mitigation measures for the golden eagle are listed below and are described fully in **Subsection 4.5.6**, Mitigation Measures.

IMPACT 4.5-12 IMPACTS TO INDIVIDUALS – GOLDEN EAGLE

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following measures to avoid, minimize, and mitigate the loss of golden eagle individuals through pre-development surveys.

SP-4.6-53 and SP-4.6-59 state that at the time of any subdivision map submittal proposing construction, the County may require updated site-specific surveys for rare, threatened, or endangered plant or animal species that may be present, and that consultation shall occur with the County and CDFG before surveys, after surveys, at subdivision map approval, and during development/disturbance. Based on the results of the surveys and consultation with the County and CDFG, additional conditions and mitigation measures may be required.

Measures Recommended by EIS/EIR

This EIS/EIR recommends two additional mitigation measures to reduce the loss of and harm to golden eagle individuals.

BIO-52 states that prior to grading and construction activities, a qualified biologist shall attend the pre-construction meeting to ensure timing/location of construction activities do not conflict with other mitigation requirements; conduct meetings with contractor describing the importance of restricting work to the restricted areas; discuss procedures for minimizing impacts to wildlife; review the construction area in the field with the contractor in accordance with the final grading plan; conduct a final field review of staking; be present during initial vegetation clearing and

grading; and provide reports of any conflicts or errors resulting in impacts to special-status biological resources.

BIO-56 states that, within 30 days of ground-disturbing activities associated with construction or grading occurring during the nesting/breeding season of native bird species potentially nesting on the site, a survey shall be conducted to determine if active nests of protected bird species are present in the disturbance zone or within 300 feet (500 feet for raptors). The surveys shall continue on a weekly basis. In the event that golden eagles establish an active nest in the River Corridor SMA, the buffers will be established in consultation with CDFG.

Finding of Significance for Impacts to Individuals After Mitigation

After mitigation, impacts to golden eagle individuals would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-13 LOSS OF HABITAT – GOLDEN EAGLE

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate the loss of habitat for the golden eagle through habitat protection, restoration and enhancement (including oaks), and management in the High Country SMA where the golden eagle is most likely to nest and forage in the Project area.

SP-4.6-36 through SP-4.6-42 describe the open space dedication of the High Country SMA, as well as guidelines for ownership, management, public access and grazing within the High Country SMA. The High Country SMA will protect and manage 2,617 acres of suitable nesting and/or foraging habitat, including 820 acres of suitable nesting and foraging habitat and 1,798 acres of foraging habitat only for the golden eagle.

SP-4.6-43 allows for the use of Open Area for mitigation of riparian or oak resources or elderberry scrub.

SP-4.6-48 lists standards for the restoration and enhancement of oak resources within the High Country SMA and Open Area. Replacement oaks shall be planted in conformance with the current oak tree ordinance, oaks planted shall be of local genetic stock, an oak resource replacement plan shall be prepared prior to restoration, and all plans and specifications shall follow County oak tree guidelines.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following additional mitigation measures to mitigate for the loss of habitat for the golden eagle through habitat protection, restoration and enhancement, and management in the Salt Creek area, where the golden eagle may also nest and forage.

BIO-19 states that the 1,518-acre Salt Creek area shall be offered for dedication to the public and managed in conjunction with the 4,205-acre High Country SMA. The existing agricultural undercrossing at SR-126 shall be enhanced to facilitate wildlife movement connecting Salt Creek Canyon to agricultural land north of SR-126.

BIO-20 states that approximately 1,900 acres of coastal scrub shall be preserved on the Project site. The preservation of this vegetation type shall occur on site within the High Country SMA, the Salt Creek area, and the River Corridor SMA within the Specific Plan site. Some of this habitat is recovering from wildfire and the expectation is that it will recover without active intervention. The functional values of any burned dedicated land areas shall be evaluated annually until such time that conditions are commensurate with the quality of the impacted habitat being mitigated.

BIO-21 requires coastal sage scrub restoration in the event that the functional value of burned habitat preserved under BIO-20 has not recovered within five years of the dedication due to invasive species, to fire ecology, erosion, drought, or unforeseen events.

BIO-42 requires that all CLAOTO-regulated oaks that will not be removed and that have driplines within 50 feet of land clearing or areas to be graded be enclosed by a temporary fence for the duration of the clearing or grading activities (County of Los Angeles 1988). Fencing shall extend to the root protection zone.

