

SOUTHERN CALIFORNIA NATIVE PLANTS FOR SCHOOL & URBAN GARDENS

By Betsey Landis

Los Angeles/Santa Monica Mountains Chapter

California Native Plant Society

August 2011

For the convenience of teachers, the Southern California Native Plants for School & Urban Gardens book has been split into three sections and saved as four separate pdf files (Section II: Planting has been split into two files because it is too big to conveniently download as one file). These files in part or as a whole are free to educators, those working on school garden projects, and those working on public urban garden sites, but the contents of the files may not be sold without permission of the Los Angeles/Santa Monica Mountains Chapter of the California Native Plant Society. The Los Angeles/Santa Monica Chapter will print copies of the book in small quantities for special orders.

Go to www.lacnps.org and find Southern California Native Plants for School & Urban Gardens to download the pdf files. The book, Southern California Native Plants for School & Urban Gardens and the author, Betsey Landis, should be cited as the source of any information, illustrations or photos from this book used in electronic media or in print.

PLANTING ADVICE

Because schools may be near industrial areas, may have had herbicides and/or other chemicals applied to the soil around the school or had chemicals dumped in the soil when the school was built, remodeled or repaired, and because knowledge of native plant edibility is imprecise and sometimes incorrect:

WARNING!

Never let students put any part of a plant in their mouths unless it is a classroom exercise and the teacher is sure that the plant parts are edible and do not cause allergic reactions.

Before planting any plant you intend to eat, have the soil tested for heavy metals and other poisonous contaminants. If the soil is contaminated, remove or treat the soil then retest the soil on the site for the garden before planting any edible plant.

1. Clearing the garden site:

Parents, teachers, students and community volunteers may all be needed to clear a site for a garden. Asphalt, root-bound ivy patches or other weedy or long-neglected plantings may need to be removed. Rototilling or loosening the soil with spades and garden forks can become a one-time gardening party or may be done in small sections by different classrooms in the school taking responsibility for one section-to clear it, to prepare the soil, to plant it and to maintain the plants.

2. Planting times:

Plant young shrubs and trees in the garden between December and March for best results. Even with summer watering, many plants will die if planted too late in the spring.

Seeds may be sown in late spring, summer or fall, depending on the normal end of flowering time of the plant species, when the plant usually distributes its seeds. Check in the native plant database in this book to see when the flowering time for each species is over.

3. Placement of plants:

To be healthy and thrive the plants must receive the correct amounts of sun, shade and water. One of the main design considerations is giving the plants room to grow. Many of these plants grow very quickly and will crowd out the other plants if too many plants are placed in too small a space. Check the growth rate and mature size when planning your garden. Species like white, black or purple sage and deer grass form large clumps quickly and have extensive root systems. They need lots of room.

Note that trees must not be planted near foundations or walls or water mains. Most of the trees have large canopies (a coast live oak needs a fifty-foot diameter clear space to grow in, for instance). Tall shrubs (small trees) might be preferable for most school situations.

Fewer plants are better. In California gardens are usually overplanted with the expectation of instant dense greenery and immediate flowers. After a year fifty percent of the plants in these gardens will be dead, crowded out by the hardiest individuals. In school gardens cost is important as is having the same plants for growth studies, plant community studies and leaf and seed experiments over several years. Plant less and harvest more.

In general, one one-gallon shrub needs at least thirty-six square feet of garden space. Annuals and other herbs can be grown in between the larger plants. Cover the garden with a thick layer of mulch and scatter the seeds of annuals or herbaceous perennials over the mulch.

4. Planting:

For best results when planting young native plants buy no larger than one-gallon plants. The best method is to dig a hole and fill it with water several times, preferably over two or three days. The purpose of deep watering the hole is to encourage the roots to grow downward, away from the surface where they might dry out in hot weather.

All of the sample selections in this book were chosen because they are able to survive in soil conditions ranging from poorly-draining clay to fast-draining sand. However, if you have clay or silty clay soil and it is very heavy, you may have to add some soil amendment and dig the hole bigger and deeper so that the water will drain away from the plant.

The plant should be placed in the hole with all the dirt from the container. The container dirt may contain mycorrhizae (fungi) that the plant roots need to survive. The plant should be watered in its container before planting.

After planting the dirt should be tamped down firmly around the plant making sure no air pockets are left around the roots. Water the dirt to make sure it has settled into the hole and that the plant is securely anchored in an upright position. More dirt may have to be added if any roots are exposed by the watering.

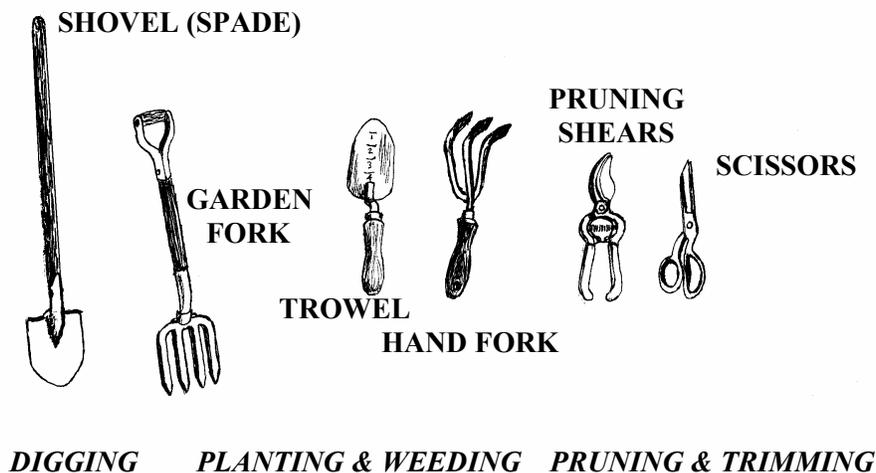

Depending on the garden's soil conditions, fertilizer usually is not necessary and may even harm the roots of some plants.