Finding of Significance for Loss of Habitat After Mitigation

After mitigation, the loss of foraging and/or nesting habitat for golden eagle would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

IMPACT 4.5-14 SECONDARY IMPACTS – GOLDEN EAGLE

Significant prior to mitigation for Alternatives 2, 3, 4, 5, 6, and 7.

Previously Incorporated Measures

The Newhall Ranch Specific Plan Program EIR identified the following mitigation measures to mitigate for long-term secondary effects on the golden eagle associated with build-out of the Specific Plan, VCC, and Entrada planning areas, such as increased human activity, nighttime

lighting, and habitat fragmentation. Mitigation measures to minimize inadvertent impacts to habitat outside construction zones will also be implemented.

SP-4.6-36 through SP-4.6-43 and SP-4.6-48, as described above and which generally refer to habitat protection, restoration and enhancement, and management in the High Country SMA, will be implemented to mitigate for the effects of increased human activity by providing for unfragmented nesting and foraging habitat with limited potential for human disturbance.

Several mitigation measures will control human activities in the High Country SMA. SP-4.6-29 through SP-4.6-32 limit access to daytime use of the designated trail system; prohibit pets (with the exception of horses on established trails); prohibit hunting, fishing, and motor or off-trail bike riding; and provide trail design guidelines to minimize impacts to native habitats within the High Country SMA.

To avoid inadvertent impacts to habitat during construction, SP-4.6-34 and SP-4.6-35 will be implemented. These mitigation measures require that all grading perimeters adjacent to the High Country SMA be clearly marked and inspected by the biologist prior to grading and that the biologist work with the contractor to avoid inadvertent impacts to riparian and biological resources outside the grading area in the High Country SMA.

SP-4.6-33 addresses edge effects along open space–urban boundary in the High Country SMA. This measure permits construction of buildings and other structures only upon developed pads within certain Planning Areas and not on southerly slopes facing the High Country SMA or in the area between the original SEA 20 boundary and the High Country SMA boundary.

SP-4.6-56 addresses nighttime illumination by requiring that all lighting along the perimeter of natural areas shall be downcast luminaries with light patterns directed away from natural areas.

Measures Recommended by EIS/EIR

This EIS/EIR recommends the following mitigation measures to mitigate for secondary impacts to the golden eagle, including short-term construction-related noise and increased human activity, as well as long-term increased human activity; harassment by pet, stray, and feral cats and dogs; increased secondary poisoning and loss of prey due to the use of pesticides; collisions with phone towers, power lines, and utility poles; and potential electrocutions.

BIO-52 and BIO-56, as described above, will mitigate the effects of construction noise and increased human activity by identifying nest sites and providing for buffers between nests and construction activities.

BIO-19 through BIO-21, as described above, will mitigate for increased human activity and habitat fragmentation the Project area through habitat protection, restoration and enhancement (if needed), and management in the Salt Creek area.

BIO-63 and BIO-69 will be implemented to mitigate for increased human activity and pet, stray, and feral cats and dogs.

BIO-63 requires each HOA to supply educational information to future residents regarding pets, wildlife, and open space areas specifying that pets must remain leashed while on designated trail systems and/or in any areas within or adjacent to open space. This measure also requires as-needed control of stray and feral cats and dogs in open space areas.

BIO-69 requires the Project applicant to develop and implement a conservation education and citizen awareness program for the High Country SMA and install signage to keep people and their animals on existing trails.

In order to mitigate for impacts from the use of pesticides, BIO-64 will be implemented to reduce the chance of secondary poisoning and loss of prey and requires preparation of an integrated pest management (IPM) plan addressing the use of pesticides (including rodenticides) on site prior to the issuance of building permits.

BIO-81 and BIO-82 will be implemented to mitigate for the impacts from phone towers, power lines, and utility poles as a result of the build-out of the Specific Plan, VCC, and Entrada planning areas.

BIO-81 requires the installation/relocation of phone and cell towers and utility poles in the High Country SMA and Salt Creek area to be coordinated with CDFG. The Project applicant shall install utility poles, phone towers, and cell towers in conformance with APLIC standards for collision-reducing techniques.

BIO-82 specifies anti-perching devices to deter golden eagles and other raptors from perching on all surfaces of new antennae and phone/utility towers. Antennae and towers shall be kept clean of debris, such as cable, trash, and construction materials.