5. Watering:

Do not water the plant again after planting until the surface inch of soil has dried out. Since clay can form a crust, break up the soil gently around the base of the plant if you see the water running off and not soaking into the soil. A two- to four-inch layer of mulch around the base of young plants will retain moisture and suppress weeds. So the water won't run off, create a basin around each plant.

Do water deeply around the base of each young tree, shrub or perennial to encourage its roots to go down. Do not wet the entire area of the garden as this encourages the young plants to grow surface roots that will dry out in hot weather.

Once established, all chaparral, coastal sage scrub and desert plants should need only winter rains except during extended periods of drought or extremely hot weather. However, monthly watering will extend the flowering season.

COLUMN HEADINGS AND TERMS FOR LANDSCAPING TABLES

The native plants in this data base were chosen because they are native to southern California and particularly to Los Angeles County, most are available from nurseries or seed companies, and the native species represent typical trees, shrubs and herbs/flowers found in natural areas. These selections are only a tiny fraction of the 6000 species native to California, but they are the most appropriate for modeling southern California habitats in a school garden situation

NUMBER COLUMN: The numbers in this first column come from the main database at the back of the book.. Each category of plant (Tree, Shrubs and Cacti, Perennials and Succulents, Annuals, Bulbs, Ferns, Perennial Grasses, and Vines) has its own set of numbers.

COMMON NAME: Generally accepted, non-scientific, name given to a plant species, subspecies or variety.

(* = **thorns**): When an asterick appears beside the common name, the part of the plant with thorns or spines will be identified. Many schools do not allow, or severely restrict, the use of plants with thorns or spines in school landscaping.

NEW SCIENTIFIC NAME: Scientific name of a plant species, subspecies or variety in the *Jepson Manual: Higher Plants of California* edited by James C. Hickman, 1993 or the latest edition (partially available online in 2011). When a genus in Jepson is rendered unusable from a landscaping standpoint, because so many previously recognized species were lumped under one name, the Jepson identification has been omitted.

(OLD SCIENTIFIC NAME): *The Jepson Manual* renamed and reclassified some species. Many of the older classifications are found in *A Flora of Southern California* by Philip A. Munz, 1974. The previously-recognized scientific names for those species are still used by many botanists, ethnobotanists, horticulturalists and herbalists, so they are included in the tables in parentheses.

HABITAT: These are very general terms that apply to the structure of the plant habitat and sometimes the location of the habitat.

Chaparral: Habitat with one or two species of trees at the most, a dominant shrub layer containing tall shrubs or small trees (10-20 feet in height) and a sparse to abundant herb layer. Vines are also often found in this habitat.

CSS, Coastal Sage Scrub: Habitat with no tree layer, a dominant shrub layer usually less than six feet in height, and an herb layer that may contain grasses, annuals, herbaceous perennials and bulbs. CSS needs fog.

Creosote Bush: Desert wash habitat dominated by creosote bush with no tree layer, a dominant shrub layer and, in season, a dominant herb layer.

Forest: Habitat with 75% to 100% tree canopy, a dominant tree layer, with a few shade-loving shrubs in the shrub layer along with ferns and shade-loving bulbs and annuals. Vines grow high in this habitat, seeking sunlight.

Grass, Grassland: Habitat with no tree layer, a sparse to non-existent shrub layer and an abundant herb layer dominated by grasses with some annuals, herbaceous perennials and bulbs.

Joshua Tree Woodland: Desert woodland dominated by Joshua Trees.

Montane or Mt. Woodland: Woodland habitat at higher elevations usually dominated by pines.

P-J, Pinyon-Juniper Woodland: is a desert or desert mountain woodland dominated by pinyon and juniper trees.

Riparian: Habitat along seasonally-flowing or year-round streams, springs or seeps. The habitat has trees that are often deciduous, an abundant shrub layer (with vines) and an herb layer containing herbaceous perennials, annuals, ferns and grasses.

Savanna: Habitat with <10% tree canopy, few shrubs and a dominant herb layer. Tree layer may be 80 – 100 feet tall. Grass dominates the herb layer.

Scrub or Sage Scrub: Desert or dry inland habitats having the same structure as Coastal Sage Scrub.

Strand: Habitat having no tree layer, a shrub layer usually less than four feet in height and an herb layer that is either very low or about the same height as the shrub layer. This habitat is sand: coastal or desert dunes.

Woodland: Habitat with a dominant tree layer, a sparse shrub layer (with vines) and an herb layer that may range from grasses to a wide variety of herbaceous perennials, annuals, ferns and bulbs.

(ALTITUDE), (=feet): This represents the range of feet above sea level in which the plant species normally lives.

FLOWER TIMES: The seasons of the year during which the plant species usually blooms, or, in the case of pines, when the cone seeds mature.

GROWTH: The shape of the plant: how fast it grows, its maximum height under ideal growing conditions and sometimes a long life, and the width of the plant. These are guides for placement in the garden or for judging the size of the container needed.

1y/Max Ht.: The "1y" represents the height a healthy plant will attain in one year. The "Max Ht." represents the maximum height the plant will attain. This could occur in one season or one hundred years.

Width: The width or diameter of the mature plant, expressed as "**number of feet spread**" since the plant shape is usually irregular. If the word "**spreads**" appears in the column with no number, this means the plant keeps growing outward either above or below the ground and may take over the garden or the container, crowding out other plants.

SOIL TYPE: The type of soil or range of soils the plants can live in. Most are self-explanatory.

(pH): pH can range from 0 to 14. Neutral pH is 7. Acid pH is less than (<) 7. Alkaline pH is greater than (>) 7. Some plants require acid soil, some require alkaline soil conditions, some plants will die if the soil is not

neutral. This is necessary information and a good basis for experimentation especially when no information is given. All pH values come from Bert Wilson, 1993, *A Manual of California Native Plants*, Las Pilitas Nursery.

WATER NEEDS: The water requirements of the plant are divided into three categories:

small: Needs water until it is established, little or no water after that and no summer water. Don't irrigate.

moderate: Needs water until it is established, occasional water (once or twice per month) during summer.

ample: Needs to have its roots moist. Water once a week. "**Deep water**" means to really soak the root system occasionally so that the water gets several feet into the ground. "**Drain well**" means that the roots will rot if the water stands around the plant and does not drain into the soil and away fairly quickly. Those plants usually require sand or gravel to grow in.

SUN or SHADE: The sun exposure for a plant is very important. There are three terms:

full sun: Plant should be in full sunlight all day.

cool sun: Plant should be in sun only part of the day and in shade the rest of the day. Or the plant may be where it receives indirect or filtered sunlight.

shade: Plant should not receive any direct sunlight. The plant should be in shade the entire day.

ATTRACTS BIRDS or INSECTS: Most plants attracts birds or insects when the plant is in bloom. If bees are a problem, then plants may be chosen that bloom in the summer when school is not in session, though not all plants attract bees. Since some schools may want a butterfly garden or a bird sanctuary, this information will help choose plants for those locations.

BUTTERFLY: This column only appears in the Butterfly Garden: Sample Selections section of this book.

COMMON NAME: Generally accepted, non-scientific, name given to a butterfly species or subspecies.

SCIENTIFIC NAME: Scientific name of a butterfly species or subspecies. References are a number of popular guides to local butterflies.

LARVAL FOOD (F), ADULT NECTAR (N): The butterflies listed in this column are known to use these plants, either as food sources (**F**) for the larval forms or as nectar sources (**N**) for adult butterflies.

Please note that butterflies vary widely in their flying range and habitat requirements. Some of the butterflies are very rare and will not normally be found in a garden situation. Do not expect that every butterfly listed for a particular plant species will show up when that plant species is added to the garden. Over time some of the wider-ranging butterfly species may find their way from nearby natural areas or roosting areas to the garden.

If student are raising butterflies, the garden design must include food plants for the butterfly larva, food sources for the adult butterfly, as well as adequate shelter and any other resources required by that butterfly species.

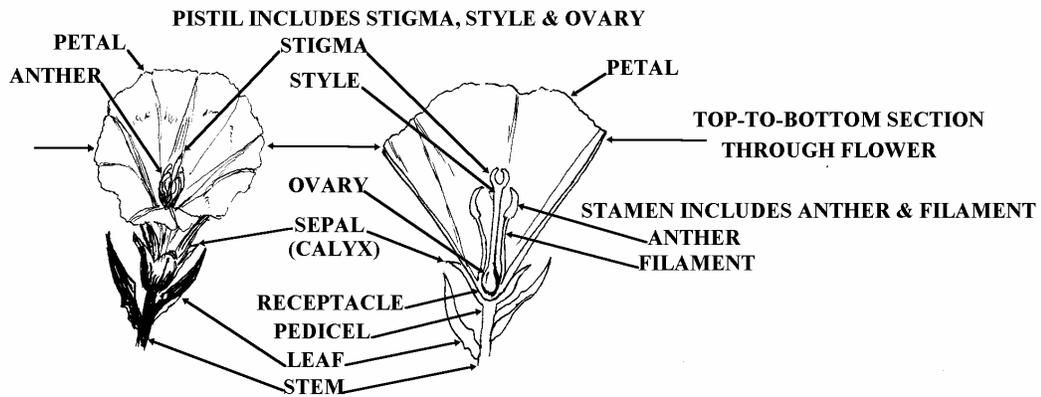

FRUITS: EDIBLE? YES or NO: This column indicates if the seed or fruit are edible or may be toxic to some degree.

“yes, with processing”: This means do not eat the fruit or seed raw! The processing may be boiling leaching, drying and/or combining with other foods. Careful research needs to be done before preparing any plant materials with that notation.

Students should not put any part of any plant in their mouths unless the teacher or a qualified expert has given permission for them to do so. An easy way to sample the aroma or flavor of a plant is to rub a leaf or bruise a fruit with your fingers and smell it, instead of tasting it. As a general rule everyone should wash their hands and face thoroughly after working with any plants.