Finding of Significance for Secondary Impacts After Mitigation

After mitigation, short-term and long-term secondary impacts to the golden eagle would be adverse but not significant for Alternatives 2, 3, 4, 5, 6, and 7.

WHITE-TAILED KITE (NESTING) (CFP)

Life History

The white-tailed kite (*Elanus leucurus*) is a California Fully Protected species and occurs in California, Texas, Florida, Oregon Washington, and the middle portions of North America (Eisenmann 1971). It is nonmigratory and populations inhabit the same geographic region year round. Prior to the 1960s, this species occurred in low numbers across much of its range. Population decreases appeared to be common during this time, especially in Mexico and Central America; however, since 1960, the population status and range of this raptor have improved markedly in North America. It has also rapidly colonized habitats throughout much of Central America (Eisenmann 1971).

The white-tailed kite's North American breeding range stronghold is California, where it is a common to uncommon year-long resident in coastal and valley lowlands up to the western Sierra Nevada foothills and southeast deserts (Small 1994; County of Riverside 2008). It is common in the Central Valley of California and along the entire length of the coast. In the Sacramento Valley in California, kite populations have predominantly increased in irrigated agricultural areas where the California vole (*Microtus californicus*) often occurs (Warner and Rudd 1975). Breeding has also been documented regularly in the far western counties of Oregon and recently in southwest Washington. It is also a common breeder in southern Texas. A small breeding population has been established in southern Florida since at least 1986, with scattered reports elsewhere in the peninsula and in the eastern panhandle (County of Riverside 2008). Its breeding range continues south along the coast of Mexico into Central America and in South America from Colombia south to Buenos Aires (County of Riverside 2008). Although it is generally a resident bird throughout most of its breeding range, some dispersal occurs during the non-breeding season, resulting in some range expansion during the fall and winter. Because white-tailed kite populations often change in direct response to changing vole and rodent populations, it is believed to be nomadic during low-abundance population cycles of California voles and other prey (Dunk and Cooper 1994).

The white-tailed kite is commonly associated with agriculture areas (Grinnell and Miller 1944), but it also inhabits low-elevation grasslands, savannah-like habitats, open sage scrub, meadows, wetlands, and oak woodlands, particularly in areas with a dense population of voles (Waian and Stendell 1970). Riparian areas adjacent to open space areas are typically used for nesting (County of Riverside 2008), where kites prefer dense, broad-leafed deciduous trees for nesting and roosting (Brown and Amadon 1968). Overall vegetation structure and prey abundance are apparently more important than the specific plant associations (County of Riverside 2008). Nest trees may be isolated or in an intact forested area and can include a variety of tree species, such as willow, oak, or other species from three to 50 meters (10 to 164 feet) in height (Dixon *et al.* 1957). Nests are generally not reused in subsequent breeding seasons, although some reuse has

been reported (County of Riverside 2008). Nest sites are closely associated with suitable foraging habitat with high rodent populations in the immediate vicinity of the nest. Erichsen *et al.* (1996) described how successful nests are more often than not surrounded by preferred foraging habitat (particularly agriculture) within a 0.5-mile radius of the nest. Hawbecker (1942) noted that during the breeding season, kites seldom forage farther than a 0.5-mile radius from the nest site; Faanes and Howard (1987) noted that within the 0.5-mile radius, there must be at least 50 acres of suitable foraging habitat to support a breeding pair of kites.

Winter habitat is not substantially different than breeding habitat but the proximity to trees is not as important. The white-tailed kite is known to communally roost in the fall and winter, generally in small stands of trees, but roosts have also been observed in open fields on the ground and in orchards (County of Riverside 2008).

White-tailed kites exhibit year-round diurnal (daytime) and crepuscular (dawn and dusk) activity (Zeiner *et al.* 1990A). They prey mostly on small mammals, with voles and other small rodents making up approximately 95% of their diet, but they occasionally take birds, insects, reptiles, and amphibians. White-tailed kites forage in undisturbed, open grasslands, meadows, farmlands, emergent wetlands, ungrazed grasslands, fence rows, and irrigation ditches adjacent to grazed lands, open shrub and scrub, and open woodlands (County of Riverside 2008).

The white-tailed kite breeds from February to October, with a peak from May to August. Clutches average four or five eggs, with a range from three to six eggs. Incubation lasts about 28 days and young fledge in 35 to 40 days.