NATIVE AMERICAN USES: The information provided may help those teachers and schools interested in an ethnobotanic garden or container garden. Since native American uses varied widely around California, only those uses identified with southern California native Americans have been included. Many of these plants were used by early settlers and some are used today by ethnic groups and people interested in natural foods and herbal remedies.

When a plant is identified as having a “**medicine**” use, this does not mean that the plant or the part having a “**medicine**” use is edible or that the class should experiment with preparing the “**medicine**”. For instance, a tea made of plant leaves steeped in boiling water for five minutes may be a good medicine, while a tea made by steeping the same plant leaves for an hour could have serious medical side effects, and the raw leaves of this same plant could well be inedible.

**SOUTHERN CALIFORNIA
NATIVE PLANTS
SUITABLE
FOR
CONTAINERS**

TABLE OF CONTENTS	33
INTRODUCTORY TEXT	35
TABLE OF NATIVE PLANTS SUITABLE FOR CONTAINERS	37

SELECTED NATIVE PLANTS SUITABLE FOR CONTAINERS

All native plants grown in containers require a well-drained soil mix. In general you can purchase prepackaged "Supersoil" and add bulk "Perlite" (=Spongerock) at a 2:1 ratio. That means 2 parts of Supersoil to 1 part of Perlite. When working with Perlite, be sure to wear an appropriate dust mask.

The plants listed here were chosen because they are native to southern California, however **all** California native plants require ample water when grown in containers (remember, they are not able to send their roots deep into the soil to search for water). Most of these plants will generally require watering several times a week. A number of them will require daily watering during summer heat waves--especially after they have filled their containers with roots.

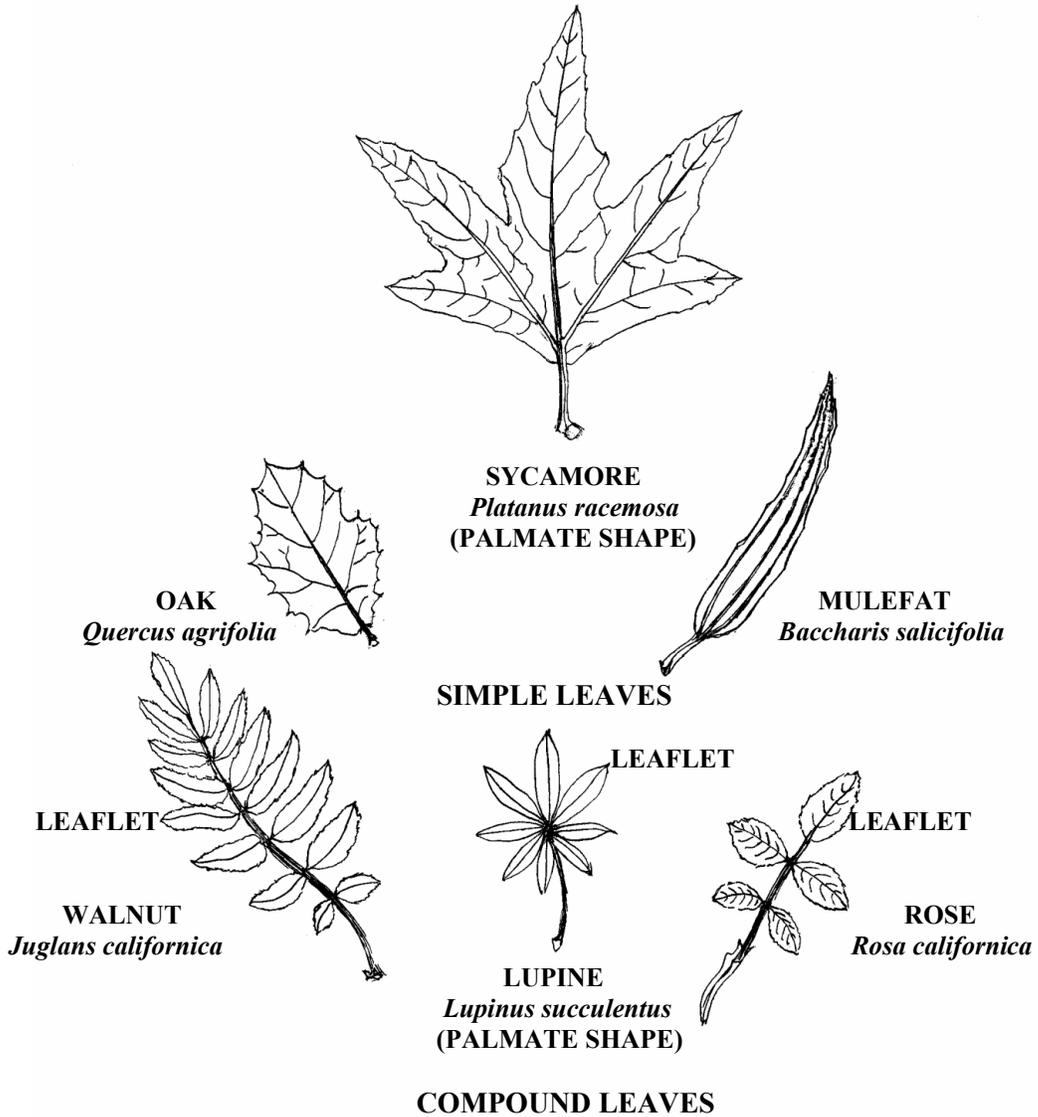

Try to shield or insulate black plastic pots from direct sun--the pots can heat up to the point that the sensitive young roots are killed, leading to the death or decline of the plant.

Container size should be the largest available for trees, shrubs and vines. This means 15- to 20-gallon pots for young trees, 36 -inch boxes for larger plants. Usually you should not buy anything bigger than a 1- to 5-gallon size in a tree, shrub or vine, if you want to be assured of a healthy plant. Then transplant the tree, shrub or vine immediately to a larger container to give its roots room to grow. The smaller the container size for these plants, the more often they will require watering and transplanting.

Nearly all the annuals, perennials, cacti and succulents may be grown and kept in 5-gallon containers.
(The above information was provided by Bart O'Brien, Director of Horticulture, Rancho Santa Ana Botanic Garden.)

Almost anything can be used as a container for plants. The one requirement is that there must be drain hole, or holes, in the bottom of the container. If a plant sits in undrained water day after day, its roots rot and the plant dies. These are not aquatic plants.

On the other hand, many of the plants will not survive if the soil is totally without moisture, because the roots then dry out and cannot take in water and nutrients to feed the plant. A moisture gauge is helpful, so is a finger thrust down into the soil to see if it is moist an inch or so below the surface. If the plant is a drought-resistant plant, only water it when the soil is dry on the surface and dry an inch or so below the soil surface. The lowest roots need to stay moist, but not wet.

TIPS:

Remember that container plants need more water than plants in the ground. Even chaparral or coastal sage scrub plants will need frequent watering to survive. Many native plants, such as white sage, are not included in the above tables because they grow too fast with too many roots, and outgrow their containers in a few months.

If your school has no room for a garden, containers of herbs, shrubs and trees can be arranged into a habitat near a wall or fence even on asphalt. Spread several inches of an insulating layer of bark, mulch or soil on top of the asphalt in your chosen location. Put a shade cloth over the area or hang shade cloth on the fence so the plants will not overheat in their containers. Place the containers on the insulating layer. Small pots can be placed on raised blocks inside larger pots to give them more protection from high outside temperatures.

Native plants can be raised from seed in small containers and sold as fund-raisers for future gardening activities. Poppies, sunflowers, tidy tips and clarkias lend themselves to this kind of activity. The students learn about different shapes of seeds, different germinating times of seeds, different growth rates and different leaf and flower shapes, as well as the care needed to produce something healthy enough to sell.

Almost anything with a hole in the bottom will work as a container for plants except concrete or cement, which leach lime into the soil in the container. The lime may make the soil too alkaline for the container plants. Bricks, railroad ties, porcelain containers, even old toilets, tires, wood barrels or wood boxes will do. Do not use plastic containers unless they are well insulated from high outside temperatures. The plastic does not "breathe" and will cook the plant roots in hot weather, especially if the plants are overwatered.

PLANT COMMUNITY GARDEN SAMPLE SELECTIONS

The following selections are meant as a guide to show how to choose plants that are compatible--that are found growing together in the wild. Plant community here is not meant to imply that these plants are interrelated, only that they require similar conditions of sunlight, soil and water. They are interdependent in that some require the shade of taller plants during part of the day, some seedlings need shade until they grow into mature plants. The architecture of the plant community--what is in the herb, shrub and tree layer--becomes important in the design of the garden.

The following sample selections cover five plant communities: chaparral, coastal sage scrub, grassland, riparian and woodland. Some of the sample selections list only a few choices, some list many; none of the sample selection charts are meant to be used in their entirety. In choosing which plants are suitable for your garden site, you should note the sizes of the various plants and plan accordingly. Often too many plants are crowded into the garden site and then die because there is no room for their root systems to properly establish. Each plant community has its own characteristic architecture, which you should simulate in designing a plant community garden.

Chaparral typically has many tall shrubs, many perennials, some annuals, several vines and a few grasses. North-facing or moister chaparral may have one or two species of trees (California walnut and/or coast live oak). The "Sample Selections" given in the chart are representative of a north-facing or east-facing chaparral. South-facing or west-facing chaparral may contain chamise, manzanita, more sage species and no trees. A garden can successfully combine any of these elements as long as proper consideration is made of amount of sun, type of soil and whether or not irrigation or hand watering is to be used.

Coastal sage scrub rarely has any trees (toyon and wax myrtle seldom reach tree size in coastal sage scrub habitat). Coastal sage scrub does have a few tall shrubs, many lower shrubs, perennials, annuals and some grasses. Coastal sage scrub and native bunch grasses historically may have taken turns being dominant on some sites largely due to the presence or absence of wildfires and/or grazing. Shrubs gradually will fill in grasslands in the long-term absence of disturbances such as grazing or wildfires. Coastal sage scrub usually occurs on drier, hotter sites with poorer soil conditions than chaparral will tolerate. Coastal sage scrub is a

tough plant community of the coastal slopes. There are other types of sage scrub communities that thrive inland in similar conditions. Sagebrush (*Artemisia*) is common to most of them, as are various sages (*Salvias*) and buckwheats (*Eriogonums*).

The drought tolerance of chaparral and coastal sage scrub plants has made them increasingly popular garden elements. Once they are established they should not require summer water. If there are normal winter rains, they will require no irrigation at all.