The California population of the white-tailed kite was historically reduced by habitat loss, shooting, and possibly egg collecting, and by the 1930s, the species bordered on extinction (Pickwell 1930). Recent population declines may be related to reductions in the prey base due to the conversion of natural or agricultural lands to urban or commercial land uses. In addition, overgrazing and "clean farming" techniques that leave little residual vegetation may also have resulted in prey base declines. Fragmentation and isolation of foraging habitat from nest sites as a result of urban development decreases the potential for nesting success because nesting white-tailed kites have to expend more energy obtaining food if foraging habitat is beyond the typical 0.5-mile radius from the nest (Erichsen *et al.* 1996; Faanes and Howard 1987). Other potential human-related impacts include nest disturbance and predation by species such as crows, raccoons, and opossums (Zeiner *et al.* 1990A); increased human activity, which may disturb nesting behavior; pesticides, which reduce prey and may cause secondary poisoning; harassment and predation by pet, stray, and feral cats and dogs; and increased incidence of collisions with vehicles and man-made structures.

Survey Results

Bird surveys have been conducted in the riparian areas of the Santa Clara River and Castaic Creek from 1988 through 2007 (Guthrie 1988, 1989, 1990, 1991A, 1991B, 1992, 1993A, 1993B, 1994A, 1994B, 1995A, 1995B, 1996A, 1996B, 1997A, 1997B, 1998A, 1998B, 1999A, 1999B, 1999C, 2000B, 2000C, 2000E, 2000F, 2001A, 2001B, 2002A, 2002C, 2003A, 2003B, 2004F, 2004H, 2004I, 2005A, 2005B, 2006A, 2006B, 2006C; Labinger *et al.* 1995, 1996, 1997A, 1997B; Labinger and Greaves 1999A); in Castaic Creek, Salt Creek area, High Country SMA, and portions of the Santa Clara River corridor adjacent to the Project site in 2005 and 2006 (Dudek and Associates 2006B, 2006D, 2006E); and in Castaic Creek and the Santa Clara River corridor from the I-5 bridge to Las Brisas Bridge west of the Ventura County line in 2007 (Bloom Biological 2007A, 2008). Although most of these surveys were focused on neotropical migrants, such as least Bell's vireo and southwestern willow flycatcher, surveys in 2007 and 2008 also focused on wintering and breeding raptor species within and adjacent to the Santa Clara River corridor (Bloom Biological 2007A, 2008, 2009).

During these surveys, the white-tailed kite has been observed primarily along the Santa Clara River, where it nests in associated riparian woodlands and forages in adjacent grasslands, open sage scrub, and agricultural fields (**Figure 4.5-78**, RMDP/SCP White-Tailed Kite Occurrences). Eight nesting pairs were documented in the Santa Clara River corridor from The Old Road Bridge to the Castaic Creek confluence and three nesting pairs were documented in Castaic Creek between the years of 1993 and 2005 (Guthrie 2005C). In 2007, at least 10 pairs were observed along the Santa Clara River within the Specific Plan and VCC planning areas and adjacent to the Project area in Castaic Junction and near the Ventura County line (Bloom Biological 2007A). Active nests for four of these pairs were observed during the 2007 surveys: one was observed along the Santa Clara River within the RMDP south of Chiquito Canyon and three were observed just outside the Project area (two north and northeast of Magic Mountain Park and one just west of the Ventura County line). In addition, a roost of up to eight individuals was observed in lower Castaic Creek within the Specific Plan area (Bloom Biological 2007A). In 2008, at least two individuals were observed periodically along the Santa Clara River: one upstream of the Las Brisas Bridge and one just west of the Ventura County line; another was observed on one occasion in an agriculture field near the Magic Mountain Park parking lot (Bloom Biological 2009). Bloom Biological (2009) noted that white-tailed kites occurred less frequently in the 2008 winter surveys than the 2007 surveys (2007A), and that no roosts were located during the 2008 surveys.

For the purpose of this analysis, it is assumed that the white-tailed kite could nest anywhere in suitable nesting habitat because nests generally are not reused in subsequent breeding seasons (County of Riverside 2008). Suitable nesting habitat includes southern cottonwood–willow riparian, southern coast live oak riparian forest, southern willow scrub, coast live oak woodland,

mixed oak woodland, valley oak woodland, and valley oak/grass. A total of 1,913 acres of suitable nesting habitat is present in the Project area.