Grassland is an interesting plant community, not least because many of the grasses have uses in basketry or ornamental work. The San Fernando Valley used to be a huge unbroken field of wildflowers in the spring. Then, as the native perennial grasses grew tall and matured, the valley floor became a grassland from late spring through the fall. In planning a grassland garden, you should plan for many spring wildflowers being gradually overtopped by the beautiful native grasses. The grasses can be harvested. If needlegrass is used, it should be mowed or cut before it produces seed since the seeds are very sharp, like small needles. Great care should be exercised in gathering any needlegrass seed.

Riparian plant communities obviously require more water than the other plant communities (riparian means streamside). Some of the plants are adapted to intermittent streams (streams which flow in the winter and are dry in the summer) and can survive on small amounts of summer water, especially if they are watered deeply to encourage their roots to grow down, away from the hot dry surface of the soil. Typically these trees and shrubs have large root systems and may not be planted near walls, foundations or water mains. The riparian community has many trees and some shrubs, perennials, bulbs, and a few ferns, vines and grasses, resulting in a complex and rich plant architecture.

Woodland plant communities contain a few or many trees. A woodland can have a tree canopy from ten percent to seventy-five percent. Below that is the savanna, above that is the forest. So you can design an open woodland with only a few trees or create a shady glen with an almost closed canopy. However, the placement of the trees is critical to their survival. Trees must have room for a strong root structure and a proper, unrestricted canopy. This requires a large garden space away from walls, building foundations or any other structures that might be damaged by the tree's growth. A one-gallon to five-gallon tree looks very small,

but it will grow quickly in the right conditions. Please note the size and growth rates in the sample selection charts and plan carefully. While the trees are maturing, an understory of shrubs, perennials, annuals, bulbs, ferns and grasses will provide plenty of variety for study and appreciation.

Students, teachers and parents should work together on garden design. The students should do follow-up studies on the growth and success of the plantings. The purpose in creating a garden simulating a natural plant community is that the plants generally fare better and the students are provided with many research opportunities--working with seeds, seedlings, growth rates, leaf patterns, flower structure, pollination patterns, seed production, bird and insect studies, and how they relate to the architecture of the plant community--that they would not have in a park where the plants are protected. If there are any natural areas near the school, the garden will attract birds, butterflies and other insects from that area, providing even more study opportunities.

When planting native plants (not seeds) use only 1-gallon, or no larger than 5-gallon plants. The best method is to dig a hole and fill it with water several times. All of the sample selections were chosen because they are able to survive in soil conditions ranging from poorly-draining clay to fast-draining sand. However, if you have clay or silty clay soil and it is very heavy, you may have to add some soil amendment and dig the hole bigger and deeper so that the water will drain away from the plant. The plant should be placed in the hole with all the dirt from the container. The container dirt may contain mycorrhizae that the plant roots need to survive. The purpose of deep watering the hole is to encourage the roots to grow downward, away from the surface where they might dry out in hot weather. The plant should be watered in its container before planting. After planting the dirt should be tamped down around the plant making sure no air pockets are left around the roots. Water the dirt to make sure it has settled into the hole and that the plant is securely anchored in an upright position. Depending on the garden's soil conditions, fertilizer usually is not necessary and may even harm the roots of some plants. Do not water the plant again until the surface inch of soil has dried out. Since clay can form a crust, break up the soil gently around the base of the plant if you see the water running off and not soaking into the soil. A two- to four-inch layer of mulch around the base of young plants will retain moisture and suppress weeds.

NATIVE AMERICAN GARDEN SAMPLE SELECTIONS

Native American gardens are colorful, beautiful and excellent sources of curriculum material for everything from history to art to creative writing to cuisine to scientific observation and experimentation. Native plants have provided us with food, medicine, cosmetics, dyes, material for rituals, basketry, tools and construction. Early settlers and present-day people still use many of the same plant species.

The focus of the native American garden may be food, basketry sources, herbs, dyes, tools etc., or a combination of resources. Different tribes of native Americans may use native plants in different ways from other tribes. In general, if there is any variation in the way a native plant species is used, only the southern California usage is listed.

The native plant data base in this book lists those plants with fruit or seeds known to be edible. **If the native plant data base says it is not edible, don't eat it!** If the native plant data base says the fruit or seed is edible only "**with processing**" you will have to research how to make that part of the plant edible before eating it. A plant part listed as "**medicine**" or as "**tea**" is not edible raw.

If you are not sure which part of a plant is edible **do not experiment. Get an expert opinion. Resource books often contradict each other.** Some plant species, such as *Rhus* or sumac, may cause allergic reactions in students. Unripe fruit, overripe fruit, moldy seeds or nuts can cause illness. Teachers need to be very careful about experiments in processing and eating native plants or in attempting to prepare medicines using native plants. There are courses in gathering and using native plants at some local colleges and some excellent references that explain both the hazards and benefits of herbal medicines.

The native American garden selections have been separated into three plant communities (chaparral, coastal sage scrub and riparian) to aid in designing with compatible plants. Read the pages on the architecture of chaparral, coastal sage scrub and riparian communities under "Plant Community Garden, Sample Selections" if you are interested in structuring your native American garden more authentically, as it would be in nature.

You will have to ensure that the plants you choose receive the correct amounts of sun, shade and water. One of the main design considerations is giving the plants room to grow. Many of these plants grow very quickly and will crowd out the other plants if too many plants are placed in too small a space. Check the growth rate and mature size when planning your garden. Species like white sage or deer grass form large clumps quickly and have extensive root systems. Note that trees must not be planted near foundations or walls or water mains. Most of the trees have large canopies (a coast live oak needs a fifty-foot diameter clear space to grow in, for instance). Tall shrubs (small trees) might be preferable for most school situations.

WARNING!

Because schools may be located near industrial sites or may have used hazardous chemicals in previous landscaping or may have dumped chemicals during previous building or remodeling projects, **you must test the soil if you intend to eat any plants from your garden.** If the soil proves to be contaminated, it must be removed or cleaned and retested.

BUTTERFLY GARDENS TABLE OF CONTENTS

INTRODUCTORY TEXT 107

TABLES:

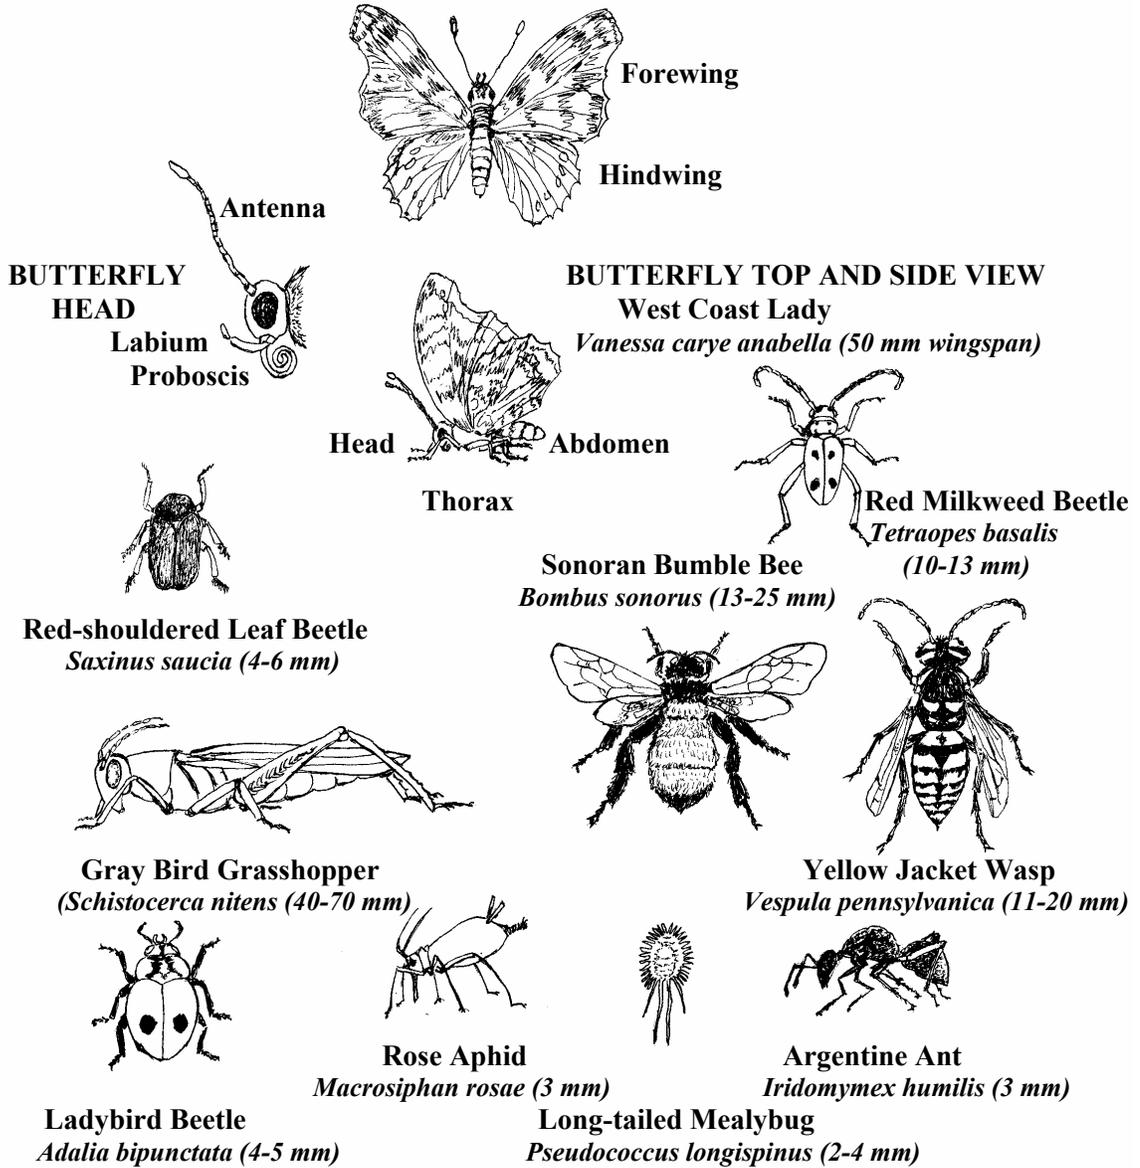

CHAPARRAL 111

COASTAL SAGE SCRUB 119

RIPARIAN 125

COMMON TYPES OF INSECTS FOUND ON PLANTS

Not drawn to scale. Body length (or butterfly wingspan) given in millimeters.
 Slugs, snails (mollusks) and spiders (arachnids) are not insects.

Information from *California Insects* by Jerry A. Powell & Charles L. Hogue, 1979, U.C. Press, & *Insects of the Los Angeles Basin* by Charles L. Hogue, 1993, Natural History Museum of Los Angeles County.

BUTTERFLY GARDEN: SAMPLE SELECTIONS

The butterfly garden is designed to attract and to nurture butterflies for study, research and aesthetic appreciation. To have a successful butterfly garden, which may take some time to develop if the intent is to attract local butterflies, the garden must have:

1. Food plants for the larval forms (caterpillars) of butterflies and safe havens for the pupas.
2. Nectar sources for the adult forms (butterflies) for both the spring and summer seasons, since butterflies may produce more than one generation per year or may pupate at different times of the year.
3. Shelter, shade and other requirements of butterfly species, such as mud or water sources.

Creating a butterfly garden still requires that soil, sun exposure and amount of water available be compatible for the plants selected. The following data base for Butterfly Garden: Sample Selections contains not only the essential information for selecting plants with similar habitat needs, but also aids in developing an attractive garden architecture by providing the size of the plants and their growth rates.

To aid in selecting compatible plants Butterfly Garden: Sample Selections has been divided into three sections (Chaparral, Coastal Sage Scrub and Riparian) based on the plant communities in which these plants are usually found and the range of soils the plants prefer. Plants that will grow in both clay and sandy soil are very tolerant of soil composition and may be easier to grow in typical school landscaping conditions, such as compacted silt or heavy clay, so those plants were included in the sections. Other plants may be found in the main native plant data base for other plant communities and soil conditions. Please note that "plant community" is not a scientific definition, but refers to plants commonly found living together in a natural environment and requiring similar conditions of sun exposure, soil composition and water availability. Information on edibility and native American uses has been eliminated from the butterfly garden sections in order to expand the information on butterflies.

Most schools will not have room for the trees in the data base since most of the trees listed have extensive root systems and develop large canopies, but existing trees may be utilized as part of the garden structure. The garden should have some shrubs, perennials and perennial grasses to provide an ongoing structure from year to year for establishing resident butterfly populations. The same annuals should be planted each year if they prove to be nectar sources for the resident butterflies.

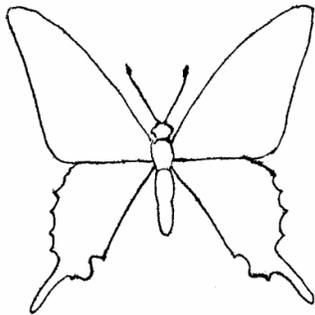

Keeping a notebook of observations of caterpillars, pupas and butterflies present in the garden will prove useful in modifying or adding to the garden each year to provide the correct balance of food and nectar sources. NOTE: The western tiger swallowtail, pale swallowtail and California sister butterflies like to sip mud as well as nectar. The mourning cloak butterfly prefers rotting fruit instead of nectar. The cabbage butterfly is non-native (it is from Europe) and is considered a pest on cole crops and some flowers. The common hairstreak larvae and sara orangetip larvae are cannibalistic. These facts and what you observe as the garden develops will help you, the teachers and students, decide how to modify the garden to encourage some species and discourage others.

The column labeled "BUTTERFLY" lists which butterflies are known to be attracted to which plants; which are food plants (F) for larvae and which plants are nectar sources (N) for adult butterflies. This list is especially important when planning what plants are needed to sustain a butterfly population. If there are garden plots with different plants and different goals nearby consider these two points:

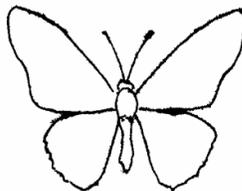

1. Your butterfly larvae may feed on plants in the other garden plots, thereby making your garden unpopular with those responsible for the other garden plots, especially if the garden plots contain vegetables or flowers for other school projects.
2. Butterfly larvae, other insect competitors (bees, wasps, flies, etc.) and birds that are feeding on plants in those other garden plots may move into your butterfly garden and displace or eat the butterfly larvae and adults you are nurturing. Again you will have to adjust your plantings and the location of your butterfly garden to encourage and shelter the species of butterfly you are interested in, while discouraging invading and competing species.

By establishing a butterfly garden with native plants in a large urban area the school is creating not only a delightful research tool, but also the school is providing a haven for some of our rapidly diminishing local butterfly species. Most butterflies do not migrate long distances (the monarch butterfly is an outstanding exception). Some, like certain blue species, are highly localized, have short-lived adults, and feed on only one or two native plant species, so their populations are heavily impacted by the loss of essential food and/or nectar plants or by an increase in insect competitors due to changes in surrounding habitat. Providing the proper native plant habitat for these butterflies in developed areas where the butterflies were previously common could help save some species from extinction.

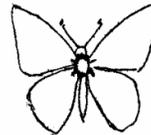

(Information on butterflies is from *Butterflies of Greater Los Angeles* by Rudi Mattoni, Lepidoptera Research Foundation, Inc., website: www.lepidopteraresearchfoundation.org, and from Las Pilitas Nursery, Bert and Celeste Wilson, website: www.laspilitas.com.)
